int	**wc_RsaPSS_VerifyCheckInline**(byte * in, word32 inLen, byte ** out, const byte * digest, word32 digentLen, enum wc_HashType hash, int mgf, RsaKey * key)Verify the message signed with RSA-PSS. The input buffer is reused for the output buffer. Salt length is equal to hash length.
int	**wc_RsaPSS_VerifyCheckInline_ex**(byte * in, word32 inLen, byte ** out, const byte * digest, word32 digentLen, enum wc_HashType hash, int mgf, int saltLen, RsaKey * key)Verify the message signed with RSA-PSS. The input buffer is reused for the output buffer. The key has to be associated with RNG by wc_RsaSetRNG when WC_RSA_BLINDING is enabled.
int	**wc_RsaPSS_CheckPadding**(const byte * in, word32 inLen, const byte * sig, word32 sigSz, enum wc_HashType hashType)Checks the PSS data to ensure that the signature matches. Salt length is equal to hash length. The key has to be associated with RNG by wc_RsaSetRNG when WC_RSA_BLINDING is enabled.
int	**wc_RsaPSS_CheckPadding_ex**(const byte * in, word32 inLen, const byte * sig, word32 sigSz, enum wc_HashType hashType, int saltLen, int bits)Checks the PSS data to ensure that the signature matches. Salt length is equal to hash length.
int	**wc_RsaEncryptSize**(const RsaKey * key)Returns the encryption size for the provided key structure.
int	**wc_RsaPrivateKeyDecode**(const byte * input, word32 * inOutIdx, RsaKey * key, word32 inSz)This function parses a DER-formatted RSA private key, extracts the private key and stores it in the given RsaKey structure. It also sets the distance parsed in idx.
int	**wc_RsaPublicKeyDecode**(const byte * input, word32 * inOutIdx, RsaKey * key, word32 inSz)This function parses a DER-formatted RSA public key, extracts the public key and stores it in the given RsaKey structure. It also sets the distance parsed in idx.
int	**wc_RsaPublicKeyDecodeRaw**(const byte * n, word32 nSz, const byte * e, word32 eSz, RsaKey * key)This function decodes the raw elements of an RSA public key, taking in the public modulus (n) and exponent (e). It stores these raw elements in the provided RsaKey structure, allowing one to use them in the encryption/decryption process.

	Name
int	**wc_RsaKeyToDer**(RsaKey * key, byte * output, word32 outLen)This function converts an RsaKey key to DER format. The result is written to output and it returns the number of bytes written.
int	**wc_RsaPublicEncrypt_ex**(const byte * in, word32 inLen, byte * out, word32 outLen, RsaKey * key, WC_RNG * rng, int type, enum wc_HashType hash, int mgf, byte * label, word32 labelSz)This function performs RSA encrypt while allowing the choice of which padding to use.
int	**wc_RsaPrivateDecrypt_ex**(const byte * in, word32 inLen, byte * out, word32 outLen, RsaKey * key, int type, enum wc_HashType hash, int mgf, byte * label, word32 labelSz)This function uses RSA to decrypt a message and gives the option of what padding type.
int	**wc_RsaPrivateDecryptInline_ex**(byte * in, word32 inLen, byte ** out, RsaKey * key, int type, enum wc_HashType hash, int mgf, byte * label, word32 labelSz)This function uses RSA to decrypt a message inline and gives the option of what padding type. The in buffer will contain the decrypted message after being called and the out byte pointer will point to the location in the “in” buffer where the plain text is.
int	**wc_RsaFlattenPublicKey**(const RsaKey * key, byte * e, word32 * eSz, byte * n, word32 * nSz)Flattens the RsaKey structure into individual elements (e, n) used for the RSA algorithm.
int	**wc_RsaKeyToPublicDer**(RsaKey * key, byte * output, word32 outLen)Convert Rsa Public key to DER format. Writes to output, and returns count of bytes written.
int	**wc_RsaKeyToPublicDer_ex**(RsaKey * key, byte * output, word32 outLen, int with_header)Convert RSA Public key to DER format. Writes to output, and returns count of bytes written. If with_header is 0 then only the (seq + n + e) is returned in ASN.1 DER format and will exclude the header.

	Name
int	**wc_MakeRsaKey**(RsaKey * key, int size, long e, WC_RNG * rng)This function generates a RSA private key of length size (in bits) and given exponent (e). It then stores this key in the provided RsaKey structure, so that it may be used for encryption/decryption. A secure number to use for e is 65537. size is required to be greater than or equal to RSA_MIN_SIZE and less than or equal to RSA_MAX_SIZE. For this function to be available, the option WOLFSSL_KEY_GEN must be enabled at compile time. This can be accomplished with –enable-keygen if using ./configure.
int	**wc_RsaSetNonBlock**(RsaKey * key, RsaNb * nb)This function sets the non-blocking RSA context. When a RsaNb context is set it enables fast math based non-blocking exptmod, which splits the RSA function into many smaller operations. Enabled when WC_RSA_NONBLOCK is defined.
int	**wc_RsaSetNonBlockTime**(RsaKey * key, word32 maxBlockUs, word32 cpuMHz)This function configures the maximum amount of blocking time in microseconds. It uses a pre_computed table (see tfm.c exptModNbInst) along with the CPU speed in megahertz to determine if the next operation can be completed within the maximum blocking time provided. Enabled when WC_RSA_NONBLOCK_TIME is defined.
int	**wc_InitRsaKey_ex**(RsaKey * key, void * heap, int devId)Initializes RSA key with heap and device ID.
RsaKey *	**wc_NewRsaKey**(void * heap, int devId, int * result_code)Allocates and initializes new RSA key. These New/Delete functions are exposed to support allocation of the structure using dynamic memory to provide better ABI compatibility.
int	**wc_DeleteRsaKey**(RsaKey * key, RsaKey ** key_p)Deletes and frees RSA key. These New/Delete functions are exposed to support allocation of the structure using dynamic memory to provide better ABI compatibility.
int	**wc_InitRsaKey_Label**(RsaKey * key, const char * label, void * heap, int devId)Initializes RSA key with label.
int	**wc_CheckRsaKey**(RsaKey * key)Checks RSA key validity.
int	**wc_RsaUseKeyId**(RsaKey * key, word32 keyId, word32 flags)Uses key ID for hardware RSA.

	Name
int	**wc_RsaGetKeyId**(RsaKey * key, word32 * keyId)Gets key ID from hardware RSA key.
int	**wc_RsaFunction**(const byte * in, word32 inLen, byte * out, word32 * outLen, int type, RsaKey * key, WC_RNG * rng)Performs RSA operation.
int	**wc_RsaPSS_Sign_ex**(const byte * in, word32 inLen, byte * out, word32 outLen, enum wc_HashType hash, int mgf, int saltLen, RsaKey * key, WC_RNG * rng)Signs with RSA-PSS extended options.
int	**wc_RsaSSL_Verify_ex**(const byte * in, word32 inLen, byte * out, word32 outLen, RsaKey * key, int pad_type)Verifies RSA signature with padding type.
int	**wc_RsaSSL_Verify_ex2**(const byte * in, word32 inLen, byte * out, word32 outLen, RsaKey * key, int pad_type, enum wc_HashType hash)Verifies RSA signature with hash type.
int	**wc_RsaPSS_VerifyInline_ex**(byte * in, word32 inLen, byte ** out, enum wc_HashType hash, int mgf, int saltLen, RsaKey * key)Verifies RSA-PSS inline with extended options.
int	**wc_RsaPSS_Verify_ex**(const byte * in, word32 inLen, byte * out, word32 outLen, enum wc_HashType hash, int mgf, int saltLen, RsaKey * key)Verifies RSA-PSS with extended options.
int	**wc_RsaPSS_CheckPadding_ex2**(const byte * in, word32 inLen, const byte * sig, word32 sigSz, enum wc_HashType hashType, int saltLen, int bits, void * heap)Checks RSA-PSS padding with extended options.
int	**wc_RsaExportKey**(const RsaKey * key, byte * e, word32 * eSz, byte * n, word32 * nSz, byte * d, word32 * dSz, byte * p, word32 * pSz, byte * q, word32 * qSz)Exports RSA key components.
int	**wc_CheckProbablePrime_ex**(const byte * p, word32 pSz, const byte * q, word32 qSz, const byte * e, word32 eSz, int nlen, int * isPrime, WC_RNG * rng)Checks probable prime with extended options.
int	**wc_CheckProbablePrime**(const byte * p, word32 pSz, const byte * q, word32 qSz, const byte * e, word32 eSz, int nlen, int * isPrime)Checks probable prime.
int	**wc_RsaPad_ex**(const byte * input, word32 inputLen, byte * pkcsBlock, word32 pkcsBlockLen, byte padValue, WC_RNG * rng, int padType, enum wc_HashType hType, int mgf, byte * optLabel, word32 labelLen, int saltLen, int bits, void * heap)Pads data with extended options.

int	**wc_RsaPrivateKeyDecodeRaw**(const byte * n, word32 nSz, const byte * e, word32 eSz, const byte * d, word32 dSz, const byte * u, word32 uSz, const byte * p, word32 pSz, const byte * q, word32 qSz, const byte * dP, word32 dPSz, const byte * dQ, word32 dQSz, RsaKey * key)Decodes raw RSA private key.

C.49.2 Functions Documentation

C.49.2.1 function wc_InitRsaKey

```
int wc_InitRsaKey(
    RsaKey * key,
    void * heap
)
```

This function initializes a provided RsaKey struct. It also takes in a heap identifier, for use with user defined memory overrides (see XMALLOC, XFREE, XREALLOC).

Parameters:

- **key** pointer to the RsaKey structure to initialize
- **heap** pointer to a heap identifier, for use with memory overrides, allowing custom handling of memory allocation. This heap will be the default used when allocating memory for use with this RSA object

See:

- wc_FreeRsaKey
- wc_RsaSetRNG

Return:

- 0 Returned upon successfully initializing the RSA structure for use with encryption and decryption
- BAD_FUNC_ARGS Returned if the RSA key pointer evaluates to NULL

The key has to be associated with RNG by wc_RsaSetRNG when WC_RSA_BLINDING is enabled.

Example

```
RsaKey enc;
int ret;
ret = wc_InitRsaKey(&enc, NULL); // not using heap hint. No custom memory
if ( ret != 0 ) {
    // error initializing RSA key
}
```

C.49.2.2 function wc_InitRsaKey_Id

```
int wc_InitRsaKey_Id(
    RsaKey * key,
    unsigned char * id,
    int len,
    void * heap,
    int devId
)
```

This function initializes a provided RsaKey struct. The id and len are used to identify the key on the device while the devId identifies the device. It also takes in a heap identifier, for use with user defined memory overrides (see XMALLOC, XFREE, XREALLOC).

Parameters:

- **key** pointer to the RsaKey structure to initialize
- **id** identifier of key on device
- **len** length of identifier in bytes
- **heap** pointer to a heap identifier, for use with memory overrides, allowing custom handling of memory allocation. This heap will be the default used when allocating memory for use with this RSA object
- **devId** ID to use with crypto callbacks or async hardware. Set to INVALID_DEVID (-2) if not used

See:

- wc_InitRsaKey
- wc_FreeRsaKey
- wc_RsaSetRNG

Return:

- 0 Returned upon successfully initializing the RSA structure for use with encryption and decryption
- BAD_FUNC_ARGS Returned if the RSA key pointer evaluates to NULL, or if id is NULL while len is positive
- BUFFER_E Returned if len is less than 0 or greater than RSA_MAX_ID_LEN.

Note: This API is only available when WOLF_PRIVATE_KEY_ID is defined, which is set for PKCS11 support.

The key has to be associated with RNG by wc_RsaSetRNG when WC_RSA_BLINDING is enabled.

Example

```
RsaKey enc;
unsigned char* id = (unsigned char*)"RSA2048";
int len = 7;
int devId = 1;
int ret;
ret = wc_CryptoDev_RegisterDevice(devId, wc_Pkcs11_CryptoDevCb,
                                  &token);
if ( ret != 0) {
    // error associating callback and token with device id
}
ret = wc_InitRsaKey_Id(&enc, id, len, NULL, devId); // not using heap hint
if ( ret != 0 ) {
    // error initializing RSA key
}
```

C.49.2.3 function wc_RsaSetRNG

```
int wc_RsaSetRNG(
    RsaKey * key,
    WC_RNG * rng
)
```

This function associates RNG with Key. It is needed when WC_RSA_BLINDING is enabled.

Parameters:

- **key** pointer to the RsaKey structure to be associated
- **rng** pointer to the WC_RNG structure to associate with

See:

- wc_InitRsaKey
- wc_RsaSetRNG

Return:

- 0 Returned upon success
- BAD_FUNC_ARGS Returned if the RSA key, rng pointer evaluates to NULL

Example

```
ret = wc_InitRsaKey(&key, NULL);
if (ret == 0) {
    ret = wc_InitRng(&rng);
} else return -1;
if (ret == 0) {
    ret = wc_RsaSetRNG(&key, &rng);
```

C.49.2.4 function wc_FreeRsaKey

```
int wc_FreeRsaKey(
    RsaKey * key
)
```

This function frees a provided RsaKey struct using mp_clear.

Parameters:

- **key** pointer to the RsaKey structure to free

See: wc_InitRsaKey

Return: 0 Returned upon successfully freeing the key

Example

```
RsaKey enc;
wc_InitRsaKey(&enc, NULL); // not using heap hint. No custom memory
... set key, do encryption

wc_FreeRsaKey(&enc);
```

C.49.2.5 function wc_RsaDirect

```
int wc_RsaDirect(
    const byte * in,
    word32 inLen,
    byte * out,
    word32 * outSz,
```

```
    RsaKey * key,
    int type,
    WC_RNG * rng
)
```

Function that does the RSA operation directly with no padding. The input size must match key size. Typically this is used when padding is already done on the RSA input.

Parameters:

- **in** buffer to do operation on
- **inLen** length of input buffer
- **out** buffer to hold results
- **outSz** gets set to size of result buffer. Should be passed in as length of out buffer. If the pointer "out" is null then outSz gets set to the expected buffer size needed and LENGTH_ONLY_E gets returned.
- **key** initialized RSA key to use for encrypt/decrypt
- **type** if using private or public key (RSA_PUBLIC_ENCRYPT, RSA_PUBLIC_DECRYPT, RSA_PRIVATE_ENCRYPT, RSA_PRIVATE_DECRYPT)
- **rng** initialized WC_RNG struct

See:

- wc_RsaPublicEncrypt
- wc_RsaPrivateDecrypt

Return:

- size On successfully encryption the size of the encrypted buffer is returned
- RSA_BUFFER_E RSA buffer error, output too small or input too large

Example

```
int ret;
WC_RNG rng;
RsaKey key;
byte  in[256];
byte out[256];
word32 outSz = (word32)sizeof(out);
…

ret = wc_RsaDirect(in, (word32)sizeof(in), out, &outSz, &key,
    RSA_PRIVATE_ENCRYPT, &rng);
if (ret < 0) {
    //handle error
}
```

C.49.2.6 function wc_RsaPublicEncrypt

```
int wc_RsaPublicEncrypt(
    const byte * in,
    word32 inLen,
    byte * out,
    word32 outLen,
    RsaKey * key,
    WC_RNG * rng
)
```

This function encrypts a message from in and stores the result in out. It requires an initialized public key and a random number generator. As a side effect, this function will return the bytes written to out in outLen.

Parameters:

- **in** pointer to a buffer containing the input message to encrypt
- **inLen** the length of the message to encrypt
- **out** pointer to the buffer in which to store the output ciphertext
- **outLen** the length of the output buffer
- **key** pointer to the RsaKey structure containing the public key to use for encryption
- **rng** The RNG structure with which to generate random block padding

See: wc_RsaPrivateDecrypt

Return:

- Success Upon successfully encrypting the input message, returns the number of bytes written on success and less than zero for failure.
- BAD_FUNC_ARG Returned if any of the input parameters are invalid
- RSA_BUFFER_E Returned if the output buffer is too small to store the ciphertext
- RNG_FAILURE_E Returned if there is an error generating a random block using the provided RNG structure
- MP_INIT_E May be returned if there is an error in the math library used while encrypting the message
- MP_READ_E May be returned if there is an error in the math library used while encrypting the message
- MP_CMP_E May be returned if there is an error in the math library used while encrypting the message
- MP_INVMOD_E May be returned if there is an error in the math library used while encrypting the message
- MP_EXPTMOD_E May be returned if there is an error in the math library used while encrypting the message
- MP_MOD_E May be returned if there is an error in the math library used while encrypting the message
- MP_MUL_E May be returned if there is an error in the math library used while encrypting the message
- MP_ADD_E May be returned if there is an error in the math library used while encrypting the message
- MP_MULMOD_E May be returned if there is an error in the math library used while encrypting the message
- MP_TO_E May be returned if there is an error in the math library used while encrypting the message
- MP_MEM May be returned if there is an error in the math library used while encrypting the message
- MP_ZERO_E May be returned if there is an error in the math library used while encrypting the message

Example

```
RsaKey pub;
int ret = 0;
byte n[] = { // initialize with received n component of public key };
byte e[] = { // initialize with received e component of public key };
byte msg[] = { // initialize with plaintext of message to encrypt };
byte cipher[256]; // 256 bytes is large enough to store 2048 bit RSA
ciphertext
```

```
wc_InitRsaKey(&pub, NULL); // not using heap hint. No custom memory
wc_RsaPublicKeyDecodeRaw(n, sizeof(n), e, sizeof(e), &pub);
// initialize with received public key parameters
ret = wc_RsaPublicEncrypt(msg, sizeof(msg), out, sizeof(out), &pub, &rng);
if ( ret != 0 ) {
    // error encrypting message
}
```

C.49.2.7 function wc_RsaPrivateDecryptInline

```
int wc_RsaPrivateDecryptInline(
    byte * in,
    word32 inLen,
    byte ** out,
    RsaKey * key
)
```

This functions is utilized by the wc_RsaPrivateDecrypt function for decrypting.

Parameters:

- **in** The byte array to be decrypted.
- **inLen** The length of in.
- **out** The byte array for the decrypted data to be stored.
- **key** The key to use for decryption.

See: wc_RsaPrivateDecrypt

Return:

- Success Length of decrypted data.
- RSA_PAD_E RsaUnPad error, bad formatting

Example

none

C.49.2.8 function wc_RsaPrivateDecrypt

```
int wc_RsaPrivateDecrypt(
    const byte * in,
    word32 inLen,
    byte * out,
    word32 outLen,
    RsaKey * key
)
```

This functions provides private RSA decryption.

Parameters:

- **in** The byte array to be decrypted.
- **inLen** The length of in.
- **out** The byte array for the decrypted data to be stored.
- **outLen** The length of out.
- **key** The key to use for decryption.

See:

- RsaUnPad
- wc_RsaFunction

- wc_RsaPrivateDecryptInline

Return:

- Success length of decrypted data.
- MEMORY_E -125, out of memory error
- BAD_FUNC_ARG -173, Bad function argument provided

Example

```
ret = wc_RsaPublicEncrypt(in, inLen, out, sizeof(out), &key, &rng);
if (ret < 0) {
    return -1;
}
ret = wc_RsaPrivateDecrypt(out, ret, plain, sizeof(plain), &key);
if (ret < 0) {
    return -1;
}
```

C.49.2.9 function wc_RsaSSL_Sign

```
int wc_RsaSSL_Sign(
    const byte * in,
    word32 inLen,
    byte * out,
    word32 outLen,
    RsaKey * key,
    WC_RNG * rng
)
```

Signs the provided array with the private key.

Parameters:

- **in** The byte array to be encrypted.
- **inLen** The length of in.
- **out** The byte array for the encrypted data to be stored.
- **outLen** The length of out.
- **key** The key to use for encryption.
- **RNG** The RNG struct to use for random number purposes.

See: wc_RsaPad

Return: RSA_BUFFER_E: -131, RSA buffer error, output too small or input too large

Example

```
ret = wc_RsaSSL_Sign(in, inLen, out, sizeof(out), &key, &rng);
if (ret < 0) {
    return -1;
}
memset(plain, 0, sizeof(plain));
ret = wc_RsaSSL_Verify(out, ret, plain, sizeof(plain), &key);
if (ret < 0) {
    return -1;
}
if (ret != inLen) {
    return -1;
}
if (XMEMCMP(in, plain, ret) != 0) {
```

```
    return -1;
}
```

C.49.2.10 function wc_RsaSSL_VerifyInline

```
int wc_RsaSSL_VerifyInline(
    byte * in,
    word32 inLen,
    byte ** out,
    RsaKey * key
)
```

Used to verify that the message was signed by RSA key. The output uses the same byte array as the input.

Parameters:

- **in** Byte array to be decrypted.
- **inLen** Length of the buffer input.
- **out** Pointer to a pointer for decrypted information.
- **key** RsaKey to use.

See:

- wc_RsaSSL_Verify
- wc_RsaSSL_Sign

Return:

- 0 Length of the digest.
- <0 An error occurred.

Example

```
RsaKey key;
WC_RNG rng;
int ret = 0;
long e = 65537; // standard value to use for exponent
wc_InitRsaKey(&key, NULL); // not using heap hint. No custom memory
wc_InitRng(&rng);
wc_MakeRsaKey(&key, 2048, e, &rng);

byte in[] = { // Initialize with some RSA encrypted information }
byte* out;
if(wc_RsaSSL_VerifyInline(in, sizeof(in), &out, &key) < 0)
{
    // handle error
}
```

C.49.2.11 function wc_RsaSSL_Verify

```
int wc_RsaSSL_Verify(
    const byte * in,
    word32 inLen,
    byte * out,
    word32 outLen,
    RsaKey * key
)
```

Used to verify that the message was signed by key.

Parameters:

- **in** The byte array to be decrypted.
- **inLen** The length of in.
- **out** The byte array for the decrypted data to be stored.
- **outLen** The length of out.
- **key** The key to use for verification.

See: wc_RsaSSL_Sign

Return:

- Success Length of digest on no error.
- MEMORY_E memory exception.

Example

```
ret = wc_RsaSSL_Sign(in, inLen, out, sizeof(out), &key, &rng);
if (ret < 0) {
    return -1;
}
memset(plain, 0, sizeof(plain));
ret = wc_RsaSSL_Verify(out, ret, plain, sizeof(plain), &key);
if (ret < 0) {
    return -1;
}
if (ret != inLen) {
    return -1;
}
if (XMEMCMP(in, plain, ret) != 0) {
    return -1;
}
```

C.49.2.12 function wc_RsaPSS_Sign

```
int wc_RsaPSS_Sign(
    const byte * in,
    word32 inLen,
    byte * out,
    word32 outLen,
    enum wc_HashType hash,
    int mgf,
    RsaKey * key,
    WC_RNG * rng
)
```

Signs the provided array with the private key.

Parameters:

- **in** The byte array to be encrypted.
- **inLen** The length of in.
- **out** The byte array for the encrypted data to be stored.
- **outLen** The length of out.
- **hash** The hash type to be in message
- **mgf** Mask Generation Function Identifiers
- **key** The key to use for verification.

See:

- wc_RsaPSS_Verify
- wc_RsaSetRNG

Return: RSA_BUFFER_E: -131, RSA buffer error, output too small or input too large

Example

```
ret = wc_InitRsaKey(&key, NULL);
if (ret == 0) {
    ret = wc_InitRng(&rng);
} else return -1;
if (ret == 0) {
    ret = wc_RsaSetRNG(&key, &rng);
} else return -1;
if (ret == 0) {
        ret = wc_MakeRsaKey(&key, 2048, WC_RSA_EXPONENT, &rng);
} else return -1;

ret = wc_RsaPSS_Sign((byte*)szMessage, (word32)XSTRLEN(szMessage)+1,
        pSignature, sizeof(pSignature),
        WC_HASH_TYPE_SHA256, WC_MGF1SHA256, &key, &rng);
if (ret > 0 ){
    sz = ret;
} else return -1;

ret = wc_RsaPSS_Verify(pSignature, sz, pt, outLen,
        WC_HASH_TYPE_SHA256, WC_MGF1SHA256, &key);
if (ret <= 0)return -1;

wc_FreeRsaKey(&key);
wc_FreeRng(&rng);
```

C.49.2.13 function wc_RsaPSS_Verify

```
int wc_RsaPSS_Verify(
    const byte * in,
    word32 inLen,
    byte * out,
    word32 outLen,
    enum wc_HashType hash,
    int mgf,
    RsaKey * key
)
```

Decrypt input signature to verify that the message was signed by key. The key has to be associated with RNG by wc_RsaSetRNG when WC_RSA_BLINDING is enabled.

Parameters:

- **in** The byte array to be decrypted.
- **inLen** The length of in.
- **out** The byte array for the decrypted data to be stored.
- **outLen** The length of out.
- **hash** The hash type to be in message
- **mgf** Mask Generation Function Identifiers
- **key** The key to use for verification.

See:

- wc_RsaPSS_Sign
- wc_RsaPSS_VerifyInline
- wc_RsaPSS_CheckPadding
- wc_RsaSetRNG

Return:

- Success Length of text on no error.
- MEMORY_E memory exception.
- MP_EXPTMOD_E - When using fastmath and FP_MAX_BITS not set to at least 2 times the keySize (Example when using 4096-bit key set FP_MAX_BITS to 8192 or greater value)

Example

```
ret = wc_InitRsaKey(&key, NULL);
if (ret == 0) {
    ret = wc_InitRng(&rng);
} else return -1;
if (ret == 0) {
    ret = wc_RsaSetRNG(&key, &rng);
} else return -1;
if (ret == 0) {
        ret = wc_MakeRsaKey(&key, 2048, WC_RSA_EXPONENT, &rng);
} else return -1;
ret = wc_RsaPSS_Sign((byte*)szMessage, (word32)XSTRLEN(szMessage)+1,
        pSignature, sizeof(pSignature),
        WC_HASH_TYPE_SHA256, WC_MGF1SHA256, &key, &rng);
if (ret > 0 ){
    sz = ret;
} else return -1;

ret = wc_RsaPSS_Verify(pSignature, sz, pt, outLen,
        WC_HASH_TYPE_SHA256, WC_MGF1SHA256, &key);
if (ret <= 0)return -1;

wc_FreeRsaKey(&key);
wc_FreeRng(&rng);
```

C.49.2.14 function wc_RsaPSS_VerifyInline

```
int wc_RsaPSS_VerifyInline(
    byte * in,
    word32 inLen,
    byte ** out,
    enum wc_HashType hash,
    int mgf,
    RsaKey * key
)
```

Decrypt input signature to verify that the message was signed by RSA key. The output uses the same byte array as the input. The key has to be associated with RNG by wc_RsaSetRNG when WC_RSA_BLINDING is enabled.

Parameters:

- **in** Byte array to be decrypted.

- **inLen** Length of the buffer input.
- **out** Pointer to address containing the PSS data.
- **hash** The hash type to be in message
- **mgf** Mask Generation Function Identifiers
- **key** RsaKey to use.

See:

- wc_RsaPSS_Verify
- wc_RsaPSS_Sign
- wc_RsaPSS_VerifyCheck
- wc_RsaPSS_VerifyCheck_ex
- wc_RsaPSS_VerifyCheckInline
- wc_RsaPSS_VerifyCheckInline_ex
- wc_RsaPSS_CheckPadding
- wc_RsaPSS_CheckPadding_ex
- wc_RsaSetRNG

Return:

- 0 Length of text.
- <0 An error occurred.

Example

```
ret = wc_InitRsaKey(&key, NULL);
if (ret == 0) {
    ret = wc_InitRng(&rng);
} else return -1;
if (ret == 0) {
    ret = wc_RsaSetRNG(&key, &rng);
} else return -1;
if (ret == 0) {
        ret = wc_MakeRsaKey(&key, 2048, WC_RSA_EXPONENT, &rng);
} else return -1;
ret = wc_RsaPSS_Sign(digest, digestSz, pSignature, pSignatureSz,
        WC_HASH_TYPE_SHA256, WC_MGF1SHA256, &key, &rng);
if (ret > 0 ){
    sz = ret;
} else return -1;

ret = wc_RsaPSS_VerifyInline(pSignature, sz, pt,
        WC_HASH_TYPE_SHA256, WC_MGF1SHA256, &key);
if (ret <= 0)return -1;

wc_FreeRsaKey(&key);
wc_FreeRng(&rng);
```

C.49.2.15 function wc_RsaPSS_VerifyCheck

```
int wc_RsaPSS_VerifyCheck(
    const byte * in,
    word32 inLen,
    byte * out,
    word32 outLen,
    const byte * digest,
    word32 digestLen,
```

```
    enum wc_HashType hash,
    int mgf,
    RsaKey * key
)
```

Verify the message signed with RSA-PSS. Salt length is equal to hash length. The key has to be associated with RNG by wc_RsaSetRNG when WC_RSA_BLINDING is enabled.

Parameters:

- **in** The byte array to be decrypted.
- **inLen** The length of in.
- **out** Pointer to address containing the PSS data. Zeroed when a crypto callback device reported only a verdict (see
- **outLen** The length of out.
- **digest** Hash of the data that is being verified.
- **digestLen** Length of hash.
- **hash** Hash algorithm.
- **mgf** Mask generation function.
- **key** Public RSA key.

See:

- wc_RsaPSS_Sign
- wc_RsaPSS_Verify
- wc_RsaPSS_VerifyCheck_ex
- wc_RsaPSS_VerifyCheckInline
- wc_RsaPSS_VerifyCheckInline_ex
- wc_RsaPSS_CheckPadding
- wc_RsaPSS_CheckPadding_ex
- wc_RsaSetRNG

Return:

- the length of the PSS data on success and negative indicates failure. A crypto callback device that returns recovered data fills out and the return is that length. A device that reports only a verdict recovers nothing: out is zeroed and the return is the length the data would have been, so callers must not read out on that path.
- MEMORY_E memory exception.
-).

Example

```
ret = wc_InitRsaKey(&key, NULL);
if (ret == 0) {
    ret = wc_InitRng(&rng);
} else return -1;
if (ret == 0) {
    ret = wc_RsaSetRNG(&key, &rng);
} else return -1;
if (ret == 0) {
        ret = wc_MakeRsaKey(&key, 2048, WC_RSA_EXPONENT, &rng);
} else return -1;

if (ret == 0) {
    digestSz = wc_HashGetDigestSize(WC_HASH_TYPE_SHA256);
    ret = wc_Hash(WC_HASH_TYPE_SHA256, message, sz, digest, digestSz);
} else return -1;
```

```
if (ret == 0) {
    ret = wc_RsaPSS_Sign(digest, digestSz, pSignature, pSignatureSz,
            WC_HASH_TYPE_SHA256, WC_MGF1SHA256, &key, &rng);
    if (ret > 0 ){
        sz = ret;
    } else return -1;
} else return -1;
if (ret == 0) {
    ret = wc_RsaPSS_VerifyCheck(pSignature, sz, pt, outLen,
            digest, digestSz, WC_HASH_TYPE_SHA256, WC_MGF1SHA256, &key);
        if (ret <= 0) return -1;
} else return -1;

wc_FreeRsaKey(&key);
wc_FreeRng(&rng);
```

C.49.2.16 function wc_RsaPSS_VerifyCheck_ex

```
int wc_RsaPSS_VerifyCheck_ex(
    byte * in,
    word32 inLen,
    byte * out,
    word32 outLen,
    const byte * digest,
    word32 digestLen,
    enum wc_HashType hash,
    int mgf,
    int saltLen,
    RsaKey * key
)
```

Verify the message signed with RSA-PSS. The key has to be associated with RNG by wc_RsaSetRNG when WC_RSA_BLINDING is enabled.

Parameters:

- **in** The byte array to be decrypted.
- **inLen** The length of in.
- **out** Pointer to address containing the PSS data.
- **outLen** The length of out.
- **digest** Hash of the data that is being verified.
- **digestLen** Length of hash.
- **hash** Hash algorithm.
- **mgf** Mask generation function.
- **saltLen** Length of salt used. RSA_PSS_SALT_LEN_DEFAULT (-1) indicates salt length is the same as the hash length. RSA_PSS_SALT_LEN_DISCOVER indicates salt length is determined from the data.
- **key** Public RSA key.

See:

- wc_RsaPSS_Sign
- wc_RsaPSS_Verify
- wc_RsaPSS_VerifyCheck
- wc_RsaPSS_VerifyCheckInline
- wc_RsaPSS_VerifyCheckInline_ex
- wc_RsaPSS_CheckPadding

- wc_RsaPSS_CheckPadding_ex
- wc_RsaSetRNG

Return:

- the length of the PSS data on success and negative indicates failure.
- MEMORY_E memory exception.

Example

```
ret = wc_InitRsaKey(&key, NULL);
if (ret == 0) {
    ret = wc_InitRng(&rng);
} else return -1;
if (ret == 0) {
    ret = wc_RsaSetRNG(&key, &rng);
} else return -1;
if (ret == 0) {
        ret = wc_MakeRsaKey(&key, 2048, WC_RSA_EXPONENT, &rng);
} else return -1;

if (ret == 0) {
    digestSz = wc_HashGetDigestSize(WC_HASH_TYPE_SHA256);
    ret = wc_Hash(WC_HASH_TYPE_SHA256, message, sz, digest, digestSz);
} else return -1;

if (ret == 0) {
    ret = wc_RsaPSS_Sign(digest, digestSz, pSignature, pSignatureSz,
            WC_HASH_TYPE_SHA256, WC_MGF1SHA256, &key, &rng);
    if (ret > 0 ){
        sz = ret;
    } else return -1;
} else return -1;
if (ret == 0) {
    ret = wc_RsaPSS_VerifyCheck_ex(pSignature, sz, pt, outLen,
            digest, digestSz, WC_HASH_TYPE_SHA256, WC_MGF1SHA256, saltLen,
 ↪  &key);
        if (ret <= 0) return -1;
} else return -1;

wc_FreeRsaKey(&key);
wc_FreeRng(&rng);
```

C.49.2.17 function wc_RsaPSS_VerifyCheckInline

```
int wc_RsaPSS_VerifyCheckInline(
    byte * in,
    word32 inLen,
    byte ** out,
    const byte * digest,
    word32 digentLen,
    enum wc_HashType hash,
    int mgf,
    RsaKey * key
)
```

Verify the message signed with RSA-PSS. The input buffer is reused for the output buffer. Salt length is equal to hash length.

Parameters:

- **in** The byte array to be decrypted.
- **inLen** The length of in.
- **out** The byte array for the decrypted data to be stored. Set to NULL when a crypto callback device reported only a verdict (see
- **digest** Hash of the data that is being verified.
- **digestLen** Length of hash.
- **hash** The hash type to be in message
- **mgf** Mask Generation Function Identifiers
- **key** The key to use for verification.

See:

- wc_RsaPSS_Sign
- wc_RsaPSS_Verify
- wc_RsaPSS_VerifyCheck
- wc_RsaPSS_VerifyCheck_ex
- wc_RsaPSS_VerifyCheckInline_ex
- wc_RsaPSS_CheckPadding
- wc_RsaPSS_CheckPadding_ex
- wc_RsaSetRNG

Return:

- the length of the PSS data on success and negative indicates failure. A crypto callback device that returns recovered data points *out into in and the return is that length. A device that reports only a verdict recovers nothing:* out is set to NULL though the return stays positive, so callers must check *out before dereferencing it.
-).

The key has to be associated with RNG by wc_RsaSetRNG when WC_RSA_BLINDING is enabled.

Example

```
ret = wc_InitRsaKey(&key, NULL);
if (ret == 0) {
    ret = wc_InitRng(&rng);
} else return -1;
if (ret == 0) {
    ret = wc_RsaSetRNG(&key, &rng);
} else return -1;
if (ret == 0) {
        ret = wc_MakeRsaKey(&key, 2048, WC_RSA_EXPONENT, &rng);
} else return -1;

if (ret == 0) {
    digestSz = wc_HashGetDigestSize(WC_HASH_TYPE_SHA256);
    ret = wc_Hash(WC_HASH_TYPE_SHA256, message, sz, digest, digestSz);
} else return -1;

if (ret == 0) {
    ret = wc_RsaPSS_Sign(digest, digestSz, pSignature, pSignatureSz,
            WC_HASH_TYPE_SHA256, WC_MGF1SHA256, &key, &rng);
    if (ret > 0 ){
        sz = ret;
```

```
    } else return -1;
} else return -1;
if (ret == 0) {
    ret = wc_RsaPSS_VerifyCheckInline(pSignature, sz, pt,
            digest, digestSz, WC_HASH_TYPE_SHA256, WC_MGF1SHA256, &key);
        if (ret <= 0) return -1;
} else return -1;

wc_FreeRsaKey(&key);
wc_FreeRng(&rng);
```

C.49.2.18 function wc_RsaPSS_VerifyCheckInline_ex

```
int wc_RsaPSS_VerifyCheckInline_ex(
    byte * in,
    word32 inLen,
    byte ** out,
    const byte * digest,
    word32 digentLen,
    enum wc_HashType hash,
    int mgf,
    int saltLen,
    RsaKey * key
)
```

Verify the message signed with RSA-PSS. The input buffer is reused for the output buffer. The key has to be associated with RNG by wc_RsaSetRNG when WC_RSA_BLINDING is enabled.

Parameters:

- **in** The byte array to be decrypted.
- **inLen** The length of in.
- **out** The byte array for the decrypted data to be stored.
- **digest** Hash of the data that is being verified.
- **digestLen** Length of hash.
- **hash** The hash type to be in message
- **mgf** Mask Generation Function Identifiers
- **saltLen** Length of salt used. RSA_PSS_SALT_LEN_DEFAULT (-1) indicates salt length is the same as the hash length. RSA_PSS_SALT_LEN_DISCOVER indicates salt length is determined from the data.
- **key** The key to use for verification.

See:

- wc_RsaPSS_Sign
- wc_RsaPSS_Verify
- wc_RsaPSS_VerifyCheck
- wc_RsaPSS_VerifyCheck_ex
- wc_RsaPSS_VerifyCheckInline
- wc_RsaPSS_CheckPadding
- wc_RsaPSS_CheckPadding_ex
- wc_RsaSetRNG

Return: the length of the PSS data on success and negative indicates failure.

Example

```
ret = wc_InitRsaKey(&key, NULL);
if (ret == 0) {
    ret = wc_InitRng(&rng);
} else return -1;
if (ret == 0) {
    ret = wc_RsaSetRNG(&key, &rng);
} else return -1;
if (ret == 0) {
        ret = wc_MakeRsaKey(&key, 2048, WC_RSA_EXPONENT, &rng);
} else return -1;

if (ret == 0) {
    digestSz = wc_HashGetDigestSize(WC_HASH_TYPE_SHA256);
    ret = wc_Hash(WC_HASH_TYPE_SHA256, message, sz, digest, digestSz);
} else return -1;

if (ret == 0) {
    ret = wc_RsaPSS_Sign(digest, digestSz, pSignature, pSignatureSz,
            WC_HASH_TYPE_SHA256, WC_MGF1SHA256, &key, &rng);
    if (ret > 0 ){
        sz = ret;
    } else return -1;
} else return -1;
if (ret == 0) {
    ret = wc_RsaPSS_VerifyCheckInline_ex(pSignature, sz, pt,
            digest, digestSz, WC_HASH_TYPE_SHA256, WC_MGF1SHA256, saltLen,
 ↪  &key);
        if (ret <= 0) return -1;
} else return -1;

wc_FreeRsaKey(&key);
wc_FreeRng(&rng);
```

C.49.2.19 function wc_RsaPSS_CheckPadding

```
int wc_RsaPSS_CheckPadding(
    const byte * in,
    word32 inLen,
    const byte * sig,
    word32 sigSz,
    enum wc_HashType hashType
)
```

Checks the PSS data to ensure that the signature matches. Salt length is equal to hash length. The key has to be associated with RNG by wc_RsaSetRNG when WC_RSA_BLINDING is enabled.

Parameters:

- **in** Hash of the data that is being verified.
- **inSz** Length of hash.
- **sig** Buffer holding PSS data.
- **sigSz** Size of PSS data.
- **hashType** Hash algorithm.

See:

- wc_RsaPSS_Sign

- wc_RsaPSS_Verify
- wc_RsaPSS_VerifyInline
- wc_RsaPSS_VerifyCheck
- wc_RsaPSS_VerifyCheck_ex
- wc_RsaPSS_VerifyCheckInline
- wc_RsaPSS_VerifyCheckInline_ex
- wc_RsaPSS_CheckPadding_ex
- wc_RsaSetRNG

Return:

- BAD_PADDING_E when the PSS data is invalid, BAD_FUNC_ARG when NULL is passed in to in or sig or inSz is not the same as the hash algorithm length and 0 on success.
- MEMORY_E memory exception.

Example

```
ret = wc_InitRsaKey(&key, NULL);
if (ret == 0) {
    ret = wc_InitRng(&rng);
} else return -1;
if (ret == 0) {
    ret = wc_RsaSetRNG(&key, &rng);
} else return -1;
if (ret == 0) {
        ret = wc_MakeRsaKey(&key, 2048, WC_RSA_EXPONENT, &rng);
} else return -1;
if (ret == 0) {
    digestSz = wc_HashGetDigestSize(WC_HASH_TYPE_SHA256);
    ret = wc_Hash(WC_HASH_TYPE_SHA256, message, sz, digest, digestSz);
} else return -1;
ret = wc_RsaPSS_Sign(digest, digestSz, pSignature, sizeof(pSignature),
        WC_HASH_TYPE_SHA256, WC_MGF1SHA256, &key, &rng);
if (ret > 0 ){
    sz = ret;
} else return -1;

verify = wc_RsaPSS_Verify(pSignature, sz, out, outLen,
        WC_HASH_TYPE_SHA256, WC_MGF1SHA256, &key);
if (verify <= 0)return -1;

ret = wc_RsaPSS_CheckPadding(digest, digestSz, out, verify, hash);

wc_FreeRsaKey(&key);
wc_FreeRng(&rng);
```

C.49.2.20 function wc_RsaPSS_CheckPadding_ex

```
int wc_RsaPSS_CheckPadding_ex(
    const byte * in,
    word32 inLen,
    const byte * sig,
    word32 sigSz,
    enum wc_HashType hashType,
    int saltLen,
    int bits
```

)

Checks the PSS data to ensure that the signature matches. Salt length is equal to hash length.

Parameters:

- **in** Hash of the data that is being verified.
- **inSz** Length of hash.
- **sig** Buffer holding PSS data.
- **sigSz** Size of PSS data.
- **hashType** Hash algorithm.
- **saltLen** Length of salt used. RSA_PSS_SALT_LEN_DEFAULT (-1) indicates salt length is the same as the hash length. RSA_PSS_SALT_LEN_DISCOVER indicates salt length is determined from the data.
- **bits** Can be used to calculate salt size in FIPS case

See:

- wc_RsaPSS_Sign
- wc_RsaPSS_Verify
- wc_RsaPSS_VerifyInline
- wc_RsaPSS_VerifyCheck
- wc_RsaPSS_VerifyCheck_ex
- wc_RsaPSS_VerifyCheckInline
- wc_RsaPSS_VerifyCheckInline_ex
- wc_RsaPSS_CheckPadding

Return:

- BAD_PADDING_E when the PSS data is invalid, BAD_FUNC_ARG when NULL is passed in to in or sig or inSz is not the same as the hash algorithm length and 0 on success.
- MEMORY_E memory exception.

Example

```
ret = wc_InitRsaKey(&key, NULL);
if (ret == 0) {
    ret = wc_InitRng(&rng);
} else return -1;
if (ret == 0) {
    ret = wc_RsaSetRNG(&key, &rng);
} else return -1;
if (ret == 0) {
        ret = wc_MakeRsaKey(&key, 2048, WC_RSA_EXPONENT, &rng);
} else return -1;
if (ret == 0) {
    digestSz = wc_HashGetDigestSize(WC_HASH_TYPE_SHA256);
    ret = wc_Hash(WC_HASH_TYPE_SHA256, message, sz, digest, digestSz);
} else return -1;
ret = wc_RsaPSS_Sign(digest, digestSz, pSignature, sizeof(pSignature),
        WC_HASH_TYPE_SHA256, WC_MGF1SHA256, &key, &rng);
if (ret > 0 ){
    sz = ret;
} else return -1;

verify = wc_RsaPSS_Verify(pSignature, sz, out, outLen,
        WC_HASH_TYPE_SHA256, WC_MGF1SHA256, &key);
if (verify <= 0)return -1;
```

```
ret = wc_RsaPSS_CheckPadding_ex(digest, digestSz, out, verify, hash, saltLen,
 ↪  0);

wc_FreeRsaKey(&key);
wc_FreeRng(&rng);
```

C.49.2.21 function wc_RsaEncryptSize

```
int wc_RsaEncryptSize(
    const RsaKey * key
)
```

Returns the encryption size for the provided key structure.

Parameters:

- **key** The key to use for verification.

See:

- wc_InitRsaKey
- wc_InitRsaKey_ex
- wc_MakeRsaKey

Return: Success Encryption size for the provided key structure.

Example

```
int sz = wc_RsaEncryptSize(&key);
```

C.49.2.22 function wc_RsaPrivateKeyDecode

```
int wc_RsaPrivateKeyDecode(
    const byte * input,
    word32 * inOutIdx,
    RsaKey * key,
    word32 inSz
)
```

This function parses a DER-formatted RSA private key, extracts the private key and stores it in the given RsaKey structure. It also sets the distance parsed in idx.

Parameters:

- **input** pointer to the buffer containing the DER formatted private key to decode
- **inOutIdx** pointer to the index in the buffer at which the key begins (usually 0). As a side effect of this function, inOutIdx will store the distance parsed through the input buffer
- **key** pointer to the RsaKey structure in which to store the decoded private key
- **inSz** size of the input buffer

See:

- wc_RsaPublicKeyDecode
- wc_MakeRsaKey

Return:

- 0 Returned upon successfully parsing the private key from the DER encoded input
- ASN_PARSE_E Returned if there is an error parsing the private key from the input buffer. This may happen if the input private key is not properly formatted according to ASN.1 standards
- ASN_RSA_KEY_E Returned if there is an error reading the private key elements of the RSA key input

Example

```
RsaKey enc;
word32 idx = 0;
int ret = 0;
byte der[] = { // initialize with DER-encoded RSA private key };

wc_InitRsaKey(&enc, NULL); // not using heap hint. No custom memory
ret = wc_RsaPrivateKeyDecode(der, &idx, &enc, sizeof(der));
if( ret != 0 ) {
    // error parsing private key
}
```

C.49.2.23 function wc_RsaPublicKeyDecode

```
int wc_RsaPublicKeyDecode(
    const byte * input,
    word32 * inOutIdx,
    RsaKey * key,
    word32 inSz
)
```

This function parses a DER-formatted RSA public key, extracts the public key and stores it in the given RsaKey structure. It also sets the distance parsed in idx.

Parameters:

- **input** pointer to the buffer containing the input DER-encoded RSA public key to decode
- **inOutIdx** pointer to the index in the buffer at which the key begins (usually 0). As a side effect of this function, inOutIdx will store the distance parsed through the input buffer
- **key** pointer to the RsaKey structure in which to store the decoded public key
- **inSz** size of the input buffer

See: wc_RsaPublicKeyDecodeRaw

Return:

- 0 Returned upon successfully parsing the public key from the DER encoded input
- ASN_PARSE_E Returned if there is an error parsing the public key from the input buffer. This may happen if the input public key is not properly formatted according to ASN.1 standards
- ASN_OBJECT_ID_E Returned if the ASN.1 Object ID does not match that of a RSA public key
- ASN_EXPECT_0_E Returned if the input key is not correctly formatted according to ASN.1 standards
- ASN_BITSTR_E Returned if the input key is not correctly formatted according to ASN.1 standards
- ASN_RSA_KEY_E Returned if there is an error reading the public key elements of the RSA key input

Example

```
RsaKey pub;
word32 idx = 0;
int ret = 0;
byte der[] = { // initialize with DER-encoded RSA public key };

wc_InitRsaKey(&pub, NULL); // not using heap hint. No custom memory
ret = wc_RsaPublicKeyDecode(der, &idx, &pub, sizeof(der));
if( ret != 0 ) {
    // error parsing public key
}
```

C.49.2.24 function wc_RsaPublicKeyDecodeRaw

```
int wc_RsaPublicKeyDecodeRaw(
    const byte * n,
    word32 nSz,
    const byte * e,
    word32 eSz,
    RsaKey * key
)
```

This function decodes the raw elements of an RSA public key, taking in the public modulus (n) and exponent (e). It stores these raw elements in the provided RsaKey structure, allowing one to use them in the encryption/decryption process.

Parameters:

- **n** pointer to a buffer containing the raw modulus parameter of the public RSA key
- **nSz** size of the buffer containing n
- **e** pointer to a buffer containing the raw exponent parameter of the public RSA key
- **eSz** size of the buffer containing e
- **key** pointer to the RsaKey struct to initialize with the provided public key elements

See: wc_RsaPublicKeyDecode

Return:

- 0 Returned upon successfully decoding the raw elements of the public key into the RsaKey structure
- BAD_FUNC_ARG Returned if any of the input arguments evaluates to NULL
- MP_INIT_E Returned if there is an error initializing an integer for use with the multiple precision integer (mp_int) library
- ASN_GETINT_E Returned if there is an error reading one of the provided RSA key elements, n or e

Example

```
RsaKey pub;
int ret = 0;
byte n[] = { // initialize with received n component of public key };
byte e[] = { // initialize with received e component of public key };

wc_InitRsaKey(&pub, NULL); // not using heap hint. No custom memory
ret = wc_RsaPublicKeyDecodeRaw(n, sizeof(n), e, sizeof(e), &pub);
if( ret != 0 ) {
    // error parsing public key elements
}
```

C.49.2.25 function wc_RsaKeyToDer

```
int wc_RsaKeyToDer(
    RsaKey * key,
    byte * output,
    word32 outLen
)
```

This function converts an RsaKey key to DER format. The result is written to output and it returns the number of bytes written.

Parameters:

- **key** Initialized RsaKey structure.
- **output** Pointer to output buffer.
- **outLen** Size of output buffer.

See:

- wc_RsaKeyToPublicDer
- wc_InitRsaKey
- wc_MakeRsaKey
- wc_InitRng

Return:

- 0 Success, number of bytes written.
- BAD_FUNC_ARG Returned if key or output is null, or if key->type is not RSA_PRIVATE, or if outLen isn't large enough for output buffer.
- MEMORY_E Returned if there is an error allocating memory.

Example

```
byte* der;
// Allocate memory for der
int derSz = // Amount of memory allocated for der;
RsaKey key;
WC_RNG rng;
long e = 65537; // standard value to use for exponent
ret = wc_MakeRsaKey(&key, 2048, e, &rng); // generate 2048 bit long
private key
wc_InitRsaKey(&key, NULL);
wc_InitRng(&rng);
if(wc_RsaKeyToDer(&key, der, derSz) != 0)
{
    // Handle the error thrown
}
```

C.49.2.26 function wc_RsaPublicEncrypt_ex

```
int wc_RsaPublicEncrypt_ex(
    const byte * in,
    word32 inLen,
    byte * out,
    word32 outLen,
    RsaKey * key,
    WC_RNG * rng,
    int type,
    enum wc_HashType hash,
    int mgf,
    byte * label,
    word32 labelSz
)
```

This function performs RSA encrypt while allowing the choice of which padding to use.

Parameters:

- **in** pointer to the buffer for encryption
- **inLen** length of the buffer to encrypt
- **out** encrypted msg created

- **outLen** length of buffer available to hold encrypted msg
- **key** initialized RSA key struct
- **rng** initialized WC_RNG struct
- **type** type of padding to use (WC_RSA_OAEP_PAD or WC_RSA_PKCSV15_PAD)
- **hash** type of hash to use (choices can be found in hash.h)
- **mgf** type of mask generation function to use
- **label** an optional label to associate with encrypted message
- **labelSz** size of the optional label used

See:

- wc_RsaPublicEncrypt
- wc_RsaPrivateDecrypt_ex

Return:

- size On successfully encryption the size of the encrypted buffer is returned
- RSA_BUFFER_E RSA buffer error, output too small or input too large

Example

```
WC_RNG rng;
RsaKey key;
byte in[] = “I use Turing Machines to ask questions”
byte out[256];
int ret;
…

ret = wc_RsaPublicEncrypt_ex(in, sizeof(in), out, sizeof(out), &key, &rng,
WC_RSA_OAEP_PAD, WC_HASH_TYPE_SHA, WC_MGF1SHA1, NULL, 0);
if (ret < 0) {
    //handle error
}
```

C.49.2.27 function wc_RsaPrivateDecrypt_ex

```
int wc_RsaPrivateDecrypt_ex(
    const byte * in,
    word32 inLen,
    byte * out,
    word32 outLen,
    RsaKey * key,
    int type,
    enum wc_HashType hash,
    int mgf,
    byte * label,
    word32 labelSz
)
```

This function uses RSA to decrypt a message and gives the option of what padding type.

Parameters:

- **in** pointer to the buffer for decryption
- **inLen** length of the buffer to decrypt
- **out** decrypted msg created
- **outLen** length of buffer available to hold decrypted msg
- **key** initialized RSA key struct
- **type** type of padding to use (WC_RSA_OAEP_PAD or WC_RSA_PKCSV15_PAD)

- **hash** type of hash to use (choices can be found in hash.h)
- **mgf** type of mask generation function to use
- **label** an optional label to associate with encrypted message
- **labelSz** size of the optional label used

See: none

Return:

- size On successful decryption, the size of the decrypted message is returned.
- MEMORY_E Returned if not enough memory on system to malloc a needed array.
- BAD_FUNC_ARG Returned if a bad argument was passed into the function.

Example

```
WC_RNG rng;
RsaKey key;
byte in[] = “I use Turing Machines to ask questions”
byte out[256];
byte plain[256];
int ret;
…
ret = wc_RsaPublicEncrypt_ex(in, sizeof(in), out, sizeof(out), &key,
&rng, WC_RSA_OAEP_PAD, WC_HASH_TYPE_SHA, WC_MGF1SHA1, NULL, 0);
if (ret < 0) {
    //handle error
}
…
ret = wc_RsaPrivateDecrypt_ex(out, ret, plain, sizeof(plain), &key,
WC_RSA_OAEP_PAD, WC_HASH_TYPE_SHA, WC_MGF1SHA1, NULL, 0);

if (ret < 0) {
    //handle error
}
```

C.49.2.28 function wc_RsaPrivateDecryptInline_ex

```
int wc_RsaPrivateDecryptInline_ex(
    byte * in,
    word32 inLen,
    byte ** out,
    RsaKey * key,
    int type,
    enum wc_HashType hash,
    int mgf,
    byte * label,
    word32 labelSz
)
```

This function uses RSA to decrypt a message inline and gives the option of what padding type. The in buffer will contain the decrypted message after being called and the out byte pointer will point to the location in the “in” buffer where the plain text is.

Parameters:

- **in** pointer to the buffer for decryption
- **inLen** length of the buffer to decrypt
- **out** pointer to location of decrypted message in “in” buffer

- **key** initialized RSA key struct
- **type** type of padding to use (WC_RSA_OAEP_PAD or WC_RSA_PKCSV15_PAD)
- **hash** type of hash to use (choices can be found in hash.h)
- **mgf** type of mask generation function to use
- **label** an optional label to associate with encrypted message
- **labelSz** size of the optional label used

See: none

Return:

- size On successful decryption, the size of the decrypted message is returned.
- MEMORY_E: Returned if not enough memory on system to malloc a needed array.
- RSA_PAD_E: Returned if an error in the padding was encountered.
- BAD_PADDING_E: Returned if an error happened during parsing past padding.
- BAD_FUNC_ARG: Returned if a bad argument was passed into the function.

Example

```
WC_RNG rng;
RsaKey key;
byte in[] = “I use Turing Machines to ask questions”
byte out[256];
byte* plain;
int ret;
…
ret = wc_RsaPublicEncrypt_ex(in, sizeof(in), out, sizeof(out), &key,
&rng, WC_RSA_OAEP_PAD, WC_HASH_TYPE_SHA, WC_MGF1SHA1, NULL, 0);

if (ret < 0) {
    //handle error
}
…
ret = wc_RsaPrivateDecryptInline_ex(out, ret, &plain, &key,
WC_RSA_OAEP_PAD, WC_HASH_TYPE_SHA, WC_MGF1SHA1, NULL, 0);

if (ret < 0) {
    //handle error
}
```

C.49.2.29 function wc_RsaFlattenPublicKey

```
int wc_RsaFlattenPublicKey(
    const RsaKey * key,
    byte * e,
    word32 * eSz,
    byte * n,
    word32 * nSz
)
```

Flattens the RsaKey structure into individual elements (e, n) used for the RSA algorithm.

Parameters:

- **key** The key to use for verification.
- **e** a buffer for the value of e. e is a large positive integer in the RSA modular arithmetic operation.
- **eSz** the size of the e buffer.
- **n** a buffer for the value of n. n is a large positive integer in the RSA modular arithmetic operation.

- **nSz** the size of the n buffer.

See:

- wc_InitRsaKey
- wc_InitRsaKey_ex
- wc_MakeRsaKey

Return:

- 0 Returned if the function executed normally, without error.
- BAD_FUNC_ARG: Returned if any of the parameters are passed in with a null value.
- RSA_BUFFER_E: Returned if the e or n buffers passed in are not the correct size.
- MP_MEM: Returned if an internal function has memory errors.
- MP_VAL: Returned if an internal function argument is not valid.

Example

```
Rsa key; // A valid RSA key.
byte e[ buffer sz E.g. 256 ];
byte n[256];
int ret;
word32 eSz = sizeof(e);
word32 nSz = sizeof(n);
...
ret = wc_RsaFlattenPublicKey(&key, e, &eSz, n, &nSz);
if (ret != 0) {
    // Failure case.
}
```

C.49.2.30 function wc_RsaKeyToPublicDer

```
int wc_RsaKeyToPublicDer(
    RsaKey * key,
    byte * output,
    word32 outLen
)
```

Convert Rsa Public key to DER format. Writes to output, and returns count of bytes written.

Parameters:

- **key** The RSA key structure to convert.
- **output** Output buffer to hold DER. (if NULL will return length only)
- **outLen** Length of buffer.

See:

- wc_RsaPublicKeyDerSize
- wc_RsaKeyToPublicDer_ex
- wc_InitRsaKey

Return:

- 0 Success, number of bytes written.
- BAD_FUNC_ARG Returned if key or output is null.
- MEMORY_E Returned when an error allocating memory occurs.
- <0 Error

Example

```
RsaKey key;

wc_InitRsaKey(&key, NULL);
// Use key

const int BUFFER_SIZE = 1024; // Some adequate size for the buffer
byte output[BUFFER_SIZE];
if (wc_RsaKeyToPublicDer(&key, output, sizeof(output)) != 0) {
    // Handle Error
}
```

C.49.2.31 function wc_RsaKeyToPublicDer_ex

```
int wc_RsaKeyToPublicDer_ex(
    RsaKey * key,
    byte * output,
    word32 outLen,
    int with_header
)
```

Convert RSA Public key to DER format. Writes to output, and returns count of bytes written. If with_header is 0 then only the (seq + n + e) is returned in ASN.1 DER format and will exclude the header.

Parameters:

- **key** The RSA key structure to convert.
- **output** Output buffer to hold DER. (if NULL will return length only)
- **outLen** Length of buffer.

See:

- wc_RsaPublicKeyDerSize
- wc_RsaKeyToPublicDer
- wc_InitRsaKey

Return:

- 0 Success, number of bytes written.
- BAD_FUNC_ARG Returned if key or output is null.
- MEMORY_E Returned when an error allocating memory occurs.
- <0 Error

Example

```
RsaKey key;

wc_InitRsaKey(&key, NULL);
// Use key

const int BUFFER_SIZE = 1024; // Some adequate size for the buffer
byte output[BUFFER_SIZE];
if (wc_RsaKeyToPublicDer_ex(&key, output, sizeof(output), 0) != 0) {
    // Handle Error
}
```

C.49.2.32 function wc_MakeRsaKey

```
int wc_MakeRsaKey(
    RsaKey * key,
    int size,
    long e,
    WC_RNG * rng
)
```

This function generates a RSA private key of length size (in bits) and given exponent (e). It then stores this key in the provided RsaKey structure, so that it may be used for encryption/decryption. A secure number to use for e is 65537. size is required to be greater than or equal to RSA_MIN_SIZE and less than or equal to RSA_MAX_SIZE. For this function to be available, the option WOLFSSL_KEY_GEN must be enabled at compile time. This can be accomplished with –enable-keygen if using ./configure.

Parameters:

- **key** pointer to the RsaKey structure in which to store the generated private key
- **size** desired key length, in bits. Required to be greater than RSA_MIN_SIZE and less than RSA_MAX_SIZE
- **e** exponent parameter to use for generating the key. A secure choice is 65537
- **rng** pointer to an RNG structure to use for random number generation while making the key

See: none

Return:

- 0 Returned upon successfully generating a RSA private key
- BAD_FUNC_ARG Returned if any of the input arguments are NULL, the size parameter falls outside of the necessary bounds, or e is incorrectly chosen
- RNG_FAILURE_E Returned if there is an error generating a random block using the provided RNG structure
- MP_INIT_E
- MP_READ_E May be May be returned if there is an error in the math library used while generating the RSA key returned if there is an error in the math library used while generating the RSA key
- MP_CMP_E May be returned if there is an error in the math library used while generating the RSA key
- MP_INVMOD_E May be returned if there is an error in the math library used while generating the RSA key
- MP_EXPTMOD_E May be returned if there is an error in the math library used while generating the RSA key
- MP_MOD_E May be returned if there is an error in the math library used while generating the RSA key
- MP_MUL_E May be returned if there is an error in the math library used while generating the RSA key
- MP_ADD_E May be returned if there is an error in the math library used while generating the RSA key
- MP_MULMOD_E May be returned if there is an error in the math library used while generating the RSA key
- MP_TO_E May be returned if there is an error in the math library used while generating the RSA key
- MP_MEM May be returned if there is an error in the math library used while generating the RSA key
- MP_ZERO_E May be returned if there is an error in the math library used while generating the RSA key

Example

```
RsaKey priv;
WC_RNG rng;
int ret = 0;
long e = 65537; // standard value to use for exponent

wc_InitRsaKey(&priv, NULL); // not using heap hint. No custom memory
wc_InitRng(&rng);
// generate 2048 bit long private key
ret = wc_MakeRsaKey(&priv, 2048, e, &rng);
if( ret != 0 ) {
    // error generating private key
}
```

C.49.2.33 function wc_RsaSetNonBlock

```
int wc_RsaSetNonBlock(
    RsaKey * key,
    RsaNb * nb
)
```

This function sets the non-blocking RSA context. When a RsaNb context is set it enables fast math based non-blocking exptmod, which splits the RSA function into many smaller operations. Enabled when WC_RSA_NONBLOCK is defined.

Parameters:

- **key** The RSA key structure
- **nb** The RSA non-blocking structure for this RSA key to use.

See: wc_RsaSetNonBlockTime

Return:

- 0 Success
- BAD_FUNC_ARG Returned if key or nb is null.

Example

```
int ret, count = 0;
RsaKey key;
RsaNb  nb;

wc_InitRsaKey(&key, NULL);

// Enable non-blocking RSA mode - provide context
ret = wc_RsaSetNonBlock(key, &nb);
if (ret != 0)
    return ret;

do {
    ret = wc_RsaSSL_Sign(in, inLen, out, outSz, key, rng);
    count++; // track number of would blocks
    if (ret == FP_WOULDBLOCK) {
        // do "other" work here
    }
} while (ret == FP_WOULDBLOCK);
if (ret < 0) {
    return ret;
```

```
}

printf("RSA non-block sign: size %d, %d times\n", ret, count);
```

C.49.2.34 function wc_RsaSetNonBlockTime

```
int wc_RsaSetNonBlockTime(
    RsaKey * key,
    word32 maxBlockUs,
    word32 cpuMHz
)
```

This function configures the maximum amount of blocking time in microseconds. It uses a pre-computed table (see tfm.c exptModNbInst) along with the CPU speed in megahertz to determine if the next operation can be completed within the maximum blocking time provided. Enabled when WC_RSA_NONBLOCK_TIME is defined.

Parameters:

- **key** The RSA key structure.
- **maxBlockUs** Maximum time to block microseconds.
- **cpuMHz** CPU speed in megahertz.

See: wc_RsaSetNonBlock

Return:

- 0 Success
- BAD_FUNC_ARG Returned if key is null or wc_RsaSetNonBlock was not previously called and key->nb is null.

Example

```
RsaKey key;
RsaNb  nb;

wc_InitRsaKey(&key, NULL);
wc_RsaSetNonBlock(key, &nb);
wc_RsaSetNonBlockTime(&key, 4000, 160); // Block Max = 4 ms, CPU = 160MHz
```

C.49.2.35 function wc_InitRsaKey_ex

```
int wc_InitRsaKey_ex(
    RsaKey * key,
    void * heap,
    int devId
)
```

Initializes RSA key with heap and device ID.

Parameters:

- **key** RSA key structure
- **heap** Heap hint
- **devId** Device ID

See: wc_InitRsaKey

Return:

- 0 on success

- negative on error

Example

```
RsaKey key;
int ret = wc_InitRsaKey_ex(&key, NULL, INVALID_DEVID);
```

C.49.2.36 function wc_NewRsaKey

```
RsaKey * wc_NewRsaKey(
    void * heap,
    int devId,
    int * result_code
)
```

Allocates and initializes new RSA key. These New/Delete functions are exposed to support allocation of the structure using dynamic memory to provide better ABI compatibility.

Parameters:

- **heap** Heap hint
- **devId** Device ID
- **result_code** Result code pointer

See: wc_DeleteRsaKey

Return:

- RsaKey pointer on success
- NULL on failure

Note: This API is only available when WC_NO_CONSTRUCTORS is not defined. WC_NO_CONSTRUCTORS is automatically defined when WOLFSSL_NO_MALLOC is defined.

Example

```
int result;
RsaKey* key = wc_NewRsaKey(NULL, INVALID_DEVID, &result);
```

C.49.2.37 function wc_DeleteRsaKey

```
int wc_DeleteRsaKey(
    RsaKey * key,
    RsaKey ** key_p
)
```

Deletes and frees RSA key. These New/Delete functions are exposed to support allocation of the structure using dynamic memory to provide better ABI compatibility.

Parameters:

- **key** RSA key to delete
- **key_p** Pointer to key pointer

See: wc_NewRsaKey

Return:

- 0 on success
- negative on error

Note: This API is only available when WC_NO_CONSTRUCTORS is not defined. WC_NO_CONSTRUCTORS is automatically defined when WOLFSSL_NO_MALLOC is defined.

Example

```
RsaKey* key;
int ret = wc_DeleteRsaKey(key, &key);
```

C.49.2.38 function wc_InitRsaKey_Label

```
int wc_InitRsaKey_Label(
    RsaKey * key,
    const char * label,
    void * heap,
    int devId
)
```

Initializes RSA key with label.

Parameters:

- **key** RSA key structure
- **label** Label string
- **heap** Heap hint
- **devId** Device ID

See: wc_InitRsaKey_ex

Return:

- 0 on success
- negative on error

Note: This API is only available when WOLF_PRIVATE_KEY_ID is defined, which is set for PKCS11 support.

Example

```
RsaKey key;
int ret = wc_InitRsaKey_Label(&key, "mykey", NULL,
                              INVALID_DEVID);
```

C.49.2.39 function wc_CheckRsaKey

```
int wc_CheckRsaKey(
    RsaKey * key
)
```

Checks RSA key validity.

Parameters:

- **key** RSA key to check

See: wc_MakeRsaKey

Return:

- 0 on success
- negative on error

Example

```
RsaKey key;
int ret = wc_CheckRsaKey(&key);
```

C.49.2.40 function wc_RsaUseKeyId

```
int wc_RsaUseKeyId(
    RsaKey * key,
    word32 keyId,
    word32 flags
)
```

Uses key ID for hardware RSA.

Parameters:

- **key** RSA key
- **keyId** Key identifier
- **flags** Flags

See: wc_RsaGetKeyId

Return:

- 0 on success
- negative on error

Example

```
RsaKey key;
int ret = wc_RsaUseKeyId(&key, 1, 0);
```

C.49.2.41 function wc_RsaGetKeyId

```
int wc_RsaGetKeyId(
    RsaKey * key,
    word32 * keyId
)
```

Gets key ID from hardware RSA key.

Parameters:

- **key** RSA key
- **keyId** Key identifier pointer

See: wc_RsaUseKeyId

Return:

- 0 on success
- negative on error

Example

```
RsaKey key;
word32 keyId;
int ret = wc_RsaGetKeyId(&key, &keyId);
```

C.49.2.42 function wc_RsaFunction

```
int wc_RsaFunction(
    const byte * in,
    word32 inLen,
    byte * out,
    word32 * outLen,
    int type,
    RsaKey * key,
    WC_RNG * rng
)
```

Performs RSA operation.

Parameters:

- **in** Input buffer
- **inLen** Input length
- **out** Output buffer
- **outLen** Output length pointer
- **type** Operation type
- **key** RSA key
- **rng** Random number generator

See: wc_RsaPublicEncrypt

Return:

- 0 on success
- negative on error

Example

```
RsaKey key;
WC_RNG rng;
byte in[256], out[256];
word32 outLen = sizeof(out);
int ret = wc_RsaFunction(in, 256, out, &outLen,
                         RSA_PUBLIC_ENCRYPT, &key, &rng);
```

C.49.2.43 function wc_RsaPSS_Sign_ex

```
int wc_RsaPSS_Sign_ex(
    const byte * in,
    word32 inLen,
    byte * out,
    word32 outLen,
    enum wc_HashType hash,
    int mgf,
    int saltLen,
    RsaKey * key,
    WC_RNG * rng
)
```

Signs with RSA-PSS extended options.

Parameters:

- **in** Input buffer
- **inLen** Input length

- **out** Output buffer
- **outLen** Output buffer size
- **hash** Hash type
- **mgf** MGF type
- **saltLen** Salt length
- **key** RSA key
- **rng** Random number generator

See: wc_RsaPSS_Sign

Return:

- Size of signature on success
- negative on error

Example

```
RsaKey key;
WC_RNG rng;
byte in[32], sig[256];
int ret = wc_RsaPSS_Sign_ex(in, 32, sig, sizeof(sig),
                            WC_HASH_TYPE_SHA256,
                            WC_MGF1SHA256, 32, &key, &rng);
```

C.49.2.44 function wc_RsaSSL_Verify_ex

```
int wc_RsaSSL_Verify_ex(
    const byte * in,
    word32 inLen,
    byte * out,
    word32 outLen,
    RsaKey * key,
    int pad_type
)
```

Verifies RSA signature with padding type.

Parameters:

- **in** Input signature
- **inLen** Signature length
- **out** Output buffer
- **outLen** Output buffer size
- **key** RSA key
- **pad_type** Padding type

See: wc_RsaSSL_Verify

Return:

- Size of decrypted data on success
- negative on error

Example

```
RsaKey key;
byte sig[256], out[256];
int ret = wc_RsaSSL_Verify_ex(sig, 256, out, sizeof(out),
                              &key, RSA_PKCS1_PADDING);
```

C.49.2.45 function wc_RsaSSL_Verify_ex2

```
int wc_RsaSSL_Verify_ex2(
    const byte * in,
    word32 inLen,
    byte * out,
    word32 outLen,
    RsaKey * key,
    int pad_type,
    enum wc_HashType hash
)
```

Verifies RSA signature with hash type.

Parameters:

- **in** Input signature
- **inLen** Signature length
- **out** Output buffer
- **outLen** Output buffer size
- **key** RSA key
- **pad_type** Padding type
- **hash** Hash type

See: wc_RsaSSL_Verify_ex

Return:

- Size of decrypted data on success
- negative on error

Example

```
RsaKey key;
byte sig[256], out[256];
int ret = wc_RsaSSL_Verify_ex2(sig, 256, out, sizeof(out),
                               &key, RSA_PKCS1_PADDING,
                               WC_HASH_TYPE_SHA256);
```

C.49.2.46 function wc_RsaPSS_VerifyInline_ex

```
int wc_RsaPSS_VerifyInline_ex(
    byte * in,
    word32 inLen,
    byte ** out,
    enum wc_HashType hash,
    int mgf,
    int saltLen,
    RsaKey * key
)
```

Verifies RSA-PSS inline with extended options.

Parameters:

- **in** Input/output buffer
- **inLen** Input length
- **out** Output pointer
- **hash** Hash type
- **mgf** MGF type

- **saltLen** Salt length
- **key** RSA key

See: wc_RsaPSS_VerifyInline

Return:

- Size of verified data on success
- negative on error

Example

```
RsaKey key;
byte sig[256];
byte* out;
int ret = wc_RsaPSS_VerifyInline_ex(sig, 256, &out,
                                    WC_HASH_TYPE_SHA256,
                                    WC_MGF1SHA256, 32, &key);
```

C.49.2.47 function wc_RsaPSS_Verify_ex

```
int wc_RsaPSS_Verify_ex(
    const byte * in,
    word32 inLen,
    byte * out,
    word32 outLen,
    enum wc_HashType hash,
    int mgf,
    int saltLen,
    RsaKey * key
)
```

Verifies RSA-PSS with extended options.

Parameters:

- **in** Input signature
- **inLen** Signature length
- **out** Output buffer
- **outLen** Output buffer size
- **hash** Hash type
- **mgf** MGF type
- **saltLen** Salt length
- **key** RSA key

See: wc_RsaPSS_Verify

Return:

- Size of verified data on success
- negative on error

Example

```
RsaKey key;
byte sig[256], out[256];
int ret = wc_RsaPSS_Verify_ex(sig, 256, out, sizeof(out),
                              WC_HASH_TYPE_SHA256,
                              WC_MGF1SHA256, 32, &key);
```

C.49.2.48 function wc_RsaPSS_CheckPadding_ex2

```
int wc_RsaPSS_CheckPadding_ex2(
    const byte * in,
    word32 inLen,
    const byte * sig,
    word32 sigSz,
    enum wc_HashType hashType,
    int saltLen,
    int bits,
    void * heap
)
```

Checks RSA-PSS padding with extended options.

Parameters:

- **in** Padded data
- **inLen** Padded data length
- **sig** Signature
- **sigSz** Signature size
- **hashType** Hash type
- **saltLen** Salt length
- **bits** Key size in bits
- **heap** Heap hint

See: wc_RsaPSS_CheckPadding_ex

Return:

- 0 on success
- negative on error

Example

```
byte padded[256], sig[256];
int ret = wc_RsaPSS_CheckPadding_ex2(padded, 256, sig, 256,
                                     WC_HASH_TYPE_SHA256, 32,
                                     2048, NULL);
```

C.49.2.49 function wc_RsaExportKey

```
int wc_RsaExportKey(
    const RsaKey * key,
    byte * e,
    word32 * eSz,
    byte * n,
    word32 * nSz,
    byte * d,
    word32 * dSz,
    byte * p,
    word32 * pSz,
    byte * q,
    word32 * qSz
)
```

Exports RSA key components.

Parameters:

- **key** RSA key
- **e** Public exponent buffer
- **eSz** Public exponent size pointer
- **n** Modulus buffer
- **nSz** Modulus size pointer
- **d** Private exponent buffer
- **dSz** Private exponent size pointer
- **p** Prime p buffer
- **pSz** Prime p size pointer
- **q** Prime q buffer
- **qSz** Prime q size pointer

See: wc_RsaFlattenPublicKey

Return:

- 0 on success
- negative on error

Example

```
RsaKey key;
byte e[3], n[256], d[256], p[128], q[128];
word32 eSz = 3, nSz = 256, dSz = 256, pSz = 128, qSz = 128;
int ret = wc_RsaExportKey(&key, e, &eSz, n, &nSz, d, &dSz,
                          p, &pSz, q, &qSz);
```

C.49.2.50 function wc_CheckProbablePrime_ex

```
int wc_CheckProbablePrime_ex(
    const byte * p,
    word32 pSz,
    const byte * q,
    word32 qSz,
    const byte * e,
    word32 eSz,
    int nlen,
    int * isPrime,
    WC_RNG * rng
)
```

Checks probable prime with extended options.

Parameters:

- **p** Prime p buffer
- **pSz** Prime p size
- **q** Prime q buffer
- **qSz** Prime q size
- **e** Public exponent buffer
- **eSz** Public exponent size
- **nlen** Modulus length
- **isPrime** Prime result pointer
- **rng** Random number generator

See: wc_CheckProbablePrime

Return:

- 0 on success

- negative on error

Example

```
byte p[128], q[128], e[3];
int isPrime;
WC_RNG rng;
int ret = wc_CheckProbablePrime_ex(p, 128, q, 128, e, 3,
                                   2048, &isPrime, &rng);
```

C.49.2.51 function wc_CheckProbablePrime

```
int wc_CheckProbablePrime(
    const byte * p,
    word32 pSz,
    const byte * q,
    word32 qSz,
    const byte * e,
    word32 eSz,
    int nlen,
    int * isPrime
)
```

Checks probable prime.

Parameters:

- **p** Prime p buffer
- **pSz** Prime p size
- **q** Prime q buffer
- **qSz** Prime q size
- **e** Public exponent buffer
- **eSz** Public exponent size
- **nlen** Modulus length
- **isPrime** Prime result pointer

See: wc_CheckProbablePrime_ex

Return:

- 0 on success
- negative on error

Example

```
byte p[128], q[128], e[3];
int isPrime;
int ret = wc_CheckProbablePrime(p, 128, q, 128, e, 3, 2048,
                                &isPrime);
```

C.49.2.52 function wc_RsaPad_ex

```
int wc_RsaPad_ex(
    const byte * input,
    word32 inputLen,
    byte * pkcsBlock,
    word32 pkcsBlockLen,
    byte padValue,
    WC_RNG * rng,
```

```
    int padType,
    enum wc_HashType hType,
    int mgf,
    byte * optLabel,
    word32 labelLen,
    int saltLen,
    int bits,
    void * heap
)
```

Pads data with extended options.

Parameters:

- **input** Input data
- **inputLen** Input length
- **pkcsBlock** Output padded block
- **pkcsBlockLen** Padded block size
- **padValue** Pad value
- **rng** Random number generator
- **padType** Padding type
- **hType** Hash type
- **mgf** MGF type
- **optLabel** Optional label
- **labelLen** Label length
- **saltLen** Salt length
- **bits** Key size in bits
- **heap** Heap hint

See: wc_RsaUnPad_ex

Return:

- 0 on success
- negative on error

Example

```
byte in[32], padded[256];
WC_RNG rng;
int ret = wc_RsaPad_ex(in, 32, padded, 256, 0x00, &rng,
                       RSA_BLOCK_TYPE_1,
                       WC_HASH_TYPE_SHA256, WC_MGF1SHA256,
                       NULL, 0, 32, 2048, NULL);
```

C.49.2.53 function wc_RsaUnPad_ex

```
int wc_RsaUnPad_ex(
    byte * pkcsBlock,
    word32 pkcsBlockLen,
    byte ** out,
    byte padValue,
    int padType,
    enum wc_HashType hType,
    int mgf,
    byte * optLabel,
    word32 labelLen,
    int saltLen,
```

```
    int bits,
    void * heap
)
```

Unpads data with extended options.

Parameters:

- **pkcsBlock** Padded block
- **pkcsBlockLen** Padded block length
- **out** Output pointer
- **padValue** Pad value
- **padType** Padding type
- **hType** Hash type
- **mgf** MGF type
- **optLabel** Optional label
- **labelLen** Label length
- **saltLen** Salt length
- **bits** Key size in bits
- **heap** Heap hint

See: wc_RsaPad_ex

Return:

- Size of unpadded data on success
- negative on error

Example

```
byte padded[256];
byte* out;
int ret = wc_RsaUnPad_ex(padded, 256, &out, 0x00,
                         RSA_BLOCK_TYPE_1,
                         WC_HASH_TYPE_SHA256, WC_MGF1SHA256,
                         NULL, 0, 32, 2048, NULL);
```

C.49.2.54 function wc_RsaPrivateKeyDecodeRaw

```
int wc_RsaPrivateKeyDecodeRaw(
    const byte * n,
    word32 nSz,
    const byte * e,
    word32 eSz,
    const byte * d,
    word32 dSz,
    const byte * u,
    word32 uSz,
    const byte * p,
    word32 pSz,
    const byte * q,
    word32 qSz,
    const byte * dP,
    word32 dPSz,
    const byte * dQ,
    word32 dQSz,
    RsaKey * key
)
```

Decodes raw RSA private key.

Parameters:

- **n** Modulus buffer
- **nSz** Modulus size
- **e** Public exponent buffer
- **eSz** Public exponent size
- **d** Private exponent buffer
- **dSz** Private exponent size
- **u** Coefficient buffer
- **uSz** Coefficient size
- **p** Prime p buffer
- **pSz** Prime p size
- **q** Prime q buffer
- **qSz** Prime q size
- **dP** dP buffer
- **dPSz** dP size
- **dQ** dQ buffer
- **dQSz** dQ size
- **key** RSA key

See: wc_RsaPrivateKeyDecode

Return:

- 0 on success
- negative on error

Example

```
RsaKey key;
byte n[256], e[3], d[256], u[256], p[128], q[128];
byte dP[128], dQ[128];
int ret = wc_RsaPrivateKeyDecodeRaw(n, 256, e, 3, d, 256,
                                    u, 256, p, 128, q, 128,
                                    dP, 128, dQ, 128, &key);
```

C.50.2 Functions Documentation

C.50.2.1 function wc_InitSakkeKey

```
int wc_InitSakkeKey(
    SakkeKey * key,
    void * heap,
    int devId
)
```

C.50.2.2 function wc_InitSakkeKey_ex

```
int wc_InitSakkeKey_ex(
    SakkeKey * key,
    int keySize,
    int curveId,
    void * heap,
    int devId
)
```

C.50.2.3 function wc_FreeSakkeKey

```
void wc_FreeSakkeKey(
    SakkeKey * key
)
```

C.50.2.4 function wc_MakeSakkeKey

```
int wc_MakeSakkeKey(
    SakkeKey * key,
    WC_RNG * rng
)
```

C.50.2.5 function wc_MakeSakkePublicKey

```
int wc_MakeSakkePublicKey(
    SakkeKey * key,
    ecc_point * pub
)
```

C.50.2.6 function wc_MakeSakkeRsk

```
int wc_MakeSakkeRsk(
    SakkeKey * key,
    const byte * id,
    word16 idSz,
    ecc_point * rsk
)
```

C.50.2.7 function wc_ValidateSakkeRsk

```
int wc_ValidateSakkeRsk(
    SakkeKey * key,
    const byte * id,
    word16 idSz,
    ecc_point * rsk,
    int * valid
)
```

C.50.2.8 function wc_GenerateSakkeRskTable

```
int wc_GenerateSakkeRskTable(
    const SakkeKey * key,
    const ecc_point * rsk,
    byte * table,
    word32 * len
)
```

C.50.2.9 function wc_ExportSakkeKey

```
int wc_ExportSakkeKey(
    SakkeKey * key,
    byte * data,
    word32 * sz
)
```

C.50.2.10 function wc_ImportSakkeKey

```
int wc_ImportSakkeKey(
    SakkeKey * key,
    const byte * data,
    word32 sz
)
```

C.50.2.11 function wc_ExportSakkePrivateKey

```
int wc_ExportSakkePrivateKey(
    SakkeKey * key,
    byte * data,
    word32 * sz
)
```

C.50.2.12 function wc_ImportSakkePrivateKey

```
int wc_ImportSakkePrivateKey(
    SakkeKey * key,
    const byte * data,
    word32 sz
)
```

C.50.2.13 function wc_EncodeSakkeRsk

```
int wc_EncodeSakkeRsk(
    const SakkeKey * key,
    ecc_point * rsk,
    byte * out,
    word32 * sz,
    int raw
)
```

C.50.2.14 function wc_DecodeSakkeRsk

```
int wc_DecodeSakkeRsk(
    const SakkeKey * key,
    const byte * data,
    word32 sz,
    ecc_point * rsk
)
```

C.50.2.15 function wc_ImportSakkeRsk

```
int wc_ImportSakkeRsk(
    SakkeKey * key,
    const byte * data,
    word32 sz
)
```

C.50.2.16 function wc_ExportSakkePublicKey

```
int wc_ExportSakkePublicKey(
    SakkeKey * key,
    byte * data,
    word32 * sz,
    int raw
)
```

C.50.2.17 function wc_ImportSakkePublicKey

```
int wc_ImportSakkePublicKey(
    SakkeKey * key,
    const byte * data,
    word32 sz,
    int trusted
)
```

C.50.2.18 function wc_GetSakkeAuthSize

```
int wc_GetSakkeAuthSize(
    SakkeKey * key,
    word16 * authSz
)
```

C.50.2.19 function wc_SetSakkeIdentity

```
int wc_SetSakkeIdentity(
    SakkeKey * key,
    const byte * id,
    word16 idSz
)
```

C.50.2.20 function wc_MakeSakkePointI

```
int wc_MakeSakkePointI(
    SakkeKey * key,
    const byte * id,
    word16 idSz
)
```

C.50.2.21 function wc_GetSakkePointI

```
int wc_GetSakkePointI(
    SakkeKey * key,
    byte * data,
    word32 * sz
)
```

C.50.2.22 function wc_SetSakkePointI

```
int wc_SetSakkePointI(
    SakkeKey * key,
    const byte * id,
    word16 idSz,
    const byte * data,
    word32 sz
)
```

C.50.2.23 function wc_GenerateSakkePointITable

```
int wc_GenerateSakkePointITable(
    SakkeKey * key,
    byte * table,
    word32 * len
)
```

C.50.2.24 function wc_SetSakkePointITable

```
int wc_SetSakkePointITable(
    SakkeKey * key,
    byte * table,
```

```
    word32 len
)
```

C.50.2.25 function wc_ClearSakkePointITable

```
int wc_ClearSakkePointITable(
    SakkeKey * key
)
```

C.50.2.26 function wc_MakeSakkeEncapsulatedSSV

```
int wc_MakeSakkeEncapsulatedSSV(
    SakkeKey * key,
    enum wc_HashType hashType,
    byte * ssv,
    word16 ssvSz,
    byte * auth,
    word16 * authSz
)
```

C.50.2.27 function wc_GenerateSakkeSSV

```
int wc_GenerateSakkeSSV(
    SakkeKey * key,
    WC_RNG * rng,
    byte * ssv,
    word16 * ssvSz
)
```

C.50.2.28 function wc_SetSakkeRsk

```
int wc_SetSakkeRsk(
    SakkeKey * key,
    const ecc_point * rsk,
    byte * table,
    word32 len
)
```

C.50.2.29 function wc_DeriveSakkeSSV

```
int wc_DeriveSakkeSSV(
    SakkeKey * key,
    enum wc_HashType hashType,
    byte * ssv,
    word16 ssvSz,
    const byte * auth,
    word16 authSz
)
```

C.50.3 Source code

        word16 authSz);
```

C.51 sha256.h

C.51.1 Functions

	Name
int	**wc_InitSha256**(wc_Sha256 * sha)This function initializes SHA256. This is automatically called by wc_Sha256Hash.
int	**wc_Sha256Update**(wc_Sha256 * sha, const byte * data, word32 len)Can be called to continually hash the provided byte array of length len.
int	**wc_Sha256Final**(wc_Sha256 * sha256, byte * hash)Finalizes hashing of data. Result is placed into hash. Resets state of sha256 struct.
void	**wc_Sha256Free**(wc_Sha256 * sha256)Resets the Sha256 structure. Note: this is only supported if you have WOLFSSL_TI_HASH defined.
int	**wc_Sha256Reset**(wc_Sha256 * sha256)Resets the sha256 structure to its freshly initialized state, continuing with its established allocations, heap hint, and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially hashed message, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Sha256Free for teardown at end of life.
int	**wc_Sha256GetHash**(wc_Sha256 * sha256, byte * hash)Gets hash data. Result is placed into hash. Does not reset state of sha256 struct.
int	**wc_InitSha224**(wc_Sha224 * sha224)Used to initialize a Sha224 struct.
int	**wc_Sha224Update**(wc_Sha224 * sha224, const byte * data, word32 len)Can be called to continually hash the provided byte array of length len.
int	**wc_Sha224Final**(wc_Sha224 * sha224, byte * hash)Finalizes hashing of data. Result is placed into hash. Resets state of sha224 struct.
int	**wc_InitSha256_ex**(wc_Sha256 * sha, void * heap, int devId)Initializes SHA256 with heap and device ID.
int	**wc_Sha256FinalRaw**(wc_Sha256 * sha256, byte * hash)Gets raw hash without finalizing.
int	**wc_Sha256Transform**(wc_Sha256 * sha, const unsigned char * data)Transforms SHA256 block.
int	**wc_Sha256HashBlock**(wc_Sha256 * sha, const unsigned char * data, unsigned char * hash)Hashes single block and outputs result.

	Name
int	**wc_Sha256_Grow**(wc_Sha256 * sha256, const byte * in, int inSz)Grows SHA256 buffer with input data. This function is only available when WOLFSSL_HASH_KEEP is defined. It is used for keeping an internal buffer to hold all data to be hashed rather than iterating over update, which is necessary for some hardware acceleration platforms that have restrictions on streaming hash operations.
int	**wc_Sha256Copy**(wc_Sha256 * src, wc_Sha256 * dst)Copies SHA256 context.
void	**wc_Sha256SizeSet**(wc_Sha256 * sha256, word32 len)Sets SHA256 size.
int	**wc_Sha256SetFlags**(wc_Sha256 * sha256, word32 flags)Sets SHA256 flags.
int	**wc_Sha256GetFlags**(wc_Sha256 * sha256, word32 * flags)Gets SHA256 flags.
int	**wc_InitSha224_ex**(wc_Sha224 * sha224, void * heap, int devId)Initializes SHA224 with heap and device ID.
void	**wc_Sha224Free**(wc_Sha224 * sha224)Frees SHA224 resources.
int	**wc_Sha224Reset**(wc_Sha224 * sha224)Resets the sha224 structure to its freshly initialized state, continuing with its established allocations, heap hint, and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially hashed message, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Sha224Free for teardown at end of life.
int	**wc_Sha224_Grow**(wc_Sha224 * sha224, const byte * in, int inSz)Grows SHA224 buffer with input data. This function is only available when WOLFSSL_HASH_KEEP is defined. It is used for keeping an internal buffer to hold all data to be hashed rather than iterating over update, which is necessary for some hardware acceleration platforms that have restrictions on streaming hash operations.
int	**wc_Sha224GetHash**(wc_Sha224 * sha224, byte * hash)Gets SHA224 hash without finalizing.
int	**wc_Sha224Copy**(wc_Sha224 * src, wc_Sha224 * dst)Copies SHA224 context.
int	**wc_Sha224SetFlags**(wc_Sha224 * sha224, word32 flags)Sets SHA224 flags.
int	**wc_Sha224GetFlags**(wc_Sha224 * sha224, word32 * flags)Gets SHA224 flags.

C.51.2 Functions Documentation

C.51.2.1 function wc_InitSha256

```
int wc_InitSha256(
    wc_Sha256 * sha
)
```

This function initializes SHA256. This is automatically called by wc_Sha256Hash.

Parameters:

- **sha256** pointer to the sha256 structure to use for encryption

See:

- wc_Sha256Hash
- wc_Sha256Update
- wc_Sha256Final

Return: 0 Returned upon successfully initializing

Example

```
Sha256 sha256[1];
if ((ret = wc_InitSha256(sha256)) != 0) {
    WOLFSSL_MSG("wc_InitSha256 failed");
}
else {
    wc_Sha256Update(sha256, data, len);
    wc_Sha256Final(sha256, hash);
}
```

C.51.2.2 function wc_Sha256Update

```
int wc_Sha256Update(
    wc_Sha256 * sha,
    const byte * data,
    word32 len
)
```

Can be called to continually hash the provided byte array of length len.

Parameters:

- **sha256** pointer to the sha256 structure to use for encryption
- **data** the data to be hashed
- **len** length of data to be hashed

See:

- wc_Sha256Hash
- wc_Sha256Final
- wc_InitSha256

Return: 0 Returned upon successfully adding the data to the digest.

Example

```
Sha256 sha256[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);
```

```
if ((ret = wc_InitSha256(sha256)) != 0) {
   WOLFSSL_MSG("wc_InitSha256 failed");
}
else {
    wc_Sha256Update(sha256, data, len);
    wc_Sha256Final(sha256, hash);
}
```

C.51.2.3 function wc_Sha256Final

```
int wc_Sha256Final(
    wc_Sha256 * sha256,
    byte * hash
)
```

Finalizes hashing of data. Result is placed into hash. Resets state of sha256 struct.

Parameters:

- **sha256** pointer to the sha256 structure to use for encryption
- **hash** Byte array to hold hash value.

See:

- wc_Sha256Hash
- wc_Sha256GetHash
- wc_InitSha256

Return: 0 Returned upon successfully finalizing.

Example

```
Sha256 sha256[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitSha256(sha256)) != 0) {
   WOLFSSL_MSG("wc_InitSha256 failed");
}
else {
   wc_Sha256Update(sha256, data, len);
   wc_Sha256Final(sha256, hash);
}
```

C.51.2.4 function wc_Sha256Free

```
void wc_Sha256Free(
    wc_Sha256 * sha256
)
```

Resets the Sha256 structure. Note: this is only supported if you have WOLFSSL_TI_HASH defined.

Parameters:

- **sha256** Pointer to the sha256 structure to be freed.

See:

- wc_InitSha256
- wc_Sha256Update
- wc_Sha256Final

Return: none No returns.

Example

```
Sha256 sha256;
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitSha256(&sha256)) != 0) {
    WOLFSSL_MSG("wc_InitSha256 failed");
}
else {
    wc_Sha256Update(&sha256, data, len);
    wc_Sha256Final(&sha256, hash);
    wc_Sha256Free(&sha256);
}
```

C.51.2.5 function wc_Sha256Reset

```
int wc_Sha256Reset(
    wc_Sha256 * sha256
)
```

Resets the sha256 structure to its freshly initialized state, continuing with its established allocations, heap hint, and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially hashed message, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Sha256Free for teardown at end of life.

Parameters:

- **sha256** Pointer to the sha256 structure to be reset.

See:

- wc_InitSha256
- wc_Sha256Final
- wc_Sha256Free

Return:

- 0 Returned upon successfully resetting the structure.
- BAD_FUNC_ARG Returned if sha256 is NULL.
- negative Other values may be returned on reinitialization failure in fallback (non-plain-software) configurations.

Example

```
wc_Sha256 sha256;
byte data[] = { Data to be discarded };
byte data2[] = { Data to be hashed };
byte hash[WC_SHA256_DIGEST_SIZE];

if ((ret = wc_InitSha256(&sha256)) == 0) {
    wc_Sha256Update(&sha256, data, sizeof(data));
    wc_Sha256Reset(&sha256); /* discard the partially hashed message */
    wc_Sha256Update(&sha256, data2, sizeof(data2));
    wc_Sha256Final(&sha256, hash);
    wc_Sha256Free(&sha256);
}
```

C.51.2.6 function wc_Sha256GetHash

```
int wc_Sha256GetHash(
    wc_Sha256 * sha256,
    byte * hash
)
```

Gets hash data. Result is placed into hash. Does not reset state of sha256 struct.

Parameters:

- **sha256** pointer to the sha256 structure to use for encryption
- **hash** Byte array to hold hash value.

See:

- wc_Sha256Hash
- wc_Sha256Final
- wc_InitSha256

Return: 0 Returned upon successfully finalizing.

Example

```
Sha256 sha256[1];
if ((ret = wc_InitSha256(sha256)) != 0) {
   WOLFSSL_MSG("wc_InitSha256 failed");
}
else {
   wc_Sha256Update(sha256, data, len);
   wc_Sha256GetHash(sha256, hash);
}
```

C.51.2.7 function wc_InitSha224

```
int wc_InitSha224(
    wc_Sha224 * sha224
)
```

Used to initialize a Sha224 struct.

Parameters:

- **sha224** Pointer to a Sha224 struct to initialize.

See:

- wc_Sha224Hash
- wc_Sha224Update
- wc_Sha224Final

Return:

- 0 Success
- 1 Error returned because sha224 is null.

Example

```
Sha224 sha224;
if(wc_InitSha224(&sha224) != 0)
{
    // Handle error
}
```

C.51.2.8 function wc_Sha224Update

```
int wc_Sha224Update(
    wc_Sha224 * sha224,
    const byte * data,
    word32 len
)
```

Can be called to continually hash the provided byte array of length len.

Parameters:

- **sha224** Pointer to the Sha224 structure to use for encryption.
- **data** Data to be hashed.
- **len** Length of data to be hashed.

See:

- wc_InitSha224
- wc_Sha224Final
- wc_Sha224Hash

Return:

- 0 Success
- 1 Error returned if function fails.
- BAD_FUNC_ARG Error returned if sha224 or data is null.

Example

```
Sha224 sha224;
byte data[]; // Data to be hashed
word32 len = sizeof(data);

if ((ret = wc_InitSha224(&sha224)) != 0) {
   WOLFSSL_MSG("wc_InitSha224 failed");
}
else {
  wc_Sha224Update(&sha224, data, len);
  wc_Sha224Final(&sha224, hash);
}
```

C.51.2.9 function wc_Sha224Final

```
int wc_Sha224Final(
    wc_Sha224 * sha224,
    byte * hash
)
```

Finalizes hashing of data. Result is placed into hash. Resets state of sha224 struct.

Parameters:

- **sha224** pointer to the sha224 structure to use for encryption
- **hash** Byte array to hold hash value.

See:

- wc_InitSha224
- wc_Sha224Hash
- wc_Sha224Update

Return:

- 0 Success
- <0 Error

Example

```
Sha224 sha224;
byte data[]; // Data to be hashed
word32 len = sizeof(data);

if ((ret = wc_InitSha224(&sha224)) != 0) {
    WOLFSSL_MSG("wc_InitSha224 failed");
}
else {
    wc_Sha224Update(&sha224, data, len);
    wc_Sha224Final(&sha224, hash);
}
```

C.51.2.10 function wc_InitSha256_ex

```
int wc_InitSha256_ex(
    wc_Sha256 * sha,
    void * heap,
    int devId
)
```

Initializes SHA256 with heap and device ID.

Parameters:

- **sha** SHA256 structure
- **heap** Heap hint
- **devId** Device ID

See: wc_InitSha256

Return:

- 0 on success
- negative on error

Example

```
wc_Sha256 sha;
int ret = wc_InitSha256_ex(&sha, NULL, INVALID_DEVID);
```

C.51.2.11 function wc_Sha256FinalRaw

```
int wc_Sha256FinalRaw(
    wc_Sha256 * sha256,
    byte * hash
)
```

Gets raw hash without finalizing.

Parameters:

- **sha256** SHA256 structure
- **hash** Output hash buffer

See: wc_Sha256Final

Return:

- 0 on success
- negative on error

Example

```
wc_Sha256 sha;
byte hash[WC_SHA256_DIGEST_SIZE];
int ret = wc_Sha256FinalRaw(&sha, hash);
```

C.51.2.12 function wc_Sha256Transform

```
int wc_Sha256Transform(
    wc_Sha256 * sha,
    const unsigned char * data
)
```

Transforms SHA256 block.

Parameters:

- **sha** SHA256 structure
- **data** Block data

See: wc_Sha256Update

Return:

- 0 on success
- negative on error

Example

```
wc_Sha256 sha;
unsigned char block[WC_SHA256_BLOCK_SIZE];
int ret = wc_Sha256Transform(&sha, block);
```

C.51.2.13 function wc_Sha256HashBlock

```
int wc_Sha256HashBlock(
    wc_Sha256 * sha,
    const unsigned char * data,
    unsigned char * hash
)
```

Hashes single block and outputs result.

Parameters:

- **sha** SHA256 structure
- **data** Block data
- **hash** Output hash buffer

See: wc_Sha256Transform

Return:

- 0 on success
- negative on error

Example

```
wc_Sha256 sha;
unsigned char block[WC_SHA256_BLOCK_SIZE];
unsigned char hash[WC_SHA256_DIGEST_SIZE];
int ret = wc_Sha256HashBlock(&sha, block, hash);
```

C.51.2.14 function wc_Sha256_Grow

```
int wc_Sha256_Grow(
    wc_Sha256 * sha256,
    const byte * in,
    int inSz
)
```

Grows SHA256 buffer with input data. This function is only available when WOLFSSL_HASH_KEEP is defined. It is used for keeping an internal buffer to hold all data to be hashed rather than iterating over update, which is necessary for some hardware acceleration platforms that have restrictions on streaming hash operations.

Parameters:

- **sha256** SHA256 structure
- **in** Input data
- **inSz** Input size

See: wc_Sha256Update

Return:

- 0 on success
- negative on error

Example

```
wc_Sha256 sha;
byte data[100];
int ret = wc_Sha256_Grow(&sha, data, sizeof(data));
```

C.51.2.15 function wc_Sha256Copy

```
int wc_Sha256Copy(
    wc_Sha256 * src,
    wc_Sha256 * dst
)
```

Copies SHA256 context.

Parameters:

- **src** Source SHA256 structure
- **dst** Destination SHA256 structure; (must be zeroed or previously initialized)

See: wc_InitSha256

Return:

- 0 on success
- negative on error

Example

```
wc_Sha256 src, dst;
memset(&dst, 0, sizeof(dst));
```

```
int ret = wc_InitSha256(&src);
if (ret == 0)
    ret = wc_Sha256Copy(&src, &dst);
```

C.51.2.16 function wc_Sha256SizeSet

```
void wc_Sha256SizeSet(
    wc_Sha256 * sha256,
    word32 len
)
```

Sets SHA256 size.

Parameters:

- **sha256** SHA256 structure
- **len** Size to set

See: wc_Sha256Update

Return: none No returns

Example

```
wc_Sha256 sha;
wc_Sha256SizeSet(&sha, 1000);
```

C.51.2.17 function wc_Sha256SetFlags

```
int wc_Sha256SetFlags(
    wc_Sha256 * sha256,
    word32 flags
)
```

Sets SHA256 flags.

Parameters:

- **sha256** SHA256 structure
- **flags** Flags to set

See: wc_InitSha256

Return:

- 0 on success
- negative on error

Example

```
wc_Sha256 sha;
int ret = wc_Sha256SetFlags(&sha, WC_HASH_FLAG_WILLCOPY);
```

C.51.2.18 function wc_Sha256GetFlags

```
int wc_Sha256GetFlags(
    wc_Sha256 * sha256,
    word32 * flags
)
```

Gets SHA256 flags.

Parameters:

- **sha256** SHA256 structure
- **flags** Pointer to store flags

See: wc_Sha256SetFlags

Return:

- 0 on success
- negative on error

Example

```
wc_Sha256 sha;
word32 flags;
int ret = wc_Sha256GetFlags(&sha, &flags);
```

C.51.2.19 function wc_InitSha224_ex

```
int wc_InitSha224_ex(
    wc_Sha224 * sha224,
    void * heap,
    int devId
)
```

Initializes SHA224 with heap and device ID.

Parameters:

- **sha224** SHA224 structure
- **heap** Heap hint
- **devId** Device ID

See: wc_InitSha224

Return:

- 0 on success
- negative on error

Example

```
wc_Sha224 sha;
int ret = wc_InitSha224_ex(&sha, NULL, INVALID_DEVID);
```

C.51.2.20 function wc_Sha224Free

```
void wc_Sha224Free(
    wc_Sha224 * sha224
)
```

Frees SHA224 resources.

Parameters:

- **sha224** SHA224 structure

See: wc_InitSha224

Return: none No returns

Example

```
wc_Sha224 sha;
wc_InitSha224(&sha);
wc_Sha224Free(&sha);
```

C.51.2.21 function wc_Sha224Reset

```
int wc_Sha224Reset(
    wc_Sha224 * sha224
)
```

Resets the sha224 structure to its freshly initialized state, continuing with its established allocations, heap hint, and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially hashed message, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Sha224Free for teardown at end of life.

Parameters:

- **sha224** Pointer to the sha224 structure to be reset.

See:

- wc_InitSha224
- wc_Sha224Final
- wc_Sha224Free

Return:

- 0 Returned upon successfully resetting the structure.
- BAD_FUNC_ARG Returned if sha224 is NULL.
- negative Other values may be returned on reinitialization failure in fallback (non-plain-software) configurations.

Example

```
wc_Sha224 sha224;
byte data[] = { Data to be discarded };
byte data2[] = { Data to be hashed };
byte hash[WC_SHA224_DIGEST_SIZE];

if ((ret = wc_InitSha224(&sha224)) == 0) {
    wc_Sha224Update(&sha224, data, sizeof(data));
    wc_Sha224Reset(&sha224); /* discard the partially hashed message */
    wc_Sha224Update(&sha224, data2, sizeof(data2));
    wc_Sha224Final(&sha224, hash);
    wc_Sha224Free(&sha224);
}
```

C.51.2.22 function wc_Sha224_Grow

```
int wc_Sha224_Grow(
    wc_Sha224 * sha224,
    const byte * in,
    int inSz
)
```

Grows SHA224 buffer with input data. This function is only available when WOLFSSL_HASH_KEEP is defined. It is used for keeping an internal buffer to hold all data to be hashed rather than iterating

over update, which is necessary for some hardware acceleration platforms that have restrictions on streaming hash operations.

Parameters:

- **sha224** SHA224 structure
- **in** Input data
- **inSz** Input size

See: wc_Sha224Update

Return:

- 0 on success
- negative on error

Example

```
wc_Sha224 sha;
byte data[100];
int ret = wc_Sha224_Grow(&sha, data, sizeof(data));
```

C.51.2.23 function wc_Sha224GetHash

```
int wc_Sha224GetHash(
    wc_Sha224 * sha224,
    byte * hash
)
```

Gets SHA224 hash without finalizing.

Parameters:

- **sha224** SHA224 structure
- **hash** Output hash buffer

See: wc_Sha224Final

Return:

- 0 on success
- negative on error

Example

```
wc_Sha224 sha;
byte hash[WC_SHA224_DIGEST_SIZE];
int ret = wc_Sha224GetHash(&sha, hash);
```

C.51.2.24 function wc_Sha224Copy

```
int wc_Sha224Copy(
    wc_Sha224 * src,
    wc_Sha224 * dst
)
```

Copies SHA224 context.

Parameters:

- **src** Source SHA224 structure
- **dst** Destination SHA224 structure (must be zeroed or previously initialized)

See: wc_InitSha224

Return:

- 0 on success
- negative on error

Example

```
wc_Sha224 src, dst;
memset(&dst, 0, sizeof(dst));
int ret = wc_InitSha224(&src);
if (ret == 0)
    ret = wc_Sha224Copy(&src, &dst);
```

C.51.2.25 function wc_Sha224SetFlags

```
int wc_Sha224SetFlags(
    wc_Sha224 * sha224,
    word32 flags
)
```

Sets SHA224 flags.

Parameters:

- **sha224** SHA224 structure
- **flags** Flags to set

See: wc_InitSha224

Return:

- 0 on success
- negative on error

Example

```
wc_Sha224 sha;
int ret = wc_Sha224SetFlags(&sha, WC_HASH_FLAG_WILLCOPY);
```

C.51.2.26 function wc_Sha224GetFlags

```
int wc_Sha224GetFlags(
    wc_Sha224 * sha224,
    word32 * flags
)
```

Gets SHA224 flags.

Parameters:

- **sha224** SHA224 structure
- **flags** Pointer to store flags

See: wc_Sha224SetFlags

Return:

- 0 on success
- negative on error

Example

```
wc_Sha224 sha;
word32 flags;
int ret = wc_Sha224GetFlags(&sha, &flags);
```

C.51.3 Source code

```
int wc_InitSha256(wc_Sha256* sha);

C.52 sha3.h

C.52.1 Functions

	Name
int	**wc_InitSha3_224**(wc_Sha3 * sha3, void * heap, int devId)This function initializes SHA3-224. This is automatically called by wc_Sha3_224Hash.
int	**wc_Sha3_224_Update**(wc_Sha3 * sha, const byte * data, word32 len)Can be called to continually hash the provided byte array of length len.
int	**wc_Sha3_224_Final**(wc_Sha3 * sha3, byte * hash)Finalizes hashing of data. Result is placed into hash. Resets state of sha3 struct.
void	**wc_Sha3_224_Free**(wc_Sha3 * sha3)Resets the wc_Sha3 structure. Note: this is only supported if you have WOLFSSL_TI_HASH defined.

	Name
int	**wc_Sha3_224_Reset**(wc_Sha3 * sha3)Resets the sha3 structure to its freshly initialized state, continuing with the established heap hint and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially hashed message, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Sha3_224_Free for teardown at end of life.
int	**wc_Sha3_224_GetHash**(wc_Sha3 * sha3, byte * hash)Gets hash data. Result is placed into hash. Does not reset state of sha3 struct.
int	**wc_Sha3_224_Copy**(wc_Sha3 * sha3, wc_Sha3 * dst)Copy the state of the hash.
int	**wc_InitSha3_256**(wc_Sha3 * sha3, void * heap, int devId)This function initializes SHA3-256. This is automatically called by wc_Sha3_256Hash.
int	**wc_Sha3_256_Update**(wc_Sha3 * sha, const byte * data, word32 len)Can be called to continually hash the provided byte array of length len.
int	**wc_Sha3_256_Final**(wc_Sha3 * sha3, byte * hash)Finalizes hashing of data. Result is placed into hash. Resets state of sha3 struct.
void	**wc_Sha3_256_Free**(wc_Sha3 * sha3)Resets the wc_Sha3 structure. Note: this is only supported if you have WOLFSSL_TI_HASH defined.
int	**wc_Sha3_256_Reset**(wc_Sha3 * sha3)Resets the sha3 structure to its freshly initialized state, continuing with the established heap hint and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially hashed message, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Sha3_256_Free for teardown at end of life.
int	**wc_Sha3_256_GetHash**(wc_Sha3 * sha3, byte * hash)Gets hash data. Result is placed into hash. Does not reset state of sha3 struct.
int	**wc_Sha3_256_Copy**(wc_Sha3 * sha3, wc_Sha3 * dst)Copy the state of the hash.
int	**wc_InitSha3_384**(wc_Sha3 * sha3, void * heap, int devId)This function initializes SHA3-384. This is automatically called by wc_Sha3_384Hash.
int	**wc_Sha3_384_Update**(wc_Sha3 * sha, const byte * data, word32 len)Can be called to continually hash the provided byte array of length len.

	Name
int	**wc_Sha3_384_Final**(wc_Sha3 * sha3, byte * hash)Finalizes hashing of data. Result is placed into hash. Resets state of sha3 struct.
void	**wc_Sha3_384_Free**(wc_Sha3 * sha3)Resets the wc_Sha3 structure. Note: this is only supported if you have WOLFSSL_TI_HASH defined.
int	**wc_Sha3_384_Reset**(wc_Sha3 * sha3)Resets the sha3 structure to its freshly initialized state, continuing with the established heap hint and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially hashed message, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Sha3_384_Free for teardown at end of life.
int	**wc_Sha3_384_GetHash**(wc_Sha3 * sha3, byte * hash)Gets hash data. Result is placed into hash. Does not reset state of sha3 struct.
int	**wc_Sha3_384_Copy**(wc_Sha3 * sha3, wc_Sha3 * dst)Copy the state of the hash.
int	**wc_InitSha3_512**(wc_Sha3 * sha3, void * heap, int devId)This function initializes SHA3-512. This is automatically called by wc_Sha3_512Hash.
int	**wc_Sha3_512_Update**(wc_Sha3 * sha, const byte * data, word32 len)Can be called to continually hash the provided byte array of length len.
int	**wc_Sha3_512_Final**(wc_Sha3 * sha3, byte * hash)Finalizes hashing of data. Result is placed into hash. Resets state of sha3 struct.
void	**wc_Sha3_512_Free**(wc_Sha3 * sha3)Resets the wc_Sha3 structure. Note: this is only supported if you have WOLFSSL_TI_HASH defined.
int	**wc_Sha3_512_Reset**(wc_Sha3 * sha3)Resets the sha3 structure to its freshly initialized state, continuing with the established heap hint and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially hashed message, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Sha3_512_Free for teardown at end of life.
int	**wc_Sha3_512_GetHash**(wc_Sha3 * sha3, byte * hash)Gets hash data. Result is placed into hash. Does not reset state of sha3 struct.
int	**wc_Sha3_512_Copy**(wc_Sha3 * sha3, wc_Sha3 * dst)Copy the state of the hash.

	Name
int	**wc_InitShake128**(wc_Shake * shake, void * heap, int devId)This function initializes SHAKE-128. This is automatically called by wc_Shake128Hash.
int	**wc_Shake128_Update**(wc_Shake * sha, const byte * data, word32 len)Can be called to continually hash the provided byte array of length len.
int	**wc_Shake128_Final**(wc_Shake * shake, byte * hash, word32 hashLen)Finalizes hashing of data. Result is placed into hash. Resets state of shake struct.
int	**wc_Shake128_Absorb**(wc_Shake * sha, const byte * data, word32 len)Called to absorb the provided byte array of length len. Cannot be called incrementally.
int	**wc_Shake128_SqueezeBlocks**(wc_Shake * shake, byte * out, word32 blockCnt)Squeeze out more blocks of data. Result is placed into out. Can be called inrementally.
void	**wc_Shake128_Free**(wc_Shake * shake)Resets the wc_Shake structure. Note: this is only supported if you have WOLFSSL_TI_HASH defined.
int	**wc_Shake128_Reset**(wc_Shake * shake)Resets the shake structure to its freshly initialized state, continuing with the established heap hint and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially absorbed input, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Shake128_Free for teardown at end of life.
int	**wc_Shake128_GetHash**(wc_Shake * shake, byte * hash)Gets hash data. Result is placed into hash. Does not reset state of shake struct.
int	**wc_Shake128_Copy**(wc_Shake * src, wc_Sha3 * dst)Copy the state of the hash.
int	**wc_InitShake256**(wc_Shake * shake, void * heap, int devId)This function initializes SHAKE-256. This is automatically called by wc_Shake256Hash.
int	**wc_Shake256_Update**(wc_Shake * sha, const byte * data, word32 len)Can be called to continually hash the provided byte array of length len.
int	**wc_Shake256_Final**(wc_Shake * shake, byte * hash, word32 hashLen)Finalizes hashing of data. Result is placed into hash. Resets state of shake struct.

	Name
int	**wc_Shake256_Absorb**(wc_Shake * sha, const byte * data, word32 len)Called to absorb the provided byte array of length len. Cannot be called incrementally.
int	**wc_Shake256_SqueezeBlocks**(wc_Shake * shake, byte * out, word32 blockCnt)Squeeze out more blocks of data. Result is placed into out. Can be called incrementally.
void	**wc_Shake256_Free**(wc_Shake * shake)Resets the wc_Shake structure. Note: this is only supported if you have WOLFSSL_TI_HASH defined.
int	**wc_Shake256_Reset**(wc_Shake * shake)Resets the shake structure to its freshly initialized state, continuing with the established heap hint and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially absorbed input, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Shake256_Free for teardown at end of life.
int	**wc_Shake256_GetHash**(wc_Shake * shake, byte * hash)Gets hash data. Result is placed into hash. Does not reset state of shake struct.
int	**wc_Shake256_Copy**(wc_Shake * src, wc_Sha3 * dst)Copy the state of the hash.
int	**wc_InitKmac128**(wc_Kmac * kmac, const byte * key, word32 keyLen, const byte * custom, word32 customLen, void * heap, int devId)This function initializes a KMAC128 operation with a key and an optional customization string, per NIST SP 800_185. KMAC128 requires SHAKE128 (WOLFSSL_SHAKE128) and is enabled with WOLFSSL_KMAC.
int	**wc_Kmac128_Update**(wc_Kmac * kmac, const byte * in, word32 inLen)This function absorbs message data into a KMAC128 operation. It may be called any number of times before finalizing.
int	**wc_Kmac128_Final**(wc_Kmac * kmac, byte * out, word32 outLen)This function finalizes a KMAC128 operation, producing outLen bytes of output. The output length is bound into the result, so a KMAC with a different length is a different value.
int	**wc_Kmac128_FinalXof**(wc_Kmac * kmac, byte * out, word32 outLen)This function finalizes a KMAC128 operation as an XOF (KMACXOF128). Unlike wc_Kmac128_Final, the output length is not bound into the result, so any amount of output may be requested.

	Name
void	**wc_Kmac128_Free**(wc_Kmac * kmac)This function releases any resources associated with a KMAC128 operation. Passing NULL is safe and does nothing.
int	**wc_Kmac128Hash**(const byte * key, word32 keyLen, const byte * custom, word32 customLen, const byte * in, word32 inLen, byte * out, word32 outLen)This function computes a KMAC128 over a single message in one call, initializing, updating and finalizing internally.
int	**wc_Kmac128HashXof**(const byte * key, word32 keyLen, const byte * custom, word32 customLen, const byte * in, word32 inLen, byte * out, word32 outLen)This function computes a KMACXOF128 over a single message in one call. Like wc_Kmac128Hash but the output length is not bound into the result, so any amount of output may be requested.
int	**wc_InitKmac256**(wc_Kmac * kmac, const byte * key, word32 keyLen, const byte * custom, word32 customLen, void * heap, int devId)This function initializes a KMAC256 operation with a key and an optional customization string, per NIST SP 800_185. KMAC256 requires SHAKE256 (WOLFSSL_SHAKE256) and is enabled with WOLFSSL_KMAC.
int	**wc_Kmac256_Update**(wc_Kmac * kmac, const byte * in, word32 inLen)This function absorbs message data into a KMAC256 operation. It may be called any number of times before finalizing.
int	**wc_Kmac256_Final**(wc_Kmac * kmac, byte * out, word32 outLen)This function finalizes a KMAC256 operation, producing outLen bytes of output. The output length is bound into the result, so a KMAC with a different length is a different value.
int	**wc_Kmac256_FinalXof**(wc_Kmac * kmac, byte * out, word32 outLen)This function finalizes a KMAC256 operation as an XOF (KMACXOF256). Unlike wc_Kmac256_Final, the output length is not bound into the result, so any amount of output may be requested.
void	**wc_Kmac256_Free**(wc_Kmac * kmac)This function releases any resources associated with a KMAC256 operation. Passing NULL is safe and does nothing.

	Name
int	**wc_Kmac256Hash**(const byte * key, word32 keyLen, const byte * custom, word32 customLen, const byte * in, word32 inLen, byte * out, word32 outLen)This function computes a KMAC256 over a single message in one call, initializing, updating and finalizing internally.
int	**wc_Kmac256HashXof**(const byte * key, word32 keyLen, const byte * custom, word32 customLen, const byte * in, word32 inLen, byte * out, word32 outLen)This function computes a KMACXOF256 over a single message in one call. Like wc_Kmac256Hash but the output length is not bound into the result, so any amount of output may be requested.
int	**wc_Kmac128_Copy**(wc_Kmac * src, wc_Kmac * dst)This function copies the state of a KMAC128 operation so it can be finalized more than once, for example over a common message prefix.
int	**wc_Kmac256_Copy**(wc_Kmac * src, wc_Kmac * dst)This function copies the state of a KMAC256 operation so it can be finalized more than once, for example over a common message prefix.
int	**wc_InitCshake128**(wc_Cshake * cshake, const byte * name, word32 nameLen, const byte * custom, word32 customLen, void * heap, int devId)This function initializes a cSHAKE128 operation (customizable SHAKE, NIST SP 800_185) with a function_name and customization string. cSHAKE is enabled together with KMAC (WOLFSSL_KMAC). When both strings are empty, cSHAKE reduces to plain SHAKE128.
int	**wc_Cshake128_Update**(wc_Cshake * cshake, const byte * in, word32 inLen)This function absorbs message data into a cSHAKE128 operation.
int	**wc_Cshake128_Final**(wc_Cshake * cshake, byte * out, word32 outLen)This function finalizes a cSHAKE128 operation, squeezing outLen bytes of output. cSHAKE is an XOF, so a longer squeeze extends a shorter one over the same input.
void	**wc_Cshake128_Free**(wc_Cshake * cshake)This function releases any resources associated with a cSHAKE128 operation. Passing NULL is safe and does nothing.
int	**wc_Cshake128**(const byte * name, word32 nameLen, const byte * custom, word32 customLen, const byte * in, word32 inLen, byte * out, word32 outLen)This function computes a cSHAKE128 over a single message in one call, initializing, updating and finalizing internally.

	Name
int	**wc_InitCshake256**(wc_Cshake * cshake, const byte * name, word32 nameLen, const byte * custom, word32 customLen, void * heap, int devId)This function initializes a cSHAKE256 operation (customizable SHAKE, NIST SP 800_185) with a function_name and customization string. cSHAKE is enabled together with KMAC (WOLFSSL_KMAC). When both strings are empty, cSHAKE reduces to plain SHAKE256.
int	**wc_Cshake256_Update**(wc_Cshake * cshake, const byte * in, word32 inLen)This function absorbs message data into a cSHAKE256 operation.
int	**wc_Cshake256_Final**(wc_Cshake * cshake, byte * out, word32 outLen)This function finalizes a cSHAKE256 operation, squeezing outLen bytes of output. cSHAKE is an XOF, so a longer squeeze extends a shorter one over the same input.
void	**wc_Cshake256_Free**(wc_Cshake * cshake)This function releases any resources associated with a cSHAKE256 operation. Passing NULL is safe and does nothing.
int	**wc_Cshake256**(const byte * name, word32 nameLen, const byte * custom, word32 customLen, const byte * in, word32 inLen, byte * out, word32 outLen)This function computes a cSHAKE256 over a single message in one call, initializing, updating and finalizing internally.
int	**wc_Cshake128_Copy**(wc_Cshake * src, wc_Cshake * dst)This function copies the state of a cSHAKE128 operation so it can be finalized more than once, for example over a common message prefix. dst must already be an initialized wc_Cshake.
int	**wc_Cshake256_Copy**(wc_Cshake * src, wc_Cshake * dst)This function copies the state of a cSHAKE256 operation so it can be finalized more than once, for example over a common message prefix. dst must already be an initialized wc_Cshake.

C.52.2 Functions Documentation

C.52.2.1 function wc_InitSha3_224

```
int wc_InitSha3_224(
    wc_Sha3 * sha3,
    void * heap,
    int devId
)
```

This function initializes SHA3-224. This is automatically called by wc_Sha3_224Hash.

Parameters:

- **sha3** pointer to the sha3 structure to use for encryption

See:

- wc_Sha3_224Hash
- wc_Sha3_224_Update
- wc_Sha3_224_Final

Return: 0 Returned upon successfully initializing

Example

```
wc_Sha3 sha3[1];
if ((ret = wc_InitSha3_224(sha3, NULL, INVALID_DEVID)) != 0) {
    WOLFSSL_MSG("wc_InitSha3_224 failed");
}
else {
    wc_Sha3_224_Update(sha3, data, len);
    wc_Sha3_224_Final(sha3, hash);
}
```

C.52.2.2 function wc_Sha3_224_Update

```
int wc_Sha3_224_Update(
    wc_Sha3 * sha,
    const byte * data,
    word32 len
)
```

Can be called to continually hash the provided byte array of length len.

Parameters:

- **sha3** pointer to the sha3 structure to use for encryption
- **data** the data to be hashed
- **len** length of data to be hashed

See:

- wc_Sha3_224Hash
- wc_Sha3_224_Final
- wc_InitSha3_224

Return: 0 Returned upon successfully adding the data to the digest.

Example

```
wc_Sha3 sha3[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitSha3_224(sha3, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitSha3_224 failed");
}
else {
    wc_Sha3_224_Update(sha3, data, len);
    wc_Sha3_224_Final(sha3, hash);
}
```

C.52.2.3 function wc_Sha3_224_Final

```
int wc_Sha3_224_Final(
    wc_Sha3 * sha3,
    byte * hash
)
```

Finalizes hashing of data. Result is placed into hash. Resets state of sha3 struct.

Parameters:

- **sha3** pointer to the sha3 structure to use for encryption
- **hash** Byte array to hold hash value.

See:

- wc_Sha3_224Hash
- wc_Sha3_224_GetHash
- wc_InitSha3_224

Return: 0 Returned upon successfully finalizing.

Example

```
wc_Sha3 sha3[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitSha3_224(sha3, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitSha3_224 failed");
}
else {
   wc_Sha3_224_Update(sha3, data, len);
   wc_Sha3_224_Final(sha3, hash);
}
```

C.52.2.4 function wc_Sha3_224_Free

```
void wc_Sha3_224_Free(
    wc_Sha3 * sha3
)
```

Resets the wc_Sha3 structure. Note: this is only supported if you have WOLFSSL_TI_HASH defined.

Parameters:

- **sha3** Pointer to the sha3 structure to be freed.

See:

- wc_InitSha3_224
- wc_Sha3_224_Update
- wc_Sha3_224_Final

Return: none No returns.

Example

```
wc_Sha3 sha3;
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitSha3_224(&sha3, NULL, INVALID_DEVID)) != 0) {
```

```
    WOLFSSL_MSG("wc_InitSha3_224 failed");
}
else {
    wc_Sha3_224_Update(&sha3, data, len);
    wc_Sha3_224_Final(&sha3, hash);
    wc_Sha3_224_Free(&sha3);
}
```

C.52.2.5 function wc_Sha3_224_Reset

```
int wc_Sha3_224_Reset(
    wc_Sha3 * sha3
)
```

Resets the sha3 structure to its freshly initialized state, continuing with the established heap hint and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially hashed message, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Sha3_224_Free for teardown at end of life.

Parameters:

- **sha3** Pointer to the sha3 structure to be reset.

See:

- wc_InitSha3_224
- wc_Sha3_224_Final
- wc_Sha3_224_Free

Return:

- 0 Returned upon successfully resetting the structure.
- BAD_FUNC_ARG Returned if sha3 is NULL.
- negative Other values may be returned on reinitialization failure in fallback (non-plain-software) configurations.

Example

```
wc_Sha3 sha3;
byte data[] = { Data to be discarded };
byte data2[] = { Data to be hashed };
byte hash[WC_SHA3_224_DIGEST_SIZE];

if ((ret = wc_InitSha3_224(&sha3, NULL, INVALID_DEVID)) == 0) {
    wc_Sha3_224_Update(&sha3, data, sizeof(data));
    wc_Sha3_224_Reset(&sha3); /* discard the partially hashed message */
    wc_Sha3_224_Update(&sha3, data2, sizeof(data2));
    wc_Sha3_224_Final(&sha3, hash);
    wc_Sha3_224_Free(&sha3);
}
```

C.52.2.6 function wc_Sha3_224_GetHash

```
int wc_Sha3_224_GetHash(
    wc_Sha3 * sha3,
    byte * hash
)
```

Gets hash data. Result is placed into hash. Does not reset state of sha3 struct.

Parameters:

- **sha3** pointer to the sha3 structure to use for encryption
- **hash** Byte array to hold hash value.

See:

- wc_Sha3_224Hash
- wc_Sha3_224_Final
- wc_InitSha3_224
- wc_Sha3_224_Copy

Return: 0 Returned upon successful copying of the hash.

Example

```
wc_Sha3 sha3[1];
if ((ret = wc_InitSha3_224(sha3, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitSha3_224 failed");
}
else {
   wc_Sha3_224_Update(sha3, data, len);
   wc_Sha3_224_GetHash(sha3, hash);
}
```

C.52.2.7 function wc_Sha3_224_Copy

```
int wc_Sha3_224_Copy(
    wc_Sha3 * sha3,
    wc_Sha3 * dst
)
```

Copy the state of the hash.

Parameters:

- **sha3** pointer to the sha3 structure to copy
- **dst** pointer to the sha3 structure to copy into (must be zeroed or previously initialized)

See:

- wc_Sha3_224Hash
- wc_Sha3_224_Final
- wc_InitSha3_224
- wc_Sha3_224_GetHash

Return: 0 Returned upon successful copying.

Example

```
wc_Sha3 sha3[1];
wc_Sha3 sha3_dup[1];
memset(sha3_dup, 0, sizeof(*sha3_dup));
if ((ret = wc_InitSha3_224(sha3, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitSha3_224 failed");
}
else {
   wc_Sha3_224_Update(sha3, data, len);
   wc_Sha3_224_Copy(sha3, sha3_dup);
}
```

C.52.2.8 function wc_InitSha3_256

```
int wc_InitSha3_256(
    wc_Sha3 * sha3,
    void * heap,
    int devId
)
```

This function initializes SHA3-256. This is automatically called by wc_Sha3_256Hash.

Parameters:

- **sha3** pointer to the sha3 structure to use for encryption

See:

- wc_Sha3_256Hash
- wc_Sha3_256_Update
- wc_Sha3_256_Final

Return: 0 Returned upon successfully initializing

Example

```
wc_Sha3 sha3[1];
if ((ret = wc_InitSha3_256(sha3, NULL, INVALID_DEVID)) != 0) {
    WOLFSSL_MSG("wc_InitSha3_256 failed");
}
else {
    wc_Sha3_256_Update(sha3, data, len);
    wc_Sha3_256_Final(sha3, hash);
}
```

C.52.2.9 function wc_Sha3_256_Update

```
int wc_Sha3_256_Update(
    wc_Sha3 * sha,
    const byte * data,
    word32 len
)
```

Can be called to continually hash the provided byte array of length len.

Parameters:

- **sha3** pointer to the sha3 structure to use for encryption
- **data** the data to be hashed
- **len** length of data to be hashed

See:

- wc_Sha3_256Hash
- wc_Sha3_256_Final
- wc_InitSha3_256

Return: 0 Returned upon successfully adding the data to the digest.

Example

```
wc_Sha3 sha3[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);
```

```
if ((ret = wc_InitSha3_256(sha3, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitSha3_256 failed");
}
else {
    wc_Sha3_256_Update(sha3, data, len);
    wc_Sha3_256_Final(sha3, hash);
}
```

C.52.2.10 function wc_Sha3_256_Final

```
int wc_Sha3_256_Final(
    wc_Sha3 * sha3,
    byte * hash
)
```

Finalizes hashing of data. Result is placed into hash. Resets state of sha3 struct.

Parameters:

- **sha3** pointer to the sha3 structure to use for encryption
- **hash** Byte array to hold hash value.

See:

- wc_Sha3_256Hash
- wc_Sha3_256_GetHash
- wc_InitSha3_256

Return: 0 Returned upon successfully finalizing.

Example

```
wc_Sha3 sha3[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitSha3_256(sha3, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitSha3_256 failed");
}
else {
   wc_Sha3_256_Update(sha3, data, len);
   wc_Sha3_256_Final(sha3, hash);
}
```

C.52.2.11 function wc_Sha3_256_Free

```
void wc_Sha3_256_Free(
    wc_Sha3 * sha3
)
```

Resets the wc_Sha3 structure. Note: this is only supported if you have WOLFSSL_TI_HASH defined.

Parameters:

- **sha3** Pointer to the sha3 structure to be freed.

See:

- wc_InitSha3_256
- wc_Sha3_256_Update
- wc_Sha3_256_Final

Return: none No returns.

Example

```
wc_Sha3 sha3;
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitSha3_256(&sha3, NULL, INVALID_DEVID)) != 0) {
    WOLFSSL_MSG("wc_InitSha3_256 failed");
}
else {
    wc_Sha3_256_Update(&sha3, data, len);
    wc_Sha3_256_Final(&sha3, hash);
    wc_Sha3_256_Free(&sha3);
}
```

C.52.2.12 function wc_Sha3_256_Reset

```
int wc_Sha3_256_Reset(
    wc_Sha3 * sha3
)
```

Resets the sha3 structure to its freshly initialized state, continuing with the established heap hint and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially hashed message, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Sha3_256_Free for teardown at end of life.

Parameters:

- **sha3** Pointer to the sha3 structure to be reset.

See:

- wc_InitSha3_256
- wc_Sha3_256_Final
- wc_Sha3_256_Free

Return:

- 0 Returned upon successfully resetting the structure.
- BAD_FUNC_ARG Returned if sha3 is NULL.
- negative Other values may be returned on reinitialization failure in fallback (non-plain-software) configurations.

Example

```
wc_Sha3 sha3;
byte data[] = { Data to be discarded };
byte data2[] = { Data to be hashed };
byte hash[WC_SHA3_256_DIGEST_SIZE];

if ((ret = wc_InitSha3_256(&sha3, NULL, INVALID_DEVID)) == 0) {
    wc_Sha3_256_Update(&sha3, data, sizeof(data));
    wc_Sha3_256_Reset(&sha3); /* discard the partially hashed message */
    wc_Sha3_256_Update(&sha3, data2, sizeof(data2));
    wc_Sha3_256_Final(&sha3, hash);
    wc_Sha3_256_Free(&sha3);
}
```

C.52.2.13 function wc_Sha3_256_GetHash

```
int wc_Sha3_256_GetHash(
    wc_Sha3 * sha3,
    byte * hash
)
```

Gets hash data. Result is placed into hash. Does not reset state of sha3 struct.

Parameters:

- **sha3** pointer to the sha3 structure to use for encryption
- **hash** Byte array to hold hash value.

See:

- wc_Sha3_256Hash
- wc_Sha3_256_Final
- wc_InitSha3_256
- wc_Sha3_256_Copy

Return: 0 Returned upon successful copying of the hash.

Example

```
wc_Sha3 sha3[1];
if ((ret = wc_InitSha3_256(sha3, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitSha3_256 failed");
}
else {
   wc_Sha3_256_Update(sha3, data, len);
   wc_Sha3_256_GetHash(sha3, hash);
}
```

C.52.2.14 function wc_Sha3_256_Copy

```
int wc_Sha3_256_Copy(
    wc_Sha3 * sha3,
    wc_Sha3 * dst
)
```

Copy the state of the hash.

Parameters:

- **sha3** pointer to the sha3 structure to copy
- **dst** pointer to the sha3 structure to copy into (must be zeroed or previously initialized)

See:

- wc_Sha3_256Hash
- wc_Sha3_256_Final
- wc_InitSha3_256
- wc_Sha3_256_GetHash

Return: 0 Returned upon successful copying.

Example

```
wc_Sha3 sha3[1];
wc_Sha3 sha3_dup[1];
memset(sha3_dup, 0, sizeof(*sha3_dup));
if ((ret = wc_InitSha3_256(sha3, NULL, INVALID_DEVID)) != 0) {
```

```
    WOLFSSL_MSG("wc_InitSha3_256 failed");
}
else {
    wc_Sha3_256_Update(sha3, data, len);
    wc_Sha3_256_Copy(sha3, sha3_dup);
}
```

C.52.2.15 function wc_InitSha3_384

```
int wc_InitSha3_384(
    wc_Sha3 * sha3,
    void * heap,
    int devId
)
```

This function initializes SHA3-384. This is automatically called by wc_Sha3_384Hash.

Parameters:

- **sha3** pointer to the sha3 structure to use for encryption

See:

- wc_Sha3_384Hash
- wc_Sha3_384_Update
- wc_Sha3_384_Final

Return: 0 Returned upon successfully initializing

Example

```
wc_Sha3 sha3[1];
if ((ret = wc_InitSha3_384(sha3, NULL, INVALID_DEVID)) != 0) {
    WOLFSSL_MSG("wc_InitSha3_384 failed");
}
else {
    wc_Sha3_384_Update(sha3, data, len);
    wc_Sha3_384_Final(sha3, hash);
}
```

C.52.2.16 function wc_Sha3_384_Update

```
int wc_Sha3_384_Update(
    wc_Sha3 * sha,
    const byte * data,
    word32 len
)
```

Can be called to continually hash the provided byte array of length len.

Parameters:

- **sha3** pointer to the sha3 structure to use for encryption
- **data** the data to be hashed
- **len** length of data to be hashed

See:

- wc_Sha3_384Hash
- wc_Sha3_384_Final
- wc_InitSha3_384

Return: 0 Returned upon successfully adding the data to the digest.

Example

```
wc_Sha3 sha3[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitSha3_384(sha3, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitSha3_384 failed");
}
else {
    wc_Sha3_384_Update(sha3, data, len);
    wc_Sha3_384_Final(sha3, hash);
}
```

C.52.2.17 function wc_Sha3_384_Final

```
int wc_Sha3_384_Final(
    wc_Sha3 * sha3,
    byte * hash
)
```

Finalizes hashing of data. Result is placed into hash. Resets state of sha3 struct.

Parameters:

- **sha3** pointer to the sha3 structure to use for encryption
- **hash** Byte array to hold hash value.

See:

- wc_Sha3_384Hash
- wc_Sha3_384_GetHash
- wc_InitSha3_384

Return: 0 Returned upon successfully finalizing.

Example

```
wc_Sha3 sha3[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitSha3_384(sha3, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitSha3_384 failed");
}
else {
   wc_Sha3_384_Update(sha3, data, len);
   wc_Sha3_384_Final(sha3, hash);
}
```

C.52.2.18 function wc_Sha3_384_Free

```
void wc_Sha3_384_Free(
    wc_Sha3 * sha3
)
```

Resets the wc_Sha3 structure. Note: this is only supported if you have WOLFSSL_TI_HASH defined.

Parameters:

- **sha3** Pointer to the sha3 structure to be freed.

See:

- wc_InitSha3_384
- wc_Sha3_384_Update
- wc_Sha3_384_Final

Return: none No returns.

Example

```
wc_Sha3 sha3;
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitSha3_384(&sha3, NULL, INVALID_DEVID)) != 0) {
    WOLFSSL_MSG("wc_InitSha3_384 failed");
}
else {
    wc_Sha3_384_Update(&sha3, data, len);
    wc_Sha3_384_Final(&sha3, hash);
    wc_Sha3_384_Free(&sha3);
}
```

C.52.2.19 function wc_Sha3_384_Reset

```
int wc_Sha3_384_Reset(
    wc_Sha3 * sha3
)
```

Resets the sha3 structure to its freshly initialized state, continuing with the established heap hint and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially hashed message, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Sha3_384_Free for teardown at end of life.

Parameters:

- **sha3** Pointer to the sha3 structure to be reset.

See:

- wc_InitSha3_384
- wc_Sha3_384_Final
- wc_Sha3_384_Free

Return:

- 0 Returned upon successfully resetting the structure.
- BAD_FUNC_ARG Returned if sha3 is NULL.
- negative Other values may be returned on reinitialization failure in fallback (non-plain-software) configurations.

Example

```
wc_Sha3 sha3;
byte data[] = { Data to be discarded };
byte data2[] = { Data to be hashed };
byte hash[WC_SHA3_384_DIGEST_SIZE];
```

```
if ((ret = wc_InitSha3_384(&sha3, NULL, INVALID_DEVID)) == 0) {
    wc_Sha3_384_Update(&sha3, data, sizeof(data));
    wc_Sha3_384_Reset(&sha3); /* discard the partially hashed message */
    wc_Sha3_384_Update(&sha3, data2, sizeof(data2));
    wc_Sha3_384_Final(&sha3, hash);
    wc_Sha3_384_Free(&sha3);
}
```

C.52.2.20 function wc_Sha3_384_GetHash

```
int wc_Sha3_384_GetHash(
    wc_Sha3 * sha3,
    byte * hash
)
```

Gets hash data. Result is placed into hash. Does not reset state of sha3 struct.

Parameters:

- **sha3** pointer to the sha3 structure to use for encryption
- **hash** Byte array to hold hash value.

See:

- wc_Sha3_384Hash
- wc_Sha3_384_Final
- wc_InitSha3_384
- wc_Sha3_384_Copy

Return: 0 Returned upon successful copying of the hash.

Example

```
wc_Sha3 sha3[1];
if ((ret = wc_InitSha3_384(sha3, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitSha3_38384ailed");
}
else {
   wc_Sha3_384_Update(sha3, data, len);
   wc_Sha3_384_GetHash(sha3, hash);
}
```

C.52.2.21 function wc_Sha3_384_Copy

```
int wc_Sha3_384_Copy(
    wc_Sha3 * sha3,
    wc_Sha3 * dst
)
```

Copy the state of the hash.

Parameters:

- **sha3** pointer to the sha3 structure to copy
- **dst** pointer to the sha3 structure to copy into (must be zeroed or previously initialized)

See:

- wc_Sha3_384Hash
- wc_Sha3_384_Final
- wc_InitSha3_384

- wc_Sha3_384_GetHash

Return: 0 Returned upon successful copying.

Example

```
wc_Sha3 sha3[1];
wc_Sha3 sha3_dup[1];
memset(sha3_dup, 0, sizeof(*sha3_dup));
if ((ret = wc_InitSha3_384(sha3, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitSha3_384 failed");
}
else {
   wc_Sha3_384_Update(sha3, data, len);
   wc_Sha3_384_Copy(sha3, sha3_dup);
}
```

C.52.2.22 function wc_InitSha3_512

```
int wc_InitSha3_512(
    wc_Sha3 * sha3,
    void * heap,
    int devId
)
```

This function initializes SHA3-512. This is automatically called by wc_Sha3_512Hash.

Parameters:

- **sha3** pointer to the sha3 structure to use for encryption

See:

- wc_Sha3_512Hash
- wc_Sha3_512_Update
- wc_Sha3_512_Final

Return: 0 Returned upon successfully initializing

Example

```
wc_Sha3 sha3[1];
if ((ret = wc_InitSha3_512(sha3, NULL, INVALID_DEVID)) != 0) {
    WOLFSSL_MSG("wc_InitSha3_512 failed");
}
else {
    wc_Sha3_512_Update(sha3, data, len);
    wc_Sha3_512_Final(sha3, hash);
}
```

C.52.2.23 function wc_Sha3_512_Update

```
int wc_Sha3_512_Update(
    wc_Sha3 * sha,
    const byte * data,
    word32 len
)
```

Can be called to continually hash the provided byte array of length len.

Parameters:

- **sha3** pointer to the sha3 structure to use for encryption
- **data** the data to be hashed
- **len** length of data to be hashed

See:

- wc_Sha3_512Hash
- wc_Sha3_512_Final
- wc_InitSha3_512

Return: 0 Returned upon successfully adding the data to the digest.

Example

```
wc_Sha3 sha3[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitSha3_512(sha3, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitSha3_512 failed");
}
else {
    wc_Sha3_512_Update(sha3, data, len);
    wc_Sha3_512_Final(sha3, hash);
}
```

C.52.2.24 function wc_Sha3_512_Final

```
int wc_Sha3_512_Final(
    wc_Sha3 * sha3,
    byte * hash
)
```

Finalizes hashing of data. Result is placed into hash. Resets state of sha3 struct.

Parameters:

- **sha3** pointer to the sha3 structure to use for encryption
- **hash** Byte array to hold hash value.

See:

- wc_Sha3_512Hash
- wc_Sha3_512_GetHash
- wc_InitSha3_512

Return: 0 Returned upon successfully finalizing.

Example

```
wc_Sha3 sha3[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitSha3_512(sha3, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitSha3_512 failed");
}
else {
   wc_Sha3_512_Update(sha3, data, len);
   wc_Sha3_512_Final(sha3, hash);
}
```

C.52.2.25 function wc_Sha3_512_Free

```
void wc_Sha3_512_Free(
    wc_Sha3 * sha3
)
```

Resets the wc_Sha3 structure. Note: this is only supported if you have WOLFSSL_TI_HASH defined.

Parameters:

- **sha3** Pointer to the sha3 structure to be freed.

See:

- wc_InitSha3_512
- wc_Sha3_512_Update
- wc_Sha3_512_Final

Return: none No returns.

Example

```
wc_Sha3 sha3;
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitSha3_512(&sha3, NULL, INVALID_DEVID)) != 0) {
    WOLFSSL_MSG("wc_InitSha3_512 failed");
}
else {
    wc_Sha3_512_Update(&sha3, data, len);
    wc_Sha3_512_Final(&sha3, hash);
    wc_Sha3_512_Free(&sha3);
}
```

C.52.2.26 function wc_Sha3_512_Reset

```
int wc_Sha3_512_Reset(
    wc_Sha3 * sha3
)
```

Resets the sha3 structure to its freshly initialized state, continuing with the established heap hint and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially hashed message, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Sha3_512_Free for teardown at end of life.

Parameters:

- **sha3** Pointer to the sha3 structure to be reset.

See:

- wc_InitSha3_512
- wc_Sha3_512_Final
- wc_Sha3_512_Free

Return:

- 0 Returned upon successfully resetting the structure.
- BAD_FUNC_ARG Returned if sha3 is NULL.
- negative Other values may be returned on reinitialization failure in fallback (non-plain-software) configurations.

Example

```
wc_Sha3 sha3;
byte data[] = { Data to be discarded };
byte data2[] = { Data to be hashed };
byte hash[WC_SHA3_512_DIGEST_SIZE];

if ((ret = wc_InitSha3_512(&sha3, NULL, INVALID_DEVID)) == 0) {
    wc_Sha3_512_Update(&sha3, data, sizeof(data));
    wc_Sha3_512_Reset(&sha3); /* discard the partially hashed message */
    wc_Sha3_512_Update(&sha3, data2, sizeof(data2));
    wc_Sha3_512_Final(&sha3, hash);
    wc_Sha3_512_Free(&sha3);
}
```

C.52.2.27 function wc_Sha3_512_GetHash

```
int wc_Sha3_512_GetHash(
    wc_Sha3 * sha3,
    byte * hash
)
```

Gets hash data. Result is placed into hash. Does not reset state of sha3 struct.

Parameters:

- **sha3** pointer to the sha3 structure to use for encryption
- **hash** Byte array to hold hash value.

See:

- wc_Sha3_512Hash
- wc_Sha3_512_Final
- wc_InitSha3_512
- wc_Sha3_512_Copy

Return: 0 Returned upon successful copying of the hash.

Example

```
wc_Sha3 sha3[1];
if ((ret = wc_InitSha3_512(sha3, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitSha3_512 failed");
}
else {
   wc_Sha3_512_Update(sha3, data, len);
   wc_Sha3_512_GetHash(sha3, hash);
}
```

C.52.2.28 function wc_Sha3_512_Copy

```
int wc_Sha3_512_Copy(
    wc_Sha3 * sha3,
    wc_Sha3 * dst
)
```

Copy the state of the hash.

Parameters:

- **sha3** pointer to the sha3 structure to copy
- **dst** pointer to the sha3 structure to copy into (must be zeroed or previously initialized)

See:

- wc_Sha3_512Hash
- wc_Sha3_512_Final
- wc_InitSha3_512
- wc_Sha3_512_GetHash

Return: 0 Returned upon successful copying.

Example

```
wc_Sha3 sha3[1];
wc_Sha3 sha3_dup[1];
memset(sha3_dup, 0, sizeof(*sha3_dup));
if ((ret = wc_InitSha3_512(sha3, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitSha3_512 failed");
}
else {
   wc_Sha3_512_Update(sha3, data, len);
   wc_Sha3_512_Copy(sha3, sha3_dup);
}
```

C.52.2.29 function wc_InitShake128

```
int wc_InitShake128(
    wc_Shake * shake,
    void * heap,
    int devId
)
```

This function initializes SHAKE-128. This is automatically called by wc_Shake128Hash.

Parameters:

- **shake** pointer to the shake structure to use for encryption

See:

- wc_Shake128Hash
- wc_Shake128_Update
- wc_Shake128_Final

Return: 0 Returned upon successfully initializing

Example

```
wc_Shake shake[1];
if ((ret = wc_InitShake128(shake, NULL, INVALID_DEVID)) != 0) {
    WOLFSSL_MSG("wc_InitShake128 failed");
}
else {
    wc_Shake128_Update(shake, data, len);
    wc_Shake128_Final(shake, hash);
}
```

C.52.2.30 function wc_Shake128_Update

```
int wc_Shake128_Update(
    wc_Shake * sha,
    const byte * data,
    word32 len
)
```

Can be called to continually hash the provided byte array of length len.

Parameters:

- **shake** pointer to the shake structure to use for encryption
- **data** the data to be hashed
- **len** length of data to be hashed

See:

- wc_Shake128Hash
- wc_Shake128_Final
- wc_InitShake128

Return: 0 Returned upon successfully adding the data to the digest.

Example

```
wc_Shake shake[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitShake128(shake, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitShake128 failed");
}
else {
    wc_Shake128_Update(shake, data, len);
    wc_Shake128_Final(shake, hash);
}
```

C.52.2.31 function wc_Shake128_Final

```
int wc_Shake128_Final(
    wc_Shake * shake,
    byte * hash,
    word32 hashLen
)
```

Finalizes hashing of data. Result is placed into hash. Resets state of shake struct.

Parameters:

- **shake** pointer to the shake structure to use for encryption
- **hash** Byte array to hold hash value.
- **hashLen** Number of bytes to write to hash.

See:

- wc_Shake128Hash
- wc_Shake128_GetHash
- wc_InitShake128

Return: 0 Returned upon successfully finalizing.

Example

```
wc_Shake shake[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitShake128(shake, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitShake128 failed");
}
else {
   wc_Shake128_Update(shake, data, len);
   wc_Shake128_Final(shake, hash);
}
```

C.52.2.32 function wc_Shake128_Absorb

```
int wc_Shake128_Absorb(
    wc_Shake * sha,
    const byte * data,
    word32 len
)
```

Called to absorb the provided byte array of length len. Cannot be called incrementally.

Parameters:

- **shake** pointer to the shake structure to use for encryption
- **data** the data to be absorbed
- **len** length of data to be absorbed

See:

- wc_Shake128_SqueezeBlocks
- wc_InitShake128

Return: 0 Returned upon successfully absorbed the data.

Example

```
wc_Shake shake[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);
byte out[2 * WC_SHA3_128_BLOCK_SIZE];
int blocks = 2;

if ((ret = wc_InitShake128(shake, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitShake128 failed");
}
else {
   wc_Shake128_Absorb(shake, data, len);
   wc_Shake128_SqueezeBlocks(shake, out, blocks);
}
```

C.52.2.33 function wc_Shake128_SqueezeBlocks

```
int wc_Shake128_SqueezeBlocks(
    wc_Shake * shake,
    byte * out,
```

```
    word32 blockCnt
)
```

Squeeze out more blocks of data. Result is placed into out. Can be called inrementally.

Parameters:

- **shake** pointer to the shake structure to use for encryption
- **hash** Byte array to hold output.
- **blocks** Number of blocks to squeeze out. Each block is WC_SHA3_128_BLOCK_SIZE bytes in length.

See:

- wc_Shake128_Absorb
- wc_InitShake128

Return: 0 Returned upon successfully squeezing.

Example

```
wc_Shake shake[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);
byte out[2 * WC_SHA3_128_BLOCK_SIZE];
int blocks = 2;

if ((ret = wc_InitShake128(shake, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitShake128 failed");
}
else {
   wc_Shake128_Absorb(shake, data, len);
   wc_Shake128_SqueezeBlocks(shake, out, blocks);
}
```

C.52.2.34 function wc_Shake128_Free

```
void wc_Shake128_Free(
    wc_Shake * shake
)
```

Resets the wc_Shake structure. Note: this is only supported if you have WOLFSSL_TI_HASH defined.

Parameters:

- **shake** Pointer to the shake structure to be freed.

See:

- wc_InitShake128
- wc_Shake128_Update
- wc_Shake128_Final

Return: none No returns.

Example

```
wc_Shake shake;
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitShake128(&shake, NULL, INVALID_DEVID)) != 0) {
```

```
    WOLFSSL_MSG("wc_InitShake128 failed");
}
else {
    wc_Shake128_Update(&shake, data, len);
    wc_Shake128_Final(&shake, hash);
    wc_Shake128_Free(&shake);
}
```

C.52.2.35 function wc_Shake128_Reset

```
int wc_Shake128_Reset(
    wc_Shake * shake
)
```

Resets the shake structure to its freshly initialized state, continuing with the established heap hint and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially absorbed input, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Shake128_Free for teardown at end of life.

Parameters:

- **shake** Pointer to the shake structure to be reset.

See:

- wc_InitShake128
- wc_Shake128_Final
- wc_Shake128_Free

Return:

- 0 Returned upon successfully resetting the structure.
- BAD_FUNC_ARG Returned if shake is NULL.
- negative Other values may be returned on reinitialization failure in fallback (non-plain-software) configurations.

Example

```
wc_Shake shake;
byte data[] = { Data to be discarded };
byte data2[] = { Data to be hashed };
byte hash[64];

if ((ret = wc_InitShake128(&shake, NULL, INVALID_DEVID)) == 0) {
    wc_Shake128_Update(&shake, data, sizeof(data));
    wc_Shake128_Reset(&shake); /* discard the partially absorbed input */
    wc_Shake128_Update(&shake, data2, sizeof(data2));
    wc_Shake128_Final(&shake, hash, sizeof(hash));
    wc_Shake128_Free(&shake);
}
```

C.52.2.36 function wc_Shake128_GetHash

```
int wc_Shake128_GetHash(
    wc_Shake * shake,
    byte * hash
)
```

Gets hash data. Result is placed into hash. Does not reset state of shake struct.

Parameters:

- **shake** pointer to the shake structure to use for encryption
- **hash** Byte array to hold hash value.

See:

- wc_Shake128Hash
- wc_Shake128_Final
- wc_InitShake128
- wc_Shake128_Copy

Return: 0 Returned upon successful copying of the hash.

Example

```
wc_Shake shake[1];
if ((ret = wc_InitShake128(shake, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitShake128 failed");
}
else {
   wc_Shake128_Update(shake, data, len);
   wc_Shake128_GetHash(shake, hash);
}
```

C.52.2.37 function wc_Shake128_Copy

```
int wc_Shake128_Copy(
    wc_Shake * src,
    wc_Sha3 * dst
)
```

Copy the state of the hash.

Parameters:

- **shake** pointer to the shake structure to copy
- **dst** pointer to the shake structure to copy into (must be zeroed or previously initialized)

See:

- wc_Shake128Hash
- wc_Shake128_Final
- wc_InitShake128
- wc_Shake128_GetHash

Return: 0 Returned upon successful copying.

Example

```
wc_Shake shake[1];
wc_Shake shake_dup[1];
memset(shake_dup, 0, sizeof(*shake_dup));
if ((ret = wc_InitShake128(shake, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitShake128 failed");
}
else {
   wc_Shake128_Update(shake, data, len);
   wc_Shake128_Copy(shake, shake_dup);
}
```

C.52.2.38 function wc_InitShake256

```
int wc_InitShake256(
    wc_Shake * shake,
    void * heap,
    int devId
)
```

This function initializes SHAKE-256. This is automatically called by wc_Shake256Hash.

Parameters:

- **shake** pointer to the shake structure to use for encryption

See:

- wc_Shake256Hash
- wc_Shake256_Update
- wc_Shake256_Final

Return: 0 Returned upon successfully initializing

Example

```
wc_Shake shake[1];
if ((ret = wc_InitShake256(shake, NULL, INVALID_DEVID)) != 0) {
    WOLFSSL_MSG("wc_InitShake256 failed");
}
else {
    wc_Shake256_Update(shake, data, len);
    wc_Shake256_Final(shake, hash, sizeof(hash));
}
```

C.52.2.39 function wc_Shake256_Update

```
int wc_Shake256_Update(
    wc_Shake * sha,
    const byte * data,
    word32 len
)
```

Can be called to continually hash the provided byte array of length len.

Parameters:

- **shake** pointer to the shake structure to use for encryption
- **data** the data to be hashed
- **len** length of data to be hashed

See:

- wc_Shake256Hash
- wc_Shake256_Final
- wc_InitShake256

Return: 0 Returned upon successfully adding the data to the digest.

Example

```
wc_Shake shake[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);
```

```
if ((ret = wc_InitShake256(shake, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitShake256 failed");
}
else {
    wc_Shake256_Update(shake, data, len);
    wc_Shake256_Final(shake, hash, sizeof(hash));
}
```

C.52.2.40 function wc_Shake256_Final

```
int wc_Shake256_Final(
    wc_Shake * shake,
    byte * hash,
    word32 hashLen
)
```

Finalizes hashing of data. Result is placed into hash. Resets state of shake struct.

Parameters:

- **shake** pointer to the shake structure to use for encryption
- **hash** Byte array to hold hash value.
- **hashLen** Size of hash in bytes.

See:

- wc_Shake256Hash
- wc_Shake256_GetHash
- wc_InitShake256

Return: 0 Returned upon successfully finalizing.

Example

```
wc_Shake shake[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitShake256(shake, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitShake256 failed");
}
else {
   wc_Shake256_Update(shake, data, len);
   wc_Shake256_Final(shake, hash, sizeof(hash));
}
```

C.52.2.41 function wc_Shake256_Absorb

```
int wc_Shake256_Absorb(
    wc_Shake * sha,
    const byte * data,
    word32 len
)
```

Called to absorb the provided byte array of length len. Cannot be called incrementally.

Parameters:

- **shake** pointer to the shake structure to use for encryption
- **data** the data to be absorbed

- **len** length of data to be absorbed

See:

- wc_Shake256_SqueezeBlocks
- wc_InitShake256

Return: 0 Returned upon successfully absorbed the data.

Example

```
wc_Shake shake[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);
byte out[2 * WC_SHA3_256_BLOCK_SIZE];
int blocks = 2;

if ((ret = wc_InitShake256(shake, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitShake256 failed");
}
else {
   wc_Shake256_Absorb(shake, data, len);
   wc_Shake256_SqueezeBlocks(shake, out, blocks);
}
```

C.52.2.42 function wc_Shake256_SqueezeBlocks

```
int wc_Shake256_SqueezeBlocks(
    wc_Shake * shake,
    byte * out,
    word32 blockCnt
)
```

Squeeze out more blocks of data. Result is placed into out. Can be called incrementally.

Parameters:

- **shake** pointer to the shake structure to use for encryption
- **hash** Byte array to hold output.
- **blocks** Number of blocks to squeeze out. Each block is WC_SHA3_256_BLOCK_SIZE bytes in length.

See:

- wc_Shake256_Absorb
- wc_InitShake256

Return: 0 Returned upon successfully squeezing.

Example

```
wc_Shake shake[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);
byte out[2 * WC_SHA3_256_BLOCK_SIZE];
int blocks = 2;

if ((ret = wc_InitShake256(shake, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitShake256 failed");
}
else {
```

```
    wc_Shake256_Absorb(shake, data, len);
    wc_Shake256_SqueezeBlocks(shake, out, blocks);
}
```

C.52.2.43 function wc_Shake256_Free

```
void wc_Shake256_Free(
    wc_Shake * shake
)
```

Resets the wc_Shake structure. Note: this is only supported if you have WOLFSSL_TI_HASH defined.

Parameters:

- **shake** Pointer to the shake structure to be freed.

See:

- wc_InitShake256
- wc_Shake256_Update
- wc_Shake256_Final

Return: none No returns.

Example

```
wc_Shake shake;
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitShake256(&shake, NULL, INVALID_DEVID)) != 0) {
    WOLFSSL_MSG("wc_InitShake256 failed");
}
else {
    wc_Shake256_Update(&shake, data, len);
    wc_Shake256_Final(&shake, hash, sizeof(hash));
    wc_Shake256_Free(&shake);
}
```

C.52.2.44 function wc_Shake256_Reset

```
int wc_Shake256_Reset(
    wc_Shake * shake
)
```

Resets the shake structure to its freshly initialized state, continuing with the established heap hint and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially absorbed input, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Shake256_Free for teardown at end of life.

Parameters:

- **shake** Pointer to the shake structure to be reset.

See:

- wc_InitShake256
- wc_Shake256_Final
- wc_Shake256_Free

Return:

- 0 Returned upon successfully resetting the structure.
- BAD_FUNC_ARG Returned if shake is NULL.
- negative Other values may be returned on reinitialization failure in fallback (non-plain-software) configurations.

Example

```
wc_Shake shake;
byte data[] = { Data to be discarded };
byte data2[] = { Data to be hashed };
byte hash[64];

if ((ret = wc_InitShake256(&shake, NULL, INVALID_DEVID)) == 0) {
    wc_Shake256_Update(&shake, data, sizeof(data));
    wc_Shake256_Reset(&shake); /* discard the partially absorbed input */
    wc_Shake256_Update(&shake, data2, sizeof(data2));
    wc_Shake256_Final(&shake, hash, sizeof(hash));
    wc_Shake256_Free(&shake);
}
```

C.52.2.45 function wc_Shake256_GetHash

```
int wc_Shake256_GetHash(
    wc_Shake * shake,
    byte * hash
)
```

Gets hash data. Result is placed into hash. Does not reset state of shake struct.

Parameters:

- **shake** pointer to the shake structure to use for encryption
- **hash** Byte array to hold hash value.

See:

- wc_Shake256Hash
- wc_Shake256_Final
- wc_InitShake256
- wc_Shake256_Copy

Return: 0 Returned upon successful copying of the hash.

Example

```
wc_Shake shake[1];
if ((ret = wc_InitShake256(shake, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitShake256 failed");
}
else {
   wc_Shake256_Update(shake, data, len);
   wc_Shake256_GetHash(shake, hash);
}
```

C.52.2.46 function wc_Shake256_Copy

```
int wc_Shake256_Copy(
    wc_Shake * src,
```

```
    wc_Sha3 * dst
)
```

Copy the state of the hash.

Parameters:

- **shake** pointer to the shake structure to copy
- **dst** pointer to the shake structure to copy into (must be zeroed or previously initialized)

See:

- wc_Shake256Hash
- wc_Shake256_Final
- wc_InitShake256
- wc_Shake256_GetHash

Return: 0 Returned upon successful copying.

Example

```
wc_Shake shake[1];
wc_Shake shake_dup[1];
memset(shake_dup, 0, sizeof(*shake_dup));
if ((ret = wc_InitShake256(shake, NULL, INVALID_DEVID)) != 0) {
   WOLFSSL_MSG("wc_InitShake256 failed");
}
else {
   wc_Shake256_Update(shake, data, len);
   wc_Shake256_Copy(shake, shake_dup);
}
```

C.52.2.47 function wc_InitKmac128

```
int wc_InitKmac128(
    wc_Kmac * kmac,
    const byte * key,
    word32 keyLen,
    const byte * custom,
    word32 customLen,
    void * heap,
    int devId
)
```

This function initializes a KMAC128 operation with a key and an optional customization string, per NIST SP 800-185. KMAC128 requires SHAKE128 (WOLFSSL_SHAKE128) and is enabled with WOLFSSL_KMAC.

Parameters:

- **kmac** pointer to the wc_Kmac structure to initialize.
- **key** the key bytes.
- **keyLen** length of the key in bytes.
- **custom** customization string, or NULL when customLen is 0.
- **customLen** length of the customization string in bytes.
- **heap** pointer to a heap hint, may be NULL.
- **devId** device identifier, or INVALID_DEVID.

See:

- wc_Kmac128_Update
- wc_Kmac128_Final

- wc_Kmac128_FinalXof
- wc_Kmac128_Free
- wc_Kmac128Hash

Return:

- 0 Returned upon successfully initializing.
- BAD_FUNC_ARG Returned when kmac is NULL, or key/custom is NULL with a non-zero length.

Example

```
wc_Kmac kmac;
byte key[32];
byte data[] = { Data to authenticate };
byte out[32];

if (wc_InitKmac128(&kmac, key, sizeof(key), NULL, 0, NULL,
        INVALID_DEVID) == 0) {
    wc_Kmac128_Update(&kmac, data, sizeof(data));
    wc_Kmac128_Final(&kmac, out, sizeof(out));
    wc_Kmac128_Free(&kmac);
}
```

C.52.2.48 function wc_Kmac128_Update

```
int wc_Kmac128_Update(
    wc_Kmac * kmac,
    const byte * in,
    word32 inLen
)
```

This function absorbs message data into a KMAC128 operation. It may be called any number of times before finalizing.

Parameters:

- **kmac** pointer to the wc_Kmac structure holding state.
- **in** the message data to authenticate.
- **inLen** length of the message data in bytes.

See:

- wc_InitKmac128
- wc_Kmac128_Final
- wc_Kmac128_Free

Return:

- 0 Returned upon successfully adding the data.
- BAD_FUNC_ARG Returned when kmac is NULL, or in is NULL with a non-zero length.

Example

```
wc_Kmac kmac;
byte data[] = { Data to authenticate };

if (wc_InitKmac128(&kmac, key, keyLen, NULL, 0, NULL,
        INVALID_DEVID) == 0) {
    wc_Kmac128_Update(&kmac, data, sizeof(data));
    wc_Kmac128_Final(&kmac, out, sizeof(out));
```

```
    wc_Kmac128_Free(&kmac);
}
```

C.52.2.49 function wc_Kmac128_Final

```
int wc_Kmac128_Final(
    wc_Kmac * kmac,
    byte * out,
    word32 outLen
)
```

This function finalizes a KMAC128 operation, producing outLen bytes of output. The output length is bound into the result, so a KMAC with a different length is a different value.

Parameters:

- **kmac** pointer to the wc_Kmac structure holding state.
- **out** buffer to hold the output.
- **outLen** number of output bytes to produce.

See:

- wc_InitKmac128
- wc_Kmac128_Update
- wc_Kmac128_FinalXof
- wc_Kmac128_Free

Return:

- 0 Returned upon successfully finalizing.
- BAD_FUNC_ARG Returned when kmac is NULL, or out is NULL with a non-zero length.

Example

```
byte out[32];
wc_Kmac128_Final(&kmac, out, sizeof(out));
```

C.52.2.50 function wc_Kmac128_FinalXof

```
int wc_Kmac128_FinalXof(
    wc_Kmac * kmac,
    byte * out,
    word32 outLen
)
```

This function finalizes a KMAC128 operation as an XOF (KMACXOF128). Unlike wc_Kmac128_Final, the output length is not bound into the result, so any amount of output may be requested.

Parameters:

- **kmac** pointer to the wc_Kmac structure holding state.
- **out** buffer to hold the output.
- **outLen** number of output bytes to produce.

See:

- wc_InitKmac128
- wc_Kmac128_Update
- wc_Kmac128_Final
- wc_Kmac128_Free

Return:

- 0 Returned upon successfully finalizing.
- BAD_FUNC_ARG Returned when kmac is NULL, or out is NULL with a non-zero length.

Example

```
byte out[64];
wc_Kmac128_FinalXof(&kmac, out, sizeof(out));
```

C.52.2.51 function wc_Kmac128_Free

```
void wc_Kmac128_Free(
    wc_Kmac * kmac
)
```

This function releases any resources associated with a KMAC128 operation. Passing NULL is safe and does nothing.

Parameters:

- **kmac** pointer to the wc_Kmac structure to free, may be NULL.

See: wc_InitKmac128

Example

```
wc_Kmac128_Free(&kmac);
```

C.52.2.52 function wc_Kmac128Hash

```
int wc_Kmac128Hash(
    const byte * key,
    word32 keyLen,
    const byte * custom,
    word32 customLen,
    const byte * in,
    word32 inLen,
    byte * out,
    word32 outLen
)
```

This function computes a KMAC128 over a single message in one call, initializing, updating and finalizing internally.

Parameters:

- **key** the key bytes.
- **keyLen** length of the key in bytes.
- **custom** customization string, or NULL when customLen is 0.
- **customLen** length of the customization string in bytes.
- **in** the message data to authenticate.
- **inLen** length of the message data in bytes.
- **out** buffer to hold the output.
- **outLen** number of output bytes to produce.

See:

- wc_InitKmac128
- wc_Kmac128_Update
- wc_Kmac128_Final

Return:

- 0 Returned upon success.
- BAD_FUNC_ARG Returned when a required pointer is NULL with a non-zero length.

Example

```
byte key[32];
byte data[] = { Data to authenticate };
byte out[32];

wc_Kmac128Hash(key, sizeof(key), NULL, 0, data, sizeof(data),
    out, sizeof(out));
```

C.52.2.53 function wc_Kmac128HashXof

```
int wc_Kmac128HashXof(
    const byte * key,
    word32 keyLen,
    const byte * custom,
    word32 customLen,
    const byte * in,
    word32 inLen,
    byte * out,
    word32 outLen
)
```

This function computes a KMACXOF128 over a single message in one call. Like wc_Kmac128Hash but the output length is not bound into the result, so any amount of output may be requested.

Parameters:

- **key** the key bytes.
- **keyLen** length of the key in bytes.
- **custom** customization string, or NULL when customLen is 0.
- **customLen** length of the customization string in bytes.
- **in** the message data to authenticate.
- **inLen** length of the message data in bytes.
- **out** buffer to hold the output.
- **outLen** number of output bytes to produce.

See:

- wc_InitKmac128
- wc_Kmac128_FinalXof
- wc_Kmac128Hash

Return:

- 0 Returned upon success.
- BAD_FUNC_ARG Returned when a required pointer is NULL with a non-zero length.

Example

```
byte key[32];
byte data[] = { Data to authenticate };
byte out[64];

wc_Kmac128HashXof(key, sizeof(key), NULL, 0, data, sizeof(data),
    out, sizeof(out));
```

C.52.2.54 function wc_InitKmac256

```
int wc_InitKmac256(
    wc_Kmac * kmac,
    const byte * key,
    word32 keyLen,
    const byte * custom,
    word32 customLen,
    void * heap,
    int devId
)
```

This function initializes a KMAC256 operation with a key and an optional customization string, per NIST SP 800-185. KMAC256 requires SHAKE256 (WOLFSSL_SHAKE256) and is enabled with WOLFSSL_KMAC.

Parameters:

- **kmac** pointer to the wc_Kmac structure to initialize.
- **key** the key bytes.
- **keyLen** length of the key in bytes.
- **custom** customization string, or NULL when customLen is 0.
- **customLen** length of the customization string in bytes.
- **heap** pointer to a heap hint, may be NULL.
- **devId** device identifier, or INVALID_DEVID.

See:

- wc_Kmac256_Update
- wc_Kmac256_Final
- wc_Kmac256_FinalXof
- wc_Kmac256_Free
- wc_Kmac256Hash

Return:

- 0 Returned upon successfully initializing.
- BAD_FUNC_ARG Returned when kmac is NULL, or key/custom is NULL with a non-zero length.

Example

```
wc_Kmac kmac;
byte key[32];
byte data[] = { Data to authenticate };
byte out[64];

if (wc_InitKmac256(&kmac, key, sizeof(key), NULL, 0, NULL,
        INVALID_DEVID) == 0) {
    wc_Kmac256_Update(&kmac, data, sizeof(data));
    wc_Kmac256_Final(&kmac, out, sizeof(out));
    wc_Kmac256_Free(&kmac);
}
```

C.52.2.55 function wc_Kmac256_Update

```
int wc_Kmac256_Update(
    wc_Kmac * kmac,
    const byte * in,
    word32 inLen
)
```

This function absorbs message data into a KMAC256 operation. It may be called any number of times before finalizing.

Parameters:

- **kmac** pointer to the wc_Kmac structure holding state.
- **in** the message data to authenticate.
- **inLen** length of the message data in bytes.

See:

- wc_InitKmac256
- wc_Kmac256_Final
- wc_Kmac256_Free

Return:

- 0 Returned upon successfully adding the data.
- BAD_FUNC_ARG Returned when kmac is NULL, or in is NULL with a non-zero length.

Example

```
wc_Kmac256_Update(&kmac, data, sizeof(data));
```

C.52.2.56 function wc_Kmac256_Final

```
int wc_Kmac256_Final(
    wc_Kmac * kmac,
    byte * out,
    word32 outLen
)
```

This function finalizes a KMAC256 operation, producing outLen bytes of output. The output length is bound into the result, so a KMAC with a different length is a different value.

Parameters:

- **kmac** pointer to the wc_Kmac structure holding state.
- **out** buffer to hold the output.
- **outLen** number of output bytes to produce.

See:

- wc_InitKmac256
- wc_Kmac256_Update
- wc_Kmac256_FinalXof
- wc_Kmac256_Free

Return:

- 0 Returned upon successfully finalizing.
- BAD_FUNC_ARG Returned when kmac is NULL, or out is NULL with a non-zero length.

Example

```
byte out[64];
wc_Kmac256_Final(&kmac, out, sizeof(out));
```

C.52.2.57 function wc_Kmac256_FinalXof

```
int wc_Kmac256_FinalXof(
    wc_Kmac * kmac,
    byte * out,
```

```
    word32 outLen
)
```

This function finalizes a KMAC256 operation as an XOF (KMACXOF256). Unlike wc_Kmac256_Final, the output length is not bound into the result, so any amount of output may be requested.

Parameters:

- **kmac** pointer to the wc_Kmac structure holding state.
- **out** buffer to hold the output.
- **outLen** number of output bytes to produce.

See:

- wc_InitKmac256
- wc_Kmac256_Update
- wc_Kmac256_Final
- wc_Kmac256_Free

Return:

- 0 Returned upon successfully finalizing.
- BAD_FUNC_ARG Returned when kmac is NULL, or out is NULL with a non-zero length.

Example

```
byte out[128];
wc_Kmac256_FinalXof(&kmac, out, sizeof(out));
```

C.52.2.58 function wc_Kmac256_Free

```
void wc_Kmac256_Free(
    wc_Kmac * kmac
)
```

This function releases any resources associated with a KMAC256 operation. Passing NULL is safe and does nothing.

Parameters:

- **kmac** pointer to the wc_Kmac structure to free, may be NULL.

See: wc_InitKmac256

Example

```
wc_Kmac256_Free(&kmac);
```

C.52.2.59 function wc_Kmac256Hash

```
int wc_Kmac256Hash(
    const byte * key,
    word32 keyLen,
    const byte * custom,
    word32 customLen,
    const byte * in,
    word32 inLen,
    byte * out,
    word32 outLen
)
```

This function computes a KMAC256 over a single message in one call, initializing, updating and finalizing internally.

Parameters:

- **key** the key bytes.
- **keyLen** length of the key in bytes.
- **custom** customization string, or NULL when customLen is 0.
- **customLen** length of the customization string in bytes.
- **in** the message data to authenticate.
- **inLen** length of the message data in bytes.
- **out** buffer to hold the output.
- **outLen** number of output bytes to produce.

See:

- wc_InitKmac256
- wc_Kmac256_Update
- wc_Kmac256_Final

Return:

- 0 Returned upon success.
- BAD_FUNC_ARG Returned when a required pointer is NULL with a non-zero length.

Example

```
byte key[32];
byte data[] = { Data to authenticate };
byte out[64];

wc_Kmac256Hash(key, sizeof(key), NULL, 0, data, sizeof(data),
    out, sizeof(out));
```

C.52.2.60 function wc_Kmac256HashXof

```
int wc_Kmac256HashXof(
    const byte * key,
    word32 keyLen,
    const byte * custom,
    word32 customLen,
    const byte * in,
    word32 inLen,
    byte * out,
    word32 outLen
)
```

This function computes a KMACXOF256 over a single message in one call. Like wc_Kmac256Hash but the output length is not bound into the result, so any amount of output may be requested.

Parameters:

- **key** the key bytes.
- **keyLen** length of the key in bytes.
- **custom** customization string, or NULL when customLen is 0.
- **customLen** length of the customization string in bytes.
- **in** the message data to authenticate.
- **inLen** length of the message data in bytes.
- **out** buffer to hold the output.
- **outLen** number of output bytes to produce.

See:

- wc_InitKmac256
- wc_Kmac256_FinalXof
- wc_Kmac256Hash

Return:

- 0 Returned upon success.
- BAD_FUNC_ARG Returned when a required pointer is NULL with a non-zero length.

Example

```
byte key[32];
byte data[] = { Data to authenticate };
byte out[128];

wc_Kmac256HashXof(key, sizeof(key), NULL, 0, data, sizeof(data),
    out, sizeof(out));
```

C.52.2.61 function wc_Kmac128_Copy

```
int wc_Kmac128_Copy(
    wc_Kmac * src,
    wc_Kmac * dst
)
```

This function copies the state of a KMAC128 operation so it can be finalized more than once, for example over a common message prefix.

Parameters:

- **src** pointer to the wc_Kmac structure to copy from.
- **dst** pointer to the wc_Kmac structure to copy into.

See:

- wc_InitKmac128
- wc_Kmac128_Update
- wc_Kmac128_Final

Return:

- 0 Returned upon success.
- BAD_FUNC_ARG Returned when src or dst is NULL.

Example

```
wc_Kmac kmac;
wc_Kmac copy;

wc_InitKmac128(&kmac, key, keyLen, NULL, 0, NULL, INVALID_DEVID);
wc_Kmac128_Update(&kmac, prefix, prefixLen);
wc_Kmac128_Copy(&kmac, &copy);
```

C.52.2.62 function wc_Kmac256_Copy

```
int wc_Kmac256_Copy(
    wc_Kmac * src,
    wc_Kmac * dst
)
```

This function copies the state of a KMAC256 operation so it can be finalized more than once, for example over a common message prefix.

Parameters:

- **src** pointer to the wc_Kmac structure to copy from.
- **dst** pointer to the wc_Kmac structure to copy into.

See:

- wc_InitKmac256
- wc_Kmac256_Update
- wc_Kmac256_Final

Return:

- 0 Returned upon success.
- BAD_FUNC_ARG Returned when src or dst is NULL.

Example

```
wc_Kmac kmac;
wc_Kmac copy;

wc_InitKmac256(&kmac, key, keyLen, NULL, 0, NULL, INVALID_DEVID);
wc_Kmac256_Update(&kmac, prefix, prefixLen);
wc_Kmac256_Copy(&kmac, &copy);
```

C.52.2.63 function wc_InitCshake128

```
int wc_InitCshake128(
    wc_Cshake * cshake,
    const byte * name,
    word32 nameLen,
    const byte * custom,
    word32 customLen,
    void * heap,
    int devId
)
```

This function initializes a cSHAKE128 operation (customizable SHAKE, NIST SP 800-185) with a function-name and customization string. cSHAKE is enabled together with KMAC (WOLFSSL_KMAC). When both strings are empty, cSHAKE reduces to plain SHAKE128.

Parameters:

- **cshake** pointer to the wc_Cshake structure to initialize.
- **name** function-name string (reserved for NIST-defined functions); use an empty string for application customization via custom.
- **nameLen** length of the function-name string in bytes.
- **custom** customization string, or NULL when customLen is 0.
- **customLen** length of the customization string in bytes.
- **heap** pointer to a heap hint, may be NULL.
- **devId** device identifier, or INVALID_DEVID.

See:

- wc_Cshake128_Update
- wc_Cshake128_Final
- wc_Cshake128_Free
- wc_Cshake128

Return:

- 0 Returned upon successfully initializing.
- BAD_FUNC_ARG Returned when a required pointer is NULL.

Example

```
wc_Cshake cshake;
byte out[32];

if (wc_InitCshake128(&cshake, NULL, 0, custom, customLen, NULL,
        INVALID_DEVID) == 0) {
    wc_Cshake128_Update(&cshake, data, dataLen);
    wc_Cshake128_Final(&cshake, out, sizeof(out));
    wc_Cshake128_Free(&cshake);
}
```

C.52.2.64 function wc_Cshake128_Update

```
int wc_Cshake128_Update(
    wc_Cshake * cshake,
    const byte * in,
    word32 inLen
)
```

This function absorbs message data into a cSHAKE128 operation.

Parameters:

- **cshake** pointer to the wc_Cshake structure holding state.
- **in** the message data.
- **inLen** length of the message data in bytes.

See:

- wc_InitCshake128
- wc_Cshake128_Final

Return:

- 0 Returned upon successfully adding the data.
- BAD_FUNC_ARG Returned when cshake is NULL, or in is NULL with a non-zero length.

Example

```
wc_Cshake128_Update(&cshake, data, dataLen);
```

C.52.2.65 function wc_Cshake128_Final

```
int wc_Cshake128_Final(
    wc_Cshake * cshake,
    byte * out,
    word32 outLen
)
```

This function finalizes a cSHAKE128 operation, squeezing outLen bytes of output. cSHAKE is an XOF, so a longer squeeze extends a shorter one over the same input.

Parameters:

- **cshake** pointer to the wc_Cshake structure holding state.
- **out** buffer to hold the output.

- **outLen** number of output bytes to produce.

See:

- wc_InitCshake128
- wc_Cshake128_Update

Return:

- 0 Returned upon successfully finalizing.
- BAD_FUNC_ARG Returned when cshake is NULL, or out is NULL with a non-zero length.

Example

```
byte out[32];
wc_Cshake128_Final(&cshake, out, sizeof(out));
```

C.52.2.66 function wc_Cshake128_Free

```
void wc_Cshake128_Free(
    wc_Cshake * cshake
)
```

This function releases any resources associated with a cSHAKE128 operation. Passing NULL is safe and does nothing.

Parameters:

- **cshake** pointer to the wc_Cshake structure to free, may be NULL.

See: wc_InitCshake128

Example

```
wc_Cshake128_Free(&cshake);
```

C.52.2.67 function wc_Cshake128

```
int wc_Cshake128(
    const byte * name,
    word32 nameLen,
    const byte * custom,
    word32 customLen,
    const byte * in,
    word32 inLen,
    byte * out,
    word32 outLen
)
```

This function computes a cSHAKE128 over a single message in one call, initializing, updating and finalizing internally.

Parameters:

- **name** function-name string, or NULL when nameLen is 0.
- **nameLen** length of the function-name string in bytes.
- **custom** customization string, or NULL when customLen is 0.
- **customLen** length of the customization string in bytes.
- **in** the message data.
- **inLen** length of the message data in bytes.
- **out** buffer to hold the output.
- **outLen** number of output bytes to produce.

See:

- wc_InitCshake128
- wc_Cshake128_Final

Return:

- 0 Returned upon success.
- BAD_FUNC_ARG Returned when a required pointer is NULL with a non-zero length.

Example

```
byte out[32];
wc_Cshake128(NULL, 0, custom, customLen, data, dataLen, out, sizeof(out));
```

C.52.2.68 function wc_InitCshake256

```
int wc_InitCshake256(
    wc_Cshake * cshake,
    const byte * name,
    word32 nameLen,
    const byte * custom,
    word32 customLen,
    void * heap,
    int devId
)
```

This function initializes a cSHAKE256 operation (customizable SHAKE, NIST SP 800-185) with a function-name and customization string. cSHAKE is enabled together with KMAC (WOLFSSL_KMAC). When both strings are empty, cSHAKE reduces to plain SHAKE256.

Parameters:

- **cshake** pointer to the wc_Cshake structure to initialize.
- **name** function-name string (reserved for NIST-defined functions); use an empty string for application customization via custom.
- **nameLen** length of the function-name string in bytes.
- **custom** customization string, or NULL when customLen is 0.
- **customLen** length of the customization string in bytes.
- **heap** pointer to a heap hint, may be NULL.
- **devId** device identifier, or INVALID_DEVID.

See:

- wc_Cshake256_Update
- wc_Cshake256_Final
- wc_Cshake256_Free
- wc_Cshake256

Return:

- 0 Returned upon successfully initializing.
- BAD_FUNC_ARG Returned when a required pointer is NULL.

Example

```
wc_Cshake cshake;
byte out[32];

if (wc_InitCshake256(&cshake, NULL, 0, custom, customLen, NULL,
        INVALID_DEVID) == 0) {
```

```
    wc_Cshake256_Update(&cshake, data, dataLen);
    wc_Cshake256_Final(&cshake, out, sizeof(out));
    wc_Cshake256_Free(&cshake);
}
```

C.52.2.69 function wc_Cshake256_Update

```
int wc_Cshake256_Update(
    wc_Cshake * cshake,
    const byte * in,
    word32 inLen
)
```

This function absorbs message data into a cSHAKE256 operation.

Parameters:

- **cshake** pointer to the wc_Cshake structure holding state.
- **in** the message data.
- **inLen** length of the message data in bytes.

See:

- wc_InitCshake256
- wc_Cshake256_Final

Return:

- 0 Returned upon successfully adding the data.
- BAD_FUNC_ARG Returned when cshake is NULL, or in is NULL with a non-zero length.

Example

```
wc_Cshake256_Update(&cshake, data, dataLen);
```

C.52.2.70 function wc_Cshake256_Final

```
int wc_Cshake256_Final(
    wc_Cshake * cshake,
    byte * out,
    word32 outLen
)
```

This function finalizes a cSHAKE256 operation, squeezing outLen bytes of output. cSHAKE is an XOF, so a longer squeeze extends a shorter one over the same input.

Parameters:

- **cshake** pointer to the wc_Cshake structure holding state.
- **out** buffer to hold the output.
- **outLen** number of output bytes to produce.

See:

- wc_InitCshake256
- wc_Cshake256_Update

Return:

- 0 Returned upon successfully finalizing.
- BAD_FUNC_ARG Returned when cshake is NULL, or out is NULL with a non-zero length.

Example

```
byte out[32];
wc_Cshake256_Final(&cshake, out, sizeof(out));
```

C.52.2.71 function wc_Cshake256_Free

```
void wc_Cshake256_Free(
    wc_Cshake * cshake
)
```

This function releases any resources associated with a cSHAKE256 operation. Passing NULL is safe and does nothing.

Parameters:

- **cshake** pointer to the wc_Cshake structure to free, may be NULL.

See: wc_InitCshake256

Example

```
wc_Cshake256_Free(&cshake);
```

C.52.2.72 function wc_Cshake256

```
int wc_Cshake256(
    const byte * name,
    word32 nameLen,
    const byte * custom,
    word32 customLen,
    const byte * in,
    word32 inLen,
    byte * out,
    word32 outLen
)
```

This function computes a cSHAKE256 over a single message in one call, initializing, updating and finalizing internally.

Parameters:

- **name** function-name string, or NULL when nameLen is 0.
- **nameLen** length of the function-name string in bytes.
- **custom** customization string, or NULL when customLen is 0.
- **customLen** length of the customization string in bytes.
- **in** the message data.
- **inLen** length of the message data in bytes.
- **out** buffer to hold the output.
- **outLen** number of output bytes to produce.

See:

- wc_InitCshake256
- wc_Cshake256_Final

Return:

- 0 Returned upon success.
- BAD_FUNC_ARG Returned when a required pointer is NULL with a non-zero length.

Example

```
byte out[32];
wc_Cshake256(NULL, 0, custom, customLen, data, dataLen, out, sizeof(out));
```

C.52.2.73 function wc_Cshake128_Copy

```
int wc_Cshake128_Copy(
    wc_Cshake * src,
    wc_Cshake * dst
)
```

This function copies the state of a cSHAKE128 operation so it can be finalized more than once, for example over a common message prefix. dst must already be an initialized wc_Cshake.

Parameters:

- **src** pointer to the wc_Cshake structure to copy from.
- **dst** pointer to the wc_Cshake structure to copy into.

See:

- wc_InitCshake128
- wc_Cshake128_Update
- wc_Cshake128_Final

Return:

- 0 Returned upon success.
- BAD_FUNC_ARG Returned when src or dst is NULL.

Example

```
wc_Cshake cshake;
wc_Cshake copy;

wc_InitCshake128(&cshake, NULL, 0, custom, customLen, NULL, INVALID_DEVID);
wc_InitCshake128(&copy, NULL, 0, custom, customLen, NULL, INVALID_DEVID);
wc_Cshake128_Update(&cshake, prefix, prefixLen);
wc_Cshake128_Copy(&cshake, &copy);
```

C.52.2.74 function wc_Cshake256_Copy

```
int wc_Cshake256_Copy(
    wc_Cshake * src,
    wc_Cshake * dst
)
```

This function copies the state of a cSHAKE256 operation so it can be finalized more than once, for example over a common message prefix. dst must already be an initialized wc_Cshake.

Parameters:

- **src** pointer to the wc_Cshake structure to copy from.
- **dst** pointer to the wc_Cshake structure to copy into.

See:

- wc_InitCshake256
- wc_Cshake256_Update
- wc_Cshake256_Final

Return:

- 0 Returned upon success.
- BAD_FUNC_ARG Returned when src or dst is NULL.

Example

```
wc_Cshake cshake;
wc_Cshake copy;

wc_InitCshake256(&cshake, NULL, 0, custom, customLen, NULL, INVALID_DEVID);
wc_InitCshake256(&copy, NULL, 0, custom, customLen, NULL, INVALID_DEVID);
wc_Cshake256_Update(&cshake, prefix, prefixLen);
wc_Cshake256_Copy(&cshake, &copy);
```

C.52.3 Source code

C.53 sha512.h

C.53.1 Functions

	Name
int	**wc_InitSha512**(wc_Sha512 * sha)This function initializes SHA512. This is automatically called by wc_Sha512Hash.
int	**wc_Sha512Update**(wc_Sha512 * sha, const byte * data, word32 len)Can be called to continually hash the provided byte array of length len.
int	**wc_Sha512Final**(wc_Sha512 * sha512, byte * hash)Finalizes hashing of data. Result is placed into hash.
int	**wc_InitSha384**(wc_Sha384 * sha)This function initializes SHA384. This is automatically called by wc_Sha384Hash.
int	**wc_Sha384Update**(wc_Sha384 * sha, const byte * data, word32 len)Can be called to continually hash the provided byte array of length len.
int	**wc_Sha384Final**(wc_Sha384 * sha384, byte * hash)Finalizes hashing of data. Result is placed into hash.
int	**wc_InitSha512_ex**(wc_Sha512 * sha, void * heap, int devId)Initializes SHA512 with heap and device ID.
int	**wc_Sha512FinalRaw**(wc_Sha512 * sha512, byte * hash)Gets raw hash without finalizing.
void	**wc_Sha512Free**(wc_Sha512 * sha)Frees SHA512 resources.

	Name
int	**wc_Sha512Reset**(wc_Sha512 * sha)Resets the sha structure to its freshly initialized state, continuing with its established allocations, heap hint, and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially hashed message, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Sha512Free for teardown at end of life.
int	**wc_Sha512GetHash**(wc_Sha512 * sha512, byte * hash)Gets SHA512 hash without finalizing.
int	**wc_Sha512Copy**(wc_Sha512 * src, wc_Sha512 * dst)Copies SHA512 context.
int	**wc_Sha512_Grow**(wc_Sha512 * sha512, const byte * in, int inSz)Grows SHA512 buffer with input data.
int	**wc_Sha512SetFlags**(wc_Sha512 * sha512, word32 flags)Sets SHA512 flags.
int	**wc_Sha512GetFlags**(wc_Sha512 * sha512, word32 * flags)Gets SHA512 flags.
int	**wc_Sha512Transform**(wc_Sha512 * sha, const unsigned char * data)Transforms SHA512 block.
int	**wc_InitSha512_224**(wc_Sha512 * sha)Initializes SHA512/224.
int	**wc_InitSha512_224_ex**(wc_Sha512 * sha, void * heap, int devId)Initializes SHA512/224 with heap and device ID.
int	**wc_Sha512_224Update**(wc_Sha512 * sha, const byte * data, word32 len)Updates SHA512/224 hash with data.
int	**wc_Sha512_224FinalRaw**(wc_Sha512 * sha512, byte * hash)Gets raw SHA512/224 hash without finalizing.
int	**wc_Sha512_224Final**(wc_Sha512 * sha512, byte * hash)Finalizes SHA512/224 hash.
void	**wc_Sha512_224Free**(wc_Sha512 * sha)Frees SHA512/224 resources.
int	**wc_Sha512_224Reset**(wc_Sha512 * sha)Resets the sha structure to its freshly initialized state, continuing with its established allocations, heap hint, and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially hashed message, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Sha512_224Free for teardown at end of life.
int	**wc_Sha512_224GetHash**(wc_Sha512 * sha512, byte * hash)Gets SHA512/224 hash without finalizing.

	Name
int	**wc_Sha512_224Copy**(wc_Sha512 * src, wc_Sha512 * dst)Copies SHA512/224 context.
int	**wc_Sha512_224SetFlags**(wc_Sha512 * sha512, word32 flags)Sets SHA512/224 flags.
int	**wc_Sha512_224GetFlags**(wc_Sha512 * sha512, word32 * flags)Gets SHA512/224 flags.
int	**wc_Sha512_224Transform**(wc_Sha512 * sha, const unsigned char * data)Transforms SHA512/224 block.
int	**wc_InitSha512_256**(wc_Sha512 * sha)Initializes SHA512/256.
int	**wc_InitSha512_256_ex**(wc_Sha512 * sha, void * heap, int devId)Initializes SHA512/256 with heap and device ID.
int	**wc_Sha512_256Update**(wc_Sha512 * sha, const byte * data, word32 len)Updates SHA512/256 hash with data.
int	**wc_Sha512_256FinalRaw**(wc_Sha512 * sha512, byte * hash)Gets raw SHA512/256 hash without finalizing.
int	**wc_Sha512_256Final**(wc_Sha512 * sha512, byte * hash)Finalizes SHA512/256 hash.
void	**wc_Sha512_256Free**(wc_Sha512 * sha)Frees SHA512/256 resources.
int	**wc_Sha512_256Reset**(wc_Sha512 * sha)Resets the sha structure to its freshly initialized state, continuing with its established allocations, heap hint, and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially hashed message, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Sha512_256Free for teardown at end of life.
int	**wc_Sha512_256GetHash**(wc_Sha512 * sha512, byte * hash)Gets SHA512/256 hash without finalizing.
int	**wc_Sha512_256Copy**(wc_Sha512 * src, wc_Sha512 * dst)Copies SHA512/256 context.
int	**wc_Sha512_256SetFlags**(wc_Sha512 * sha512, word32 flags)Sets SHA512/256 flags.
int	**wc_Sha512_256GetFlags**(wc_Sha512 * sha512, word32 * flags)Gets SHA512/256 flags.
int	**wc_Sha512_256Transform**(wc_Sha512 * sha, const unsigned char * data)Transforms SHA512/256 block.
int	**wc_InitSha384_ex**(wc_Sha384 * sha, void * heap, int devId)Initializes SHA384 with heap and device ID.
int	**wc_Sha384FinalRaw**(wc_Sha384 * sha384, byte * hash)Gets raw SHA384 hash without finalizing.

	Name
void	**wc_Sha384Free**(wc_Sha384 * sha)Frees SHA384 resources.
int	**wc_Sha384Reset**(wc_Sha384 * sha)Resets the sha structure to its freshly initialized state, continuing with its established allocations, heap hint, and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially hashed message, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Sha384Free for teardown at end of life.
int	**wc_Sha384GetHash**(wc_Sha384 * sha384, byte * hash)Gets SHA384 hash without finalizing.
int	**wc_Sha384Copy**(wc_Sha384 * src, wc_Sha384 * dst)Copies SHA384 context.
int	**wc_Sha384_Grow**(wc_Sha384 * sha384, const byte * in, int inSz)Grows SHA384 buffer with input data.
int	**wc_Sha384SetFlags**(wc_Sha384 * sha384, word32 flags)Sets SHA384 flags.
int	**wc_Sha384GetFlags**(wc_Sha384 * sha384, word32 * flags)Gets SHA384 flags.
int	**wc_Sha384Transform**(wc_Sha384 * sha, const unsigned char * data)Transforms SHA384 block.

C.53.2 Functions Documentation

C.53.2.1 function wc_InitSha512

```
int wc_InitSha512(
    wc_Sha512 * sha
)
```

This function initializes SHA512. This is automatically called by wc_Sha512Hash.

Parameters:

- **sha512** pointer to the sha512 structure to use for encryption

See:

- wc_Sha512Hash
- wc_Sha512Update
- wc_Sha512Final

Return: 0 Returned upon successfully initializing

Example

```
Sha512 sha512[1];
if ((ret = wc_InitSha512(sha512)) != 0) {
   WOLFSSL_MSG("wc_InitSha512 failed");
}
else {
```

```
   wc_Sha512Update(sha512, data, len);
   wc_Sha512Final(sha512, hash);
}
```

C.53.2.2 function wc_Sha512Update

```
int wc_Sha512Update(
    wc_Sha512 * sha,
    const byte * data,
    word32 len
)
```

Can be called to continually hash the provided byte array of length len.

Parameters:

- **sha512** pointer to the sha512 structure to use for encryption
- **data** the data to be hashed
- **len** length of data to be hashed

See:

- wc_Sha512Hash
- wc_Sha512Final
- wc_InitSha512

Return: 0 Returned upon successfully adding the data to the digest.

Example

```
Sha512 sha512[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitSha512(sha512)) != 0) {
   WOLFSSL_MSG("wc_InitSha512 failed");
}
else {
   wc_Sha512Update(sha512, data, len);
   wc_Sha512Final(sha512, hash);
}
```

C.53.2.3 function wc_Sha512Final

```
int wc_Sha512Final(
    wc_Sha512 * sha512,
    byte * hash
)
```

Finalizes hashing of data. Result is placed into hash.

Parameters:

- **sha512** pointer to the sha512 structure to use for encryption
- **hash** Byte array to hold hash value.

See:

- wc_Sha512Hash
- wc_Sha512Final
- wc_InitSha512

Return: 0 Returned upon successfully finalizing the hash.

Example

```
Sha512 sha512[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitSha512(sha512)) != 0) {
    WOLFSSL_MSG("wc_InitSha512 failed");
}
else {
   wc_Sha512Update(sha512, data, len);
   wc_Sha512Final(sha512, hash);
}
```

C.53.2.4 function wc_InitSha384

```
int wc_InitSha384(
    wc_Sha384 * sha
)
```

This function initializes SHA384. This is automatically called by wc_Sha384Hash.

Parameters:

- **sha384** pointer to the sha384 structure to use for encryption

See:

- wc_Sha384Hash
- wc_Sha384Update
- wc_Sha384Final

Return: 0 Returned upon successfully initializing

Example

```
Sha384 sha384[1];
if ((ret = wc_InitSha384(sha384)) != 0) {
   WOLFSSL_MSG("wc_InitSha384 failed");
}
else {
   wc_Sha384Update(sha384, data, len);
   wc_Sha384Final(sha384, hash);
}
```

C.53.2.5 function wc_Sha384Update

```
int wc_Sha384Update(
    wc_Sha384 * sha,
    const byte * data,
    word32 len
)
```

Can be called to continually hash the provided byte array of length len.

Parameters:

- **sha384** pointer to the sha384 structure to use for encryption
- **data** the data to be hashed

- **len** length of data to be hashed

See:

- wc_Sha384Hash
- wc_Sha384Final
- wc_InitSha384

Return: 0 Returned upon successfully adding the data to the digest.

Example

```
Sha384 sha384[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitSha384(sha384)) != 0) {
   WOLFSSL_MSG("wc_InitSha384 failed");
}
else {
   wc_Sha384Update(sha384, data, len);
   wc_Sha384Final(sha384, hash);
}
```

C.53.2.6 function wc_Sha384Final

```
int wc_Sha384Final(
    wc_Sha384 * sha384,
    byte * hash
)
```

Finalizes hashing of data. Result is placed into hash.

Parameters:

- **sha384** pointer to the sha384 structure to use for encryption
- **hash** Byte array to hold hash value.

See:

- wc_Sha384Hash
- wc_Sha384Final
- wc_InitSha384

Return: 0 Returned upon successfully finalizing.

Example

```
Sha384 sha384[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitSha384(sha384)) != 0) {
   WOLFSSL_MSG("wc_InitSha384 failed");
}
else {
   wc_Sha384Update(sha384, data, len);
   wc_Sha384Final(sha384, hash);
}
```

C.53.2.7 function wc_InitSha512_ex

```
int wc_InitSha512_ex(
    wc_Sha512 * sha,
    void * heap,
    int devId
)
```

Initializes SHA512 with heap and device ID.

Parameters:

- **sha** SHA512 structure
- **heap** Heap hint
- **devId** Device ID

See: wc_InitSha512

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
int ret = wc_InitSha512_ex(&sha, NULL, INVALID_DEVID);
```

C.53.2.8 function wc_Sha512FinalRaw

```
int wc_Sha512FinalRaw(
    wc_Sha512 * sha512,
    byte * hash
)
```

Gets raw hash without finalizing.

Parameters:

- **sha512** SHA512 structure
- **hash** Output hash buffer

See: wc_Sha512Final

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
byte hash[WC_SHA512_DIGEST_SIZE];
int ret = wc_Sha512FinalRaw(&sha, hash);
```

C.53.2.9 function wc_Sha512Free

```
void wc_Sha512Free(
    wc_Sha512 * sha
)
```

Frees SHA512 resources.

Parameters:

- **sha** SHA512 structure

See: wc_InitSha512

Return: none No returns

Example

```
wc_Sha512 sha;
wc_InitSha512(&sha);
wc_Sha512Free(&sha);
```

C.53.2.10 function wc_Sha512Reset

```
int wc_Sha512Reset(
    wc_Sha512 * sha
)
```

Resets the sha structure to its freshly initialized state, continuing with its established allocations, heap hint, and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially hashed message, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Sha512Free for teardown at end of life.

Parameters:

- **sha** Pointer to the sha structure to be reset.

See:

- wc_InitSha512
- wc_Sha512Final
- wc_Sha512Free

Return:

- 0 Returned upon successfully resetting the structure.
- BAD_FUNC_ARG Returned if sha is NULL.
- negative Other values may be returned on reinitialization failure in fallback (non-plain-software) configurations.

Example

```
wc_Sha512 sha;
byte data[] = { Data to be discarded };
byte data2[] = { Data to be hashed };
byte hash[WC_SHA512_DIGEST_SIZE];

if ((ret = wc_InitSha512(&sha)) == 0) {
    wc_Sha512Update(&sha, data, sizeof(data));
    wc_Sha512Reset(&sha); /* discard the partially hashed message */
    wc_Sha512Update(&sha, data2, sizeof(data2));
    wc_Sha512Final(&sha, hash);
    wc_Sha512Free(&sha);
}
```

C.53.2.11 function wc_Sha512GetHash

```
int wc_Sha512GetHash(
    wc_Sha512 * sha512,
    byte * hash
)
```

Gets SHA512 hash without finalizing.

Parameters:

- **sha512** SHA512 structure
- **hash** Output hash buffer

See: wc_Sha512Final

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
byte hash[WC_SHA512_DIGEST_SIZE];
int ret = wc_Sha512GetHash(&sha, hash);
```

C.53.2.12 function wc_Sha512Copy

```
int wc_Sha512Copy(
    wc_Sha512 * src,
    wc_Sha512 * dst
)
```

Copies SHA512 context.

Parameters:

- **src** Source SHA512 structure
- **dst** Destination SHA512 structure (must be zeroed or previously initialized)

See: wc_InitSha512

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 src, dst;
memset(&dst, 0, sizeof(dst));
int ret = wc_InitSha512(&src);
if (ret == 0)
    ret = wc_Sha512Copy(&src, &dst);
```

C.53.2.13 function wc_Sha512_Grow

```
int wc_Sha512_Grow(
    wc_Sha512 * sha512,
    const byte * in,
    int inSz
)
```

Grows SHA512 buffer with input data.

Parameters:

- **sha512** SHA512 structure
- **in** Input data

- **inSz** Input size

See: wc_Sha512Update

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
byte data[100];
int ret = wc_Sha512_Grow(&sha, data, sizeof(data));
```

C.53.2.14 function wc_Sha512SetFlags

```
int wc_Sha512SetFlags(
    wc_Sha512 * sha512,
    word32 flags
)
```

Sets SHA512 flags.

Parameters:

- **sha512** SHA512 structure
- **flags** Flags to set

See: wc_InitSha512

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
int ret = wc_Sha512SetFlags(&sha, WC_HASH_FLAG_WILLCOPY);
```

C.53.2.15 function wc_Sha512GetFlags

```
int wc_Sha512GetFlags(
    wc_Sha512 * sha512,
    word32 * flags
)
```

Gets SHA512 flags.

Parameters:

- **sha512** SHA512 structure
- **flags** Pointer to store flags

See: wc_Sha512SetFlags

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
word32 flags;
int ret = wc_Sha512GetFlags(&sha, &flags);
```

C.53.2.16 function wc_Sha512Transform

```
int wc_Sha512Transform(
    wc_Sha512 * sha,
    const unsigned char * data
)
```

Transforms SHA512 block.

Parameters:

- **sha** SHA512 structure
- **data** Block data

See: wc_Sha512Update

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
unsigned char block[WC_SHA512_BLOCK_SIZE];
int ret = wc_Sha512Transform(&sha, block);
```

C.53.2.17 function wc_InitSha512_224

```
int wc_InitSha512_224(
    wc_Sha512 * sha
)
```

Initializes SHA512/224.

Parameters:

- **sha** SHA512 structure

See: wc_Sha512_224Update

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
int ret = wc_InitSha512_224(&sha);
```

C.53.2.18 function wc_InitSha512_224_ex

```
int wc_InitSha512_224_ex(
    wc_Sha512 * sha,
    void * heap,
    int devId
)
```

Initializes SHA512/224 with heap and device ID.

Parameters:

- **sha** SHA512 structure
- **heap** Heap hint
- **devId** Device ID

See: wc_InitSha512_224

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
int ret = wc_InitSha512_224_ex(&sha, NULL, INVALID_DEVID);
```

C.53.2.19 function wc_Sha512_224Update

```
int wc_Sha512_224Update(
    wc_Sha512 * sha,
    const byte * data,
    word32 len
)
```

Updates SHA512/224 hash with data.

Parameters:

- **sha** SHA512 structure
- **data** Input data
- **len** Input size

See: wc_InitSha512_224

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
byte data[100];
int ret = wc_Sha512_224Update(&sha, data, sizeof(data));
```

C.53.2.20 function wc_Sha512_224FinalRaw

```
int wc_Sha512_224FinalRaw(
    wc_Sha512 * sha512,
    byte * hash
)
```

Gets raw SHA512/224 hash without finalizing.

Parameters:

- **sha512** SHA512 structure
- **hash** Output hash buffer

See: wc_Sha512_224Final

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
byte hash[WC_SHA512_224_DIGEST_SIZE];
int ret = wc_Sha512_224FinalRaw(&sha, hash);
```

C.53.2.21 function wc_Sha512_224Final

```
int wc_Sha512_224Final(
    wc_Sha512 * sha512,
    byte * hash
)
```

Finalizes SHA512/224 hash.

Parameters:

- **sha512** SHA512 structure
- **hash** Output hash buffer

See: wc_Sha512_224Update

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
byte hash[WC_SHA512_224_DIGEST_SIZE];
int ret = wc_Sha512_224Final(&sha, hash);
```

C.53.2.22 function wc_Sha512_224Free

```
void wc_Sha512_224Free(
    wc_Sha512 * sha
)
```

Frees SHA512/224 resources.

Parameters:

- **sha** SHA512 structure

See: wc_InitSha512_224

Return: none No returns

Example

```
wc_Sha512 sha;
wc_InitSha512_224(&sha);
wc_Sha512_224Free(&sha);
```

C.53.2.23 function wc_Sha512_224Reset

```
int wc_Sha512_224Reset(
    wc_Sha512 * sha
)
```

Resets the sha structure to its freshly initialized state, continuing with its established allocations, heap hint, and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially hashed message, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Sha512_224Free for teardown at end of life.

Parameters:

- **sha** Pointer to the sha structure to be reset.

See:

- wc_InitSha512_224
- wc_Sha512_224Final
- wc_Sha512_224Free

Return:

- 0 Returned upon successfully resetting the structure.
- BAD_FUNC_ARG Returned if sha is NULL.
- negative Other values may be returned on reinitialization failure in fallback (non-plain-software) configurations.

Example

```
wc_Sha512 sha;
byte data[] = { Data to be discarded };
byte data2[] = { Data to be hashed };
byte hash[WC_SHA512_224_DIGEST_SIZE];

if ((ret = wc_InitSha512_224(&sha)) == 0) {
    wc_Sha512_224Update(&sha, data, sizeof(data));
    wc_Sha512_224Reset(&sha); /* discard the partially hashed message */
    wc_Sha512_224Update(&sha, data2, sizeof(data2));
    wc_Sha512_224Final(&sha, hash);
    wc_Sha512_224Free(&sha);
}
```

C.53.2.24 function wc_Sha512_224GetHash

```
int wc_Sha512_224GetHash(
    wc_Sha512 * sha512,
    byte * hash
)
```

Gets SHA512/224 hash without finalizing.

Parameters:

- **sha512** SHA512 structure
- **hash** Output hash buffer

See: wc_Sha512_224Final

Return:

- 0 on success

- negative on error

Example

```
wc_Sha512 sha;
byte hash[WC_SHA512_224_DIGEST_SIZE];
int ret = wc_Sha512_224GetHash(&sha, hash);
```

C.53.2.25 function wc_Sha512_224Copy

```
int wc_Sha512_224Copy(
    wc_Sha512 * src,
    wc_Sha512 * dst
)
```

Copies SHA512/224 context.

Parameters:

- **src** Source SHA512 structure
- **dst** Destination SHA512 structure (must be zeroed or previously initialized)

See: wc_InitSha512_224

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 src, dst;
memset(&dst, 0, sizeof(dst));
int ret = wc_InitSha512_224(&src);
if (ret == 0)
    ret = wc_Sha512_224Copy(&src, &dst);
```

C.53.2.26 function wc_Sha512_224SetFlags

```
int wc_Sha512_224SetFlags(
    wc_Sha512 * sha512,
    word32 flags
)
```

Sets SHA512/224 flags.

Parameters:

- **sha512** SHA512 structure
- **flags** Flags to set

See: wc_InitSha512_224

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
int ret = wc_Sha512_224SetFlags(&sha, WC_HASH_FLAG_WILLCOPY);
```

C.53.2.27 function wc_Sha512_224GetFlags

```
int wc_Sha512_224GetFlags(
    wc_Sha512 * sha512,
    word32 * flags
)
```

Gets SHA512/224 flags.

Parameters:

- **sha512** SHA512 structure
- **flags** Pointer to store flags

See: wc_Sha512_224SetFlags

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
word32 flags;
int ret = wc_Sha512_224GetFlags(&sha, &flags);
```

C.53.2.28 function wc_Sha512_224Transform

```
int wc_Sha512_224Transform(
    wc_Sha512 * sha,
    const unsigned char * data
)
```

Transforms SHA512/224 block.

Parameters:

- **sha** SHA512 structure
- **data** Block data

See: wc_Sha512_224Update

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
unsigned char block[WC_SHA512_BLOCK_SIZE];
int ret = wc_Sha512_224Transform(&sha, block);
```

C.53.2.29 function wc_InitSha512_256

```
int wc_InitSha512_256(
    wc_Sha512 * sha
)
```

Initializes SHA512/256.

Parameters:

- **sha** SHA512 structure

See: wc_Sha512_256Update

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
int ret = wc_InitSha512_256(&sha);
```

C.53.2.30 function wc_InitSha512_256_ex

```
int wc_InitSha512_256_ex(
    wc_Sha512 * sha,
    void * heap,
    int devId
)
```

Initializes SHA512/256 with heap and device ID.

Parameters:

- **sha** SHA512 structure
- **heap** Heap hint
- **devId** Device ID

See: wc_InitSha512_256

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
int ret = wc_InitSha512_256_ex(&sha, NULL, INVALID_DEVID);
```

C.53.2.31 function wc_Sha512_256Update

```
int wc_Sha512_256Update(
    wc_Sha512 * sha,
    const byte * data,
    word32 len
)
```

Updates SHA512/256 hash with data.

Parameters:

- **sha** SHA512 structure
- **data** Input data
- **len** Input size

See: wc_InitSha512_256

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
byte data[100];
int ret = wc_Sha512_256Update(&sha, data, sizeof(data));
```

C.53.2.32 function wc_Sha512_256FinalRaw

```
int wc_Sha512_256FinalRaw(
    wc_Sha512 * sha512,
    byte * hash
)
```

Gets raw SHA512/256 hash without finalizing.

Parameters:

- **sha512** SHA512 structure
- **hash** Output hash buffer

See: wc_Sha512_256Final

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
byte hash[WC_SHA512_256_DIGEST_SIZE];
int ret = wc_Sha512_256FinalRaw(&sha, hash);
```

C.53.2.33 function wc_Sha512_256Final

```
int wc_Sha512_256Final(
    wc_Sha512 * sha512,
    byte * hash
)
```

Finalizes SHA512/256 hash.

Parameters:

- **sha512** SHA512 structure
- **hash** Output hash buffer

See: wc_Sha512_256Update

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
byte hash[WC_SHA512_256_DIGEST_SIZE];
int ret = wc_Sha512_256Final(&sha, hash);
```

C.53.2.34 function wc_Sha512_256Free

```
void wc_Sha512_256Free(
    wc_Sha512 * sha
)
```

Frees SHA512/256 resources.

Parameters:

- **sha** SHA512 structure

See: wc_InitSha512_256

Return: none No returns

Example

```
wc_Sha512 sha;
wc_InitSha512_256(&sha);
wc_Sha512_256Free(&sha);
```

C.53.2.35 function wc_Sha512_256Reset

```
int wc_Sha512_256Reset(
    wc_Sha512 * sha
)
```

Resets the sha structure to its freshly initialized state, continuing with its established allocations, heap hint, and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially hashed message, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Sha512_256Free for teardown at end of life.

Parameters:

- **sha** Pointer to the sha structure to be reset.

See:

- wc_InitSha512_256
- wc_Sha512_256Final
- wc_Sha512_256Free

Return:

- 0 Returned upon successfully resetting the structure.
- BAD_FUNC_ARG Returned if sha is NULL.
- negative Other values may be returned on reinitialization failure in fallback (non-plain-software) configurations.

Example

```
wc_Sha512 sha;
byte data[] = { Data to be discarded };
byte data2[] = { Data to be hashed };
byte hash[WC_SHA512_256_DIGEST_SIZE];

if ((ret = wc_InitSha512_256(&sha)) == 0) {
    wc_Sha512_256Update(&sha, data, sizeof(data));
    wc_Sha512_256Reset(&sha); /* discard the partially hashed message */
    wc_Sha512_256Update(&sha, data2, sizeof(data2));
    wc_Sha512_256Final(&sha, hash);
```

```
    wc_Sha512_256Free(&sha);
}
```

C.53.2.36 function wc_Sha512_256GetHash

```
int wc_Sha512_256GetHash(
    wc_Sha512 * sha512,
    byte * hash
)
```

Gets SHA512/256 hash without finalizing.

Parameters:

- **sha512** SHA512 structure
- **hash** Output hash buffer

See: wc_Sha512_256Final

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
byte hash[WC_SHA512_256_DIGEST_SIZE];
int ret = wc_Sha512_256GetHash(&sha, hash);
```

C.53.2.37 function wc_Sha512_256Copy

```
int wc_Sha512_256Copy(
    wc_Sha512 * src,
    wc_Sha512 * dst
)
```

Copies SHA512/256 context.

Parameters:

- **src** Source SHA512 structure
- **dst** Destination SHA512 structure (must be zeroed or previously initialized)

See: wc_InitSha512_256

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 src, dst;
memset(&dst, 0, sizeof(dst));
int ret = wc_InitSha512_256(&src);
if (ret == 0)
    ret = wc_Sha512_256Copy(&src, &dst);
```

C.53.2.38 function wc_Sha512_256SetFlags

```
int wc_Sha512_256SetFlags(
    wc_Sha512 * sha512,
    word32 flags
)
```

Sets SHA512/256 flags.

Parameters:

- **sha512** SHA512 structure
- **flags** Flags to set

See: wc_InitSha512_256

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
int ret = wc_Sha512_256SetFlags(&sha, WC_HASH_FLAG_WILLCOPY);
```

C.53.2.39 function wc_Sha512_256GetFlags

```
int wc_Sha512_256GetFlags(
    wc_Sha512 * sha512,
    word32 * flags
)
```

Gets SHA512/256 flags.

Parameters:

- **sha512** SHA512 structure
- **flags** Pointer to store flags

See: wc_Sha512_256SetFlags

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
word32 flags;
int ret = wc_Sha512_256GetFlags(&sha, &flags);
```

C.53.2.40 function wc_Sha512_256Transform

```
int wc_Sha512_256Transform(
    wc_Sha512 * sha,
    const unsigned char * data
)
```

Transforms SHA512/256 block.

Parameters:

- **sha** SHA512 structure
- **data** Block data

See: wc_Sha512_256Update

Return:

- 0 on success
- negative on error

Example

```
wc_Sha512 sha;
unsigned char block[WC_SHA512_BLOCK_SIZE];
int ret = wc_Sha512_256Transform(&sha, block);
```

C.53.2.41 function wc_InitSha384_ex

```
int wc_InitSha384_ex(
    wc_Sha384 * sha,
    void * heap,
    int devId
)
```

Initializes SHA384 with heap and device ID.

Parameters:

- **sha** SHA384 structure
- **heap** Heap hint
- **devId** Device ID

See: wc_InitSha384

Return:

- 0 on success
- negative on error

Example

```
wc_Sha384 sha;
int ret = wc_InitSha384_ex(&sha, NULL, INVALID_DEVID);
```

C.53.2.42 function wc_Sha384FinalRaw

```
int wc_Sha384FinalRaw(
    wc_Sha384 * sha384,
    byte * hash
)
```

Gets raw SHA384 hash without finalizing.

Parameters:

- **sha384** SHA384 structure
- **hash** Output hash buffer

See: wc_Sha384Final

Return:

- 0 on success
- negative on error

Example

```
wc_Sha384 sha;
byte hash[WC_SHA384_DIGEST_SIZE];
int ret = wc_Sha384FinalRaw(&sha, hash);
```

C.53.2.43 function wc_Sha384Free

```
void wc_Sha384Free(
    wc_Sha384 * sha
)
```

Frees SHA384 resources.

Parameters:

- **sha** SHA384 structure

See: wc_InitSha384

Return: none No returns

Example

```
wc_Sha384 sha;
wc_InitSha384(&sha);
wc_Sha384Free(&sha);
```

C.53.2.44 function wc_Sha384Reset

```
int wc_Sha384Reset(
    wc_Sha384 * sha
)
```

Resets the sha structure to its freshly initialized state, continuing with its established allocations, heap hint, and device association. Equivalent to a fresh init for all subsequent operations; useful for abandoning a partially hashed message, including after a failed Update or Final. Like the Final functions, Reset does not destroy sensitive internal state; use wc_Sha384Free for teardown at end of life.

Parameters:

- **sha** Pointer to the sha structure to be reset.

See:

- wc_InitSha384
- wc_Sha384Final
- wc_Sha384Free

Return:

- 0 Returned upon successfully resetting the structure.
- BAD_FUNC_ARG Returned if sha is NULL.
- negative Other values may be returned on reinitialization failure in fallback (non-plain-software) configurations.

Example

```
wc_Sha384 sha;
byte data[] = { Data to be discarded };
byte data2[] = { Data to be hashed };
byte hash[WC_SHA384_DIGEST_SIZE];
```

```
if ((ret = wc_InitSha384(&sha)) == 0) {
    wc_Sha384Update(&sha, data, sizeof(data));
    wc_Sha384Reset(&sha); /* discard the partially hashed message */
    wc_Sha384Update(&sha, data2, sizeof(data2));
    wc_Sha384Final(&sha, hash);
    wc_Sha384Free(&sha);
}
```

C.53.2.45 function wc_Sha384GetHash

```
int wc_Sha384GetHash(
    wc_Sha384 * sha384,
    byte * hash
)
```

Gets SHA384 hash without finalizing.

Parameters:

- **sha384** SHA384 structure
- **hash** Output hash buffer

See: wc_Sha384Final

Return:

- 0 on success
- negative on error

Example

```
wc_Sha384 sha;
byte hash[WC_SHA384_DIGEST_SIZE];
int ret = wc_Sha384GetHash(&sha, hash);
```

C.53.2.46 function wc_Sha384Copy

```
int wc_Sha384Copy(
    wc_Sha384 * src,
    wc_Sha384 * dst
)
```

Copies SHA384 context.

Parameters:

- **src** Source SHA384 structure
- **dst** Destination SHA384 structure (must be zeroed or previously initialized)

See: wc_InitSha384

Return:

- 0 on success
- negative on error

Example

```
wc_Sha384 src, dst;
memset(&dst, 0, sizeof(dst));
int ret = wc_InitSha384(&src);
```

```
if (ret == 0)
    ret = wc_Sha384Copy(&src, &dst);
```

C.53.2.47 function wc_Sha384_Grow

```
int wc_Sha384_Grow(
    wc_Sha384 * sha384,
    const byte * in,
    int inSz
)
```

Grows SHA384 buffer with input data.

Parameters:

- **sha384** SHA384 structure
- **in** Input data
- **inSz** Input size

See: wc_Sha384Update

Return:

- 0 on success
- negative on error

Example

```
wc_Sha384 sha;
byte data[100];
int ret = wc_Sha384_Grow(&sha, data, sizeof(data));
```

C.53.2.48 function wc_Sha384SetFlags

```
int wc_Sha384SetFlags(
    wc_Sha384 * sha384,
    word32 flags
)
```

Sets SHA384 flags.

Parameters:

- **sha384** SHA384 structure
- **flags** Flags to set

See: wc_InitSha384

Return:

- 0 on success
- negative on error

Example

```
wc_Sha384 sha;
int ret = wc_Sha384SetFlags(&sha, WC_HASH_FLAG_WILLCOPY);
```

C.53.2.49 function wc_Sha384GetFlags

```
int wc_Sha384GetFlags(
    wc_Sha384 * sha384,
    word32 * flags
)
```

Gets SHA384 flags.

Parameters:

- **sha384** SHA384 structure
- **flags** Pointer to store flags

See: wc_Sha384SetFlags

Return:

- 0 on success
- negative on error

Example

```
wc_Sha384 sha;
word32 flags;
int ret = wc_Sha384GetFlags(&sha, &flags);
```

C.53.2.50 function wc_Sha384Transform

```
int wc_Sha384Transform(
    wc_Sha384 * sha,
    const unsigned char * data
)
```

Transforms SHA384 block.

Parameters:

- **sha** SHA384 structure
- **data** Block data

See: wc_Sha384Update

Return:

- 0 on success
- negative on error

Example

```
wc_Sha384 sha;
unsigned char block[WC_SHA384_BLOCK_SIZE];
int ret = wc_Sha384Transform(&sha, block);
```

C.53.3 Source code

int	**wc_ShaTransform**(wc_Sha * sha, const unsigned char * data)Transforms SHA block.

	Name
void	**wc_ShaSizeSet**(wc_Sha * sha, word32 len)Sets SHA size.
int	**wc_ShaSetFlags**(wc_Sha * sha, word32 flags)Sets SHA flags.

C.54.2 Functions Documentation

C.54.2.1 function wc_InitSha

```
int wc_InitSha(
    wc_Sha * sha
)
```

This function initializes SHA. This is automatically called by wc_ShaHash.

Parameters:

- **sha** pointer to the sha structure to use for encryption

See:

- wc_ShaHash
- wc_ShaUpdate
- wc_ShaFinal

Return: 0 Returned upon successfully initializing

Example

```
Sha sha[1];
if ((ret = wc_InitSha(sha)) != 0) {
   WOLFSSL_MSG("wc_InitSha failed");
}
else {
   wc_ShaUpdate(sha, data, len);
   wc_ShaFinal(sha, hash);
}
```

C.54.2.2 function wc_ShaUpdate

```
int wc_ShaUpdate(
    wc_Sha * sha,
    const byte * data,
    word32 len
)
```

Can be called to continually hash the provided byte array of length len.

Parameters:

- **sha** pointer to the sha structure to use for encryption
- **data** the data to be hashed
- **len** length of data to be hashed

See:

- wc_ShaHash
- wc_ShaFinal
- wc_InitSha

Return: 0 Returned upon successfully adding the data to the digest.

Example

```
Sha sha[1];
byte data[] = { // Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitSha(sha)) != 0) {
   WOLFSSL_MSG("wc_InitSha failed");
}
else {
   wc_ShaUpdate(sha, data, len);
   wc_ShaFinal(sha, hash);
}
```

C.54.2.3 function wc_ShaFinal

```
int wc_ShaFinal(
    wc_Sha * sha,
    byte * hash
)
```

Finalizes hashing of data. Result is placed into hash. Resets state of sha struct.

Parameters:

- **sha** pointer to the sha structure to use for encryption
- **hash** Byte array to hold hash value.

See:

- wc_ShaHash
- wc_InitSha
- wc_ShaGetHash

Return: 0 Returned upon successfully finalizing.

Example

```
Sha sha[1];
byte data[] = { Data to be hashed };
word32 len = sizeof(data);

if ((ret = wc_InitSha(sha)) != 0) {
   WOLFSSL_MSG("wc_InitSha failed");
}
else {
   wc_ShaUpdate(sha, data, len);
   wc_ShaFinal(sha, hash);
}
```

C.54.2.4 function wc_ShaFree

```
void wc_ShaFree(
    wc_Sha * sha
)
```

Used to clean up memory used by an initialized Sha struct.

Parameters:

- **sha** Pointer to the Sha struct to free.

See:

- wc_InitSha
- wc_ShaUpdate
- wc_ShaFinal

Return: No returns.

Example

```
Sha sha;
wc_InitSha(&sha);
// Use sha
wc_ShaFree(&sha);
```

C.54.2.5 function wc_ShaGetHash

```
int wc_ShaGetHash(
    wc_Sha * sha,
    byte * hash
)
```

Gets hash data. Result is placed into hash. Does not reset state of sha struct.

Parameters:

- **sha** pointer to the sha structure to use for encryption
- **hash** Byte array to hold hash value.

See:

- wc_ShaHash
- wc_ShaFinal
- wc_InitSha

Return: 0 Returned upon successfully finalizing.

Example

```
Sha sha[1];
if ((ret = wc_InitSha(sha)) != 0) {
WOLFSSL_MSG("wc_InitSha failed");
}
else {
    wc_ShaUpdate(sha, data, len);
    wc_ShaGetHash(sha, hash);
}
```

C.54.2.6 function wc_InitSha_ex

```
int wc_InitSha_ex(
    wc_Sha * sha,
    void * heap,
    int devId
)
```

Initializes SHA with heap and device ID.

Parameters:

- **sha** SHA structure
- **heap** Heap hint
- **devId** Device ID

See: wc_InitSha

Return:

- 0 on success
- negative on error

Example

```
wc_Sha sha;
int ret = wc_InitSha_ex(&sha, NULL, INVALID_DEVID);
```

C.54.2.7 function wc_ShaFinalRaw

```
int wc_ShaFinalRaw(
    wc_Sha * sha,
    byte * hash
)
```

Gets raw hash without finalizing.

Parameters:

- **sha** SHA structure
- **hash** Output hash buffer

See: wc_ShaFinal

Return:

- 0 on success
- negative on error

Example

```
wc_Sha sha;
byte hash[WC_SHA_DIGEST_SIZE];
int ret = wc_ShaFinalRaw(&sha, hash);
```

C.54.2.8 function wc_ShaCopy

```
int wc_ShaCopy(
    wc_Sha * src,
    wc_Sha * dst
)
```

Copies SHA context.

Parameters:

- **src** Source SHA structure
- **dst** Destination SHA structure (must be zeroed or previously initialized)

See: wc_InitSha

Return:

- 0 on success
- negative on error

Example

```
wc_Sha src, dst;
memset(&dst, 0, sizeof(dst));
int ret = wc_InitSha(&src);
if (ret == 0)
    ret = wc_ShaCopy(&src, &dst);
```

C.54.2.9 function wc_ShaTransform

```
int wc_ShaTransform(
    wc_Sha * sha,
    const unsigned char * data
)
```

Transforms SHA block.

Parameters:

- **sha** SHA structure
- **data** Block data

See: wc_ShaUpdate

Return:

- 0 on success
- negative on error

Example

```
wc_Sha sha;
unsigned char block[WC_SHA_BLOCK_SIZE];
int ret = wc_ShaTransform(&sha, block);
```

C.54.2.10 function wc_ShaSizeSet

```
void wc_ShaSizeSet(
    wc_Sha * sha,
    word32 len
)
```

Sets SHA size.

Parameters:

- **sha** SHA structure
- **len** Size to set

See: wc_ShaUpdate

Return: none No returns

Example

```
wc_Sha sha;
wc_ShaSizeSet(&sha, 1000);
```

C.54.2.11 function wc_ShaSetFlags

```
int wc_ShaSetFlags(
    wc_Sha * sha,
    word32 flags
)
```

Sets SHA flags.

Parameters:

- **sha** SHA structure
- **flags** Flags to set

See: wc_InitSha

Return:

- 0 on success
- negative on error

Example

```
wc_Sha sha;
int ret = wc_ShaSetFlags(&sha, WC_HASH_FLAG_WILLCOPY);
```

C.54.3 Source code

```
int wc_InitSha(wc_Sha* sha);

int wc_ShaUpdate(wc_Sha* sha, const byte* data, word32 len);

int wc_ShaFinal(wc_Sha* sha, byte* hash);

void wc_ShaFree(wc_Sha* sha);

int wc_ShaGetHash(wc_Sha* sha, byte* hash);
int wc_InitSha_ex(wc_Sha* sha, void* heap, int devId);

int wc_ShaFinalRaw(wc_Sha* sha, byte* hash);

int wc_ShaCopy(wc_Sha* src, wc_Sha* dst);

int wc_ShaTransform(wc_Sha* sha, const unsigned char* data);

void wc_ShaSizeSet(wc_Sha* sha, word32 len);

int wc_ShaSetFlags(wc_Sha* sha, word32 flags);
```

C.55 signature.h

C.55.1 Functions

	Name
int	**wc_SignatureGetSize**(enum wc_SignatureType sig_type, const void * key, word32 key_len)This function returns the maximum size of the resulting signature.
int	**wc_SignatureVerify**(enum wc_HashType hash_type, enum wc_SignatureType sig_type, const byte * data, word32 data_len, const byte * sig, word32 sig_len, void * key, word32 key_len)This function validates a signature by hashing the data and using the resulting hash and key to verify the signature.
int	**wc_SignatureGenerate**(enum wc_HashType hash_type, enum wc_SignatureType sig_type, const byte * data, word32 data_len, byte * sig, word32 * sig_len, void * key, word32 key_len, WC_RNG * rng)This function generates a signature from the data using a key. It first creates a hash of the data then signs the hash using the key.
int	**wc_SignatureVerifyHash**(enum wc_HashType hash_type, enum wc_SignatureType sig_type, const byte * hash_data, word32 hash_len, const byte * sig, word32 sig_len, void * key, word32 key_len)This function verifies a signature using a pre-computed hash. Unlike wc_SignatureVerify which hashes the data first, this function takes the hash directly and verifies the signature against it. If sig_type is WC_SIGNATURE_TYPE_RSA_W_ENC, hash data must be encoded with wc_EncodeSignature prior to calling.
int	**wc_SignatureGenerateHash**(enum wc_HashType hash_type, enum wc_SignatureType sig_type, const byte * hash_data, word32 hash_len, byte * sig, word32 * sig_len, void * key, word32 key_len, WC_RNG * rng)This function generates a signature from a pre-computed hash. Unlike wc_SignatureGenerate which hashes the data first, this function takes the hash directly and signs it. If sig_type is WC_SIGNATURE_TYPE_RSA_W_ENC, hash data must be encoded with wc_EncodeSignature prior to calling.

	Name
int	**wc_SignatureGenerateHash_ex**(enum wc_HashType hash_type, enum wc_SignatureType sig_type, const byte * hash_data, word32 hash_len, byte * sig, word32 * sig_len, void * key, word32 key_len, WC_RNG * rng, int verify)This function generates a signature from a pre-computed hash with extended options. This is similar to wc_SignatureGenerateHash but allows optional verification of the signature after generation.
int	**wc_SignatureGenerate_ex**(enum wc_HashType hash_type, enum wc_SignatureType sig_type, const byte * data, word32 data_len, byte * sig, word32 * sig_len, void * key, word32 key_len, WC_RNG * rng, int verify)This function generates a signature from data with extended options. This is similar to wc_SignatureGenerate but allows optional verification of the signature after generation.

C.55.2 Functions Documentation

C.55.2.1 function wc_SignatureGetSize

```
int wc_SignatureGetSize(
    enum wc_SignatureType sig_type,
    const void * key,
    word32 key_len
)
```

This function returns the maximum size of the resulting signature.

Parameters:

- **sig_type** A signature type enum value such as WC_SIGNATURE_TYPE_ECC or WC_SIGNATURE_TYPE_RSA.
- **key** Pointer to the key structure corresponding to sig_type: pass an ecc_key* for WC_SIGNATURE_TYPE_ECC, or a RsaKey* for WC_SIGNATURE_TYPE_RSA / WC_SIGNATURE_TYPE_RSA_W_ENC. The caller is responsible for ensuring the pointer refers to the correct type; this function cannot verify the actual runtime type of the object.
- **key_len** If key is non-NULL, key_len must be exactly sizeof(ecc_key) or sizeof(RsaKey) matching the sig_type. Passing any other value causes the function to return BAD_FUNC_ARG without dereferencing key. Always pass the size of the concrete key type at the call site: if you have a typed pointer (e.g., ecc_key* k), use sizeof(k); otherwise use sizeof(ecc_key) or sizeof(RsaKey) directly. Do not use sizeof(*key) on the const void parameter itself, as dereferencing void is invalid.

See:

- wc_HashGetDigestSize
- wc_SignatureGenerate
- wc_SignatureVerify

Return: Returns SIG_TYPE_E if sig_type is not supported. Returns BAD_FUNC_ARG if sig_type was invalid or key_len does not exactly match the size of the expected key structure. A positive return value indicates the maximum size of a signature.

Example

```
// Get signature length
enum wc_SignatureType sig_type = WC_SIGNATURE_TYPE_ECC;
ecc_key eccKey;
word32 sigLen;
wc_ecc_init(&eccKey);
sigLen = wc_SignatureGetSize(sig_type, &eccKey, sizeof(eccKey));
if (sigLen > 0) {
    // Success
}
```

C.55.2.2 function wc_SignatureVerify

```
int wc_SignatureVerify(
    enum wc_HashType hash_type,
    enum wc_SignatureType sig_type,
    const byte * data,
    word32 data_len,
    const byte * sig,
    word32 sig_len,
    void * key,
    word32 key_len
)
```

This function validates a signature by hashing the data and using the resulting hash and key to verify the signature.

Parameters:

- **hash_type** A hash type from the “enum wc_HashType” such as “WC_HASH_TYPE_SHA256”.
- **sig_type** A signature type enum value such as WC_SIGNATURE_TYPE_ECC or WC_SIGNATURE_TYPE_RSA.
- **data** Pointer to buffer containing the data to hash.
- **data_len** Length of the data buffer.
- **sig** Pointer to buffer to output signature.
- **sig_len** Length of the signature output buffer.
- **key** Pointer to the key structure corresponding to sig_type. See wc_SignatureGetSize() for the type-safety constraints that apply to this parameter.
- **key_len** Must be exactly sizeof(ecc_key) or sizeof(RsaKey) matching sig_type. See wc_SignatureGetSize().

See:

- wc_SignatureGetSize
- wc_SignatureGenerate

Return:

- 0 Success
- SIG_TYPE_E -231, signature type not enabled/ available
- BAD_FUNC_ARG -173, bad function argument provided
- BUFFER_E -132, output buffer too small or input too large.

Example

```
int ret;
ecc_key eccKey;

// Import the public key
wc_ecc_init(&eccKey);
ret = wc_ecc_import_x963(eccPubKeyBuf, eccPubKeyLen, &eccKey);
// Perform signature verification using public key
```

```
ret = wc_SignatureVerify(
WC_HASH_TYPE_SHA256, WC_SIGNATURE_TYPE_ECC,
fileBuf, fileLen,
sigBuf, sigLen,
&eccKey, sizeof(eccKey));
printf("Signature Verification: %s
(%d)\n", (ret == 0) ? "Pass" : "Fail", ret);
wc_ecc_free(&eccKey);
```

C.55.2.3 function wc_SignatureGenerate

```
int wc_SignatureGenerate(
    enum wc_HashType hash_type,
    enum wc_SignatureType sig_type,
    const byte * data,
    word32 data_len,
    byte * sig,
    word32 * sig_len,
    void * key,
    word32 key_len,
    WC_RNG * rng
)
```

This function generates a signature from the data using a key. It first creates a hash of the data then signs the hash using the key.

Parameters:

- **hash_type** A hash type from the "enum wc_HashType" such as "WC_HASH_TYPE_SHA256".
- **sig_type** A signature type enum value such as WC_SIGNATURE_TYPE_ECC or WC_SIGNATURE_TYPE_RSA.
- **data** Pointer to buffer containing the data to hash.
- **data_len** Length of the data buffer.
- **sig** Pointer to buffer to output signature.
- **sig_len** Length of the signature output buffer.
- **key** Pointer to the key structure corresponding to sig_type. See wc_SignatureGetSize() for the type-safety constraints that apply to this parameter.
- **key_len** Must be exactly sizeof(ecc_key) or sizeof(RsaKey) matching sig_type. See wc_SignatureGetSize().
- **rng** Pointer to an initialized RNG structure.

See:

- wc_SignatureGetSize
- wc_SignatureVerify

Return:

- 0 Success
- SIG_TYPE_E -231, signature type not enabled/ available
- BAD_FUNC_ARG -173, bad function argument provided
- BUFFER_E -132, output buffer too small or input too large.

Example

```
int ret;
WC_RNG rng;
ecc_key eccKey;

wc_InitRng(&rng);
wc_ecc_init(&eccKey);
```

```
// Generate key
ret = wc_ecc_make_key(&rng, 32, &eccKey);

// Get signature length and allocate buffer
sigLen = wc_SignatureGetSize(sig_type, &eccKey, sizeof(eccKey));
sigBuf = malloc(sigLen);

// Perform signature verification using public key
ret = wc_SignatureGenerate(
    WC_HASH_TYPE_SHA256, WC_SIGNATURE_TYPE_ECC,
    fileBuf, fileLen,
    sigBuf, &sigLen,
    &eccKey, sizeof(eccKey),
    &rng);
printf("Signature Generation: %s
(%d)\n", (ret == 0) ? "Pass" : "Fail", ret);

free(sigBuf);
wc_ecc_free(&eccKey);
wc_FreeRng(&rng);
```

C.55.2.4 function wc_SignatureVerifyHash

```
int wc_SignatureVerifyHash(
    enum wc_HashType hash_type,
    enum wc_SignatureType sig_type,
    const byte * hash_data,
    word32 hash_len,
    const byte * sig,
    word32 sig_len,
    void * key,
    word32 key_len
)
```

This function verifies a signature using a pre-computed hash. Unlike wc_SignatureVerify which hashes the data first, this function takes the hash directly and verifies the signature against it. If sig_type is WC_SIGNATURE_TYPE_RSA_W_ENC, hash data must be encoded with wc_EncodeSignature prior to calling.

Parameters:

- **hash_type** A hash type from enum wc_HashType
- **sig_type** A signature type such as WC_SIGNATURE_TYPE_ECC or WC_SIGNATURE_TYPE_RSA
- **hash_data** Pointer to buffer containing the hash to verify
- **hash_len** Length of the hash buffer
- **sig** Pointer to buffer containing the signature
- **sig_len** Length of the signature buffer
- **key** Pointer to the key structure corresponding to sig_type. See wc_SignatureGetSize() for the type-safety constraints that apply to this parameter.
- **key_len** Must be exactly sizeof(ecc_key) or sizeof(RsaKey) matching sig_type. See wc_SignatureGetSize().

See:

- wc_SignatureVerify
- wc_SignatureGenerateHash

Return:

- 0 Success
- SIG_TYPE_E Signature type not enabled/available
- BAD_FUNC_ARG Bad function argument provided
- BUFFER_E Output buffer too small or input too large

Example

```
ecc_key eccKey;
byte hash[WC_SHA256_DIGEST_SIZE];
byte sig[ECC_MAX_SIG_SIZE];
word32 sigLen = sizeof(sig);

wc_ecc_init(&eccKey);
// import public key, signature, and pre-computed hash ...
int ret = wc_SignatureVerifyHash(WC_HASH_TYPE_SHA256,
                                 WC_SIGNATURE_TYPE_ECC, hash,
                                 sizeof(hash), sig, sigLen,
                                 &eccKey, sizeof(eccKey));
if (ret == 0) {
    // signature verified
}
```

C.55.2.5 function wc_SignatureGenerateHash

```
int wc_SignatureGenerateHash(
    enum wc_HashType hash_type,
    enum wc_SignatureType sig_type,
    const byte * hash_data,
    word32 hash_len,
    byte * sig,
    word32 * sig_len,
    void * key,
    word32 key_len,
    WC_RNG * rng
)
```

This function generates a signature from a pre-computed hash. Unlike wc_SignatureGenerate which hashes the data first, this function takes the hash directly and signs it. If sig_type is WC_SIGNATURE_TYPE_RSA_W_ENC, hash data must be encoded with wc_EncodeSignature prior to calling.

Parameters:

- **hash_type** A hash type from enum wc_HashType
- **sig_type** A signature type such as WC_SIGNATURE_TYPE_ECC or WC_SIGNATURE_TYPE_RSA
- **hash_data** Pointer to buffer containing the hash to sign
- **hash_len** Length of the hash buffer
- **sig** Pointer to buffer to output signature
- **sig_len** Pointer to length of signature output buffer
- **key** Pointer to the key structure corresponding to sig_type. See wc_SignatureGetSize() for the type-safety constraints that apply to this parameter.
- **key_len** Must be exactly sizeof(ecc_key) or sizeof(RsaKey) matching sig_type. See wc_SignatureGetSize().
- **rng** Pointer to an initialized RNG structure

See:

- wc_SignatureGenerate
- wc_SignatureVerifyHash

Return:

- 0 Success
- SIG_TYPE_E Signature type not enabled/available
- BAD_FUNC_ARG Bad function argument provided
- BUFFER_E Output buffer too small or input too large

Example

```
WC_RNG rng;
ecc_key eccKey;
byte hash[WC_SHA256_DIGEST_SIZE];
byte sig[ECC_MAX_SIG_SIZE];
word32 sigLen = sizeof(sig);

wc_InitRng(&rng);
wc_ecc_init(&eccKey);
wc_ecc_make_key(&rng, 32, &eccKey);
// generate signature from pre-computed hash
int ret = wc_SignatureGenerateHash(WC_HASH_TYPE_SHA256,
                                   WC_SIGNATURE_TYPE_ECC, hash,
                                   sizeof(hash), sig, &sigLen,
                                   &eccKey, sizeof(eccKey), &rng);
```

C.55.2.6 function wc_SignatureGenerateHash_ex

```
int wc_SignatureGenerateHash_ex(
    enum wc_HashType hash_type,
    enum wc_SignatureType sig_type,
    const byte * hash_data,
    word32 hash_len,
    byte * sig,
    word32 * sig_len,
    void * key,
    word32 key_len,
    WC_RNG * rng,
    int verify
)
```

This function generates a signature from a pre-computed hash with extended options. This is similar to wc_SignatureGenerateHash but allows optional verification of the signature after generation.

Parameters:

- **hash_type** A hash type from enum wc_HashType
- **sig_type** A signature type such as WC_SIGNATURE_TYPE_ECC or WC_SIGNATURE_TYPE_RSA
- **hash_data** Pointer to buffer containing the hash to sign
- **hash_len** Length of the hash buffer
- **sig** Pointer to buffer to output signature
- **sig_len** Pointer to length of signature output buffer
- **key** Pointer to the key structure corresponding to sig_type. See wc_SignatureGetSize() for the type-safety constraints that apply to this parameter.
- **key_len** Must be exactly sizeof(ecc_key) or sizeof(RsaKey) matching sig_type. See wc_SignatureGetSize().
- **rng** Pointer to an initialized RNG structure
- **verify** If non-zero, verify the signature after generation

See:

- wc_SignatureGenerateHash
- wc_SignatureGenerate_ex

Return:

- 0 Success
- SIG_TYPE_E Signature type not enabled/available
- BAD_FUNC_ARG Bad function argument provided
- BUFFER_E Output buffer too small or input too large

Example

```
WC_RNG rng;
ecc_key eccKey;
byte hash[WC_SHA256_DIGEST_SIZE];
byte sig[ECC_MAX_SIG_SIZE];
word32 sigLen = sizeof(sig);

wc_InitRng(&rng);
wc_ecc_init(&eccKey);
wc_ecc_make_key(&rng, 32, &eccKey);
int ret = wc_SignatureGenerateHash_ex(WC_HASH_TYPE_SHA256,
                                      WC_SIGNATURE_TYPE_ECC, hash,
                                      sizeof(hash), sig, &sigLen,
                                      &eccKey, sizeof(eccKey),
                                      &rng, 1);
```

C.55.2.7 function wc_SignatureGenerate_ex

```
int wc_SignatureGenerate_ex(
    enum wc_HashType hash_type,
    enum wc_SignatureType sig_type,
    const byte * data,
    word32 data_len,
    byte * sig,
    word32 * sig_len,
    void * key,
    word32 key_len,
    WC_RNG * rng,
    int verify
)
```

This function generates a signature from data with extended options. This is similar to wc_SignatureGenerate but allows optional verification of the signature after generation.

Parameters:

- **hash_type** A hash type from enum wc_HashType
- **sig_type** A signature type such as WC_SIGNATURE_TYPE_ECC or WC_SIGNATURE_TYPE_RSA
- **data** Pointer to buffer containing the data to hash and sign
- **data_len** Length of the data buffer
- **sig** Pointer to buffer to output signature
- **sig_len** Pointer to length of signature output buffer
- **key** Pointer to the key structure corresponding to sig_type. See wc_SignatureGetSize() for the type-safety constraints that apply to this parameter.
- **key_len** Must be exactly sizeof(ecc_key) or sizeof(RsaKey) matching sig_type. See wc_SignatureGetSize().

- **rng** Pointer to an initialized RNG structure
- **verify** If non-zero, verify the signature after generation

See:

- wc_SignatureGenerate
- wc_SignatureGenerateHash_ex

Return:

- 0 Success
- SIG_TYPE_E Signature type not enabled/available
- BAD_FUNC_ARG Bad function argument provided
- BUFFER_E Output buffer too small or input too large

Example

```
WC_RNG rng;
ecc_key eccKey;
byte data[]; // data to sign
byte sig[ECC_MAX_SIG_SIZE];
word32 sigLen = sizeof(sig);

wc_InitRng(&rng);
wc_ecc_init(&eccKey);
wc_ecc_make_key(&rng, 32, &eccKey);
int ret = wc_SignatureGenerate_ex(WC_HASH_TYPE_SHA256,
                                  WC_SIGNATURE_TYPE_ECC, data,
                                  sizeof(data), sig, &sigLen,
                                  &eccKey, sizeof(eccKey), &rng, 1);
```

C.55.3 Source code

```
int wc_SignatureGetSize(enum wc_SignatureType sig_type,
    const void* key, word32 key_len);

int wc_SignatureVerify(
    enum wc_HashType hash_type, enum wc_SignatureType sig_type,
    const byte* data, word32 data_len,

    void* key, word32 key_len,
    WC_RNG* rng);

int wc_SignatureVerifyHash(enum wc_HashType hash_type,
                           enum wc_SignatureType sig_type,
                           const byte* hash_data, word32 hash_len,
                           const byte* sig, word32 sig_len,
                           void* key, word32 key_len);

int wc_SignatureGenerateHash(enum wc_HashType hash_type,
```

```
                                enum wc_SignatureType sig_type,
                                const byte* hash_data, word32 hash_len,
                                byte* sig, word32 *sig_len,
                                void* key, word32 key_len,
                                WC_RNG* rng);

int wc_SignatureGenerateHash_ex(enum wc_HashType hash_type,
                                   enum wc_SignatureType sig_type,
                                   const byte* hash_data, word32 hash_len,
                                   byte* sig, word32 *sig_len,
                                   void* key, word32 key_len,
                                   WC_RNG* rng, int verify);

int wc_SignatureGenerate_ex(enum wc_HashType hash_type,
                               enum wc_SignatureType sig_type,
                               const byte* data, word32 data_len,
                               byte* sig, word32 *sig_len,
                               void* key, word32 key_len,
                               WC_RNG* rng, int verify);
```

C.56 siphash.h

C.56.1 Functions

	Name
int	**wc_InitSipHash**(SipHash * siphash, const unsigned char * key, unsigned char outSz)This function initializes SipHash with a key for a MAC size.
int	**wc_SipHashUpdate**(SipHash * siphash, const unsigned char * in, word32 inSz)Can be called to continually hash the provided byte array of length len.
int	**wc_SipHashFinal**(SipHash * siphash, unsigned char * out, unsigned char outSz)Finalizes MACing of data. Result is placed into out.
int	**wc_SipHash**(const unsigned char * key, const unsigned char * in, word32 inSz, unsigned char * out, unsigned char outSz)This function one-shots the data using SipHash to calculate a MAC based on the key.

C.56.2 Functions Documentation

C.56.2.1 function wc_InitSipHash

```
int wc_InitSipHash(
    SipHash * siphash,
    const unsigned char * key,
    unsigned char outSz
)
```

This function initializes SipHash with a key for a MAC size.

Parameters:

- **siphash** pointer to the SipHash structure to use for MACing
- **key** pointer to the 16-byte array
- **outSz** number of bytes to output as MAC

See:

- wc_SipHash
- wc_SipHashUpdate
- wc_SipHashFinal

Return:

- 0 Returned upon successfully initializing
- BAD_FUNC_ARG Returned when siphash or key is NULL
- BAD_FUNC_ARG Returned when outSz is neither 8 nor 16

Example

```
SipHash siphash[1];
unsigned char key[16] = { ... };
byte macSz = 8; // 8 or 16

if ((ret = wc_InitSipHash(siphash, key, macSz)) != 0) {
    WOLFSSL_MSG("wc_InitSipHash failed");
}
else if ((ret = wc_SipHashUpdate(siphash, data, len)) != 0) {
    WOLFSSL_MSG("wc_SipHashUpdate failed");
}
else if ((ret = wc_SipHashFinal(siphash, mac, macSz)) != 0) {
    WOLFSSL_MSG("wc_SipHashFinal failed");
}
```

C.56.2.2 function wc_SipHashUpdate

```
int wc_SipHashUpdate(
    SipHash * siphash,
    const unsigned char * in,
    word32 inSz
)
```

Can be called to continually hash the provided byte array of length len.

Parameters:

- **siphash** pointer to the SipHash structure to use for MACing
- **in** the data to be MACed
- **inSz** size of data to be MACed

See:

- wc_SipHash
- wc_InitSipHash
- wc_SipHashFinal

Return:

- 0 Returned upon successfully adding the data to the MAC
- BAD_FUNC_ARG Returned when siphash is NULL
- BAD_FUNC_ARG Returned when in is NULL and inSz is not zero

Example

```
SipHash siphash[1];
byte data[] = { Data to be MACed };
word32 len = sizeof(data);

if ((ret = wc_InitSipHash(siphash, key, macSz)) != 0) {
    WOLFSSL_MSG("wc_InitSipHash failed");
}
else if ((ret = wc_SipHashUpdate(siphash, data, len)) != 0) {
    WOLFSSL_MSG("wc_SipHashUpdate failed");
}
else if ((ret = wc_SipHashFinal(siphash, mac, macSz)) != 0) {
    WOLFSSL_MSG("wc_SipHashFinal failed");
}
```

C.56.2.3 function wc_SipHashFinal

```
int wc_SipHashFinal(
    SipHash * siphash,
    unsigned char * out,
    unsigned char outSz
)
```

Finalizes MACing of data. Result is placed into out.

Parameters:

- **siphash** pointer to the SipHash structure to use for MACing
- **out** Byte array to hold MAC value
- **outSz** number of bytes to output as MAC

See:

- wc_SipHash
- wc_InitSipHash
- wc_SipHashUpdate

Return:

- 0 Returned upon successfully finalizing.
- BAD_FUNC_ARG Returned when siphash of out is NULL
- BAD_FUNC_ARG Returned when outSz is not the same as the initialized value

Example

```
SipHash siphash[1];
byte mac[8] = { ... }; // 8 or 16 bytes
byte macSz = sizeof(mac);

if ((ret = wc_InitSipHash(siphash, key, macSz)) != 0) {
    WOLFSSL_MSG("wc_InitSipHash failed");
}
else if ((ret = wc_SipHashUpdate(siphash, data, len)) != 0) {
    WOLFSSL_MSG("wc_SipHashUpdate failed");
}
else if ((ret = wc_SipHashFinal(siphash, mac, macSz)) != 0) {
    WOLFSSL_MSG("wc_SipHashFinal failed");
}
```

C.56.2.4 function wc_SipHash

```
int wc_SipHash(
    const unsigned char * key,
    const unsigned char * in,
    word32 inSz,
    unsigned char * out,
    unsigned char outSz
)
```

This function one-shots the data using SipHash to calculate a MAC based on the key.

Parameters:

- **key** pointer to the 16-byte array
- **in** the data to be MACed
- **inSz** size of data to be MACed
- **out** Byte array to hold MAC value
- **outSz** number of bytes to output as MAC

See:

- wc_InitSipHash
- wc_SipHashUpdate
- wc_SipHashFinal

Return:

- 0 Returned upon successfully MACing
- BAD_FUNC_ARG Returned when key or out is NULL
- BAD_FUNC_ARG Returned when in is NULL and inSz is not zero
- BAD_FUNC_ARG Returned when outSz is neither 8 nor 16

Example

```
unsigned char key[16] = { ... };
byte data[] = { Data to be MACed };
word32 len = sizeof(data);
byte mac[8] = { ... }; // 8 or 16 bytes
byte macSz = sizeof(mac);

if ((ret = wc_SipHash(key, data, len, mac, macSz)) != 0) {
    WOLFSSL_MSG("wc_SipHash failed");
}
```

C.56.3 Source code

```
int wc_InitSipHash(SipHash* siphash, const unsigned char* key,
    unsigned char outSz);

int wc_SipHashUpdate(SipHash* siphash, const unsigned char* in,
    word32 inSz);

int wc_SipHashFinal(SipHash* siphash, unsigned char* out,
    unsigned char outSz);

int wc_SipHash(const unsigned char* key, const unsigned char* in,
    word32 inSz, unsigned char* out, unsigned char outSz);
```

C.57 srp.h

C.57.1 Functions

	Name
int	**wc_SrpInit**(Srp * srp, SrpType type, SrpSide side)Initializes the Srp struct for usage.
int	**wc_SrpInit_ex**(Srp * srp, SrpType type, SrpSide side, void * heap, int devId)Initializes the Srp struct for usage with extended parameters. This function is similar to wc_SrpInit but allows specification of a custom heap hint and device ID for hardware acceleration.
void	**wc_SrpTerm**(Srp * srp)Releases the Srp struct resources after usage.
int	**wc_SrpSetUsername**(Srp * srp, const byte * username, word32 size)Sets the username. This function MUST be called after wc_SrpInit.
int	**wc_SrpSetParams**(Srp * srp, const byte * N, word32 nSz, const byte * g, word32 gSz, const byte * salt, word32 saltSz)Sets the srp parameters based on the username.. Must be called after wc_SrpSetUsername.
int	**wc_SrpSetPassword**(Srp * srp, const byte * password, word32 size)Sets the password. Setting the password does not persists the clear password data in the srp structure. The client calculates x = H(salt + H(user:pswd)) and stores it in the auth field. This function MUST be called after wc_SrpSetParams and is CLIENT SIDE ONLY.
int	**wc_SrpSetVerifier**(Srp * srp, const byte * verifier, word32 size)Sets the verifier. This function MUST be called after wc_SrpSetParams and is SERVER SIDE ONLY.
int	**wc_SrpGetVerifier**(Srp * srp, byte * verifier, word32 * size)Gets the verifier. The client calculates the verifier with v = g ^ x % N. This function MAY be called after wc_SrpSetPassword and is CLIENT SIDE ONLY.
int	**wc_SrpSetPrivate**(Srp * srp, const byte * priv, word32 size)Sets the private ephemeral value. The private ephemeral value is known as: a at the client side. a = random() b at the server side. b = random() This function is handy for unit test cases or if the developer wants to use an external random source to set the ephemeral value. This function MAY be called before wc_SrpGetPublic.

	Name
int	**wc_SrpGetPublic**(Srp * srp, byte * pub, word32 * size)Gets the public ephemeral value. The public ephemeral value is known as: A at the client side. A = g ^ a % N B at the server side. B = (k * v + (g ^ b % N)) % N This function MUST be called after wc_SrpSetPassword or wc_SrpSetVerifier. The function wc_SrpSetPrivate may be called before wc_SrpGetPublic.
int	**wc_SrpComputeKey**(Srp * srp, byte * clientPubKey, word32 clientPubKeySz, byte * serverPubKey, word32 serverPubKeySz)Computes the session key. The key can be accessed at srp->key after success.
int	**wc_SrpGetProof**(Srp * srp, byte * proof, word32 * size)Gets the proof. This function MUST be called after wc_SrpComputeKey.
int	**wc_SrpVerifyPeersProof**(Srp * srp, byte * proof, word32 size)Verifies the peers proof. This function MUST be called before wc_SrpGetSessionKey.

C.57.2 Functions Documentation

C.57.2.1 function wc_SrpInit

```
int wc_SrpInit(
    Srp * srp,
    SrpType type,
    SrpSide side
)
```

Initializes the Srp struct for usage.

Parameters:

- **srp** the Srp structure to be initialized.
- **type** the hash type to be used.
- **side** the side of the communication.

See:

- wc_SrpTerm
- wc_SrpSetUsername

Return:

- 0 on success.
- BAD_FUNC_ARG Returns when there's an issue with the arguments such as srp being null or SrpSide not being SRP_CLIENT_SIDE or SRP_SERVER_SIDE.
- NOT_COMPILED_IN Returns when a type is passed as an argument but hasn't been configured in the wolfCrypt build.
- <0 on error.

Example

```
Srp srp;
if (wc_SrpInit(&srp, SRP_TYPE_SHA, SRP_CLIENT_SIDE) != 0)
{
    // Initialization error
}
else
{
    wc_SrpTerm(&srp);
}
```

C.57.2.2 function wc_SrpInit_ex

```
int wc_SrpInit_ex(
    Srp * srp,
    SrpType type,
    SrpSide side,
    void * heap,
    int devId
)
```

Initializes the Srp struct for usage with extended parameters. This function is similar to wc_SrpInit but allows specification of a custom heap hint and device ID for hardware acceleration.

Parameters:

- **srp** the Srp structure to be initialized.
- **type** the hash type to be used.
- **side** the side of the communication.
- **heap** pointer to heap hint for memory allocation (can be NULL).
- **devId** device ID for hardware acceleration (use INVALID_DEVID for software only).

See:

- wc_SrpInit
- wc_SrpTerm
- wc_SrpSetUsername

Return:

- 0 on success.
- BAD_FUNC_ARG Returns when there's an issue with the arguments such as srp being null or SrpSide not being SRP_CLIENT_SIDE or SRP_SERVER_SIDE.
- NOT_COMPILED_IN Returns when a type is passed as an argument but hasn't been configured in the wolfCrypt build.
- <0 on error.

Example

```
Srp srp;
void* heap = NULL;
int devId = INVALID_DEVID;

if (wc_SrpInit_ex(&srp, SRP_TYPE_SHA, SRP_CLIENT_SIDE, heap,
                  devId) != 0) {
    // Initialization error
}
else {
    wc_SrpTerm(&srp);
}
```

C.57.2.3 function wc_SrpTerm

```
void wc_SrpTerm(
    Srp * srp
)
```

Releases the Srp struct resources after usage.

Parameters:

- **srp** Pointer to the Srp structure to be terminated.

See: wc_SrpInit

Return: none No returns.

Example

```
Srp srp;
wc_SrpInit(&srp, SRP_TYPE_SHA, SRP_CLIENT_SIDE);
// Use srp
wc_SrpTerm(&srp)
```

C.57.2.4 function wc_SrpSetUsername

```
int wc_SrpSetUsername(
    Srp * srp,
    const byte * username,
    word32 size
)
```

Sets the username. This function MUST be called after wc_SrpInit.

Parameters:

- **srp** the Srp structure.
- **username** the buffer containing the username.
- **size** the username size in bytes

See:

- wc_SrpInit
- wc_SrpSetParams
- wc_SrpTerm

Return:

- 0 Username set successfully.
- BAD_FUNC_ARG: Return if srp or username is null.
- MEMORY_E: Returns if there is an issue allocating memory for srp->user
- < 0: Error.

Example

```
Srp srp;
byte username[] = "user";
word32 usernameSize = 4;

wc_SrpInit(&srp, SRP_TYPE_SHA, SRP_CLIENT_SIDE);
if(wc_SrpSetUsername(&srp, username, usernameSize) != 0)
{
    // Error occurred setting username.
```

```
}
wc_SrpTerm(&srp);
```

C.57.2.5 function wc_SrpSetParams

```
int wc_SrpSetParams(
    Srp * srp,
    const byte * N,
    word32 nSz,
    const byte * g,
    word32 gSz,
    const byte * salt,
    word32 saltSz
)
```

Sets the srp parameters based on the username.. Must be called after wc_SrpSetUsername.

Parameters:

- **srp** the Srp structure.
- **N** the Modulus. N = 2q+1, [q, N] are primes.
- **nSz** the N size in bytes.
- **g** the Generator modulo N.
- **gSz** the g size in bytes
- **salt** a small random salt. Specific for each username.
- **saltSz** the salt size in bytes

See:

- wc_SrpInit
- wc_SrpSetUsername
- wc_SrpTerm

Return:

- 0 Success
- BAD_FUNC_ARG Returns if srp, N, g, or salt is null or if nSz < gSz.
- SRP_CALL_ORDER_E Returns if wc_SrpSetParams is called before wc_SrpSetUsername.
- <0 Error

Example

```
Srp srp;
byte username[] = "user";
word32 usernameSize = 4;

byte N[] = { }; // Contents of byte array N
byte g[] = { }; // Contents of byte array g
byte salt[] = { }; // Contents of byte array salt

wc_SrpInit(&srp, SRP_TYPE_SHA, SRP_CLIENT_SIDE);
wc_SrpSetUsername(&srp, username, usernameSize);

if(wc_SrpSetParams(&srp, N, sizeof(N), g, sizeof(g), salt,
sizeof(salt)) != 0)
{
    // Error setting params
}
wc_SrpTerm(&srp);
```

C.57.2.6 function wc_SrpSetPassword

```
int wc_SrpSetPassword(
    Srp * srp,
    const byte * password,
    word32 size
)
```

Sets the password. Setting the password does not persists the clear password data in the srp structure. The client calculates x = H(salt + H(user:pswd)) and stores it in the auth field. This function MUST be called after wc_SrpSetParams and is CLIENT SIDE ONLY.

Parameters:

- **srp** The Srp structure.
- **password** The buffer containing the password.
- **size** The size of the password in bytes.

See:

- wc_SrpInit
- wc_SrpSetUsername
- wc_SrpSetParams

Return:

- 0 Success
- BAD_FUNC_ARG Returns if srp or password is null or if srp->side is not set to SRP_CLIENT_SIDE.
- SRP_CALL_ORDER_E Returns when wc_SrpSetPassword is called out of order.
- <0 Error

Example

```
Srp srp;
byte username[] = "user";
word32 usernameSize = 4;
byte password[] = "password";
word32 passwordSize = 8;

byte N[] = { }; // Contents of byte array N
byte g[] = { }; // Contents of byte array g
byte salt[] = { }; // Contents of byte array salt

wc_SrpInit(&srp, SRP_TYPE_SHA, SRP_CLIENT_SIDE);
wc_SrpSetUsername(&srp, username, usernameSize);
wc_SrpSetParams(&srp, N, sizeof(N), g, sizeof(g), salt, sizeof(salt));

if(wc_SrpSetPassword(&srp, password, passwordSize) != 0)
{
    // Error setting password
}

wc_SrpTerm(&srp);
```

C.57.2.7 function wc_SrpSetVerifier

```
int wc_SrpSetVerifier(
    Srp * srp,
    const byte * verifier,
```

```
    word32 size
)
```

Sets the verifier. This function MUST be called after wc_SrpSetParams and is SERVER SIDE ONLY.

Parameters:

- **srp** The Srp structure.
- **verifier** The structure containing the verifier.
- **size** The verifier size in bytes.

See:

- wc_SrpInit
- wc_SrpSetParams
- wc_SrpGetVerifier

Return:

- 0 Success
- BAD_FUNC_ARG Returned if srp or verifier is null or srp->side is not SRP_SERVER_SIDE.
- <0 Error

Example

```
Srp srp;
byte username[] = "user";
word32 usernameSize = 4;

byte N[] = { }; // Contents of byte array N
byte g[] = { }; // Contents of byte array g
byte salt[] = { }; // Contents of byte array salt
wc_SrpInit(&srp, SRP_TYPE_SHA, SRP_SERVER_SIDE);
wc_SrpSetUsername(&srp, username, usernameSize);
wc_SrpSetParams(&srp, N, sizeof(N), g, sizeof(g), salt, sizeof(salt))
byte verifier[] = { }; // Contents of some verifier

if(wc_SrpSetVerifier(&srp, verifier, sizeof(verifier)) != 0)
{
    // Error setting verifier
}

wc_SrpTerm(&srp);
```

C.57.2.8 function wc_SrpGetVerifier

```
int wc_SrpGetVerifier(
    Srp * srp,
    byte * verifier,
    word32 * size
)
```

Gets the verifier. The client calculates the verifier with v = g ^ x % N. This function MAY be called after wc_SrpSetPassword and is CLIENT SIDE ONLY.

Parameters:

- **srp** The Srp structure.
- **verifier** The buffer to write the verifier.
- **size** Buffer size in bytes. Updated with the verifier size.

See:

- wc_SrpSetVerifier
- wc_SrpSetPassword

Return:

- 0 Success
- BAD_FUNC_ARG Returned if srp, verifier or size is null or if srp->side is not SRP_CLIENT_SIDE.
- SRP_CALL_ORDER_E Returned if wc_SrpGetVerifier is called out of order.
- <0 Error

Example

```
Srp srp;
byte username[] = "user";
word32 usernameSize = 4;
byte password[] = "password";
word32 passwordSize = 8;

byte N[] = { }; // Contents of byte array N
byte g[] = { }; // Contents of byte array g
byte salt[] = { }; // Contents of byte array salt
byte v[64];
word32 vSz = 0;
vSz = sizeof(v);

wc_SrpInit(&srp, SRP_TYPE_SHA, SRP_CLIENT_SIDE);
wc_SrpSetUsername(&srp, username, usernameSize);
wc_SrpSetParams(&srp, N, sizeof(N), g, sizeof(g), salt, sizeof(salt))
wc_SrpSetPassword(&srp, password, passwordSize)

if( wc_SrpGetVerifier(&srp, v, &vSz ) != 0)
{
    // Error getting verifier
}
wc_SrpTerm(&srp);
```

C.57.2.9 function wc_SrpSetPrivate

```
int wc_SrpSetPrivate(
    Srp * srp,
    const byte * priv,
    word32 size
)
```

Sets the private ephemeral value. The private ephemeral value is known as: a at the client side. a = random() b at the server side. b = random() This function is handy for unit test cases or if the developer wants to use an external random source to set the ephemeral value. This function MAY be called before wc_SrpGetPublic.

Parameters:

- **srp** the Srp structure.
- **priv** the ephemeral value.
- **size** the private size in bytes.

See: wc_SrpGetPublic

Return:

- 0 Success
- BAD_FUNC_ARG Returned if srp, private, or size is null.
- SRP_CALL_ORDER_E Returned if wc_SrpSetPrivate is called out of order.
- <0 Error

Example

```
Srp srp;
byte username[] = "user";
word32 usernameSize = 4;

byte N[] = { }; // Contents of byte array N
byte g[] = { }; // Contents of byte array g
byte salt[] = { }; // Contents of byte array salt
byte verifier = { }; // Contents of some verifier
wc_SrpInit(&srp, SRP_TYPE_SHA, SRP_SERVER_SIDE);
wc_SrpSetUsername(&srp, username, usernameSize);
wc_SrpSetParams(&srp, N, sizeof(N), g, sizeof(g), salt, sizeof(salt))
wc_SrpSetVerifier(&srp, verifier, sizeof(verifier))

byte b[] = { }; // Some ephemeral value
if( wc_SrpSetPrivate(&srp, b, sizeof(b)) != 0)
{
    // Error setting private ephemeral
}

wc_SrpTerm(&srp);
```

C.57.2.10 function wc_SrpGetPublic

```
int wc_SrpGetPublic(
    Srp * srp,
    byte * pub,
    word32 * size
)
```

Gets the public ephemeral value. The public ephemeral value is known as: A at the client side. A = g ^ a % N B at the server side. B = (k * v + (g ^ b % N)) % N This function MUST be called after wc_SrpSetPassword or wc_SrpSetVerifier. The function wc_SrpSetPrivate may be called before wc_SrpGetPublic.

Parameters:

- **srp** the Srp structure.
- **pub** the buffer to write the public ephemeral value.
- **size** IN: the buffer size in bytes. OUT: Will be updated with the ephemeral value size.

See:

- wc_SrpSetPrivate
- wc_SrpSetPassword
- wc_SrpSetVerifier

Return:

- 0 Success
- BAD_FUNC_ARG Returned if srp, pub, or size is null.

- SRP_CALL_ORDER_E Returned if wc_SrpGetPublic is called out of order.
- BUFFER_E Returned if size < srp.N.
- <0 Error

Caller must observe value of size upon return to know the actual size.

Example

```
Srp srp;
byte username[] = "user";
word32 usernameSize = 4;
byte password[] = "password";
word32 passwordSize = 8;

byte N[] = { }; // Contents of byte array N
byte g[] = { }; // Contents of byte array g
byte salt[] = { }; // Contents of byte array salt
wc_SrpInit(&srp, SRP_TYPE_SHA, SRP_CLIENT_SIDE);
wc_SrpSetUsername(&srp, username, usernameSize);
wc_SrpSetParams(&srp, N, sizeof(N), g, sizeof(g), salt, sizeof(salt));
wc_SrpSetPassword(&srp, password, passwordSize)

byte public[64];
word32 publicSz = sizeof(public);

if( wc_SrpGetPublic(&srp, public, &publicSz) != 0)
{
    // Error getting public ephemeral
}

wc_SrpTerm(&srp);
```

C.57.2.11 function wc_SrpComputeKey

```
int wc_SrpComputeKey(
    Srp * srp,
    byte * clientPubKey,
    word32 clientPubKeySz,
    byte * serverPubKey,
    word32 serverPubKeySz
)
```

Computes the session key. The key can be accessed at srp->key after success.

Parameters:

- **srp** the Srp structure.
- **clientPubKey** the client's public ephemeral value.
- **clientPubKeySz** the client's public ephemeral value size.
- **serverPubKey** the server's public ephemeral value.
- **serverPubKeySz** the server's public ephemeral value size.

See: wc_SrpGetPublic

Return:

- 0 Success
- BAD_FUNC_ARG Returned if srp, clientPubKey, or serverPubKey or if clientPubKeySz or server-PubKeySz is 0.

- SRP_CALL_ORDER_E Returned if wc_SrpComputeKey is called out of order.
- <0 Error

Example

```
Srp server;

byte username[] = "user";
    word32 usernameSize = 4;
byte password[] = "password";
word32 passwordSize = 8;
byte N[] = { }; // Contents of byte array N
byte g[] = { }; // Contents of byte array g
byte salt[] = { }; // Contents of byte array salt
byte verifier[] = { }; // Contents of some verifier
byte serverPubKey[] = { }; // Contents of server pub key
word32 serverPubKeySize = sizeof(serverPubKey);
byte clientPubKey[64];
word32 clientPubKeySize = 64;

wc_SrpInit(&server, SRP_TYPE_SHA, SRP_SERVER_SIDE);
wc_SrpSetUsername(&server, username, usernameSize);
wc_SrpSetParams(&server, N, sizeof(N), g, sizeof(g), salt, sizeof(salt));
wc_SrpSetVerifier(&server, verifier, sizeof(verifier));
wc_SrpGetPublic(&server, serverPubKey, &serverPubKeySize);

wc_SrpComputeKey(&server, clientPubKey, clientPubKeySz,
                                    serverPubKey, serverPubKeySize)
wc_SrpTerm(&server);
```

C.57.2.12 function wc_SrpGetProof

```
int wc_SrpGetProof(
    Srp * srp,
    byte * proof,
    word32 * size
)
```

Gets the proof. This function MUST be called after wc_SrpComputeKey.

Parameters:

- **srp** the Srp structure.
- **proof** the peers proof.
- **size** the proof size in bytes.

See: wc_SrpComputeKey

Return:

- 0 Success
- BAD_FUNC_ARG Returns if srp, proof, or size is null.
- BUFFER_E Returns if size is less than the hash size of srp->type.
- <0 Error

Example

```
Srp cli;
byte clientProof[SRP_MAX_DIGEST_SIZE];
```

```
word32 clientProofSz = SRP_MAX_DIGEST_SIZE;

// Initialize Srp following steps from previous examples

if (wc_SrpGetProof(&cli, clientProof, &clientProofSz) != 0)
{
    // Error getting proof
}
```

C.57.2.13 function wc_SrpVerifyPeersProof

```
int wc_SrpVerifyPeersProof(
    Srp * srp,
    byte * proof,
    word32 size
)
```

Verifies the peers proof. This function MUST be called before wc_SrpGetSessionKey.

Parameters:

- **srp** the Srp structure.
- **proof** the peers proof.
- **size** the proof size in bytes.

See:

- wc_SrpGetSessionKey
- wc_SrpGetProof
- wc_SrpTerm

Return:

- 0 Success
- <0 Error

Example

```
Srp cli;
Srp srv;
byte clientProof[SRP_MAX_DIGEST_SIZE];
word32 clientProofSz = SRP_MAX_DIGEST_SIZE;

// Initialize Srp following steps from previous examples
// First get the proof
wc_SrpGetProof(&cli, clientProof, &clientProofSz)

if (wc_SrpVerifyPeersProof(&srv, clientProof, clientProofSz) != 0)
{
    // Error verifying proof
}
```

C.57.3 Source code

```
int wc_SrpInit(Srp* srp, SrpType type, SrpSide side);

int wc_SrpInit_ex(Srp* srp, SrpType type, SrpSide side, void* heap,
                  int devId);
```

```
void wc_SrpTerm(Srp* srp);

int wc_SrpSetUsername(Srp* srp, const byte* username, word32 size);

int wc_SrpSetParams(Srp* srp, const byte* N,    word32 nSz,
                                      const byte* g,    word32 gSz,
                                      const byte* salt, word32 saltSz);

int wc_SrpSetPassword(Srp* srp, const byte* password, word32 size);

int wc_SrpSetVerifier(Srp* srp, const byte* verifier, word32 size);

int wc_SrpGetVerifier(Srp* srp, byte* verifier, word32* size);

int wc_SrpSetPrivate(Srp* srp, const byte* priv, word32 size);

int wc_SrpGetPublic(Srp* srp, byte* pub, word32* size);

int wc_SrpComputeKey(Srp* srp,
                                 byte* clientPubKey, word32 clientPubKeySz,
                                 byte* serverPubKey, word32 serverPubKeySz);

int wc_SrpGetProof(Srp* srp, byte* proof, word32* size);

int wc_SrpVerifyPeersProof(Srp* srp, byte* proof, word32 size);
```

C.58 ssl.h

C.58.1 Types

	Name
typedef void()(*WOLFSSL* ssl, int client_server, int type, const byte *data, int len, void* arg)	**WOLFSSL_TLSEXT_DEBUG_CB** Callback type for the TLS extension debug callback.

C.58.2 Functions

	Name
WOLFSSL_METHOD *	**wolfDTLSv1_2_client_method_ex**(void * heap)This function initializes the DTLS v1.2 client method.
WOLFSSL_METHOD *	**wolfSSLv23_method**(void)This function returns a WOLFSSL_METHOD similar to wolfSSLv23_client_method except that it is not determined which side yet (server/client).

	Name
WOLFSSL_METHOD *	**wolfSSLv3_server_method**(void)The wolfSSLv3_server_method() function is used to indicate that the application is a server and will only support the SSL 3.0 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().
WOLFSSL_METHOD *	**wolfSSLv3_client_method**(void)The wolfSSLv3_client_method() function is used to indicate that the application is a client and will only support the SSL 3.0 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().
WOLFSSL_METHOD *	**wolfTLSv1_server_method**(void)The wolfTLSv1_server_method() function is used to indicate that the application is a server and will only support the TLS 1.0 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().
WOLFSSL_METHOD *	**wolfTLSv1_client_method**(void)The wolfTLSv1_client_method() function is used to indicate that the application is a client and will only support the TLS 1.0 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().
WOLFSSL_METHOD *	**wolfTLSv1_1_server_method**(void)The wolfTLSv1_1_server_method() function is used to indicate that the application is a server and will only support the TLS 1.1 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().
WOLFSSL_METHOD *	**wolfTLSv1_1_client_method**(void)The wolfTLSv1_1_client_method() function is used to indicate that the application is a client and will only support the TLS 1.0 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().

	Name
WOLFSSL_METHOD *	**wolfTLSv1_2_server_method**(void)The wolfTLSv1_2_server_method() function is used to indicate that the application is a server and will only support the TLS 1.2 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().
WOLFSSL_METHOD *	**wolfTLSv1_2_client_method**(void)The wolfTLSv1_2_client_method() function is used to indicate that the application is a client and will only support the TLS 1.2 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().
WOLFSSL_METHOD *	**wolfDTLSv1_client_method**(void)The wolfDTLSv1_client_method() function is used to indicate that the application is a client and will only support the DTLS 1.0 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new(). This function is only available when wolfSSL has been compiled with DTLS support (–enable_dtls, or by defining wolfSSL_DTLS).
WOLFSSL_METHOD *	**wolfDTLSv1_server_method**(void)The wolfDTLSv1_server_method() function is used to indicate that the application is a server and will only support the DTLS 1.0 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new(). This function is only available when wolfSSL has been compiled with DTLS support (–enable_dtls, or by defining wolfSSL_DTLS).
WOLFSSL_METHOD *	**wolfDTLSv1_3_server_method**(void)The wolfDTLSv1_3_server_method() function is used to indicate that the application is a server and will only support the DTLS 1.3 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new(). This function is only available when wolfSSL has been compiled with DTLSv1.3 support (–enable_dtls13, or by defining wolfSSL_DTLS13).

	Name
WOLFSSL_METHOD *	**wolfDTLSv1_3_client_method**(void)The wolfDTLSv1_3_client_method() function is used to indicate that the application is a client and will only support the DTLS 1.3 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new(). This function is only available when wolfSSL has been compiled with DTLSv1.3 support (–enable_dtls13, or by defining wolfSSL_DTLS13).
WOLFSSL_METHOD *	**wolfDTLS_server_method**(void)The wolfDTLS_server_method() function is used to indicate that the application is a server and will support the highest version of DTLS available and all the version up to the minimum version allowed. The default minimum version allowed is based on the define WOLFSSL_MIN_DTLS_DOWNGRADE and can be changed at runtime using wolfSSL_SetMinVersion(). This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new(). This function is only available when wolfSSL has been compiled with DTLS support (–enable_dtls, or by defining wolfSSL_DTLS).
WOLFSSL_METHOD *	**wolfDTLS_client_method**(void)The wolfDTLS_client_method() function is used to indicate that the application is a client and will support the highest version of DTLS available and all the version up to the minimum version allowed. The default minimum version allowed is based on the define WOLFSSL_MIN_DTLS_DOWNGRADE and can be changed at runtime using wolfSSL_SetMinVersion(). This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new(). This function is only available when wolfSSL has been compiled with DTLS support (–enable_dtls, or by defining wolfSSL_DTLS).
WOLFSSL_METHOD *	**wolfDTLSv1_2_server_method**(void)This function creates and initializes a WOLFSSL_METHOD for the server side.

	Name
int	**wolfSSL_use_old_poly**(WOLFSSL * ssl, int value)Since there is some differences between the first release and newer versions of chacha-poly AEAD construction we have added an option to communicate with servers/clients using the older version. By default wolfSSL uses the new version.
int	**wolfSSL_dtls_import**(WOLFSSL * ssl, const unsigned char * buf, unsigned int sz)The wolfSSL_dtls_import() function is used to parse in a serialized session state. This allows for picking up the connection after the handshake has been completed. Post-handshake authentication is not available on an imported connection.
int	**wolfSSL_tls_import**(WOLFSSL * ssl, const unsigned char * buf, unsigned int sz)Used to import a serialized TLS session. This function is for importing the state of the connection. A TLS 1.3 session serialized with export version 7 or later carries its traffic and resumption secrets, so a KeyUpdate and the issuing of a NewSessionTicket work on the imported connection; an older serialization restores the record layer alone. WARNING: buf contains sensitive information about the state and is best to be encrypted before storing if stored. Additional debug info can be displayed with the macro WOLFSSL_SESSION_EXPORT_DEBUG defined.
int	**wolfSSL_CTX_dtls_set_export**(WOLFSSL_CTX * ctx, wc_dtls_export func)The wolfSSL_CTX_dtls_set_export() function is used to set the callback function for exporting a session. It is allowed to pass in NULL as the parameter func to clear the export function previously stored. Used on the server side and is called immediately after handshake is completed, for DTLS 1.2 only; a DTLS 1.3 session is exported with wolfSSL_dtls_export().
int	**wolfSSL_dtls_set_export**(WOLFSSL * ssl, wc_dtls_export func)The wolfSSL_dtls_set_export() function is used to set the callback function for exporting a session. It is allowed to pass in NULL as the parameter func to clear the export function previously stored. Used on the server side and is called immediately after handshake is completed, for DTLS 1.2 only; a DTLS 1.3 session is exported with wolfSSL_dtls_export().

	Name
int	**wolfSSL_dtls_export**(WOLFSSL * ssl, unsigned char * buf, unsigned int * sz)The wolfSSL_dtls_export() function is used to serialize a WOLFSSL session into the provided buffer. Allows for less memory overhead than using a function callback for sending a session and choice over when the session is serialized. If buffer is NULL when passed to function then sz will be set to the size of buffer needed for serializing the WOLFSSL session. The export is refused with a negative return before a DTLS 1.3 handshake is done, while a KeyUpdate is in progress, a fragmented message is half sent, a handshake message other than NewSessionTicket is waiting for the peer's ACK, a post-handshake CertificateRequest is unanswered, or a write dup of the object exists. A NewSessionTicket still waiting for its ACK is not exported and is lost. The session tickets themselves are not serialized: any ticket already issued or received is discarded by the export. For a DTLS 1.3 session the blob carries the resumption secret and the ticket nonce, so an imported server can still issue a NewSessionTicket that resumes; use wolfSSL_get1_session before exporting to keep a received ticket.
int	**wolfSSL_tls_export**(WOLFSSL * ssl, unsigned char * buf, unsigned int * sz)Used to export a serialized TLS session. This function is for exporting a serialized state of the connection. In most cases wolfSSL_get1_session should be used instead of wolfSSL_tls_export. The export of a TLS 1.3 session is refused with a negative return before the handshake is done or while a KeyUpdate response is pending. The session tickets themselves are not serialized: any ticket already issued or received is discarded by the export. A TLS 1.3 blob carries the resumption secret and the ticket nonce, so an imported server can still issue a NewSessionTicket that resumes; use wolfSSL_get1_session before exporting to keep a received ticket. Additional debug info can be displayed with the macro WOLFSSL_SESSION_EXPORT_DEBUG defined. WARNING: buf contains sensitive information about the state and is best to be encrypted before storing if stored.

	Name
int	**wolfSSL_CTX_load_static_memory**(WOLFSSL_CTX ** ctx, wolfSSL_method_func method, unsigned char * buf, unsigned int sz, int flag, int max)This function is used to set aside static memory for a CTX. Memory set aside is then used for the CTX's lifetime and for any SSL objects created from the CTX. By passing in a NULL ctx pointer and a wolfSSL_method_func function the creation of the CTX itself will also use static memory. wolfSSL_method_func has the function signature of WOLFSSL_METHOD* (*wolfSSL_method_func)(void* heap);. Passing in 0 for max makes it behave as if not set and no max concurrent use restrictions is in place. The flag value passed in determines how the memory is used and behavior while operating. Available flags are the following: 0 - default general memory, WOLFMEM_IO_POOL - used for input/output buffer when sending receiving messages and overrides general memory, so all memory in buffer passed in is used for IO, WOLFMEM_IO_FIXED - same as WOLFMEM_IO_POOL but each SSL now keeps two buffers to themselves for their lifetime, WOLFMEM_TRACK_STATS - each SSL keeps track of memory stats while running.
int	**wolfSSL_CTX_is_static_memory**(WOLFSSL_CTX * ctx, WOLFSSL_MEM_STATS * mem_stats)This function does not change any of the connections behavior and is used only for gathering information about the static memory usage.
int	**wolfSSL_is_static_memory**(WOLFSSL * ssl, WOLFSSL_MEM_CONN_STATS * mem_stats)wolfSSL_is_static_memory is used to gather information about a SSL's static memory usage. The return value indicates if static memory is being used and WOLFSSL_MEM_CONN_STATS will be filled out if and only if the flag WOLFMEM_TRACK_STATS was passed to the parent CTX when loading in static memory.
int	**wolfSSL_CTX_use_certificate_file**(WOLFSSL_CTX * ctx, const char * file, int format)This function loads a certificate file into the SSL context (WOLFSSL_CTX). The file is provided by the file argument. The format argument specifies the format type of the file, either SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM. Please see the examples for proper usage.

COPYRIGHT ©2024 wolfSSL Inc.

	Name
int	**wolfSSL_CTX_use_PrivateKey_file**(WOLFSSL_CTX * ctx, const char * file, int format)This function loads a private key file into the SSL context (WOLFSSL_CTX). The file is provided by the file argument. The format argument specifies the format type of the file - SSL_FILETYPE_ASN1or SSL_FILETYPE_PEM. Please see the examples for proper usage.
int	**wolfSSL_CTX_load_verify_locations**(WOLFSSL_CTX * ctx, const char * file, const char * path)This function loads PEM_formatted CA certificate files into the SSL context (WOLFSSL_CTX). These certificates will be treated as trusted root certificates and used to verify certs received from peers during the SSL handshake. The root certificate file, provided by the file argument, may be a single certificate or a file containing multiple certificates. If multiple CA certs are included in the same file, wolfSSL will load them in the same order they are presented in the file. The path argument is a pointer to the name of a directory that contains certificates of trusted root CAs. If the value of file is not NULL, path may be specified as NULL if not needed. If path is specified and NO_WOLFSSL_DIR was not defined when building the library, wolfSSL will load all CA certificates located in the given directory. This function will attempt to load all files in the directory. This function expects PEM formatted CERT_TYPE file with header “—–BEGIN CERTIFICATE—–”.

	Name
int	**wolfSSL_CTX_load_verify_locations_ex**(WOLFSSL_CTX * ctx, const char * file, const char * path, word32 flags)This function loads PEM_formatted CA certificate files into the SSL context (WOLFSSL_CTX). These certificates will be treated as trusted root certificates and used to verify certs received from peers during the SSL handshake. The root certificate file, provided by the file argument, may be a single certificate or a file containing multiple certificates. If multiple CA certs are included in the same file, wolfSSL will load them in the same order they are presented in the file. The path argument is a pointer to the name of a directory that contains certificates of trusted root CAs. If the value of file is not NULL, path may be specified as NULL if not needed. If path is specified and NO_WOLFSSL_DIR was not defined when building the library, wolfSSL will load all CA certificates located in the given directory. This function will attempt to load all files in the directory based on flags specified. This function expects PEM formatted CERT_TYPE files with header "—–BEGIN CERTIFICATE—–".
const char **	**wolfSSL_get_system_CA_dirs**(word32 * num)This function returns a pointer to an array of strings representing directories wolfSSL will search for system CA certs when wolfSSL_CTX_load_system_CA_certs is called. On systems that don't store certificates in an accessible system directory (such as Apple platforms), this function will always return NULL.
int	**wolfSSL_CTX_load_system_CA_certs**(WOLFSSL_CTX * ctx)On most platforms (including Linux and Windows), this function attempts to load CA certificates into a WOLFSSL_CTX from an OS-dependent CA certificate store. Loaded certificates will be trusted.
int	**wolfSSL_CTX_trust_peer_cert**(WOLFSSL_CTX * ctx, const char * file, int type)This function loads a certificate to use for verifying a peer when performing a TLS/SSL handshake. The peer certificate sent during the handshake is compared by using the SKID when available and the signature. If these two things do not match then any loaded CAs are used. Feature is enabled by defining the macro WOLFSSL_TRUST_PEER_CERT. Please see the examples for proper usage.

	Name
int	**wolfSSL_CTX_use_certificate_chain_file**(WOLFSSL_CTX * ctx, const char * file)This function loads a chain of certificates into the SSL context (WOLFSSL_CTX). The file containing the certificate chain is provided by the file argument, and must contain PEM_formatted certificates. This function will process up to MAX_CHAIN_DEPTH (default = 9, defined in internal.h) certificates, plus the subject cert.
int	**wolfSSL_CTX_use_RSAPrivateKey_file**(WOLFSSL_CTX * ctx, const char * file, int format)This function loads the private RSA key used in the SSL connection into the SSL context (WOLFSSL_CTX). This function is only available when wolfSSL has been compiled with the OpenSSL compatibility layer enabled (–enable_opensslExtra, #define OPENSSL_EXTRA), and is identical to the more_typically used wolfSSL_CTX_use_PrivateKey_file() function. The file argument contains a pointer to the RSA private key file, in the format specified by format.
long	**wolfSSL_get_verify_depth**(WOLFSSL * ssl)This function returns the maximum chain depth allowed, which is 9 by default, for a valid session i.e. there is a non_null session object (ssl).
long	**wolfSSL_CTX_get_verify_depth**(WOLFSSL_CTX * ctx)This function gets the certificate chaining depth using the CTX structure.
int	**wolfSSL_use_certificate_file**(WOLFSSL * ssl, const char * file, int format)This function loads a certificate file into the SSL session (WOLFSSL structure). The certificate file is provided by the file argument. The format argument specifies the format type of the file - either SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM.
int	**wolfSSL_use_PrivateKey_file**(WOLFSSL * ssl, const char * file, int format)This function loads a private key file into the SSL session (WOLFSSL structure). The key file is provided by the file argument. The format argument specifies the format type of the file - SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM.

	Name
int	**wolfSSL_use_certificate_chain_file**(WOLFSSL * ssl, const char * file)This function loads a chain of certificates into the SSL session (WOLFSSL structure). The file containing the certificate chain is provided by the file argument, and must contain PEM_formatted certificates. This function will process up to MAX_CHAIN_DEPTH (default = 9, defined in internal.h) certificates, plus the subject certificate.
int	**wolfSSL_use_RSAPrivateKey_file**(WOLFSSL * ssl, const char * file, int format)This function loads the private RSA key used in the SSL connection into the SSL session (WOLFSSL structure). This function is only available when wolfSSL has been compiled with the OpenSSL compatibility layer enabled (–enable_opensslExtra, #define OPENSSL_EXTRA), and is identical to the more_typically used wolfSSL_use_PrivateKey_file() function. The file argument contains a pointer to the RSA private key file, in the format specified by format.
int	**wolfSSL_CTX_der_load_verify_locations**(WOLFSSL_CTX * ctx, const char * file, int format)This function is similar to wolfSSL_CTX_load_verify_locations, but allows the loading of DER_formatted CA files into the SSL context (WOLFSSL_CTX). It may still be used to load PEM_formatted CA files as well. These certificates will be treated as trusted root certificates and used to verify certs received from peers during the SSL handshake. The root certificate file, provided by the file argument, may be a single certificate or a file containing multiple certificates. If multiple CA certs are included in the same file, wolfSSL will load them in the same order they are presented in the file. The format argument specifies the format which the certificates are in either, SSL_FILETYPE_PEM or SSL_FILETYPE_ASN1 (DER). Unlike wolfSSL_CTX_load_verify_locations, this function does not allow the loading of CA certificates from a given directory path. Note that this function is only available when the wolfSSL library was compiled with WOLFSSL_DER_LOAD defined.
WOLFSSL_CTX *	**wolfSSL_CTX_new**(WOLFSSL_METHOD *)This function creates a new SSL context, taking a desired SSL/TLS protocol method for input.
WOLFSSL *	**wolfSSL_new**(WOLFSSL_CTX *)This function creates a new SSL session, taking an already created SSL context as input.

	Name
int	**wolfSSL_set_fd**(WOLFSSL * ssl, int fd)This function assigns a file descriptor (fd) as the input/output facility for the SSL connection. Typically this will be a socket file descriptor.
int	**wolfSSL_set_dtls_fd_connected**(WOLFSSL * ssl, int fd)This function assigns a file descriptor (fd) as the input/output facility for the SSL connection. Typically this will be a socket file descriptor. This is a DTLS specific API because it marks that the socket is connected. recvfrom and sendto calls on this fd will have the addr and addr_len parameters set to NULL.

	Name
int	**wolfDTLS_SetChGoodCb**(WOLFSSL * ssl, ClientHelloGoodCb cb, void * user_ctx)Allows setting a callback for a correctly processed and verified DTLS client hello. When using a cookie exchange mechanism (either the HelloVerifyRequest in DTLS 1.2 or the HelloRetryRequest with a cookie extension in DTLS 1.3) this callback is called after the cookie exchange has succeeded. This is useful to use one WOLFSSL object as the listener for new connections and being able to isolate the WOLFSSL object once the ClientHello is verified (either through a cookie exchange or just checking if the ClientHello had the correct format). With DTLS cookies disabled, the callback is invoked once per ClientHello, only after complete successful ClientHello processing, not on its first fragment. Retries, retransmitted fragments and a second ClientHello after a key_share HelloRetryRequest do not repeat the notification. The object is already stateful before input is read, but the peer's return_routability has not been verified. Returning 0 accepts the ClientHello and the handshake continues. Any negative return stops the accept call with that error and leaves the accept state machine at the ClientHello, so nothing is sent to the peer and the next accept call asks the callback again instead of continuing the handshake. All negative returns behave this way; the value only decides what wolfSSL_get_error() reports, so what it means is the application's choice. A callback that is not ready to decide can return WANT_READ or WANT_WRITE and be asked again as many times as it needs, and one that refuses the peer returns its own error and keeps the server silent by refusing again on every later accept call. The cookie mode cannot be changed from the callback; see wolfSSL_disable_cookie(). DTLS 1.2: https://datatracker.ietf.org/doc/html/rfc6347#section_4.2.1 DTLS 1.3: https://www.rfc_editor.org/rfc/rfc8446#section_4.2.2.
char *	**wolfSSL_get_cipher_list**(int priority)Get the name of cipher at priority level passed in.
int	**wolfSSL_get_ciphers**(char * buf, int len)This function gets the ciphers enabled in wolfSSL.
const char *	**wolfSSL_get_cipher_name**(WOLFSSL * ssl)This function gets the cipher name in the format DHE-RSA by passing through argument to wolfSSL_get_cipher_name_internal.

	Name
int	**wolfSSL_get_fd**(const WOLFSSL * ssl)This function returns the read file descriptor (fd) used as the input facility for the SSL connection. Typically this will be a socket file descriptor.
int	**wolfSSL_get_wfd**(const WOLFSSL * ssl)This function returns the write file descriptor (fd) used as the output facility for the SSL connection. Typically this will be a socket file descriptor.
void	**wolfSSL_set_using_nonblock**(WOLFSSL * ssl, int nonblock)This function informs the WOLFSSL object that the underlying I/O is non_blocking. After an application creates a WOLFSSL object, if it will be used with a non_blocking socket, call wolfSSL_set_using_nonblock() on it. This lets the WOLFSSL object know that receiving EWOULDBLOCK means that the recvfrom call would block rather than that it timed out.
int	**wolfSSL_get_using_nonblock**(WOLFSSL *)This function allows the application to determine if wolfSSL is using non_blocking I/O. If wolfSSL is using non_blocking I/O, this function will return 1, otherwise 0. After an application creates a WOLFSSL object, if it will be used with a non_blocking socket, call wolfSSL_set_using_nonblock() on it. This lets the WOLFSSL object know that receiving EWOULDBLOCK means that the recvfrom call would block rather than that it timed out.

	Name
int	**wolfSSL_write**(WOLFSSL * ssl, const void * data, int sz)This function writes sz bytes from the buffer, data, to the SSL connection, ssl. If necessary, wolfSSL_write() will negotiate an SSL/TLS session if the handshake has not already been performed yet by wolfSSL_connect() or wolfSSL_accept(). When using (D)TLSv1.3 and early data feature is compiled in, this function progresses the handshake only up to the point when it is possible to send data. Next invocations of wolfSSL_Connect()/wolfSSL_Accept()/wolfSSL_read() will complete the handshake. wolfSSL_write() works with both blocking and non_blocking I/O. When the underlying I/O is non_blocking, wolfSSL_write() will return when the underlying I/O could not satisfy the needs of wolfSSL_write() to continue. In this case, a call to wolfSSL_get_error() will yield either SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE. The calling process must then repeat the call to wolfSSL_write() when the underlying I/O is ready. If the underlying I/O is blocking, wolfSSL_write() will only return once the buffer data of size sz has been completely written or an error occurred.
int	**wolfSSL_write_ex**(WOLFSSL * ssl, const void * data, size_t sz, size_t * wr)This function writes sz bytes from the buffer, data, to the SSL connection, ssl, and reports the number of bytes written. It is equivalent to wolfSSL_write() except that the length written is returned through wr and the return value only indicates success or failure. Whether a partial write counts as success depends on WOLFSSL_MODE_ENABLE_PARTIAL_WRITE having been set with wolfSSL_CTX_set_mode(); without it, anything short of the full length is a failure.

	Name
int	**wolfSSL_read**(WOLFSSL * ssl, void * data, int sz)This function reads sz bytes from the SSL session (ssl) internal read buffer into the buffer data. The bytes read are removed from the internal receive buffer. If necessary wolfSSL_read() will negotiate an SSL/TLS session if the handshake has not already been performed yet by wolfSSL_connect() or wolfSSL_accept(). The SSL/TLS protocol uses SSL records which have a maximum size of 16kB (the max record size can be controlled by the MAX_RECORD_SIZE define in /wolfssl/internal.h). As such, wolfSSL needs to read an entire SSL record internally before it is able to process and decrypt the record. Because of this, a call to wolfSSL_read() will only be able to return the maximum buffer size which has been decrypted at the time of calling. There may be additional not_yet_decrypted data waiting in the internal wolfSSL receive buffer which will be retrieved and decrypted with the next call to wolfSSL_read(). If sz is larger than the number of bytes in the internal read buffer, SSL_read() will return the bytes available in the internal read buffer. If no bytes are buffered in the internal read buffer yet, a call to wolfSSL_read() will trigger processing of the next record.
int	**wolfSSL_read_ex**(WOLFSSL * ssl, void * data, size_t sz, size_t * rd)This function reads up to sz bytes of decrypted application data from the SSL connection, ssl, into the buffer, data, and reports the number of bytes read. It is equivalent to wolfSSL_read() except that the length read is returned through rd and the return value only indicates whether any application data was read.

	Name
int	**wolfSSL_peek**(WOLFSSL * ssl, void * data, int sz)This function copies sz bytes from the SSL session (ssl) internal read buffer into the buffer data. This function is identical to wolfSSL_read() except that the data in the internal SSL session receive buffer is not removed or modified. If necessary, like wolfSSL_read(), wolfSSL_peek() will negotiate an SSL/TLS session if the handshake has not already been performed yet by wolfSSL_connect() or wolfSSL_accept(). The SSL/TLS protocol uses SSL records which have a maximum size of 16kB (the max record size can be controlled by the MAX_RECORD_SIZE define in /wolfssl/internal.h). As such, wolfSSL needs to read an entire SSL record internally before it is able to process and decrypt the record. Because of this, a call to wolfSSL_peek() will only be able to return the maximum buffer size which has been decrypted at the time of calling. There may be additional not_yet_decrypted data waiting in the internal wolfSSL receive buffer which will be retrieved and decrypted with the next call to wolfSSL_peek() / wolfSSL_read(). If sz is larger than the number of bytes in the internal read buffer, SSL_peek() will return the bytes available in the internal read buffer. If no bytes are buffered in the internal read buffer yet, a call to wolfSSL_peek() will trigger processing of the next record.
int	**wolfSSL_accept**(WOLFSSL * ssl)This function is called on the server side and waits for an SSL client to initiate the SSL/TLS handshake. When this function is called, the underlying communication channel has already been set up. wolfSSL_accept() works with both blocking and non_blocking I/O. When the underlying I/O is non_blocking, wolfSSL_accept() will return when the underlying I/O could not satisfy the needs of wolfSSL_accept to continue the handshake. In this case, a call to wolfSSL_get_error() will yield either SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE. The calling process must then repeat the call to wolfSSL_accept when data is available to read and wolfSSL will pick up where it left off. When using a non_blocking socket, nothing needs to be done, but select() can be used to check for the required condition. If the underlying I/O is blocking, wolfSSL_accept() will only return once the handshake has been finished or an error occurred.

	Name
int	**wolfDTLS_accept_stateless**(WOLFSSL * ssl)This function statelessly listens for an SSL client to initiate the DTLS handshake. Cookies must be enabled. A cookie_disabled DTLS object is rejected before I/O or callback changes: WOLFSSL_FATAL_ERROR is returned and wolfSSL_get_error() reports BAD_STATE_E. Use wolfSSL_accept() for cookie-disabled connections instead.
int	**wolfSSL_disable_cookie**(WOLFSSL * ssl)Disable server cookies for DTLS 1.2, DTLS 1.3 and TLS 1.3, including DTLS 1.2 fallback from DTLS 1.3. Cookies are enabled by default for DTLS. For DTLS, ordinary wolfSSL_accept() or wolfSSL_accept_TLSv13() commits it to stateful processing before the first read, even if a nonblocking accept has no input available. The application must isolate/demultiplex the peer before accepting; disabling cookies removes return_routability verification and exposes the server to DoS/amplification attacks. wolfDTLS_accept_stateless() cannot be used.
int	**wolfSSL_enable_cookie**(WOLFSSL * ssl)Enable server cookies for DTLS 1.2, DTLS 1.3 and TLS 1.3. Like wolfSSL_disable_cookie(), this does not change stateful processing. It can undo a disable before accept begins, including wolfSSL_disable_hrr_cookie(). Missing primary cookie secrets are randomly generated immediately; existing primary and secondary secrets are preserved.
void	**wolfSSL_CTX_free**(WOLFSSL_CTX * ctx)This function frees an allocated WOLFSSL_CTX object. This function decrements the CTX reference count and only frees the context when the reference count has reached 0.
void	**wolfSSL_free**(WOLFSSL * ssl)This function frees an allocated wolfSSL object.

COPYRIGHT ©2024 wolfSSL Inc.

	Name
int	**wolfSSL_shutdown**(WOLFSSL * ssl)This function shuts down an active SSL/TLS connection using the SSL session, ssl. This function will try to send a “close notify” alert to the peer. The calling application can choose to wait for the peer to send its “close notify” alert in response or just go ahead and shut down the underlying connection after directly calling wolfSSL_shutdown (to save resources). Either option is allowed by the TLS specification. If the underlying connection will be used again in the future, the complete two_directional shutdown procedure must be performed to keep synchronization intact between the peers. wolfSSL_shutdown() works with both blocking and non_blocking I/O. When the underlying I/O is non_blocking, wolfSSL_shutdown() will return an error if the underlying I/O could not satisfy the needs of wolfSSL_shutdown() to continue. In this case, a call to wolfSSL_get_error() will yield either SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE. The calling process must then repeat the call to wolfSSL_shutdown() when the underlying I/O is ready.
int	**wolfSSL_SendUserCanceled**(WOLFSSL * ssl)This function sends a user_canceled alert to the peer and then shuts the connection down by calling wolfSSL_shutdown(). It is used when the application abandons a connection for its own reasons rather than because of a protocol failure.

	Name
int	**wolfSSL_send**(WOLFSSL * ssl, const void * data, int sz, int flags)This function writes sz bytes from the buffer, data, to the SSL connection, ssl, using the specified flags for the underlying write operation. If necessary wolfSSL_send() will negotiate an SSL/TLS session if the handshake has not already been performed yet by wolfSSL_connect() or wolfSSL_accept(). wolfSSL_send() works with both blocking and non_blocking I/O. When the underlying I/O is non_blocking, wolfSSL_send() will return when the underlying I/O could not satisfy the needs of wolfSSL_send to continue. In this case, a call to wolfSSL_get_error() will yield either SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE. The calling process must then repeat the call to wolfSSL_send() when the underlying I/O is ready. If the underlying I/O is blocking, wolfSSL_send() will only return once the buffer data of size sz has been completely written or an error occurred.

COPYRIGHT ©2024 wolfSSL Inc.

	Name
int	**wolfSSL_recv**(WOLFSSL * ssl, void * data, int sz, int flags)This function reads sz bytes from the SSL session (ssl) internal read buffer into the buffer data using the specified flags for the underlying recv operation. The bytes read are removed from the internal receive buffer. This function is identical to wolfSSL_read() except that it allows the application to set the recv flags for the underlying read operation. If necessary wolfSSL_recv() will negotiate an SSL/TLS session if the handshake has not already been performed yet by wolfSSL_connect() or wolfSSL_accept(). The SSL/TLS protocol uses SSL records which have a maximum size of 16kB (the max record size can be controlled by the MAX_RECORD_SIZE define in /wolfssl/internal.h). As such, wolfSSL needs to read an entire SSL record internally before it is able to process and decrypt the record. Because of this, a call to wolfSSL_recv() will only be able to return the maximum buffer size which has been decrypted at the time of calling. There may be additional not_yet_decrypted data waiting in the internal wolfSSL receive buffer which will be retrieved and decrypted with the next call to wolfSSL_recv(). If sz is larger than the number of bytes in the internal read buffer, SSL_recv() will return the bytes available in the internal read buffer. If no bytes are buffered in the internal read buffer yet, a call to wolfSSL_recv() will trigger processing of the next record.
int	**wolfSSL_get_error**(WOLFSSL * ssl, int ret)This function returns a unique error code describing why the previous API function call (wolfSSL_connect, wolfSSL_accept, wolfSSL_read, wolfSSL_write, etc.) resulted in an error return code (SSL_FAILURE). The return value of the previous function is passed to wolfSSL_get_error through ret. After wolfSSL_get_error is called and returns the unique error code, wolfSSL_ERR_error_string() may be called to get a human_readable error string. See wolfSSL_ERR_error_string() for more information.
int	**wolfSSL_get_alert_history**(WOLFSSL * ssl, WOLFSSL_ALERT_HISTORY * h)This function gets the alert history.

	Name
int	**wolfSSL_set_session**(WOLFSSL * ssl, WOLFSSL_SESSION * session)This function sets the session to be used when the SSL object, ssl, is used to establish a SSL/TLS connection. For session resumption, before calling wolfSSL_shutdown() with your session object, an application should save the session ID from the object with a call to wolfSSL_get1_session(), which returns a pointer to the session. Later, the application should create a new WOLFSSL object and assign the saved session with wolfSSL_set_session(). At this point, the application may call wolfSSL_connect() and wolfSSL will try to resume the session. The wolfSSL server code allows session resumption by default. The object returned by wolfSSL_get1_session() needs to be freed after the application is done with it by calling wolfSSL_SESSION_free() on it.
WOLFSSL_SESSION *	**wolfSSL_get_session**(WOLFSSL * ssl)Returns a pointer to the current session (WOLFSSL_SESSION) used in ssl. This is a non_persistent pointer to the WOLFSSL_SESSION object, freed when wolfSSL_free is called, so the call should only be used to inspect or modify the current session. For session resumption use wolfSSL_get1_session(), which returns a reference the caller owns and releases with wolfSSL_SESSION_free().
void	**wolfSSL_flush_sessions**(WOLFSSL_CTX * ctx, long tm)This function flushes session from the session cache which have expired. The time, tm, is used for the time comparison. Note that wolfSSL currently uses a static table for sessions, so no flushing is needed. As such, this function is currently just a stub. This function provides OpenSSL compatibility (SSL_flush_sessions) when wolfSSL is compiled with the OpenSSL compatibility layer.
int	**wolfSSL_SetServerID**(WOLFSSL * ssl, const unsigned char * id, int len, int newSession)This function associates the client session with the server id. If the newSession flag is on, an existing session won't be reused.
int	**wolfSSL_GetSessionIndex**(WOLFSSL * ssl)This function gets the session index of the WOLFSSL structure.

	Name
int	**wolfSSL_GetSessionAtIndex**(int index, WOLFSSL_SESSION * session)This function gets the session at specified index of the session cache and copies it into memory. The WOLFSSL_SESSION structure holds the session information. The copy is independent of the cache entry: it does not share the ticket buffer, peer certificate or ex_data with the cache, and it stays valid after the cache entry is overwritten or evicted. The caller owns the copy and releases it with wolfSSL_SESSION_free().
WOLFSSL_X509_CHAIN *	**wolfSSL_SESSION_get_peer_chain**(WOLFSSL_SESSION * session)Returns the peer certificate chain from the WOLFSSL_SESSION struct.

	Name
void	**wolfSSL_CTX_set_verify**(WOLFSSL_CTX * ctx, int mode, VerifyCallback verify_callback)This function sets the verification method for remote peers and also allows a verify callback to be registered with the SSL context. The verify callback will be called only when a verification failure has occurred. If no verify callback is desired, the NULL pointer can be used for verify_callback. The verification mode of peer certificates is a logically OR'd list of flags. The possible flag values include: SSL_VERIFY_NONE Client mode: the client will not verify the certificate received from the server and the handshake will continue as normal. Server mode: the server will not send a certificate request to the client. As such, client verification will not be enabled. SSL_VERIFY_PEER Client mode: the client will verify the certificate received from the server during the handshake. This is turned on by default in wolfSSL, therefore, using this option has no effect. Server mode: the server will send a certificate request to the client and verify the client certificate received. SSL_VERIFY_FAIL_IF_NO_PEER_CERT Client mode: no effect when used on the client side. Server mode: the verification will fail on the server side if the client fails to send a certificate when requested to do so (when using SSL_VERIFY_PEER on the SSL server). SSL_VERIFY_FAIL_EXCEPT_PSK Client mode: no effect when used on the client side. Server mode: the verification is the same as SSL_VERIFY_FAIL_IF_NO_PEER_CERT except in the case of a PSK connection. If a PSK connection is being made then the connection will go through without a peer cert. SSL_VERIFY_CLIENT_ONCE Accepted and ignored. It is present so that OpenSSL_derived code compiles unchanged; wolfSSL does not act on it, does not store it, and wolfSSL_get_verify_mode() / wolfSSL_CTX_get_verify_mode() will not report it back. Including it in mode has no effect on any of the other flags.

COPYRIGHT ©2024 wolfSSL Inc.

	Name
void	**wolfSSL_set_verify**(WOLFSSL * ssl, int mode, VerifyCallback verify_callback)This function sets the verification method for remote peers and also allows a verify callback to be registered with the SSL session. The verify callback will be called only when a verification failure has occurred. If no verify callback is desired, the NULL pointer can be used for verify_callback. The verification mode of peer certificates is a logically OR'd list of flags. The possible flag values include: SSL_VERIFY_NONE Client mode: the client will not verify the certificate received from the server and the handshake will continue as normal. Server mode: the server will not send a certificate request to the client. As such, client verification will not be enabled. SSL_VERIFY_PEER Client mode: the client will verify the certificate received from the server during the handshake. This is turned on by default in wolfSSL, therefore, using this option has no effect. Server mode: the server will send a certificate request to the client and verify the client certificate received. SSL_VERIFY_FAIL_IF_NO_PEER_CERT Client mode: no effect when used on the client side. Server mode: the verification will fail on the server side if the client fails to send a certificate when requested to do so (when using SSL_VERIFY_PEER on the SSL server). SSL_VERIFY_FAIL_EXCEPT_PSK Client mode: no effect when used on the client side. Server mode: the verification is the same as SSL_VERIFY_FAIL_IF_NO_PEER_CERT except in the case of a PSK connection. If a PSK connection is being made then the connection will go through without a peer cert. SSL_VERIFY_CLIENT_ONCE Accepted and ignored. It is present so that OpenSSL_derived code compiles unchanged; wolfSSL does not act on it, does not store it, and wolfSSL_get_verify_mode() / wolfSSL_CTX_get_verify_mode() will not report it back. Including it in mode has no effect on any of the other flags.
void	**wolfSSL_SetCertCbCtx**(WOLFSSL * ssl, void * ctx)This function stores user CTX object information for verify callback.
void	**wolfSSL_CTX_SetCertCbCtx**(WOLFSSL_CTX * ctx, void * userCtx)This function stores user CTX object information for verify callback.

	Name
int	**wolfSSL_CTX_SetChainVerifyCb**(WOLFSSL_CTX * ctx, ChainVerifyCb cb)Replaces wolfSSL's verification of the peer's certificate chain with an application callback, for every SSL/TLS object created from the context. When a callback is set, wolfSSL decodes the certificates from the Certificate message and hands them to the callback as raw DER, the peer's own certificate first. It builds no chain, verifies no signature and checks no date, revocation status, key usage or host name, and the verify callback set with wolfSSL_CTX_set_verify() is not called; the callback is consulted for any certificate the peer sends, even under WOLFSSL_VERIFY_NONE. A server only requests a client certificate under WOLFSSL_VERIFY_PEER and only requires one with WOLFSSL_VERIFY_FAIL_IF_NO_PEER_CERT, so a server that relies on the callback for client authentication must set both. Malformed DER, a certificate the parser refuses regardless of the verify mode such as one with a zero serial number, or one whose decoding stops part way such as one with an unsupported key algorithm, still fails the handshake before the callback is called. An unknown critical extension or a key usage inconsistent with the basic constraints is left for the callback to judge. The callback returns 0 to accept, CHAIN_VERIFY_WANT_E to suspend the handshake until the application re_enters wolfSSL_connect(), wolfSSL_accept(), wolfSSL_read() or wolfSSL_write() (a certificate received after the handshake is resumed by wolfSSL_read() only, and wolfSSL_write() fails with CHAIN_VERIFY_WANT_E until then), or any other value to reject with CHAIN_VERIFY_CB_E and a fatal bad_certificate alert; 0 is the only accepting value, so returning WOLFSSL_SUCCESS rejects. Because wolfSSL checks nothing itself, wolfSSL_get_verify_result() reports WOLFSSL_X509_V_OK once the callback accepts, recording its verdict rather than a verification wolfSSL performed. DTLS, raw public keys and verifying a stapled OCSP response are not supported with the callback: setting it on a context configured for one of them fails, and so does the handshake of a connection using one of them, with CHAIN_VERIFY_UNSUPPORTED_E. The stapling check covers the client, the side that verifies a stapled response; a server may still staple its own status. Requires WOLFSSL_CHAIN_VERIFY_CB (–enable_chain_verify_cb).

	Name
int	**wolfSSL_SetChainVerifyCb**(WOLFSSL * ssl, ChainVerifyCb cb)Sets the chain verification callback for one SSL/TLS object. It takes precedence over the callback set on the context with wolfSSL_CTX_SetChainVerifyCb(), which documents the callback's contract.
void	**wolfSSL_CTX_SetChainVerifyCtx**(WOLFSSL_CTX * ctx, void * userCtx)Sets the user context passed to the chain verification callback for every SSL/TLS object created from the context.
void	**wolfSSL_SetChainVerifyCtx**(WOLFSSL * ssl, void * ctx)Sets the user context passed to the chain verification callback for one SSL/TLS object. It takes precedence over the value set on the context with wolfSSL_CTX_SetChainVerifyCtx().
void *	**wolfSSL_GetChainVerifyCtx**(const WOLFSSL * ssl)Returns the user context the chain verification callback is called with for this SSL/TLS object: the value set with wolfSSL_SetChainVerifyCtx() when there is one, otherwise the context's.
int	**wolfSSL_pending**(WOLFSSL * ssl)This function returns the number of bytes which are buffered and available in the SSL object to be read by wolfSSL_read().
void	**wolfSSL_load_error_strings**(void)This function is for OpenSSL compatibility (SSL_load_error_string) only and takes no action.
int	**wolfSSL_library_init**(void)This function is called internally in wolfSSL_CTX_new(). This function is a wrapper around wolfSSL_Init() and exists for OpenSSL compatibility (SSL_library_init) when wolfSSL has been compiled with OpenSSL compatibility layer. wolfSSL_Init() is the more typically-used wolfSSL initialization function.
int	**wolfSSL_SetDevId**(WOLFSSL * ssl, int devId)This function sets the Device Id at the WOLFSSL session level.
int	**wolfSSL_CTX_SetDevId**(WOLFSSL_CTX * ctx, int devId)This function sets the Device Id at the WOLFSSL_CTX context level.
int	**wolfSSL_CTX_GetDevId**(WOLFSSL_CTX * ctx, WOLFSSL * ssl)This function retrieves the Device Id.

	Name
long	**wolfSSL_CTX_set_session_cache_mode**(WOLFSSL_CTX * ctx, long mode)This function enables or disables SSL session caching. Behavior depends on the value used for mode. The following values for mode are available: SSL_SESS_CACHE_OFF- disable session caching. Session caching is turned on by default. SSL_SESS_CACHE_NO_AUTO_CLEAR - Disable auto-flushing of the session cache. Auto-flushing is turned on by default.
void	**wolfSSL_CTX_sess_set_get_cb**(WOLFSSL_CTX * ctx, WOLFSSL_SESSION *()*(WOLFSSL *ssl, const unsigned char* , int, int *) f)This function registers the callback wolfSSL uses to look a session up in an application managed (external) session cache. It is called on the server side when a peer offers a session id to resume, before the internal cache is consulted. Compatibility layer equivalent of SSL_CTX_sess_set_get_cb().
int	**wolfSSL_set_session_secret_cb**(WOLFSSL * ssl, SessionSecretCb cb, void * ctx)This function sets the session secret callback function. The SessionSecretCb type has the signature: int (*SessionSecretCb)(WOLFSSL* ssl, void* secret, int* secretSz, void* ctx). The sessionSecretCb member of the WOLFSSL struct is set to the parameter cb.
int	**wolfSSL_save_session_cache**(const char * fname)This function persists the session cache to file. It doesn't use memsave because of additional memory use.
int	**wolfSSL_restore_session_cache**(const char * fname)This function restores the persistent session cache from file. It does not use memstore because of additional memory use.
int	**wolfSSL_memsave_session_cache**(void * mem, int sz)This function persists session cache to memory.
int	**wolfSSL_memrestore_session_cache**(const void * mem, int sz)This function restores the persistent session cache from memory.
int	**wolfSSL_get_session_cache_memsize**(void)This function returns how large the session cache save buffer should be.
int	**wolfSSL_CTX_save_cert_cache**(WOLFSSL_CTX * ctx, const char * fname)This function writes the cert cache from memory to file.
int	**wolfSSL_CTX_restore_cert_cache**(WOLFSSL_CTX * ctx, const char * fname)This function persistes certificate cache from a file.

	Name
int	**wolfSSL_CTX_memsave_cert_cache**(WOLFSSL_CTX * ctx, void * mem, int sz, int * used)This function persists the certificate cache to memory.
int	**wolfSSL_CTX_memrestore_cert_cache**(WOLFSSL_CTX * ctx, const void * mem, int sz)This function restores the certificate cache from memory.
int	**wolfSSL_CTX_get_cert_cache_memsize**(WOLFSSL_CTX * ctx)Returns the size the certificate cache save buffer needs to be.
int	**wolfSSL_CTX_set_cipher_list**(WOLFSSL_CTX * ctx, const char * list)This function sets the cipher suite list for a given WOLFSSL_CTX. The list becomes the default cipher suite list for any new WOLFSSL sessions created from the context, and the order in the string is the local preference order from highest to lowest. Each call replaces the previous list. The list is a null-terminated, colon-delimited text string of suite names and/or OpenSSL-style group keywords, for example “TLS13-AES128-GCM-SHA256:ECDHE-RSA-AES128-GCM-SHA256:DHE-RSA-AES256-SHA256”.
int	**wolfSSL_set_cipher_list**(WOLFSSL * ssl, const char * list)This function sets the cipher suite list for a given WOLFSSL session. The list format and the set of recognized suite names and keywords are identical to those documented for wolfSSL_CTX_set_cipher_list(); refer to that function for the full keyword/suite tables and required build options. Each call replaces the previous list on the session.
void	**wolfSSL_dtls_set_using_nonblock**(WOLFSSL * ssl, int nonblock)This function informs the WOLFSSL DTLS object that the underlying UDP I/O is non_blocking. After an application creates a WOLFSSL object, if it will be used with a non_blocking UDP socket, call wolfSSL_dtls_set_using_nonblock() on it. This lets the WOLFSSL object know that receiving EWOULDBLOCK means that the recvfrom call would block rather than that it timed out.

	Name
int	**wolfSSL_dtls_get_using_nonblock**(WOLFSSL * ssl)This function allows the application to determine if wolfSSL is using non_blocking I/O with UDP. If wolfSSL is using non_blocking I/O, this function will return 1, otherwise 0. After an application creates a WOLFSSL object, if it will be used with a non_blocking UDP socket, call wolfSSL_dtls_set_using_nonblock() on it. This lets the WOLFSSL object know that receiving EWOULDBLOCK means that the recvfrom call would block rather than that it timed out. This function is only meaningful to DTLS sessions.
int	**wolfSSL_dtls_get_current_timeout**(WOLFSSL * ssl)This function returns the current timeout value in seconds for the WOLFSSL object. When using non-blocking sockets, something in the user code needs to decide when to check for available recv data and how long it has been waiting. The value returned by this function indicates how long the application should wait.
int	**wolfSSL_dtls13_use_quick_timeout**(WOLFSSL * ssl)This function returns true if the application should setup a quicker timeout. When using non_blocking sockets, something in the user code needs to decide when to check for available data and how long it needs to wait. If this function returns true, it means that the library already detected some disruption in the communication, but it wants to wait for a little longer in case some messages from the other peers are still in flight. Is up to the application to fine tune the value of this timer, a good one may be dtls_get_current_timeout() / 4.
void	**wolfSSL_dtls13_set_send_more_acks**(WOLFSSL * ssl, int value)This function sets whether the library should send ACKs to the other peer immediately when detecting disruption or not. Sending ACKs immediately assures minimum latency but it may consume more bandwidth than necessary. If the application manages the timer by itself and this option is set to 0 then application code can use wolfSSL_dtls13_use_quick_timeout() to determine if it should setup a quicker timeout to send those delayed ACKs.
int	**wolfSSL_dtls_set_timeout_init**(WOLFSSL * ssl, int timeout)This function sets the dtls timeout.
int	**wolfSSL_dtls_set_timeout_max**(WOLFSSL * ssl, int timeout)This function sets the maximum dtls timeout.

COPYRIGHT ©2024 wolfSSL Inc.

	Name
int	**wolfSSL_dtls_got_timeout**(WOLFSSL * ssl)When using non-blocking sockets with DTLS, this function should be called on the WOLFSSL object when the controlling code thinks the transmission has timed out. It performs the actions needed to retry the last transmit, including adjusting the timeout value. If it has been too long, this will return a failure.
int	**wolfSSL_dtls_retransmit**(WOLFSSL * ssl)When using non-blocking sockets with DTLS, this function retransmits the last handshake flight ignoring the expected timeout value and retransmit count. It is useful for applications that are using DTLS and need to manage even the timeout and retry count.
int	**wolfSSL_dtls13_do_scheduled_work**(WOLFSSL * ssl)Sends the DTLS 1.3 work that was scheduled while reading. With WOLFSSL_RW_THREADED the read path never transmits, because that would race the write thread over the output buffer and the sending key schedule, so ACKs, retransmissions and a KeyUpdate the peer asked for are only sent from the write side. An application that reads without writing must call this, from the same thread it uses for writing, or those messages are never sent and the peer keeps retransmitting what it is waiting to have acknowledged. Not for write_dup applications, which drain through wolfSSL_write().
int	**wolfSSL_dtls13_pending_work**(WOLFSSL * ssl)Reports whether the object has DTLS 1.3 work waiting to be sent by wolfSSL_dtls13_do_scheduled_work(). Only meaningful with WOLFSSL_RW_THREADED. The answer is advisory and can change as soon as it is returned. Only work the pump can actually carry out is reported, so a drain loop over the pair terminates; waiting for the peer to acknowledge a key update we sent is not reported, as there is nothing to send for it. A record the pump could only write in part is reported, so that the retry it owes is not lost.
int	**wolfSSL_dtls**(WOLFSSL * ssl)This function is used to determine if the SSL session has been configured to use DTLS.
int	**wolfSSL_dtls_set_peer**(WOLFSSL * ssl, void * peer, unsigned int peerSz)This function sets the DTLS peer, peer (sockaddr_in) with size of peerSz.

	Name
int	**wolfSSL_dtls_set_pending_peer**(WOLFSSL * ssl, void * peer, unsigned int peerSz)This function sets the pending DTLS peer, peer (sockaddr_in) with size of peerSz. This sets the pending peer that will be upgraded to a regular peer when we successfully de-protect the next record. This is useful in scenarios where the peer's address can change to avoid off-path attackers from changing the peer address. This should be used with Connection ID's to allow seamless and safe transition to a new peer address.
int	**wolfSSL_dtls_get_peer**(WOLFSSL * ssl, void * peer, unsigned int * peerSz)This function gets the sockaddr_in (of size peerSz) of the current DTLS peer. The function will compare peerSz to the actual DTLS peer size stored in the SSL session. If the peer will fit into peer, the peer's sockaddr_in will be copied into peer, with peerSz set to the size of peer.
int	**wolfSSL_dtls_get0_peer**(WOLFSSL * ssl, const void ** peer, unsigned int * peerSz)This function gets the sockaddr_in (of size peerSz) of the current DTLS peer. This is a zero_copy alternative to wolfSSL_dtls_get_peer().
char *	**wolfSSL_ERR_error_string**(unsigned long errNumber, char * data)This function converts an error code returned by wolfSSL_get_error() into a more human_readable error string. errNumber is the error code returned by wolfSSL_get_error() and data is the storage buffer which the error string will be placed in. The maximum length of data is 80 characters by default, as defined by MAX_ERROR_SZ is wolfssl/wolfcrypt/error.h.
void	**wolfSSL_ERR_error_string_n**(unsigned long e, char * buf, unsigned long len)This function is a version of wolfSSL_ERR_error_string() where len specifies the maximum number of characters that may be written to buf. Like wolfSSL_ERR_error_string(), this function converts an error code returned from wolfSSL_get_error() into a more human-readable error string. The human-readable string is placed in buf.
int	**wolfSSL_get_shutdown**(const WOLFSSL * ssl)This function checks the shutdown conditions in closeNotify or connReset or sentNotify members of the Options structure. The Options structure is within the WOLFSSL structure.

	Name
int	**wolfSSL_session_reused**(WOLFSSL * ssl)This function returns the resuming member of the options struct. The flag indicates whether or not to reuse a session. If not, a new session must be established.
int	**wolfSSL_is_init_finished**(const WOLFSSL * ssl)This function checks to see if the connection is established.
const char *	**wolfSSL_get_version**(WOLFSSL * ssl)Returns the SSL version being used as a string.
int	**wolfSSL_get_current_cipher_suite**(WOLFSSL * ssl)Returns the current cipher suit an ssl session is using.
WOLFSSL_CIPHER *	**wolfSSL_get_current_cipher**(WOLFSSL * ssl)This function returns a pointer to the current cipher in the ssl session. The cipher is filled in from the session on each call, so call it again after the session changes, e.g. after the handshake.
const char *	**wolfSSL_CIPHER_get_name**(const WOLFSSL_CIPHER * cipher)This function matches the cipher suite in the SSL object with the available suites and returns the string representation.
const char *	**wolfSSL_get_cipher**(WOLFSSL *)This function matches the cipher suite in the SSL object with the available suites.
WOLFSSL_SESSION *	**wolfSSL_get1_session**(WOLFSSL * ssl)This function returns the WOLFSSL_SESSION from the WOLFSSL structure as a reference type. This requires calling wolfSSL_SESSION_free to release the session reference. The WOLFSSL_SESSION pointed to contains all the necessary information required to perform a session resumption and reestablish the connection without a new handshake. For session resumption, before calling wolfSSL_shutdown() with your session object, an application should save the session ID from the object with a call to wolfSSL_get1_session(), which returns a pointer to the session. Later, the application should create a new WOLFSSL object and assign the saved session with wolfSSL_set_session(). At this point, the application may call wolfSSL_connect() and wolfSSL will try to resume the session. The wolfSSL server code allows session resumption by default. The object returned by wolfSSL_get1_session() needs to be freed after the application is done with it by calling wolfSSL_SESSION_free() on it.

	Name
WOLFSSL_METHOD *	**wolfSSLv23_client_method**(void)The wolfSSLv23_client_method() function is used to indicate that the application is a client and will support the highest protocol version supported by the server between SSL 3.0 _ TLS 1.3. This function allocates memory for and initializes a new WOLFSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new(). Both wolfSSL clients and servers have robust version downgrade capability. If a specific protocol version method is used on either side, then only that version will be negotiated or an error will be returned. For example, a client that uses TLSv1 and tries to connect to a SSLv3 only server will fail, likewise connecting to a TLSv1.1 will fail as well. To resolve this issue, a client that uses the wolfSSLv23_client_method() function will use the highest protocol version supported by the server and downgrade to SSLv3 if needed. In this case, the client will be able to connect to a server running SSLv3 - TLSv1.3.
int	**wolfSSL_BIO_get_mem_data**(WOLFSSL_BIO * bio, void * p)This is used to set a byte pointer to the start of the internal memory buffer.
void	**wolfSSL_BIO_set_init**(WOLFSSL_BIO * bio, int init)This is used to set the init flag of a BIO, indicating whether the BIO has been initialised and is ready for use. Typically called from a custom BIO create callback.
int	**wolfSSL_BIO_get_init**(WOLFSSL_BIO * bio)This is used to retrieve the init flag of a BIO, indicating whether the BIO has been initialised and is ready for use.
long	**wolfSSL_BIO_set_fd**(WOLFSSL_BIO * b, int fd, int flag)Sets the file descriptor for bio to use.
int	**wolfSSL_BIO_set_close**(WOLFSSL_BIO * b, long flag)Sets the close flag, used to indicate that the i/o stream should be closed when the BIO is freed.
WOLFSSL_BIO_METHOD *	**wolfSSL_BIO_s_socket**(void)This is used to get a BIO_SOCKET type WOLFSSL_BIO_METHOD.
int	**wolfSSL_BIO_set_write_buf_size**(WOLFSSL_BIO * b, long size)This is used to set the size of write buffer for a WOLFSSL_BIO. If write buffer has been previously set this function will free it when resetting the size. It is similar to wolfSSL_BIO_reset in that it resets read and write indexes to 0.

	Name
int	**wolfSSL_BIO_make_bio_pair**(WOLFSSL_BIO * b1, WOLFSSL_BIO * b2)This is used to pair two bios together. A pair of bios acts similar to a two way pipe writing to one can be read by the other and vice versa. It is expected that both bios be in the same thread, this function is not thread safe. Freeing one of the two bios removes both from being paired. If a write buffer size was not previously set for either of the bios it is set to a default size of 17000 (WOLFSSL_BIO_SIZE) before being paired.
int	**wolfSSL_BIO_ctrl_reset_read_request**(WOLFSSL_BIO * b)This is used to set the read request flag back to 0.
int	**wolfSSL_BIO_nread0**(WOLFSSL_BIO * bio, char ** buf)This is used to get a buffer pointer for reading from. Unlike wolfSSL_BIO_nread the internal read index is not advanced by the number returned from the function call. Reading past the value returned can result in reading out of array bounds.
int	**wolfSSL_BIO_nread**(WOLFSSL_BIO * bio, char ** buf, int num)This is used to get a buffer pointer for reading from. The internal read index is advanced by the number returned from the function call with buf being pointed to the beginning of the buffer to read from. In the case that less bytes are in the read buffer than the value requested with num the lesser value is returned. Reading past the value returned can result in reading out of array bounds.
int	**wolfSSL_BIO_nwrite**(WOLFSSL_BIO * bio, char ** buf, int num)Gets a pointer to the buffer for writing as many bytes as returned by the function. Writing more bytes to the pointer returned then the value returned can result in writing out of bounds.
int	**wolfSSL_BIO_reset**(WOLFSSL_BIO * bio)Resets bio to an initial state. As an example for type BIO_BIO this resets the read and write index.
int	**wolfSSL_BIO_seek**(WOLFSSL_BIO * bio, int ofs)This function adjusts the file pointer to the offset given. This is the offset from the head of the file.
int	**wolfSSL_BIO_write_filename**(WOLFSSL_BIO * bio, char * name)This is used to set and write to a file. WIll overwrite any data currently in the file and is set to close the file when the bio is freed.

	Name
long	**wolfSSL_BIO_set_mem_eof_return**(WOLFSSL_BIO * bio, int v)This is used to set the end of file value. Common value is -1 so as not to get confused with expected positive values.
long	**wolfSSL_BIO_get_mem_ptr**(WOLFSSL_BIO * bio, WOLFSSL_BUF_MEM ** m)This is a getter function for WOLFSSL_BIO memory pointer.
char *	**wolfSSL_X509_NAME_oneline**(WOLFSSL_X509_NAME * name, char * in, int sz)This function copies the name of the x509 into a buffer.
WOLFSSL_X509_NAME *	**wolfSSL_X509_get_issuer_name**(WOLFSSL_X509 * cert)This function returns the name of the certificate issuer.
WOLFSSL_X509_NAME *	**wolfSSL_X509_get_subject_name**(WOLFSSL_X509 * cert)This function returns the subject member of the WOLFSSL_X509 structure.
int	**wolfSSL_X509_get_isCA**(WOLFSSL_X509 * x509)Checks the isCa member of the WOLFSSL_X509 structure and returns the value.
int	**wolfSSL_X509_NAME_get_text_by_NID**(const WOLFSSL_X509_NAME * name, int nid, char * buf, int len)This function gets the text related to the passed in NID value.
int	**wolfSSL_X509_get_signature_type**(WOLFSSL_X509 * x509)This function returns the value stored in the sigOID member of the WOLFSSL_X509 structure.
void	**wolfSSL_X509_free**(WOLFSSL_X509 * x509)This function frees a WOLFSSL_X509 structure.
int	**wolfSSL_X509_get_signature**(WOLFSSL_X509 * x509, unsigned char * buf, int * bufSz)Gets the X509 signature and stores it in the buffer.
int	**wolfSSL_X509_STORE_add_cert**(WOLFSSL_X509_STORE * store, WOLFSSL_X509 * x509)This function adds a certificate to the WOLFSSL_X509_STRE structure.
WOLFSSL_STACK *	**wolfSSL_X509_STORE_CTX_get_chain**(WOLFSSL_X509_STORE_CT * ctx)This function is a getter function for chain variable in WOLFSSL_X509_STORE_CTX structure. Currently chain is not populated.
int	**wolfSSL_X509_STORE_set_flags**(WOLFSSL_X509_STORE * store, unsigned long flag)This function takes in a flag to change the behavior of the WOLFSSL_X509_STORE structure passed in. An example of a flag used is WOLFSSL_CRL_CHECK. X509_V_FLAG_CRL_CHECK and X509_V_FLAG_CRL_CHECK_ALL enable CRL checking like WOLFSSL_CRL_CHECK and WOLFSSL_CRL_CHECKALL.
const byte *	**wolfSSL_X509_notBefore**(WOLFSSL_X509 * x509)This function the certificate “not before” validity encoded as a byte array.

	Name
const byte *	**wolfSSL_X509_notAfter**(WOLFSSL_X509 * x509)This function the certificate “not after” validity encoded as a byte array.
WOLFSSL_BIGNUM *	**wolfSSL_ASN1_INTEGER_to_BN**(const WOLFSSL_ASN1_INTEGER * ai, WOLFSSL_BIGNUM * bn)This function is used to copy a WOLFSSL_ASN1_INTEGER value to a WOLFSSL_BIGNUM structure.
long	**wolfSSL_CTX_add_extra_chain_cert**(WOLFSSL_CTX * ctx, WOLFSSL_X509 * x509)This function adds the certificate to the internal chain being built in the WOLFSSL_CTX structure.
int	**wolfSSL_CTX_get_read_ahead**(WOLFSSL_CTX * ctx)This function returns the get read ahead flag from a WOLFSSL_CTX structure.
int	**wolfSSL_CTX_set_read_ahead**(WOLFSSL_CTX * ctx, int v)This function sets the read ahead flag in the WOLFSSL_CTX structure. When enabled, the record_header read pulls in up to a full TLS record in a single recv(), so the body (and any following buffered records) is obtained without a second syscall. The flag only changes I/O behaviour when the library is built with read_ahead support (–enable_readahead / WOLFSSL_TLS_READ_AHEAD); otherwise it is stored but inert.
int	**wolfSSL_CTX_set_default_read_buffer_len**(WOLFSSL_CTX * ctx, size_t len)This function sets the read_ahead receive window size for contexts created from this WOLFSSL_CTX. When read_ahead is enabled (wolfSSL_CTX_set_read_ahead()), a single recv() pulls in up to len bytes:
int	**wolfSSL_set_default_read_buffer_len**(WOLFSSL * ssl, size_t len)This function sets the read_ahead coalescing buffer size on a single WOLFSSL session, overriding the value inherited from its WOLFSSL_CTX. See wolfSSL_CTX_set_default_read_buffer_len() for the full description, the one-record default, and the memory-vs-syscall trade-off.
long	**wolfSSL_CTX_get_default_read_buffer_len**(WOLFSSL_CTX * ctx)This function returns the read_ahead coalescing buffer size configured on a WOLFSSL_CTX by wolfSSL_CTX_set_default_read_buffer_len(). Because a length of 0 and oversized values are normalised when set, the value reported is the effective window actually in use (the one_record default rather than 0 when the length was never changed), not the raw argument last passed.

	Name
long	**wolfSSL_get_default_read_buffer_len**(const WOLFSSL * ssl)This function returns the read_ahead coalescing buffer size in effect for a single WOLFSSL session, whether inherited from its WOLFSSL_CTX or overridden by wolfSSL_set_default_read_buffer_len(). As with the WOLFSSL_CTX getter, the value reported is the effective window in use, not the raw argument last passed.
int	**wolfSSL_CTX_set_max_send_fragment**(WOLFSSL_CTX * ctx, long max_fragment)This function caps the plaintext carried in each record sent by WOLFSSL objects created from the context afterwards. It is the wolfSSL equivalent of OpenSSL's SSL_CTX_set_max_send_fragment(). The cap is local and send only: the peer is not told and records received are not limited. Unset, there is no cap. wolfSSL_new() copies the value, so a later call does not change existing objects, as in OpenSSL. With a negotiated max_fragment_length the smaller of the two limits applies, where OpenSSL uses the negotiated length instead. A DTLS write larger than the cap fails with DTLS_SIZE_ERROR, like one larger than the MTU, unless WOLFSSL_NO_DTLS_SIZE_CHECK is defined. In TLS 1.3 only Certificate and CertificateVerify are split to the cap. Other handshake messages, such as ClientHello, ServerHello, EncryptedExtensions, CertificateRequest and NewSessionTicket, are sent in one record each, as they are with a negotiated max_fragment_length. Application data is always split.
int	**wolfSSL_set_max_send_fragment**(WOLFSSL * ssl, long max_fragment)This function caps the plaintext carried in each record sent by a single WOLFSSL object, replacing the value copied from its WOLFSSL_CTX. It is the wolfSSL equivalent of OpenSSL's SSL_set_max_send_fragment() and takes effect from the next record sent. See wolfSSL_CTX_set_max_send_fragment() for the full description.
long	**wolfSSL_CTX_set_tlsext_status_arg**(WOLFSSL_CTX * ctx, void * arg)This function sets the argument to be passed to the OCSP status callback.
void	**wolfSSL_CTX_set_client_cert_cb**(WOLFSSL_CTX * ctx, client_cert_cb cb)Sets a callback to select the client certificate and private key.

	Name
void	**wolfSSL_CTX_set_cert_cb**(WOLFSSL_CTX * ctx, CertSetupCallback cb, void * arg)Sets a generic certificate setup callback.
int	**wolfSSL_CTX_set_tlsext_status_cb**(WOLFSSL_CTX * ctx, tlsextStatusCb cb)Sets the callback to be used for handling OCSP status requests (OCSP stapling).
int	**wolfSSL_CTX_get_tlsext_status_cb**(WOLFSSL_CTX * ctx, tlsextStatusCb * cb)Gets the currently set OCSP status callback for the context.
long	**wolfSSL_get_tlsext_status_ocsp_resp**(WOLFSSL * ssl, unsigned char ** resp)Gets the OCSP response that will be sent (stapled) to the peer.
long	**wolfSSL_set_tlsext_status_ocsp_resp**(WOLFSSL * ssl, unsigned char * resp, int len)Sets the OCSP response to be sent (stapled) to the peer.
int	**wolfSSL_set_tlsext_status_ocsp_resp_multi**(WOLFSSL * ssl, unsigned char * resp, int len, word32 idx)Sets multiple OCSP responses for TLS multi-certificate chains.
void	**wolfSSL_CTX_set_ocsp_status_verify_cb**(WOLFSSL_CTX * ctx, ocspVerifyStatusCb cb, void * cbArg)Sets a callback to verify the OCSP status response.
long	**wolfSSL_CTX_set_tlsext_opaque_prf_input_callback_arg**(WOLF * ctx, void * arg)This function sets the optional argument to be passed to the PRF callback.
long	**wolfSSL_CTX_set_options**(WOLFSSL_CTX * ctx, long opt)This function ORs the bits in opt into the options mask of the given WOLFSSL_CTX. The options mask is inherited by every WOLFSSL session later created from this context. Bits are accumulated — to remove an option, use wolfSSL_CTX_clear_options(). The OpenSSL-style "SSL_OP_" *macros are aliases for the corresponding "WOLFSSL_OP_"* values; either spelling may be used.
long	**wolfSSL_set_options**(WOLFSSL * s, long op)This function ORs the bits in op into the options mask of the given WOLFSSL session. The set of recognized "SSL_OP_" / *"WOLFSSL_OP_"* flags is identical to that documented for wolfSSL_CTX_set_options(); refer to that function for the full options table and the build-option requirements of individual flags. Flags inherited from the parent WOLFSSL_CTX remain set; setting SSL_OP_NO_TLSv1_3 here lowers the session's negotiated minor version to TLS 1.2.
long	**wolfSSL_get_options**(const WOLFSSL * s)This function returns the current options mask.

	Name
long	**wolfSSL_set_tlsext_debug_arg**(WOLFSSL * s, void * arg)This is used to set the debug argument passed around.
long	**wolfSSL_set_tlsext_debug_callback**(WOLFSSL * s, WOLFSSL_TLSEXT_DEBUG_CB cb)This is used to set the TLS extension debug callback on the object.
long	**wolfSSL_set_tlsext_status_type**(WOLFSSL * s, int type)This function is called when the client application request that a server send back an OCSP status response (also known as OCSP stapling).Currently, the only supported type is TLSEXT_STATUSTYPE_ocsp.
long	**wolfSSL_get_verify_result**(const WOLFSSL * ssl)This is used to get the results after trying to verify the peer's certificate.
void	**wolfSSL_ERR_print_errors_fp**(XFILE fp, int err)This function converts an error code returned by wolfSSL_get_error() into a more human_readable error string and prints that string to the output file _ fp. err is the error code returned by wolfSSL_get_error() and fp is the file which the error string will be placed in.
void	**wolfSSL_ERR_print_errors_cb**(int*)(const char* str, size_t len, void *u) cb, void* u)This function uses the provided callback to handle error reporting. The callback function is executed for each error line. The string, length, and userdata are passed into the callback parameters.
void	**wolfSSL_CTX_set_psk_client_callback**(WOLFSSL_CTX * ctx, wc_psk_client_callback cb)The function sets the client_psk_cb member of the WOLFSSL_CTX structure.
void	**wolfSSL_set_psk_client_callback**(WOLFSSL * ssl, wc_psk_client_callback cb)Sets the PSK client side callback.
const char *	**wolfSSL_get_psk_identity_hint**(const WOLFSSL *)This function returns the psk identity hint.
const char *	**wolfSSL_get_psk_identity**(const WOLFSSL *)The function returns a constant pointer to the client_identity member of the Arrays structure.
int	**wolfSSL_CTX_use_psk_identity_hint**(WOLFSSL_CTX * ctx, const char * hint)This function stores the hint argument in the server_hint member of the WOLFSSL_CTX structure.
int	**wolfSSL_use_psk_identity_hint**(WOLFSSL * ssl, const char * hint)This function stores the hint argument in the server_hint member of the Arrays structure within the WOLFSSL structure.

	Name
void	**wolfSSL_CTX_set_psk_server_callback**(WOLFSSL_CTX * ctx, wc_psk_server_callback cb)This function sets the psk callback for the server side in the WOLFSSL_CTX structure.
void	**wolfSSL_set_psk_server_callback**(WOLFSSL * ssl, wc_psk_server_callback cb)Sets the psk callback for the server side by setting the WOLFSSL structure options members.
int	**wolfSSL_set_psk_callback_ctx**(WOLFSSL * ssl, void * psk_ctx)Sets a PSK user context in the WOLFSSL structure options member.
int	**wolfSSL_CTX_set_psk_callback_ctx**(WOLFSSL_CTX * ctx, void * psk_ctx)Sets a PSK user context in the WOLFSSL_CTX structure.
void *	**wolfSSL_get_psk_callback_ctx**(WOLFSSL * ssl)Get a PSK user context in the WOLFSSL structure options member.
void *	**wolfSSL_CTX_get_psk_callback_ctx**(WOLFSSL_CTX * ctx)Get a PSK user context in the WOLFSSL_CTX structure.
int	**wolfSSL_CTX_allow_anon_cipher**(WOLFSSL_CTX * ctx)This function enables the havAnon member of the CTX structure if HAVE_ANON is defined during compilation.
WOLFSSL_METHOD *	**wolfSSLv23_server_method**(void)The wolfSSLv23_server_method() function is used to indicate that the application is a server and will support clients connecting with protocol version from SSL 3.0 _ TLS 1.3. This function allocates memory for and initializes a new WOLFSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().
int	**wolfSSL_state**(WOLFSSL * ssl)This is used to get the internal error state of the WOLFSSL structure.
WOLFSSL_X509 *	**wolfSSL_get_peer_certificate**(WOLFSSL * ssl)This function gets the peer's certificate.
int	**wolfSSL_want_read**(WOLFSSL * ssl)This function is similar to calling wolfSSL_get_error() and getting SSL_ERROR_WANT_READ in return. If the underlying error state is SSL_ERROR_WANT_READ, this function will return 1, otherwise, 0.
int	**wolfSSL_want_write**(WOLFSSL * ssl)This function is similar to calling wolfSSL_get_error() and getting SSL_ERROR_WANT_WRITE in return. If the underlying error state is SSL_ERROR_WANT_WRITE, this function will return 1, otherwise, 0.

	Name
int	**wolfSSL_want**(WOLFSSL * ssl)This function reports which I/O operation, if any, the SSL session is waiting on. It reflects the same state that wolfSSL_want_read() and wolfSSL_want_write() report individually. Unlike those two, which are always available, this function is only built when OPENSSL_EXTRA is defined.
int	**wolfSSL_check_domain_name**(WOLFSSL * ssl, const char * dn)wolfSSL by default checks the peer certificate for a valid date range and a verified signature. Calling this function before wolfSSL_connect() or wolfSSL_accept() will add a domain name check to the list of checks to perform. dn holds the domain name to check against the peer certificate when it's received.
int	**wolfSSL_check_ip_address**(WOLFSSL * ssl, const char * ipaddr)Calling this function before wolfSSL_connect() or wolfSSL_accept() adds an IP-address identity check against the peer certificate SAN iPAddress entries.
int	**wolfSSL_Init**(void)Initializes the wolfSSL library for use. Must be called once per application and before any other call to the library.
int	**wolfSSL_Cleanup**(void)Un-initializes the wolfSSL library from further use. Doesn't have to be called, though it will free any resources used by the library.
const char *	**wolfSSL_lib_version**(void)This function returns the current library version.
word32	**wolfSSL_lib_version_hex**(void)This function returns the current library version in hexadecimal notation.
int	**wolfSSL_negotiate**(WOLFSSL * ssl)Performs the actual connect or accept based on the side of the SSL method. If called from the client side then an wolfSSL_connect() is done while a wolfSSL_accept() is performed if called from the server side.

COPYRIGHT ©2024 wolfSSL Inc.

	Name
int	**wolfSSL_set_compression**(WOLFSSL * ssl)Turns on the ability to use compression for the SSL connection. Both sides must have compression turned on otherwise compression will not be used. The zlib library performs the actual data compression. To compile into the library use –with-libz for the configure system and define HAVE_LIBZ otherwise. Keep in mind that while compressing data before sending decreases the actual size of the messages being sent and received, the amount of data saved by compression usually takes longer in time to analyze than it does to send it raw on all but the slowest of networks.
int	**wolfSSL_set_timeout**(WOLFSSL * ssl, unsigned int to)This function sets the SSL session timeout value in seconds.
int	**wolfSSL_CTX_set_timeout**(WOLFSSL_CTX * ctx, unsigned int to)This function sets the timeout value for SSL sessions, in seconds, for the specified SSL context.
WOLFSSL_X509_CHAIN *	**wolfSSL_get_peer_chain**(WOLFSSL * ssl)Retrieves the peer's certificate chain.
int	**wolfSSL_get_chain_count**(WOLFSSL_X509_CHAIN * chain)Retrieve's the peers certificate chain count.
int	**wolfSSL_get_chain_length**(WOLFSSL_X509_CHAIN * chain, int idx)Retrieves the peer's ASN1.DER certificate length in bytes at index (idx).
unsigned char *	**wolfSSL_get_chain_cert**(WOLFSSL_X509_CHAIN * chain, int idx)Retrieves the peer's ASN1.DER certificate at index (idx).
WOLFSSL_X509 *	**wolfSSL_get_chain_X509**(WOLFSSL_X509_CHAIN * chain, int idx)This function gets the peer's wolfSSL_X509_certificate at index (idx) from the chain of certificates.
int	**wolfSSL_get_chain_cert_pem**(WOLFSSL_X509_CHAIN * chain, int idx, unsigned char * buf, int inLen, int * outLen)Retrieves the peer's PEM certificate at index (idx).
const unsigned char *	**wolfSSL_get_sessionID**(const WOLFSSL_SESSION * s)Retrieves the session's ID. The session ID is always 32 bytes long.
int	**wolfSSL_X509_get_serial_number**(WOLFSSL_X509 * x509, unsigned char * in, int * inOutSz)Retrieves the peer's certificate serial number. The serial number buffer (in) should be at least 32 bytes long and be provided as the *inOutSz argument as input. After calling the function* inOutSz will hold the actual length in bytes written to the in buffer.

	Name
char *	**wolfSSL_X509_get_subjectCN**(WOLFSSL_X509 *)Returns the common name of the subject from the certificate.
const unsigned char *	**wolfSSL_X509_get_der**(WOLFSSL_X509 * x509, int * outSz)This function gets the DER encoded certificate in the WOLFSSL_X509 struct.
WOLFSSL_ASN1_TIME *	**wolfSSL_X509_get_notAfter**(WOLFSSL_X509 *)This function checks to see if x509 is NULL and if it's not, it returns the notAfter member of the x509 struct.
int	**wolfSSL_X509_version**(WOLFSSL_X509 * x509)This function retrieves the version of the X509 certificate.
WOLFSSL_X509 *	**wolfSSL_X509_d2i_fp**(WOLFSSL_X509 ** x509, FILE * file)If NO_STDIO_FILESYSTEM is defined this function will allocate heap memory, initialize a WOLFSSL_X509 structure and return a pointer to it.
WOLFSSL_X509 *	**wolfSSL_X509_load_certificate_file**(const char * fname, int format)The function loads the x509 certificate into memory.
unsigned char *	**wolfSSL_X509_get_device_type**(WOLFSSL_X509 * x509, unsigned char * in, int * inOutSz)This function copies the device type from the x509 structure to the buffer.
unsigned char *	**wolfSSL_X509_get_hw_type**(WOLFSSL_X509 * x509, unsigned char * in, int * inOutSz)The function copies the hwType member of the WOLFSSL_X509 structure to the buffer.
unsigned char *	**wolfSSL_X509_get_hw_serial_number**(WOLFSSL_X509 * x509, unsigned char * in, int * inOutSz)This function returns the hwSerialNum member of the x509 object.

COPYRIGHT ©2024 wolfSSL Inc.

	Name
int	**wolfSSL_connect_cert**(WOLFSSL * ssl)This function is called on the client side and initiates an SSL/TLS handshake with a server only long enough to get the peer's certificate chain. When this function is called, the underlying communication channel has already been set up. wolfSSL_connect_cert() works with both blocking and non_blocking I/O. When the underlying I/O is non_blocking, wolfSSL_connect_cert() will return when the underlying I/O could not satisfy the needs of wolfSSL_connect_cert() to continue the handshake. In this case, a call to wolfSSL_get_error() will yield either SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE. The calling process must then repeat the call to wolfSSL_connect_cert() when the underlying I/O is ready and wolfSSL will pick up where it left off. When using a non_blocking socket, nothing needs to be done, but select() can be used to check for the required condition. If the underlying I/O is blocking, wolfSSL_connect_cert() will only return once the peer's certificate chain has been received.
WC_PKCS12 *	**wolfSSL_d2i_PKCS12_bio**(WOLFSSL_BIO * bio, WC_PKCS12 ** pkcs12)wolfSSL_d2i_PKCS12_bio (d2i_PKCS12_bio) copies in the PKCS12 information from WOLFSSL_BIO to the structure WC_PKCS12. The information is divided up in the structure as a list of Content Infos along with a structure to hold optional MAC information. After the information has been divided into chunks (but not decrypted) in the structure WC_PKCS12, it can then be parsed and decrypted by calling.
WC_PKCS12 *	**wolfSSL_i2d_PKCS12_bio**(WOLFSSL_BIO * bio, WC_PKCS12 * pkcs12)wolfSSL_i2d_PKCS12_bio (i2d_PKCS12_bio) copies in the cert information from the structure WC_PKCS12 to WOLFSSL_BIO.

	Name
int	**wolfSSL_PKCS12_parse**(WC_PKCS12 * pkcs12, const char * psw, WOLFSSL_EVP_PKEY ** pkey, WOLFSSL_X509 ** cert, WOLF_STACK_OF(WOLFSSL_X509) ** ca)PKCS12 can be enabled with adding –enable_opensslextra to the configure command. It can use triple DES and RC4 for decryption so would recommend also enabling these features when enabling opensslextra (–enable_des3 –enable_arc4). wolfSSL does not currently support RC2 so decryption with RC2 is currently not available. This may be noticeable with default encryption schemes used by OpenSSL command line to create .p12 files. wolfSSL_PKCS12_parse (PKCS12_parse). The first thing this function does is check the MAC is correct if present. If the MAC fails then the function returns and does not try to decrypt any of the stored Content Infos. This function then parses through each Content Info looking for a bag type, if the bag type is known it is decrypted as needed and either stored in the list of certificates being built or as a key found. After parsing through all bags the key found is then compared with the certificate list until a matching pair is found. This matching pair is then returned as the key and certificate, optionally the certificate list found is returned as a STACK_OF certificates. At the moment a CRL, Secret or SafeContents bag will be skipped over and not parsed. It can be seen if these or other “Unknown” bags are skipped over by viewing the debug print out. Additional attributes such as friendly name are skipped over when parsing a PKCS12 file.
int	**wolfSSL_SetTmpDH**(WOLFSSL * ssl, const unsigned char * p, int pSz, const unsigned char * g, int gSz)Server Diffie-Hellman Ephemeral parameters setting. This function sets up the group parameters to be used if the server negotiates a cipher suite that uses DHE.
int	**wolfSSL_SetTmpDH_buffer**(WOLFSSL * ssl, const unsigned char * b, long sz, int format)The function calls the wolfSSL_SetTMpDH_buffer_wrapper, which is a wrapper for Diffie-Hellman parameters.
int	**wolfSSL_SetTmpDH_file**(WOLFSSL * ssl, const char * f, int format)This function calls wolfSSL_SetTmpDH_file_wrapper to set server Diffie-Hellman parameters.

	Name
int	**wolfSSL_CTX_SetTmpDH**(WOLFSSL_CTX * ctx, const unsigned char * p, int pSz, const unsigned char * g, int gSz)Sets the parameters for the server CTX Diffie-Hellman.
int	**wolfSSL_CTX_SetTmpDH_buffer**(WOLFSSL_CTX * ctx, const unsigned char * b, long sz, int format)A wrapper function that calls wolfSSL_SetTmpDH_buffer_wrapper.
int	**wolfSSL_CTX_SetTmpDH_file**(WOLFSSL_CTX * ctx, const char * f, int format)The function calls wolfSSL_SetTmpDH_file_wrapper to set the server Diffie-Hellman parameters.
int	**wolfSSL_CTX_SetMinDhKey_Sz**(WOLFSSL_CTX * ctx, word16 keySz_bits)This function sets the minimum size (in bits) of the Diffie Hellman key size by accessing the minDhKeySz member in the WOLFSSL_CTX structure.
int	**wolfSSL_SetMinDhKey_Sz**(WOLFSSL * ssl, word16 keySz_bits)Sets the minimum size (in bits) for a Diffie-Hellman key in the WOLFSSL structure.
int	**wolfSSL_CTX_SetMaxDhKey_Sz**(WOLFSSL_CTX * ctx, word16 keySz_bits)This function sets the maximum size (in bits) of the Diffie Hellman key size by accessing the maxDhKeySz member in the WOLFSSL_CTX structure.
int	**wolfSSL_SetMaxDhKey_Sz**(WOLFSSL * ssl, word16 keySz_bits)Sets the maximum size (in bits) for a Diffie-Hellman key in the WOLFSSL structure.
int	**wolfSSL_GetDhKey_Sz**(WOLFSSL * ssl)Returns the value of dhKeySz (in bits) that is a member of the options structure. This value represents the Diffie-Hellman key size in bytes.
int	**wolfSSL_CTX_SetMinRsaKey_Sz**(WOLFSSL_CTX * ctx, short keySz)Sets the minimum RSA key size in both the WOLFSSL_CTX structure and the WOLFSSL_CERT_MANAGER structure.
int	**wolfSSL_SetMinRsaKey_Sz**(WOLFSSL * ssl, short keySz)Sets the minimum allowable key size in bits for RSA located in the WOLFSSL structure.
int	**wolfSSL_CTX_SetMinEccKey_Sz**(WOLFSSL_CTX * ctx, short keySz)Sets the minimum size in bits for the ECC key in the WOLF_CTX structure and the WOLFSSL_CERT_MANAGER structure.
int	**wolfSSL_SetMinEccKey_Sz**(WOLFSSL * ssl, short keySz)Sets the value of the minEccKeySz member of the options structure. The options struct is a member of the WOLFSSL structure and is accessed through the ssl parameter.

	Name
int	**wolfSSL_make_eap_keys**(WOLFSSL * ssl, void * key, unsigned int len, const char * label)This function is used by EAP_TLS and EAP-TTLS to derive keying material from the master secret.
int	**wolfSSL_writev**(WOLFSSL * ssl, const struct iovec * iov, int iovcnt)Simulates writev semantics but doesn't actually do block at a time because of SSL_write() behavior and because front adds may be small. Makes porting into software that uses writev easier.
int	**wolfSSL_CTX_UnloadCAs**(WOLFSSL_CTX * ctx)This function unloads the CA signer list and frees the whole signer table.
int	**wolfSSL_CTX_UnloadIntermediateCerts**(WOLFSSL_CTX * ctx)This function unloads intermediate certificates added to the CA signer list and frees them.
int	**wolfSSL_CTX_Unload_trust_peers**(WOLFSSL_CTX * ctx)This function is used to unload all previously loaded trusted peer certificates. Feature is enabled by defining the macro WOLFSSL_TRUST_PEER_CERT.
int	**wolfSSL_CTX_trust_peer_buffer**(WOLFSSL_CTX * ctx, const unsigned char * in, long sz, int format)This function loads a certificate to use for verifying a peer when performing a TLS/SSL handshake. The peer certificate sent during the handshake is compared by using the SKID when available and the signature. If these two things do not match then any loaded CAs are used. Is the same functionality as wolfSSL_CTX_trust_peer_cert except is from a buffer instead of a file. Feature is enabled by defining the macro WOLFSSL_TRUST_PEER_CERT Please see the examples for proper usage.
int	**wolfSSL_CTX_load_verify_buffer**(WOLFSSL_CTX * ctx, const unsigned char * in, long sz, int format)This function loads a CA certificate buffer into the WOLFSSL Context. It behaves like the non-buffered version, only differing in its ability to be called with a buffer as input instead of a file. The buffer is provided by the in argument of size sz. format specifies the format type of the buffer; SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM. More than one CA certificate may be loaded per buffer as long as the format is in PEM. Please see the examples for proper usage.

	Name
int	**wolfSSL_CTX_load_verify_buffer_ex**(WOLFSSL_CTX * ctx, const unsigned char * in, long sz, int format, int userChain, word32 flags)This function loads a CA certificate buffer into the WOLFSSL Context. It behaves like the non-buffered version, only differing in its ability to be called with a buffer as input instead of a file. The buffer is provided by the in argument of size sz. format specifies the format type of the buffer; SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM. More than one CA certificate may be loaded per buffer as long as the format is in PEM. The _ex version was added in PR 2413 and supports additional arguments for userChain and flags.
int	**wolfSSL_CTX_load_verify_chain_buffer_format**(WOLFSSL_CTX * ctx, const unsigned char * in, long sz, int format)This function loads a CA certificate chain buffer into the WOLFSSL Context. It behaves like the non-buffered version, only differing in its ability to be called with a buffer as input instead of a file. The buffer is provided by the in argument of size sz. format specifies the format type of the buffer; SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM. More than one CA certificate may be loaded per buffer as long as the format is in PEM. Please see the examples for proper usage.
int	**wolfSSL_CTX_use_certificate_buffer**(WOLFSSL_CTX * ctx, const unsigned char * in, long sz, int format)This function loads a certificate buffer into the WOLFSSL Context. It behaves like the non-buffered version, only differing in its ability to be called with a buffer as input instead of a file. The buffer is provided by the in argument of size sz. format specifies the format type of the buffer; SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM. Please see the examples for proper usage.
int	**wolfSSL_CTX_use_PrivateKey_buffer**(WOLFSSL_CTX * ctx, const unsigned char * in, long sz, int format)This function loads a private key buffer into the SSL Context. It behaves like the non-buffered version, only differing in its ability to be called with a buffer as input instead of a file. The buffer is provided by the in argument of size sz. format specifies the format type of the buffer; SSL_FILETYPE_ASN1or SSL_FILETYPE_PEM. Please see the examples for proper usage.

	Name
int	**wolfSSL_CTX_use_certificate_chain_buffer**(WOLFSSL_CTX * ctx, const unsigned char * in, long sz)This function loads a certificate chain buffer into the WOLFSSL Context. It behaves like the non-buffered version, only differing in its ability to be called with a buffer as input instead of a file. The buffer is provided by the in argument of size sz. The buffer must be in PEM format and start with the subject's certificate, ending with the root certificate. Please see the examples for proper usage.
int	**wolfSSL_use_certificate_buffer**(WOLFSSL * ssl, const unsigned char * in, long sz, int format)This function loads a certificate buffer into the WOLFSSL object. It behaves like the non-buffered version, only differing in its ability to be called with a buffer as input instead of a file. The buffer is provided by the in argument of size sz. format specifies the format type of the buffer; SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM. Please see the examples for proper usage.
int	**wolfSSL_use_PrivateKey_buffer**(WOLFSSL * ssl, const unsigned char * in, long sz, int format)This function loads a private key buffer into the WOLFSSL object. It behaves like the non-buffered version, only differing in its ability to be called with a buffer as input instead of a file. The buffer is provided by the in argument of size sz. format specifies the format type of the buffer; SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM. Please see the examples for proper usage.
int	**wolfSSL_use_certificate_chain_buffer**(WOLFSSL * ssl, const unsigned char * in, long sz)This function loads a certificate chain buffer into the WOLFSSL object. It behaves like the non-buffered version, only differing in its ability to be called with a buffer as input instead of a file. The buffer is provided by the in argument of size sz. The buffer must be in PEM format and start with the subject's certificate, ending with the root certificate. Please see the examples for proper usage.
int	**wolfSSL_UnloadCertsKeys**(WOLFSSL * ssl)This function unloads any certificates or keys that SSL owns.
int	**wolfSSL_CTX_set_group_messages**(WOLFSSL_CTX * ctx)This function turns on grouping of handshake messages where possible.

	Name
int	**wolfSSL_set_group_messages**(WOLFSSL * ssl)This function turns on grouping of handshake messages where possible.
void	**wolfSSL_SetFuzzerCb**(WOLFSSL * ssl, CallbackFuzzer cbf, void * fCtx)This function sets the fuzzer callback.
int	**wolfSSL_DTLS_SetCookieSecret**(WOLFSSL * ssl, const byte * secret, word32 secretSz)This function sets a new dtls cookie secret.
int	**wolfSSL_DTLS_SetCookieSecretSecondary**(WOLFSSL * ssl, const byte * secret, word32 secretSz)This function sets a secondary DTLS 1.2 cookie secret used only when verifying a received HelloVerifyRequest cookie, and only if the primary secret (set with wolfSSL_DTLS_SetCookieSecret()) fails to verify it. This lets an application rotate the cookie secret on a stateless server without rejecting clients whose cookie was issued under the previous secret: install the new secret as the primary and the previous secret here for an overlap window. The secondary secret is never used to issue cookies. It is the DTLS 1.2 counterpart of wolfSSL_set_hrr_cookie_secret_secondary().
WC_RNG *	**wolfSSL_GetRNG**(WOLFSSL * ssl)This function retrieves the random number.
int	**wolfSSL_CTX_SetMinVersion**(WOLFSSL_CTX * ctx, int version)This function sets the minimum downgrade version allowed. Applicable only when the connection allows downgrade using (wolfSSLv23_client_method or wolfSSLv23_server_method).
int	**wolfSSL_SetMinVersion**(WOLFSSL * ssl, int version)This function sets the minimum downgrade version allowed. Applicable only when the connection allows downgrade using (wolfSSLv23_client_method or wolfSSLv23_server_method).
int	**wolfSSL_GetObjectSize**(void)This function returns the size of the WOLFSSL object and will be dependent on build options and settings. If SHOW_SIZES has been defined when building wolfSSL, this function will also print the sizes of individual objects within the WOLFSSL object (Suites, Ciphers, etc.) to stdout.

COPYRIGHT ©2024 wolfSSL Inc.

	Name
int	**wolfSSL_GetOutputSize**(WOLFSSL * ssl, int inSz)Returns the record layer size of the plaintext input. This is helpful when an application wants to know how many bytes will be sent across the Transport layer, given a specified plaintext input size. This function must be called after the SSL/TLS handshake has been completed.
int	**wolfSSL_GetMaxOutputSize**(WOLFSSL * ssl)Returns the maximum record layer size for plaintext data. This will correspond to either the maximum SSL/TLS record size as specified by the protocol standard, the maximum TLS fragment size as set by the TLS Max Fragment Length extension. This function is helpful when the application has called wolfSSL_GetOutputSize() and received a INPUT_SIZE_E error. This function must be called after the SSL/TLS handshake has been completed.
int	**wolfSSL_SetVersion**(WOLFSSL * ssl, int version)This function sets the SSL/TLS protocol version for the specified SSL session (WOLFSSL object) using the version as specified by version. This will override the protocol setting for the SSL session (ssl) _ originally defined and set by the SSL context (wolfSSL_CTX_new()) method type.
void	**wolfSSL_CTX_SetMacEncryptCb**(WOLFSSL_CTX * ctx, CallbackMacEncrypt cb)Allows caller to set the Atomic User Record Processing Mac/Encrypt Callback. The callback should return 0 for success or < 0 for an error. The ssl and ctx pointers are available for the user's convenience. macOut is the output buffer where the result of the mac should be stored. macIn is the mac input buffer and macInSz notes the size of the buffer. macContent and macVerify are needed for wolfSSL_SetTlsHmacInner() and be passed along as is. encOut is the output buffer where the result on the encryption should be stored. encIn is the input buffer to encrypt while encSz is the size of the input. An example callback can be found wolfssl/test.h myMacEncryptCb().
void	**wolfSSL_SetMacEncryptCtx**(WOLFSSL * ssl, void * ctx)Allows caller to set the Atomic User Record Processing Mac/Encrypt Callback Context to ctx.

	Name
void *	**wolfSSL_GetMacEncryptCtx**(WOLFSSL * ssl)Allows caller to retrieve the Atomic User Record Processing Mac/Encrypt Callback Context previously stored with wolfSSL_SetMacEncryptCtx().
void	**wolfSSL_CTX_SetDecryptVerifyCb**(WOLFSSL_CTX * ctx, CallbackDecryptVerify cb)Allows caller to set the Atomic User Record Processing Decrypt/Verify Callback. The callback should return 0 for success or < 0 for an error. The ssl and ctx pointers are available for the user's convenience. decOut is the output buffer where the result of the decryption should be stored. decIn is the encrypted input buffer and decInSz notes the size of the buffer. content and verify are needed for wolfSSL_SetTlsHmacInner() and be passed along as is. padSz is an output variable that should be set with the total value of the padding. That is, the mac size plus any padding and pad bytes. An example callback can be found wolfssl/test.h myDecryptVerifyCb().
void	**wolfSSL_SetDecryptVerifyCtx**(WOLFSSL * ssl, void * ctx)Allows caller to set the Atomic User Record Processing Decrypt/Verify Callback Context to ctx.
void *	**wolfSSL_GetDecryptVerifyCtx**(WOLFSSL * ssl)Allows caller to retrieve the Atomic User Record Processing Decrypt/Verify Callback Context previously stored with wolfSSL_SetDecryptVerifyCtx().
const unsigned char *	**wolfSSL_GetMacSecret**(WOLFSSL * ssl, int verify)Allows retrieval of the Hmac/Mac secret from the handshake process. The verify parameter specifies whether this is for verification of a peer message.
const unsigned char *	**wolfSSL_GetClientWriteKey**(WOLFSSL *)Allows retrieval of the client write key from the handshake process.
const unsigned char *	**wolfSSL_GetClientWriteIV**(WOLFSSL *)Allows retrieval of the client write IV (initialization vector) from the handshake process.
const unsigned char *	**wolfSSL_GetServerWriteKey**(WOLFSSL *)Allows retrieval of the server write key from the handshake process.
const unsigned char *	**wolfSSL_GetServerWriteIV**(WOLFSSL *)Allows retrieval of the server write IV (initialization vector) from the handshake process.
int	**wolfSSL_GetKeySize**(WOLFSSL * ssl)Allows retrieval of the key size from the handshake process.

	Name
int	**wolfSSL_GetIVSize**(WOLFSSL * ssl)Returns the iv_size member of the specs structure held in the WOLFSSL struct.
int	**wolfSSL_GetSide**(WOLFSSL * ssl)Allows retrieval of the side of this WOLFSSL connection.
int	**wolfSSL_IsTLSv1_1**(WOLFSSL * ssl)Allows caller to determine if the negotiated protocol version is at least TLS version 1.1 or greater.
int	**wolfSSL_GetBulkCipher**(WOLFSSL * ssl)Allows caller to determine the negotiated bulk cipher algorithm from the handshake.
int	**wolfSSL_GetCipherBlockSize**(WOLFSSL * ssl)Allows caller to determine the negotiated cipher block size from the handshake.
int	**wolfSSL_GetAeadMacSize**(WOLFSSL * ssl)Allows caller to determine the negotiated aead mac size from the handshake. For cipher type WOLFSSL_AEAD_TYPE.
int	**wolfSSL_GetHmacSize**(WOLFSSL * ssl)Allows caller to determine the negotiated (h)mac size from the handshake. For cipher types except WOLFSSL_AEAD_TYPE.
int	**wolfSSL_GetHmacType**(WOLFSSL * ssl)Allows caller to determine the negotiated (h)mac type from the handshake. For cipher types except WOLFSSL_AEAD_TYPE.
int	**wolfSSL_GetCipherType**(WOLFSSL * ssl)Allows caller to determine the negotiated cipher type from the handshake.
int	**wolfSSL_SetTlsHmacInner**(WOLFSSL * ssl, byte * inner, word32 sz, int content, int verify)Allows caller to set the Hmac Inner vector for message sending/receiving. The result is written to inner which should be at least wolfSSL_GetHmacSize() bytes. The size of the message is specified by sz, content is the type of message, and verify specifies whether this is a verification of a peer message. Valid for cipher types excluding WOLFSSL_AEAD_TYPE.

	Name
void	**wolfSSL_CTX_SetEccSignCb**(WOLFSSL_CTX * ctx, CallbackEccSign cb)Allows caller to set the Public Key Callback for ECC Signing. The callback should return 0 for success or < 0 for an error. The ssl and ctx pointers are available for the user's convenience. in is the input buffer to sign while inSz denotes the length of the input. out is the output buffer where the result of the signature should be stored. outSz is an input/output variable that specifies the size of the output buffer upon invocation and the actual size of the signature should be stored there before returning. keyDer is the ECC Private key in ASN1 format and keySz is the length of the key in bytes. An example callback can be found wolfssl/test.h myEccSign().
void	**wolfSSL_SetEccSignCtx**(WOLFSSL * ssl, void * ctx)Allows caller to set the Public Key Ecc Signing Callback Context to ctx.
void *	**wolfSSL_GetEccSignCtx**(WOLFSSL * ssl)Allows caller to retrieve the Public Key Ecc Signing Callback Context previously stored with wolfSSL_SetEccSignCtx().
void	**wolfSSL_CTX_SetEccSignCtx**(WOLFSSL_CTX * ctx, void * userCtx)Allows caller to set the Public Key Ecc Signing Callback Context to ctx.
void *	**wolfSSL_CTX_GetEccSignCtx**(WOLFSSL_CTX * ctx)Allows caller to retrieve the Public Key Ecc Signing Callback Context previously stored with wolfSSL_SetEccSignCtx().
void	**wolfSSL_CTX_SetEccVerifyCb**(WOLFSSL_CTX * ctx, CallbackEccVerify cb)Allows caller to set the Public Key Callback for ECC Verification. The callback should return 0 for success or < 0 for an error. The ssl and ctx pointers are available for the user's convenience. sig is the signature to verify and sigSz denotes the length of the signature. hash is an input buffer containing the digest of the message and hashSz denotes the length in bytes of the hash. result is an output variable where the result of the verification should be stored, 1 for success and 0 for failure. keyDer is the ECC Private key in ASN1 format and keySz is the length of the key in bytes. keyDer is NULL with keySz 0 when only the callback holds the key, so the callback must then supply it. An example callback can be found wolfssl/test.h myEccVerify().
void	**wolfSSL_SetEccVerifyCtx**(WOLFSSL * ssl, void * ctx)Allows caller to set the Public Key Ecc Verification Callback Context to ctx.

	Name
void *	**wolfSSL_GetEccVerifyCtx**(WOLFSSL * ssl)Allows caller to retrieve the Public Key Ecc Verification Callback Context previously stored with wolfSSL_SetEccVerifyCtx().
void	**wolfSSL_CTX_SetRsaSignCb**(WOLFSSL_CTX * ctx, CallbackRsaSign cb)Allows caller to set the Public Key Callback for RSA Signing. The callback should return 0 for success or < 0 for an error. The ssl and ctx pointers are available for the user's convenience. in is the input buffer to sign while inSz denotes the length of the input. out is the output buffer where the result of the signature should be stored. outSz is an input/output variable that specifies the size of the output buffer upon invocation and the actual size of the signature should be stored there before returning. keyDer is the RSA Private key in ASN1 format and keySz is the length of the key in bytes. An example callback can be found wolfssl/test.h myRsaSign().
void	**wolfSSL_SetRsaSignCtx**(WOLFSSL * ssl, void * ctx)Allows caller to set the Public Key RSA Signing Callback Context to ctx.
void *	**wolfSSL_GetRsaSignCtx**(WOLFSSL * ssl)Allows caller to retrieve the Public Key RSA Signing Callback Context previously stored with wolfSSL_SetRsaSignCtx().
void	**wolfSSL_CTX_SetRsaVerifyCb**(WOLFSSL_CTX * ctx, CallbackRsaVerify cb)Allows caller to set the Public Key Callback for RSA Verification. The callback should return the number of plaintext bytes for success or < 0 for an error. The ssl and ctx pointers are available for the user's convenience. sig is the signature to verify and sigSz denotes the length of the signature. out should be set to the beginning of the verification buffer after the decryption process and any padding. keyDer is the RSA Public key in ASN1 format and keySz is the length of the key in bytes. An example callback can be found wolfssl/test.h myRsaVerify().
void	**wolfSSL_SetRsaVerifyCtx**(WOLFSSL * ssl, void * ctx)Allows caller to set the Public Key RSA Verification Callback Context to ctx.
void *	**wolfSSL_GetRsaVerifyCtx**(WOLFSSL * ssl)Allows caller to retrieve the Public Key RSA Verification Callback Context previously stored with wolfSSL_SetRsaVerifyCtx().

	Name
void	**wolfSSL_CTX_SetRsaEncCb**(WOLFSSL_CTX * ctx, CallbackRsaEnc cb)Allows caller to set the Public Key Callback for RSA Public Encrypt. The callback should return 0 for success or < 0 for an error. The ssl and ctx pointers are available for the user's convenience. in is the input buffer to encrypt while inSz denotes the length of the input. out is the output buffer where the result of the encryption should be stored. outSz is an input/output variable that specifies the size of the output buffer upon invocation and the actual size of the encryption should be stored there before returning. keyDer is the RSA Public key in ASN1 format and keySz is the length of the key in bytes. An example callback can be found wolfssl/test.h myRsaEnc().
void	**wolfSSL_SetRsaEncCtx**(WOLFSSL * ssl, void * ctx)Allows caller to set the Public Key RSA Public Encrypt Callback Context to ctx.
void *	**wolfSSL_GetRsaEncCtx**(WOLFSSL * ssl)Allows caller to retrieve the Public Key RSA Public Encrypt Callback Context previously stored with wolfSSL_SetRsaEncCtx().
void	**wolfSSL_CTX_SetRsaDecCb**(WOLFSSL_CTX * ctx, CallbackRsaDec cb)Allows caller to set the Public Key Callback for RSA Private Decrypt. The callback should return the number of plaintext bytes for success or < 0 for an error. The ssl and ctx pointers are available for the user's convenience. in is the input buffer to decrypt and inSz denotes the length of the input. out should be set to the beginning of the decryption buffer after the decryption process and any padding. keyDer is the RSA Private key in ASN1 format and keySz is the length of the key in bytes. An example callback can be found wolfssl/test.h myRsaDec().
void	**wolfSSL_SetRsaDecCtx**(WOLFSSL * ssl, void * ctx)Allows caller to set the Public Key RSA Private Decrypt Callback Context to ctx.
void *	**wolfSSL_GetRsaDecCtx**(WOLFSSL * ssl)Allows caller to retrieve the Public Key RSA Private Decrypt Callback Context previously stored with wolfSSL_SetRsaDecCtx().
void	**wolfSSL_CTX_SetCACb**(WOLFSSL_CTX * ctx, CallbackCACache cb)This function registers a callback with the SSL context (WOLFSSL_CTX) to be called when a new CA certificate is loaded into wolfSSL. The callback is given a buffer with the DER-encoded certificate.

	Name
WOLFSSL_CERT_MANAGER *	**wolfSSL_CertManagerNew_ex**(void * heap)Allocates and initializes a new Certificate Manager context. This context may be used independent of SSL needs. It may be used to load certificates, verify certificates, and check the revocation status.
WOLFSSL_CERT_MANAGER *	**wolfSSL_CertManagerNew**(void)Allocates and initializes a new Certificate Manager context. This context may be used independent of SSL needs. It may be used to load certificates, verify certificates, and check the revocation status.
void	**wolfSSL_CertManagerFree**(WOLFSSL_CERT_MANAGER * cm)Frees all resources associated with the Certificate Manager context. Call this when you no longer need to use the Certificate Manager.
int	**wolfSSL_CertManagerLoadCA**(WOLFSSL_CERT_MANAGER * cm, const char * f, const char * d)Specifies the locations for CA certificate loading into the manager context. The PEM certificate CAfile may contain several trusted CA certificates. If CApath is not NULL it specifies a directory containing CA certificates in PEM format.
int	**wolfSSL_CertManagerLoadCABuffer**(WOLFSSL_CERT_MANAGER * cm, const unsigned char * buff, long sz, int format)Loads the CA Buffer by calling wolfSSL_CTX_load_verify_buffer and returning that result using a temporary cm so as not to lose the information in the cm passed into the function.
int	**wolfSSL_CertManagerUnloadCAs**(WOLFSSL_CERT_MANAGER * cm)This function unloads the CA signer list.
int	**wolfSSL_CertManagerUnloadIntermediateCerts**(WOLFSSL_CE * cm)This function unloads intermediate certificates add to the CA signer list.
int	**wolfSSL_CertManagerUnload_trust_peers**(WOLFSSL_CERT_MA * cm)The function will free the Trusted Peer linked list and unlocks the trusted peer list.
int	**wolfSSL_CertManagerVerify**(WOLFSSL_CERT_MANAGER * cm, const char * f, int format)Specifies the certificate to verify with the Certificate Manager context. The format can be SSL_FILETYPE_PEM or SSL_FILETYPE_ASN1.
int	**wolfSSL_CertManagerVerifyBuffer**(WOLFSSL_CERT_MANAGER * cm, const unsigned char * buff, long sz, int format)Specifies the certificate buffer to verify with the Certificate Manager context. The format can be SSL_FILETYPE_PEM or SSL_FILETYPE_ASN1.

	Name
void	**wolfSSL_CertManagerSetVerify**(WOLFSSL_CERT_MANAGER * cm, VerifyCallback verify_callback)The function sets the verifyCallback function in the Certificate Manager. If present, it will be called for each cert loaded. If there is a verification error, the verify callback can be used to over-ride the error.
int	**wolfSSL_CertManagerCheckCRL**(WOLFSSL_CERT_MANAGER * cm, const unsigned char * der, int sz)Check CRL if the option is enabled and compares the cert to the CRL list.
int	**wolfSSL_CertManagerEnableCRL**(WOLFSSL_CERT_MANAGER * cm, int options)Turns on Certificate Revocation List checking when verifying certificates with the Certificate Manager. By default, CRL checking is off. options include WOLFSSL_CRL_CHECKALL which performs CRL checking on each certificate in the chain versus the Leaf certificate only which is the default.
int	**wolfSSL_CertManagerDisableCRL**(WOLFSSL_CERT_MANAGER * cm)Turns off Certificate Revocation List checking when verifying certificates with the Certificate Manager. By default, CRL checking is off. You can use this function to temporarily or permanently disable CRL checking with this Certificate Manager context that previously had CRL checking enabled.
int	**wolfSSL_CertManagerLoadCRL**(WOLFSSL_CERT_MANAGER * cm, const char * path, int type, int monitor)Error checks and passes through to LoadCRL() in order to load the cert into the CRL for revocation checking. An updated CRL can be loaded by first calling wolfSSL_CertManagerFreeCRL, then loading the new CRL.
int	**wolfSSL_CertManagerLoadCRLBuffer**(WOLFSSL_CERT_MANAGE * cm, const unsigned char * buff, long sz, int type)The function loads the CRL file by calling BufferLoadCRL.
int	**wolfSSL_CertManagerSetCRL_Cb**(WOLFSSL_CERT_MANAGER * cm, CbMissingCRL cb)This function sets the CRL Certificate Manager callback. If HAVE_CRL is defined and a matching CRL record is not found then the cbMissingCRL is called (set via wolfSSL_CertManagerSetCRL_Cb). This allows you to externally retrieve the CRL and load it.

	Name
int	**wolfSSL_CertManagerSetCRLUpdate_Cb**(WOLFSSL_CERT_MANA * cm, CbUpdateCRL cb)This function sets the CRL Update callback. If HAVE_CRL and HAVE_CRL_UPDATE_CB is defined , and an entry with the same issuer and a lower CRL number exists when a CRL is added, then the CbUpdateCRL is called with the details of the existing entry and the new one replacing it.
int	**wolfSSL_CertManagerGetCRLInfo**(WOLFSSL_CERT_MANAGER * cm, CrlInfo * info, const byte * buff, long sz, int type)This function yields a structure with parsed CRL information from an encoded CRL buffer.
int	**wolfSSL_CertManagerCheckOCSP**(WOLFSSL_CERT_MANAGER * cm, const unsigned char * der, int sz)The function enables the WOLFSSL_CERT_MANAGER's member, ocspEnabled to signify that the OCSP check option is enabled.
int	**wolfSSL_CertManagerEnableOCSP**(WOLFSSL_CERT_MANAGER * cm, int options)Turns on OCSP if it's turned off and if compiled with the set option available.
int	**wolfSSL_CertManagerDisableOCSP**(WOLFSSL_CERT_MANAGER * cm)Disables OCSP certificate revocation.
int	**wolfSSL_CertManagerSetOCSPOverrideURL**(WOLFSSL_CERT_M * cm, const char * url)The function copies the url to the ocspOverrideURL member of the WOLFSSL_CERT_MANAGER structure.
int	**wolfSSL_CertManagerSetOCSP_Cb**(WOLFSSL_CERT_MANAGER * cm, CbOCSPIO ioCb, CbOCSPRespFree respFreeCb, void * ioCbCtx)The function sets the OCSP callback in the WOLFSSL_CERT_MANAGER.
int	**wolfSSL_CertManagerEnableOCSPStapling**(WOLFSSL_CERT_MA * cm)This function turns on OCSP stapling if it is not turned on as well as set the options.
int	**wolfSSL_EnableCRL**(WOLFSSL * ssl, int options)Enables CRL certificate revocation.
int	**wolfSSL_DisableCRL**(WOLFSSL * ssl)Disables CRL certificate revocation.
int	**wolfSSL_LoadCRL**(WOLFSSL * ssl, const char * path, int type, int monitor)A wrapper function that ends up calling LoadCRL to load the certificate for revocation checking.
int	**wolfSSL_SetCRL_Cb**(WOLFSSL * ssl, CbMissingCRL cb)Sets the CRL callback in the WOLFSSL_CERT_MANAGER structure.

	Name
int	**wolfSSL_EnableOCSP**(WOLFSSL * ssl, int options)This function enables OCSP certificate verification. The value of options if formed by or'ing one or more of the following options: WOLFSSL_OCSP_URL_OVERRIDE _ use the override URL instead of the URL in certificates. The override URL is specified using the wolfSSL_CTX_SetOCSP_OverrideURL() function. WOLFSSL_OCSP_CHECKALL - Set all OCSP checks on WOLFSSL_OCSP_NO_NONCE - Set nonce option for creating OCSP requests.
int	**wolfSSL_DisableOCSP**(WOLFSSL * ssl)Disables the OCSP certificate revocation option.
int	**wolfSSL_SetOCSP_OverrideURL**(WOLFSSL * ssl, const char * url)This function sets the ocspOverrideURL member in the WOLFSSL_CERT_MANAGER structure.
int	**wolfSSL_SetOCSP_Cb**(WOLFSSL * ssl, CbOCSPIO ioCb, CbOCSPRespFree respFreeCb, void * ioCbCtx)This function sets the OCSP callback in the WOLFSSL_CERT_MANAGER structure.
int	**wolfSSL_CTX_EnableCRL**(WOLFSSL_CTX * ctx, int options)Enables CRL certificate verification through the CTX.
int	**wolfSSL_CTX_DisableCRL**(WOLFSSL_CTX * ctx)This function disables CRL verification in the CTX structure.
int	**wolfSSL_CTX_LoadCRL**(WOLFSSL_CTX * ctx, const char * path, int type, int monitor)This function loads CRL into the WOLFSSL_CTX structure through wolfSSL_CertManagerLoadCRL().
int	**wolfSSL_CTX_SetCRL_Cb**(WOLFSSL_CTX * ctx, CbMissingCRL cb)This function will set the callback argument to the cbMissingCRL member of the WOLFSSL_CERT_MANAGER structure by calling wolfSSL_CertManagerSetCRL_Cb.
int	**wolfSSL_CTX_EnableOCSP**(WOLFSSL_CTX * ctx, int options)This function sets options to configure behavior of OCSP functionality in wolfSSL. The value of options if formed by or'ing one or more of the following options: WOLFSSL_OCSP_URL_OVERRIDE _ use the override URL instead of the URL in certificates. The override URL is specified using the wolfSSL_CTX_SetOCSP_OverrideURL() function. WOLFSSL_OCSP_CHECKALL - Set all OCSP checks on WOLFSSL_OCSP_NO_NONCE - Set nonce option for creating OCSP requests.

	Name
int	**wolfSSL_CTX_DisableOCSP**(WOLFSSL_CTX * ctx)This function disables OCSP certificate revocation checking by affecting the ocspEnabled member of the WOLFSSL_CERT_MANAGER structure.
int	**wolfSSL_CTX_SetOCSP_OverrideURL**(WOLFSSL_CTX * ctx, const char * url)This function manually sets the URL for OCSP to use. By default, OCSP will use the URL found in the individual certificate unless the WOLFSSL_OCSP_URL_OVERRIDE option is set using the wolfSSL_CTX_EnableOCSP.
int	**wolfSSL_CTX_SetOCSP_Cb**(WOLFSSL_CTX * ctx, CbOCSPIO ioCb, CbOCSPRespFree respFreeCb, void * ioCbCtx)Sets the callback for the OCSP in the WOLFSSL_CTX structure.
int	**wolfSSL_CTX_EnableOCSPStapling**(WOLFSSL_CTX * ctx)This function enables OCSP stapling by calling wolfSSL_CertManagerEnableOCSPStapling().
void	**wolfSSL_KeepArrays**(WOLFSSL * ssl)Normally, at the end of the SSL handshake, wolfSSL frees temporary arrays. Calling this function before the handshake begins will prevent wolfSSL from freeing temporary arrays. Temporary arrays may be needed for things such as wolfSSL_get_keys() or PSK hints. When the user is done with temporary arrays, either wolfSSL_FreeArrays() may be called to free the resources immediately, or alternatively the resources will be freed when the associated SSL object is freed.
void	**wolfSSL_FreeArrays**(WOLFSSL * ssl)Normally, at the end of the SSL handshake, wolfSSL frees temporary arrays. If wolfSSL_KeepArrays() has been called before the handshake, wolfSSL will not free temporary arrays. This function explicitly frees temporary arrays and should be called when the user is done with temporary arrays and does not want to wait for the SSL object to be freed to free these resources.
int	**wolfSSL_UseSNI**(WOLFSSL * ssl, unsigned char type, const void * data, unsigned short size)This function enables the use of Server Name Indication in the SSL object passed in the 'ssl' parameter. It means that the SNI extension will be sent on ClientHello by wolfSSL client and wolfSSL server will respond ClientHello + SNI with either ServerHello + blank SNI or alert fatal in case of SNI mismatch.

	Name
int	**wolfSSL_CTX_UseSNI**(WOLFSSL_CTX * ctx, unsigned char type, const void * data, unsigned short size)This function enables the use of Server Name Indication for SSL objects created from the SSL context passed in the 'ctx' parameter. It means that the SNI extension will be sent on ClientHello by wolfSSL clients and wolfSSL servers will respond ClientHello + SNI with either ServerHello + blank SNI or alert fatal in case of SNI mismatch.
void	**wolfSSL_SNI_SetOptions**(WOLFSSL * ssl, unsigned char type, unsigned char options)This function is called on the server side to configure the behavior of the SSL session using Server Name Indication in the SSL object passed in the 'ssl' parameter. The options are explained below.
void	**wolfSSL_CTX_SNI_SetOptions**(WOLFSSL_CTX * ctx, unsigned char type, unsigned char options)This function is called on the server side to configure the behavior of the SSL sessions using Server Name Indication for SSL objects created from the SSL context passed in the 'ctx' parameter. The options are explained below.
int	**wolfSSL_SNI_GetFromBuffer**(const unsigned char * clientHello, unsigned int helloSz, unsigned char type, unsigned char * sni, unsigned int * inOutSz)This function is called on the server side to retrieve the Server Name Indication provided by the client from the Client Hello message sent by the client to start a session. It does not requires context or session setup to retrieve the SNI.
unsigned char	**wolfSSL_SNI_Status**(WOLFSSL * ssl, unsigned char type)This function gets the status of an SNI object.
unsigned short	**wolfSSL_SNI_GetRequest**(WOLFSSL * ssl, unsigned char type, void ** data)This function is called on the server side to retrieve the Server Name Indication provided by the client in a SSL session.
int	**wolfSSL_UseALPN**(WOLFSSL * ssl, char * protocol_name_list, unsigned int protocol_name_listSz, unsigned char options)Setup ALPN use for a wolfSSL session.
int	**wolfSSL_ALPN_GetProtocol**(WOLFSSL * ssl, char ** protocol_name, unsigned short * size)This function gets the protocol name set by the server.

	Name
int	**wolfSSL_ALPN_GetPeerProtocol**(WOLFSSL * ssl, char ** list, unsigned short * listSz)This function copies the alpn_client_list data from the SSL object to the buffer.
int	**wolfSSL_UseMaxFragment**(WOLFSSL * ssl, unsigned char mfl)This function is called on the client side to enable the use of Maximum Fragment Length in the SSL object passed in the 'ssl' parameter. It means that the Maximum Fragment Length extension will be sent on ClientHello by wolfSSL clients.
int	**wolfSSL_CTX_UseMaxFragment**(WOLFSSL_CTX * ctx, unsigned char mfl)This function is called on the client side to enable the use of Maximum Fragment Length for SSL objects created from the SSL context passed in the 'ctx' parameter. It means that the Maximum Fragment Length extension will be sent on ClientHello by wolfSSL clients.
int	**wolfSSL_UseTruncatedHMAC**(WOLFSSL * ssl)This function is called on the client side to enable the use of Truncated HMAC in the SSL object passed in the 'ssl' parameter. It means that the Truncated HMAC extension will be sent on ClientHello by wolfSSL clients.
int	**wolfSSL_CTX_UseTruncatedHMAC**(WOLFSSL_CTX * ctx)This function is called on the client side to enable the use of Truncated HMAC for SSL objects created from the SSL context passed in the 'ctx' parameter. It means that the Truncated HMAC extension will be sent on ClientHello by wolfSSL clients.
int	**wolfSSL_UseOCSPStapling**(WOLFSSL * ssl, unsigned char status_type, unsigned char options)Stapling eliminates the need to contact the CA. Stapling lowers the cost of certificate revocation check presented in OCSP.
int	**wolfSSL_CTX_UseOCSPStapling**(WOLFSSL_CTX * ctx, unsigned char status_type, unsigned char options)This function requests the certificate status during the handshake.
int	**wolfSSL_UseOCSPStaplingV2**(WOLFSSL * ssl, unsigned char status_type, unsigned char options)The function sets the status type and options for OCSP.
int	**wolfSSL_CTX_UseOCSPStaplingV2**(WOLFSSL_CTX * ctx, unsigned char status_type, unsigned char options)Creates and initializes the certificate status request for OCSP Stapling.

	Name
int	**wolfSSL_UseSupportedCurve**(WOLFSSL * ssl, word16 name)This function is called on the client side to enable the use of Supported Elliptic Curves Extension in the SSL object passed in the 'ssl' parameter. It means that the supported curves enabled will be sent on ClientHello by wolfSSL clients. This function can be called more than one time to enable multiple curves.
int	**wolfSSL_CTX_UseSupportedCurve**(WOLFSSL_CTX * ctx, word16 name)This function is called on the client side to enable the use of Supported Elliptic Curves Extension for SSL objects created from the SSL context passed in the 'ctx' parameter. It means that the supported curves enabled will be sent on ClientHello by wolfSSL clients. This function can be called more than one time to enable multiple curves.
int	**wolfSSL_UseSecureRenegotiation**(WOLFSSL * ssl)This function forces secure renegotiation for the supplied WOLFSSL structure. This is not recommended.
int	**wolfSSL_Rehandshake**(WOLFSSL * ssl)This function executes a secure renegotiation handshake; this is user forced as wolfSSL discourages this functionality.
int	**wolfSSL_UseSessionTicket**(WOLFSSL * ssl)Force provided WOLFSSL structure to use session ticket. The constant HAVE_SESSION_TICKET should be defined and the constant NO_WOLFSSL_CLIENT should not be defined to use this function.
int	**wolfSSL_CTX_UseSessionTicket**(WOLFSSL_CTX * ctx)This function sets wolfSSL context to use a session ticket.
int	**wolfSSL_get_SessionTicket**(WOLFSSL * ssl, unsigned char * buf, word32 * bufSz)This function copies the ticket member of the Session structure to the buffer. If buf is NULL and bufSz is non-NULL, bufSz will be set to the ticket length.
int	**wolfSSL_set_SessionTicket**(WOLFSSL * ssl, const unsigned char * buf, word32 bufSz)This function sets the ticket member of the WOLFSSL_SESSION structure within the WOLFSSL struct. The buffer passed into the function is copied to memory.

	Name
int	**wolfSSL_set_SessionTicket_cb**(WOLFSSL * ssl, CallbackSessionTicket cb, void * ctx)This function sets the session ticket callback. The type CallbackSessionTicket is a function pointer with the signature of: int (*CallbackSessionTicket)(WOLFSSL*, const unsigned char*, int, void*)
int	**wolfSSL_send_SessionTicket**(WOLFSSL * ssl)This function sends a session ticket to the client after a TLS v1.3 handhsake has been established.
int	**wolfSSL_CTX_set_TicketEncCb**(WOLFSSL_CTX * ctx, SessionTicketEncCb cb)This function sets the session ticket key encrypt callback function for a server to support session tickets as specified in RFC 5077.
int	**wolfSSL_CTX_set_TicketHint**(WOLFSSL_CTX * ctx, int hint)This function sets the session ticket hint relayed to the client. For server side use.
int	**wolfSSL_CTX_set_TicketEncCtx**(WOLFSSL_CTX * ctx, void * userCtx)This function sets the session ticket encrypt user context for the callback. For server side use.
void *	**wolfSSL_CTX_get_TicketEncCtx**(WOLFSSL_CTX * ctx)This function gets the session ticket encrypt user context for the callback. For server side use.
int	**wolfSSL_SetHsDoneCb**(WOLFSSL * ssl, HandShakeDoneCb cb, void * user_ctx)This function sets the handshake done callback. The hsDoneCb and hsDoneCtx members of the WOLFSSL structure are set in this function.
int	**wolfSSL_PrintSessionStats**(void)This function prints the statistics from the session.
int	**wolfSSL_get_session_stats**(unsigned int * active, unsigned int * total, unsigned int * peak, unsigned int * maxSessions)This function gets the statistics for the session.
int	**wolfSSL_MakeTlsMasterSecret**(unsigned char * ms, word32 msLen, const unsigned char * pms, word32 pmsLen, const unsigned char * cr, const unsigned char * sr, int tls1_2, int hash_type)This function copies the values of cr and sr then passes through to wc_PRF (pseudo random function) and returns that value.
int	**wolfSSL_DeriveTlsKeys**(unsigned char * key_data, word32 keyLen, const unsigned char * ms, word32 msLen, const unsigned char * sr, const unsigned char * cr, int tls1_2, int hash_type)An external facing wrapper to derive TLS Keys.

	Name
int	**wolfSSL_connect_ex**(WOLFSSL * ssl, HandShakeCallBack hsCb, TimeoutCallBack toCb, WOLFSSL_TIMEVAL timeout)wolfSSL_connect_ex() is an extension that allows a HandShake Callback to be set. This can be useful in embedded systems for debugging support when a debugger isn't available and sniffing is impractical. The HandShake Callback will be called whether or not a handshake error occurred. No dynamic memory is used since the maximum number of SSL packets is known. Packet names can be accessed through packetNames[]. The connect extension also allows a Timeout Callback to be set along with a timeout value. This is useful if the user doesn't want to wait for the TCP stack to timeout. This extension can be called with either, both, or neither callbacks.
int	**wolfSSL_accept_ex**(WOLFSSL * ssl, HandShakeCallBack hsCb, TimeoutCallBack toCb, WOLFSSL_TIMEVAL timeout)wolfSSL_accept_ex() is an extension that allows a HandShake Callback to be set. This can be useful in embedded systems for debugging support when a debugger isn't available and sniffing is impractical. The HandShake Callback will be called whether or not a handshake error occurred. No dynamic memory is used since the maximum number of SSL packets is known. Packet names can be accessed through packetNames[]. The connect extension also allows a Timeout Callback to be set along with a timeout value. This is useful if the user doesn't want to wait for the TCP stack to timeout. This extension can be called with either, both, or neither callbacks.
long	**wolfSSL_BIO_set_fp**(WOLFSSL_BIO * bio, XFILE fp, int c)This is used to set the internal file pointer for a BIO.
long	**wolfSSL_BIO_get_fp**(WOLFSSL_BIO * bio, XFILE * fp)This is used to get the internal file pointer for a BIO.
int	**wolfSSL_check_private_key**(const WOLFSSL * ssl)This function checks that the private key is a match with the certificate being used.
int	**wolfSSL_X509_get_ext_by_NID**(const WOLFSSL_X509 * x, int nid, int lastpos)This function looks for and returns the extension index matching the passed in NID value.

	Name
void *	**wolfSSL_X509_get_ext_d2i**(const WOLFSSL_X509 * x509, int nid, int * c, int * idx)This function looks for and returns the extension matching the passed in NID value.
int	**wolfSSL_X509_digest**(const WOLFSSL_X509 * x509, const WOLFSSL_EVP_MD * digest, unsigned char * buf, unsigned int * len)This function returns the hash of the DER certificate.
int	**wolfSSL_use_certificate**(WOLFSSL * ssl, WOLFSSL_X509 * x509)his is used to set the certificate for WOLFSSL structure to use during a handshake.
int	**wolfSSL_use_certificate_ASN1**(WOLFSSL * ssl, const unsigned char * der, int derSz)This is used to set the certificate for WOLFSSL structure to use during a handshake. A DER formatted buffer is expected.
int	**wolfSSL_use_PrivateKey**(WOLFSSL * ssl, WOLFSSL_EVP_PKEY * pkey)This is used to set the private key for the WOLFSSL structure.
int	**wolfSSL_use_PrivateKey_ASN1**(int pri, WOLFSSL * ssl, const unsigned char * der, long derSz)This is used to set the private key for the WOLFSSL structure. A DER formatted key buffer is expected.
int	**wolfSSL_use_RSAPrivateKey_ASN1**(WOLFSSL * ssl, unsigned char * der, long derSz)This is used to set the private key for the WOLFSSL structure. A DER formatted RSA key buffer is expected.
WOLFSSL_DH *	**wolfSSL_DSA_dup_DH**(const WOLFSSL_DSA * r)This function duplicates the parameters in dsa to a newly created WOLFSSL_DH structure.
int	**wolfSSL_SESSION_get_master_key**(const WOLFSSL_SESSION * ses, unsigned char * out, int outSz)This is used to get the master key after completing a handshake.
int	**wolfSSL_SESSION_get_master_key_length**(const WOLFSSL_SESSION * ses)This is used to get the master secret key length.
void	**wolfSSL_CTX_set_cert_store**(WOLFSSL_CTX * ctx, WOLFSSL_X509_STORE * str)This is a setter function for the WOLFSSL_X509_STORE structure in ctx.
WOLFSSL_X509 *	**wolfSSL_d2i_X509_bio**(WOLFSSL_BIO * bio, WOLFSSL_X509 ** x509)This function get the DER buffer from bio and converts it to a WOLFSSL_X509 structure.
WOLFSSL_X509_STORE *	**wolfSSL_CTX_get_cert_store**(WOLFSSL_CTX * ctx)This is a getter function for the WOLFSSL_X509_STORE structure in ctx.

	Name
size_t	**wolfSSL_BIO_ctrl_pending**(WOLFSSL_BIO * b)Gets the number of pending bytes to read. If BIO type is BIO_BIO then is the number to read from pair. If BIO contains an SSL object then is pending data from SSL object (wolfSSL_pending(ssl)). If is BIO_MEMORY type then returns the size of memory buffer.
size_t	**wolfSSL_get_server_random**(const WOLFSSL * ssl, unsigned char * out, size_t outlen)This is used to get the random data sent by the server during the handshake.
size_t	**wolfSSL_get_client_random**(const WOLFSSL * ssl, unsigned char * out, size_t outSz)This is used to get the random data sent by the client during the handshake.
wc_pem_password_cb *	**wolfSSL_CTX_get_default_passwd_cb**(WOLFSSL_CTX * ctx)This is a getter function for the password callback set in ctx.
void *	**wolfSSL_CTX_get_default_passwd_cb_userdata**(WOLFSSL_CTX * ctx)This is a getter function for the password callback user data set in ctx.
WOLFSSL_X509 *	**wolfSSL_PEM_read_bio_X509_AUX**(WOLFSSL_BIO * bp, WOLFSSL_X509 ** x, wc_pem_password_cb * cb, void * u)This function behaves the same as wolfSSL_PEM_read_bio_X509. AUX signifies containing extra information such as trusted/rejected use cases and friendly name for human readability.
long	**wolfSSL_CTX_set_tmp_dh**(WOLFSSL_CTX * ctx, WOLFSSL_DH * dh)Initializes the WOLFSSL_CTX structure's dh member with the Diffie-Hellman parameters.
WOLFSSL_DSA *	**wolfSSL_PEM_read_bio_DSAparams**(WOLFSSL_BIO * bp, WOLFSSL_DSA ** x, wc_pem_password_cb * cb, void * u)This function get the DSA parameters from a PEM buffer in bio.
unsigned long	**wolfSSL_ERR_peek_last_error**(void)This function returns the absolute value of the last error from WOLFSSL_ERROR encountered.
	WOLF_STACK_OF(WOLFSSL_X509) constThis function gets the peer's certificate chain.
long	**wolfSSL_CTX_clear_options**(WOLFSSL_CTX * ctx, long opt)This function resets option bits of WOLFSSL_CTX object.
int	**wolfSSL_set_jobject**(WOLFSSL * ssl, void * objPtr)This function sets the jObjectRef member of the WOLFSSL structure.
void *	**wolfSSL_get_jobject**(WOLFSSL * ssl)This function returns the jObjectRef member of the WOLFSSL structure.

	Name
int	**wolfSSL_set_msg_callback**(WOLFSSL * ssl, SSL_Msg_Cb cb)This function sets a callback in the ssl. The callback is to observe handshake messages. NULL value of cb resets the callback.
int	**wolfSSL_set_msg_callback_arg**(WOLFSSL * ssl, void * arg)This function sets associated callback context value in the ssl. The value is handed over to the callback argument.
char *	**wolfSSL_X509_get_next_altname**(WOLFSSL_X509 *)This function returns the next, if any, altname from the peer certificate.
WOLFSSL_ASN1_TIME *	**wolfSSL_X509_get_notBefore**(WOLFSSL_X509 *)The function checks to see if x509 is NULL and if it's not, it returns the notBefore member of the x509 struct.
int	**wolfSSL_connect**(WOLFSSL * ssl)This function is called on the client side and initiates an SSL/TLS handshake with a server. When this function is called, the underlying communication channel has already been set up. wolfSSL_connect() works with both blocking and non_blocking I/O. When the underlying I/O is non_blocking, wolfSSL_connect() will return when the underlying I/O could not satisfy the needs of wolfSSL_connect to continue the handshake. In this case, a call to wolfSSL_get_error() will yield either SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE. The calling process must then repeat the call to wolfSSL_connect() when the underlying I/O is ready and wolfSSL will pick up where it left off. When using a non_blocking socket, nothing needs to be done, but select() can be used to check for the required condition. If the underlying I/O is blocking, wolfSSL_connect() will only return once the handshake has been finished or an error occurred. wolfSSL takes a different approach to certificate verification than OpenSSL does. The default policy for the client is to verify the server, this means that if you don't load CAs to verify the server you'll get a connect error, unable to verify (_155). It you want to mimic OpenSSL behavior of having SSL_connect succeed even if verifying the server fails and reducing security you can do this by calling: SSL_CTX_set_verify(ctx, SSL_VERIFY_NONE, 0); before calling SSL_new(); Though it's not recommended.

	Name
int	**wolfSSL_send_hrr_cookie**(WOLFSSL * ssl, const unsigned char * secret, unsigned int secretSz)This function is called on the server side to indicate that a HelloRetryRequest message must contain a Cookie and, in case of using protocol DTLS v1.3, that the handshake will always include a cookie exchange. Please note that when using protocol DTLS v1.3, the cookie exchange is enabled by default. The Cookie holds a hash of the current transcript so that another server process can handle the ClientHello in reply. The secret is used when generating the integrity check on the Cookie data. This replaces or regenerates the HRR secret, then delegates to wolfSSL_enable_cookie(). Changing cookie mode after handshake processing starts is unsupported; rotating a secret while cookies are already enabled remains supported. DTLS 1.2_only callers should use wolfSSL_enable_cookie() and wolfSSL_DTLS_SetCookieSecret().
int	**wolfSSL_set_hrr_cookie_secret_secondary**(WOLFSSL * ssl, const unsigned char * secret, unsigned int secretSz)This function sets a secondary HelloRetryRequest cookie secret on a DTLS 1.3 server. It is used only when verifying a received cookie, and only if the primary secret (set with wolfSSL_send_hrr_cookie()) fails to verify it. This lets an application rotate the cookie secret on a stateless DTLS 1.3 server without rejecting clients whose cookie was issued under the previous secret: install the new secret as the primary and the previous secret here for an overlap window. The secondary secret is never used to issue cookies. This API is DTLS only; TLS 1.3 over a reliable transport does not verify cookies statelessly across the HelloRetryRequest exchange.

	Name
int	**wolfSSL_disable_hrr_cookie**(WOLFSSL * ssl)This function is called on the server side to indicate that a HelloRetryRequest message must NOT contain a Cookie and that, if using protocol DTLS v1.3, a cookie exchange will not be included in the handshake. Please note that not doing a cookie exchange when using protocol DTLS v1.3 can make the server susceptible to DoS/Amplification attacks. This delegates to wolfSSL_disable_cookie(): on a DTLS object it also disables the DTLS 1.2 HelloVerifyRequest exchange, and it fails with BAD_STATE_E once the handshake has committed to stateful processing.
int	**wolfSSL_CTX_no_ticket_TLSv13**(WOLFSSL_CTX * ctx)This function is called on the server to stop it from sending a resumption session ticket once the handshake is complete.
int	**wolfSSL_no_ticket_TLSv13**(WOLFSSL * ssl)This function is called on the server to stop it from sending a resumption session ticket once the handshake is complete.
int	**wolfSSL_CTX_no_dhe_psk**(WOLFSSL_CTX * ctx)This function is called on a TLS v1.3 wolfSSL context to disallow Diffie_Hellman (DH) style key exchanges when handshakes are using pre-shared keys for authentication.
int	**wolfSSL_no_dhe_psk**(WOLFSSL * ssl)This function is called on a TLS v1.3 client or server wolfSSL to disallow Diffie_Hellman (DH) style key exchanges when handshakes are using pre-shared keys for authentication.

	Name
int	**wolfSSL_CTX_require_psk**(WOLFSSL_CTX * ctx)This function is called on a TLS v1.3 / DTLS v1.3 context to require that an external Pre_Shared Key is negotiated for the handshake to succeed. When set, a handshake that completes without negotiating an external PSK is aborted with PSK_MISSING_ERROR instead of falling back to a certificate handshake, so the PSK acts as an additional security factor. The requirement keys off the external_PSK callback (it has no effect unless one is registered) and session_ticket resumption is exempt. To preserve forward secrecy a mandatory external PSK must also use an (EC)DHE key exchange; a pure psk_ke handshake is rejected with PSK_KEY_ERROR. This applies to TLS 1.3 and DTLS 1.3 only; in (D)TLS 1.2 the use of a PSK is determined by the negotiated cipher suite, so a mandatory PSK is instead configured by restricting the cipher suite list to (preferably (EC)DHE_)PSK suites.
int	**wolfSSL_require_psk**(WOLFSSL * ssl)This function is called on a TLS v1.3 / DTLS v1.3 wolfSSL object to require that an external Pre_Shared Key is negotiated for the handshake to succeed. See wolfSSL_CTX_require_psk() for the full behaviour.
int	**wolfSSL_update_keys**(WOLFSSL * ssl)This function is called on a TLS v1.3 client or server wolfSSL to force the rollover of keys. A KeyUpdate message is sent to the peer and new keys are calculated for encryption. The peer will send back a KeyUpdate message and the new decryption keys will then be calculated. This function can only be called after a handshake has been completed.
int	**wolfSSL_key_update_response**(WOLFSSL * ssl, int * required)This function is called on a TLS v1.3 client or server wolfSSL to determine whether a rollover of keys is in progress. When wolfSSL_update_keys() is called, a KeyUpdate message is sent and the encryption key is updated. The decryption key is updated when the response is received.
int	**wolfSSL_CTX_allow_post_handshake_auth**(WOLFSSL_CTX * ctx)This function is called on a TLS v1.3 client wolfSSL context to allow a client certificate to be sent post handshake upon request from server. This is useful when connecting to a web server that has some pages that require client authentication and others that don't.

	Name
int	**wolfSSL_allow_post_handshake_auth**(WOLFSSL * ssl)This function is called on a TLS v1.3 client wolfSSL to allow a client certificate to be sent post handshake upon request from server. A Post-Handshake Client Authentication extension is sent in the ClientHello. This is useful when connecting to a web server that has some pages that require client authentication and others that don't.
int	**wolfSSL_request_certificate**(WOLFSSL * ssl)This function requests a client certificate from the TLS v1.3 client. This is useful when a web server is serving some pages that require client authentication and others that don't. A maximum of 256 requests can be sent on a connection.
int	**wolfSSL_CTX_set1_sigalgs_list**(WOLFSSL_CTX * ctx, const char * list)This function sets the list of signature algorithms to allow on a wolfSSL context in order of preference. The list is a null_terminated text string and a colon_delimited list, where each element is of the form "+" (for example "RSA_PSS+SHA256:ECDSA+SHA384"). The Edwards-curve algorithms "ED25519" and "ED448" are written without a digest suffix, since the hash is implied by the algorithm. The previous list stored in the context is replaced.
int	**wolfSSL_set1_sigalgs_list**(WOLFSSL * ssl, const char * list)This function sets the list of signature algorithms to allow on a wolfSSL session in order of preference. The list format and the set of recognized public_key and digest tokens are identical to those documented for wolfSSL_CTX_set1_sigalgs_list(); refer to that function for the full token tables and TLS 1.3 caveats. The previous list stored in the session is replaced.
int	**wolfSSL_CTX_set1_groups_list**(WOLFSSL_CTX * ctx, const char * list)This function sets the list of key_exchange groups (named elliptic curves and KEMs) to allow on a wolfSSL context in order of preference. The list is a null_terminated, colon_delimited text string of group names, for example "P_384:P_256:X25519". Call this function to set the key_exchange parameters used with TLS v1.3 connections (the function is compiled in only when HAVE_ECC, WOLFSSL_TLS13, and HAVE_SUPPORTED_CURVES are defined).

	Name
int	**wolfSSL_set1_groups_list**(WOLFSSL * ssl, const char * list)This function sets the list of key_exchange groups (named elliptic curves and KEMs) to allow on a wolfSSL session in order of preference. The list format and the set of recognized group names are identical to those documented for wolfSSL_CTX_set1_groups_list(); refer to that function for the full token tables and required build options.
int	**wolfSSL_preferred_group**(WOLFSSL * ssl)This function returns the key exchange group the client prefers to use in the TLS v1.3 handshake. Call this function to after a handshake is complete to determine which group the server prefers so that this information can be used in future connections to pre-generate a key pair for key exchange.
int	**wolfSSL_CTX_set_groups**(WOLFSSL_CTX * ctx, int * groups, int count)This function sets the list of key_exchange groups (named elliptic curves and KEMs) to allow on a wolfSSL context in order of preference. The list is an array of named_group identifiers (see the table below) and count is the number of identifiers in the array. Use this function to set the key-exchange parameters used by TLS v1.3 connections; the order of the array becomes the local KeyShare preference order.
int	**wolfSSL_set_groups**(WOLFSSL * ssl, int * groups, int count)This function sets the list of key_exchange groups (named elliptic curves and KEMs) to allow on a wolfSSL session in order of preference. The array format and the set of recognized identifiers are identical to those documented for wolfSSL_CTX_set_groups(); refer to that function for the full identifier table and required build options.

	Name
int	**wolfSSL_connect_TLSv13**(WOLFSSL * ssl)This function is called on the client side and initiates a TLS v1.3 handshake with a server. When this function is called, the underlying communication channel has already been set up. wolfSSL_connect() works with both blocking and non_blocking I/O. When the underlying I/O is non_blocking, wolfSSL_connect() will return when the underlying I/O could not satisfy the needs of wolfSSL_connect to continue the handshake. In this case, a call to wolfSSL_get_error() will yield either SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE. The calling process must then repeat the call to wolfSSL_connect() when the underlying I/O is ready and wolfSSL will pick up where it left off. When using a non_blocking socket, nothing needs to be done, but select() can be used to check for the required condition. If the underlying I/O is blocking, wolfSSL_connect() will only return once the handshake has been finished or an error occurred. wolfSSL takes a different approach to certificate verification than OpenSSL does. The default policy for the client is to verify the server, this means that if you don't load CAs to verify the server you'll get a connect error, unable to verify (_155). It you want to mimic OpenSSL behavior of having SSL_connect succeed even if verifying the server fails and reducing security you can do this by calling: SSL_CTX_set_verify(ctx, SSL_VERIFY_NONE, 0); before calling SSL_new(); Though it's not recommended.

	Name
	wolfSSL_accept_TLSv13(WOLFSSL * ssl)This function is called on the server side and waits for a SSL/TLS client to initiate the SSL/TLS handshake. When this function is called, the underlying communication channel has already been set up. wolfSSL_accept() works with both blocking and non_blocking I/O. When the underlying I/O is non_blocking, wolfSSL_accept() will return when the underlying I/O could not satisfy the needs of wolfSSL_accept to continue the handshake. In this case, a call to wolfSSL_get_error() will yield either SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE. The calling process must then repeat the call to wolfSSL_accept when data is available to read and wolfSSL will pick up where it left off. When using a non_blocking socket, nothing needs to be done, but select() can be used to check for the required condition. If the underlying I/O is blocking, wolfSSL_accept() will only return once the handshake has been finished or an error occurred. Call this function when expecting a TLS v1.3 connection though older version ClientHello messages are supported.
int	**wolfSSL_CTX_set_max_early_data**(WOLFSSL_CTX * ctx, unsigned int sz)This function sets the maximum amount of early data that a TLS v1.3 client or server is willing to exchange using the wolfSSL context. Call this function to limit the amount of early data to process to mitigate replay attacks. Early data is protected by keys derived from those of the connection that the session ticket was sent and therefore will be the same every time a session ticket is used in resumption. The value is included in the session ticket for resumption. A server value of zero indicates no early data is to be sent by client using session tickets. A client value of zero indicates that the client will not send any early data. The default value is zero: per RFC 8446 Appendix E.5, TLS implementations “MUST NOT enable 0_RTT (either sending or accepting) unless specifically requested by the application.” Servers must call this function (or the per_SSL equivalent) with a non-zero value to opt in. It is recommended that the number of early data bytes be kept as low as practically possible in the application.

	Name
int	**wolfSSL_set_max_early_data**(WOLFSSL * ssl, unsigned int sz)This function sets the maximum amount of early data that a TLS v1.3 client or server is willing to exchange. Call this function to limit the amount of early data to process to mitigate replay attacks. Early data is protected by keys derived from those of the connection that the session ticket was sent and therefore will be the same every time a session ticket is used in resumption. The value is included in the session ticket for resumption. A server value of zero indicates no early data is to be sent by client using session tickets. A client value of zero indicates that the client will not send any early data. It is recommended that the number of early data bytes be kept as low as practically possible in the application.
int	**wolfSSL_write_early_data**(WOLFSSL * ssl, const void * data, int sz, int * outSz)This function writes early data to the server on resumption. Call this function before wolfSSL_connect() or wolfSSL_connect_TLSv13(). This function is only used with clients.
int	**wolfSSL_read_early_data**(WOLFSSL * ssl, void * data, int sz, int * outSz)This function reads any early data from a client on resumption. Call this function instead of wolfSSL_accept() or wolfSSL_accept_TLSv13() to accept a client and read any early data in the handshake. The function should be invoked until wolfSSL_is_init_finished() returns true. Early data may be sent by the client in multiple messages. If there is no early data then the handshake will be processed as normal. This function is only used with servers.
int	**wolfSSL_CTX_no_early_data_fresh_start_check**(WOLFSSL_CTX * ctx)This function is called on the server to disable the RFC 8446 Section 8.2 fresh start protection. By default a freshly created context rejects early data, but not resumption, for session tickets minted before the context was created, since the anti_replay state for those tickets may not have survived a server restart. Only call this function when the anti_replay state (session cache or external cache) reliably survives server restarts.

COPYRIGHT ©2024 wolfSSL Inc.

	Name
int	**wolfSSL_inject**(WOLFSSL * ssl, const void * data, int sz)This function is called to inject data into the WOLFSSL object. This is useful when data needs to be read from a single place and demultiplexed into multiple connections. The caller should then call wolfSSL_read() to extract the plaintext data from the WOLFSSL object.
void	**wolfSSL_CTX_set_psk_client_tls13_callback**(WOLFSSL_CTX * ctx, wc_psk_client_tls13_callback cb)This function sets the Pre_Shared Key (PSK) client side callback for TLS v1.3 connections. The callback is used to find a PSK identity and return its key and the name of the cipher to use for the handshake. The function sets the client_psk_tls13_cb member of the WOLFSSL_CTX structure.
void	**wolfSSL_set_psk_client_tls13_callback**(WOLFSSL * ssl, wc_psk_client_tls13_callback cb)This function sets the Pre_Shared Key (PSK) client side callback for TLS v1.3 connections. The callback is used to find a PSK identity and return its key and the name of the cipher to use for the handshake. The function sets the client_psk_tls13_cb member of the options field in WOLFSSL structure.
void	**wolfSSL_CTX_set_psk_server_tls13_callback**(WOLFSSL_CTX * ctx, wc_psk_server_tls13_callback cb)This function sets the Pre_Shared Key (PSK) server side callback for TLS v1.3 connections. The callback is used to find a PSK identity and return its key and the name of the cipher to use for the handshake. The function sets the server_psk_tls13_cb member of the WOLFSSL_CTX structure.
void	**wolfSSL_set_psk_server_tls13_callback**(WOLFSSL * ssl, wc_psk_server_tls13_callback cb)This function sets the Pre_Shared Key (PSK) server side callback for TLS v1.3 connections. The callback is used to find a PSK identity and return its key and the name of the cipher to use for the handshake. The function sets the server_psk_tls13_cb member of the options field in WOLFSSL structure.
int	**wolfSSL_CTX_set_cert_with_extern_psk**(WOLFSSL_CTX * ctx, int state)Enable or disable TLS 1.3 certificate authentication with external PSK (RFC 9973) on a context.
int	**wolfSSL_set_cert_with_extern_psk**(WOLFSSL * ssl, int state)Enable or disable TLS 1.3 certificate authentication with external PSK (RFC 9973) on a connection.

	Name
int	**wolfSSL_UseKeyShare**(WOLFSSL * ssl, word16 group)This function creates a key share entry from the group including generating a key pair. The KeyShare extension contains all the generated public keys for key exchange. If this function is called, then only the groups specified will be included. Call this function when a preferred group has been previously established for the server.
int	**wolfSSL_NoKeyShares**(WOLFSSL * ssl)This function is called to ensure no key shares are sent in the ClientHello. This will force the server to respond with a HelloRetryRequest if a key exchange is required in the handshake. Call this function when the expected key exchange group is not known and to avoid the generation of keys unnecessarily. Note that an extra round-trip will be required to complete the handshake when a key exchange is required.
WOLFSSL_METHOD *	**wolfTLSv1_3_server_method_ex**(void * heap)This function is used to indicate that the application is a server and will only support the TLS 1.3 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().
WOLFSSL_METHOD *	**wolfTLSv1_3_client_method_ex**(void * heap)This function is used to indicate that the application is a client and will only support the TLS 1.3 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().
WOLFSSL_METHOD *	**wolfTLSv1_3_server_method**(void)This function is used to indicate that the application is a server and will only support the TLS 1.3 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().
WOLFSSL_METHOD *	**wolfTLSv1_3_client_method**(void)This function is used to indicate that the application is a client and will only support the TLS 1.3 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().

	Name
int	**wolfSSL_CTX_set_client_cert_type**(WOLFSSL_CTX * ctx, const char * buf, int len)In case this function is called in a client side, set certificate types that can be sent to its peer. In case called in a server side, set certificate types that can be acceptable from its peer. Put cert types in the buffer with prioritised order. To reset the settings to default, pass NULL for the buffer or pass zero for len. By default, certificate type is only X509. In case both side intend to send or accept “Raw public key” cert, WOLFSSL_CERT_TYPE_RPK should be included in the buffer to set.
int	**wolfSSL_CTX_set_server_cert_type**(WOLFSSL_CTX * ctx, const char * buf, int len)In case this function is called in a server side, set certificate types that can be sent to its peer. In case called in a client side, set certificate types that can be acceptable from its peer. Put cert types in the buffer with prioritised order. To reset the settings to default, pass NULL for the buffer or pass zero for len. By default, certificate type is only X509. In case both side intend to send or accept “Raw public key” cert, WOLFSSL_CERT_TYPE_RPK should be included in the buffer to set.
int	**wolfSSL_set_client_cert_type**(WOLFSSL * ssl, const char * buf, int len)In case this function is called in a client side, set certificate types that can be sent to its peer. In case called in a server side, set certificate types that can be acceptable from its peer. Put cert types in the buffer with prioritised order. To reset the settings to default, pass NULL for the buffer or pass zero for len. By default, certificate type is only X509. In case both side intend to send or accept “Raw public key” cert, WOLFSSL_CERT_TYPE_RPK should be included in the buffer to set.
int	**wolfSSL_set_server_cert_type**(WOLFSSL * ssl, const char * buf, int len)In case this function is called in a server side, set certificate types that can be sent to its peer. In case called in a client side, set certificate types that can be acceptable from its peer. Put cert types in the buffer with prioritised order. To reset the settings to default, pass NULL for the buffer or pass zero for len. By default, certificate type is only X509. In case both side intend to send or accept “Raw public key” cert, WOLFSSL_CERT_TYPE_RPK should be included in the buffer to set.

	Name
int	**wolfSSL_CTX_clear_group_messages**(WOLFSSL_CTX * ctx)Disables handshake message grouping for the given WOLFSSL_CTX context.
int	**wolfSSL_clear_group_messages**(WOLFSSL * ssl)Disables handshake message grouping for the given WOLFSSL object.
int	**wolfSSL_get_negotiated_client_cert_type**(WOLFSSL * ssl, int * tp)This function returns the result of the client certificate type negotiation done in ClientHello and ServerHello. WOLFSSL_SUCCESS is returned as a return value if no negotiation occurs and WOLFSSL_CERT_TYPE_UNKNOWN is returned as the certificate type.
int	**wolfSSL_get_negotiated_server_cert_type**(WOLFSSL * ssl, int * tp)This function returns the result of the server certificate type negotiation done in ClientHello and ServerHello. WOLFSSL_SUCCESS is returned as a return value if no negotiation occurs and WOLFSSL_CERT_TYPE_UNKNOWN is returned as the certificate type.
int	**wolfSSL_CTX_set_expected_rpk**(WOLFSSL_CTX * ctx, const unsigned char * spki, unsigned int spkiSz)Pin a DER_encoded SubjectPublicKeyInfo that the peer is expected to present as a Raw Public Key (RFC 7250), establishing out_of_band trust on the WOLFSSL_CTX object. An unauthenticated RPK peer is otherwise rejected: when the peer is being authenticated (any verify mode other than WOLFSSL_VERIFY_NONE) the handshake fails closed unless the presented key matches a pin (or a verify callback accepts it). May be called more than once to pin several keys, up to WOLFSSL_MAX_RPK_PINS. The key is stored as its SHA_256 digest, so this API requires SHA_256. Pins are append_only _ there is no per_entry remove, but wolfSSL_CTX_clear_expected_rpk() empties the table so it can be repopulated.

	Name
int	**wolfSSL_set_expected_rpk**(WOLFSSL * ssl, const unsigned char * spki, unsigned int spkiSz)Pin a DER_encoded SubjectPublicKeyInfo that the peer is expected to present as a Raw Public Key (RFC 7250), establishing out_of_band trust on the WOLFSSL object. An unauthenticated RPK peer is otherwise rejected: when the peer is being authenticated (any verify mode other than WOLFSSL_VERIFY_NONE) the handshake fails closed unless the presented key matches a pin (or a verify callback accepts it). May be called more than once to pin several keys, up to WOLFSSL_MAX_RPK_PINS. The key is stored as its SHA_256 digest, so this API requires SHA_256. Pins are append_only _ there is no per_entry remove, but wolfSSL_clear_expected_rpk() empties the table so it can be repopulated.
int	**wolfSSL_CTX_clear_expected_rpk**(WOLFSSL_CTX * ctx)Remove all pinned expected peer Raw Public Keys (RFC 7250) from the WOLFSSL_CTX object, emptying the table so it can be repopulated _ for example across a peer key rotation, since the pinning APIs are otherwise append_only. Like other WOLFSSL_CTX setters this is not locked, so reconfigure the pins on a shared CTX while no handshakes are in flight (a WOLFSSL created with wolfSSL_new() copies the pin table by value at creation time).
int	**wolfSSL_clear_expected_rpk**(WOLFSSL * ssl)Remove all pinned expected peer Raw Public Keys (RFC 7250) from the WOLFSSL object, emptying the table so it can be repopulated - for example across a peer key rotation, since the pinning APIs are otherwise append-only.
int	**wolfSSL_dtls_cid_use**(WOLFSSL * ssl)Enable use of ConnectionID extensions for the SSL object. See RFC 9146 and RFC 9147.
int	**wolfSSL_dtls_cid_is_enabled**(WOLFSSL * ssl)If invoked after the handshake is complete it checks if ConnectionID was successfully negotiated for the SSL object. See RFC 9146 and RFC 9147.

	Name
int	**wolfSSL_dtls_cid_set**(WOLFSSL * ssl, unsigned char * cid, unsigned int size)Set the ConnectionID used by the other peer to send records in this connection. See RFC 9146 and RFC 9147. The ConnectionID must be at maximum DTLS_CID_MAX_SIZE, that is an tunable compile time define, and it can't never be bigger than 255 bytes.
int	**wolfSSL_dtls_cid_get_rx_size**(WOLFSSL * ssl, unsigned int * size)Get the size of the ConnectionID used by the other peer to send records in this connection. See RFC 9146 and RFC 9147. The size is stored in the parameter size.
int	**wolfSSL_dtls_cid_get_rx**(WOLFSSL * ssl, unsigned char * buffer, unsigned int bufferSz)Copy the ConnectionID used by the other peer to send records in this connection into the buffer pointed by the parameter buffer. See RFC 9146 and RFC.
int	**wolfSSL_dtls_cid_get0_rx**(WOLFSSL * ssl, unsigned char ** cid)Get the ConnectionID used by the other peer. See RFC 9146 and RFC 9147.
int	**wolfSSL_dtls_cid_get_tx_size**(WOLFSSL * ssl, unsigned int * size)Get the size of the ConnectionID used to send records in this connection. See RFC 9146 and RFC 9147. The size is stored in the parameter size. The send ConnectionID is chosen by the peer. On DTLS 1.3 it may be up to 255 bytes and is not bounded by wolfSSL_dtls_cid_max_size(); on DTLS 1.2 it never exceeds wolfSSL_dtls_cid_max_size().
int	**wolfSSL_dtls_cid_get_tx**(WOLFSSL * ssl, unsigned char * buffer, unsigned int bufferSz)Copy the ConnectionID used when sending records in this connection into the buffer pointer by the parameter buffer. See RFC 9146 and RFC 9147. The available size need to be provided in bufferSz. The send ConnectionID is chosen by the peer. On DTLS 1.3 it may be up to 255 bytes and is not bounded by wolfSSL_dtls_cid_max_size(), so size the buffer from wolfSSL_dtls_cid_get_tx_size() (or use 255 bytes) rather than from wolfSSL_dtls_cid_max_size(), otherwise this returns LENGTH_ERROR.

	Name
int	**wolfSSL_dtls_cid_get0_tx**(WOLFSSL * ssl, unsigned char ** cid)Get the ConnectionID used when sending records in this connection. See RFC 9146 and RFC 9147. The send ConnectionID is chosen by the peer. On DTLS 1.3 it may be up to 255 bytes and is not bounded by wolfSSL_dtls_cid_max_size(); use wolfSSL_dtls_cid_get_tx_size() to learn its length.
int	**wolfSSL_dtls_cid_max_size**(void)Get the maximum size of the ConnectionID that this build can receive, that is the largest size accepted by wolfSSL_dtls_cid_set(). This is the compile time define DTLS_CID_MAX_SIZE and it can never be bigger than 255 bytes. It does not bound the ConnectionID used to send records, which is chosen by the peer and, on DTLS 1.3, may be up to 255 bytes.
const unsigned char *	**wolfSSL_dtls_cid_parse**(const unsigned char * msg, unsigned int msgSz, unsigned int cidSz)Extract the ConnectionID from a record datagram/message. See RFC 9146 and RFC 9147.
void	**wolfSSL_CTX_set_client_CA_list**(WOLFSSL_CTX * ctx, WOLF_STACK_OF(WOLFSSL_X509_NAME) * names)On the server, this sets a list of CA names to be sent to clients in certificate requests as a hint for which CA's are supported by the server.
WOLFSSL_STACK *	**wolfSSL_CTX_get_client_CA_list**(const WOLFSSL_CTX * ctx)This retrieves the list previously set via wolfSSL_CTX_set_client_CA_list, or NULL if no list has been set.
void	**wolfSSL_set_client_CA_list**(WOLFSSL * ssl, WOLF_STACK_OF(WOLFSSL_X509_NAME) * names)Same as wolfSSL_CTX_set_client_CA_list, but specific to a session. If a CA list is set on both the context and the session, the list on the session is used.
WOLFSSL_STACK *	**wolfSSL_get_client_CA_list**(const WOLFSSL * ssl)On the server, this retrieves the list previously set via wolfSSL_set_client_CA_list. If none was set, returns the list previously set via wolfSSL_CTX_set_client_CA_list. If no list at all was set, returns NULL.
void	**wolfSSL_CTX_set0_CA_list**(WOLFSSL_CTX * ctx, WOLF_STACK_OF(WOLFSSL_X509_NAME) * names)This function sets a list of CA names to be sent to the peer as a hint for which CA's are supported for its authentication.

	Name
WOLFSSL_STACK *	**wolfSSL_CTX_get0_CA_list**(const WOLFSSL_CTX * ctx)This retrieves the list previously set via wolfSSL_CTX_set0_CA_list, or NULL if no list has been set.
void	**wolfSSL_set0_CA_list**(WOLFSSL * ssl, WOLF_STACK_OF(WOLFSSL_X509_NAME) * names)Same as wolfSSL_CTX_set0_CA_list, but specific to a session. If a CA list is set on both the context and the session, the list on the session is used.
WOLFSSL_STACK *	**wolfSSL_get0_CA_list**(const WOLFSSL * ssl)This retrieves the list previously set via wolfSSL_set0_CA_list. If none was set, returns the list previously set via wolfSSL_CTX_set0_CA_list. If no list at all was set, returns NULL.
WOLFSSL_STACK *	**wolfSSL_get0_peer_CA_list**(const WOLFSSL * ssl)This returns the CA list received from the peer.
int	**wolfSSL_get_client_suites_sigalgs**(const WOLFSSL * ssl, const byte ** suites, word16 * suiteSz, const byte ** hashSigAlgo, word16 * hashSigAlgoSz)This function returns the raw list of ciphersuites and signature algorithms offered by the client. The lists are only stored and returned inside a callback setup with wolfSSL_CTX_set_cert_cb(). This is useful to be able to dynamically load certificates and keys based on the available ciphersuites and signature algorithms.
WOLFSSL_CIPHERSUITE_INFO	**wolfSSL_get_ciphersuite_info**(byte first, byte second)This returns information about the ciphersuite directly from the raw ciphersuite bytes.
int	**wolfSSL_get_sigalg_info**(byte first, byte second, int * hashAlgo, int * sigAlgo)This returns information about the hash and signature algorithm directly from the raw ciphersuite bytes.
void	**wolfSSL_CTX_set_default_passwd_cb**(WOLFSSL_CTX * ctx, wc_pem_password_cb * cb)This function will set the password callback in the provided CTX. This callback is used when loading an encrypted cert or key which requires a password.
void	**wolfSSL_CTX_set_default_passwd_cb_userdata**(WOLFSSL_CTX * ctx, void * userdata)This function will set the userdata argument to the passwd_userdata member of the WOLFSSL_CTX structure. This member is passed into the CTX's password callback when called.

	Name
int	**wolfSSL_get_scr_check_enabled**(const WOLFSSL * ssl)Gets the state of the secure renegotiation (SCR) check requirement.
int	**wolfSSL_set_scr_check_enabled**(WOLFSSL * ssl, byte enabled)Sets the state of the secure renegotiation (SCR) check requirement.
int	**wolfSSL_CTX_DisableExtendedMasterSecret**(WOLFSSL_CTX * ctx)Disables the TLS Extended Master Secret extension (RFC 7627) on the context: a client stops advertising it and a server ignores the peer's request, so a standard master secret is negotiated. A server also declines resumption of sessions or tickets that used EMS and does a full handshake instead. TLS 1.2 and earlier only. Requires HAVE_EXTENDED_MASTER.
int	**wolfSSL_DisableExtendedMasterSecret**(WOLFSSL * ssl)Disables the TLS Extended Master Secret extension (RFC 7627) on the SSL object: a client stops advertising it and a server ignores the peer's request, so a standard master secret is negotiated. A server also declines resumption of sessions or tickets that used EMS and does a full handshake instead. Call before the handshake starts, or after wolfSSL_clear. TLS 1.2 and earlier only. Requires HAVE_EXTENDED_MASTER.
int	**wolfSSL_CTX_EnableExtendedMasterSecret**(WOLFSSL_CTX * ctx)Re_enables the TLS Extended Master Secret extension (RFC 7627) on the context (the default): EMS is used when the peer supports it but is not mandatory. Undoes a previous disable or require. Requires HAVE_EXTENDED_MASTER.
int	**wolfSSL_EnableExtendedMasterSecret**(WOLFSSL * ssl)Re_enables the TLS Extended Master Secret extension (RFC 7627) on the SSL object (the default): EMS is used when the peer supports it but is not mandatory. Undoes a previous disable or require. Call before the handshake starts, or after wolfSSL_clear. Requires HAVE_EXTENDED_MASTER.
int	**wolfSSL_CTX_RequireExtendedMasterSecret**(WOLFSSL_CTX * ctx)Makes the TLS Extended Master Secret extension (RFC 7627) mandatory on the context: if it is not negotiated, the connection is aborted with EXT_MASTER_SECRET_NEEDED_E. A client advertises the extension even after a previous disable. TLS 1.2 and earlier only. Requires HAVE_EXTENDED_MASTER.

	Name
int	**wolfSSL_RequireExtendedMasterSecret**(WOLFSSL * ssl)Makes the TLS Extended Master Secret extension (RFC 7627) mandatory on the SSL object: if it is not negotiated, including on resumption, the connection is aborted with EXT_MASTER_SECRET_NEEDED_E. A client advertises the extension even after a previous disable. Call before the handshake starts, or after wolfSSL_clear. TLS 1.2 and earlier only. Requires HAVE_EXTENDED_MASTER.
int	**wolfSSL_UseCertificateAuthority**(WOLFSSL * ssl, const unsigned char * dn, unsigned int dnSz)Adds a CA distinguished name to the list of certificate authorities announced via the TLS 1.3 certificate_authorities extension (RFC 8446 section 4.2.4) on the given SSL session. The DN must be the inner content of a DER_encoded X.509 Name (the bytes after the SEQUENCE tag and length), as returned by wc_GetDecodedCertSubjectRaw(). The library copies the bytes and prepends the SEQUENCE header on the wire automatically.
int	**wolfSSL_CTX_UseCertificateAuthority**(WOLFSSL_CTX * ctx, const unsigned char * dn, unsigned int dnSz)Adds a CA distinguished name to the list of certificate authorities announced via the TLS 1.3 certificate_authorities extension (RFC 8446 section 4.2.4) on all SSL sessions created from this context. The DN format and requirements are identical to wolfSSL_UseCertificateAuthority().
void	**wolfSSL_ClearCertificateAuthorities**(WOLFSSL * ssl)Frees and removes all CA distinguished names previously added to the SSL session via wolfSSL_UseCertificateAuthority(). After this call the session_level native CA list is empty; the CTX_level list (if any) is not affected.
void	**wolfSSL_CTX_ClearCertificateAuthorities**(WOLFSSL_CTX * ctx)Frees and removes all CA distinguished names previously added to the context via wolfSSL_CTX_UseCertificateAuthority(). After this call the CTX-level native CA list is empty.
int	**wolfSSL_GetPeerCertificateAuthorityCount**(const WOLFSSL * ssl)Returns the number of CA distinguished names received from the peer in the TLS 1.3 certificate_authorities extension. This is typically called inside a cert_cb (WOLFSSL_CERT_SETUP_CB) on the server side to inspect which CAs the client trusts.

	Name
int	**wolfSSL_GetPeerCertificateAuthority**(const WOLFSSL * ssl, int idx, unsigned char * outDn, unsigned int outDnSz)Copies the idx_th CA distinguished name received from the peer in the TLS 1.3 certificate_authorities extension into the caller's buffer. The DN is the inner content of the DER_encoded Name (without the SEQUENCE header), matching the format accepted by wolfSSL_UseCertificateAuthority().

C.58.3 Types Documentation

C.58.3.1 typedef WOLFSSL_TLSEXT_DEBUG_CB

```
typedef void(* WOLFSSL_TLSEXT_DEBUG_CB) (WOLFSSL *ssl, int client_server, int
 ↪  type, const byte *data, int len, void *arg);
```

Callback type for the TLS extension debug callback.

Parameters:

- **ssl** The WOLFSSL object receiving the extension.
- **client_server** 1 if the WOLFSSL object is a client, 0 if a server.
- **type** The extension type, e.g. TLSX_SERVER_NAME.
- **data** The raw extension content (data after the 2-byte length).
- **len** Length of the extension content in bytes.
- **arg** The argument set with wolfSSL_set_tlsext_debug_arg().

Invoked once for every TLS extension received during the handshake, in wire order, before the extension is processed.

Note that, unlike OpenSSL 3.x, the callback also reports unknown (unregistered) extension types.

C.58.4 Functions Documentation

C.58.4.1 function wolfDTLSv1_2_client_method_ex

```
WOLFSSL_METHOD * wolfDTLSv1_2_client_method_ex(
    void * heap
)
```

This function initializes the DTLS v1.2 client method.

Parameters:

- **heap** pointer to a heap hint for memory allocation.

See:

- wolfSSL_Init
- wolfSSL_CTX_new

Return: pointer This function returns a pointer to a new WOLFSSL_METHOD structure.

Example

```
wolfSSL_Init();
WOLFSSL_CTX* ctx = wolfSSL_CTX_new(wolfDTLSv1_2_client_method());
…
```

```
WOLFSSL* ssl = wolfSSL_new(ctx);
…
```

C.58.4.2 function wolfSSLv23_method

```
WOLFSSL_METHOD * wolfSSLv23_method(
    void
)
```

This function returns a WOLFSSL_METHOD similar to wolfSSLv23_client_method except that it is not determined which side yet (server/client).

Parameters:

- **none** No parameters.

See:

- wolfSSL_new
- wolfSSL_free

Return:

- WOLFSSL_METHOD* On successful creations returns a WOLFSSL_METHOD pointer
- NULL Null if memory allocation error or failure to create method

Example

```
WOLFSSL* ctx;
ctx  = wolfSSL_CTX_new(wolfSSLv23_method());
// check ret value
```

C.58.4.3 function wolfSSLv3_server_method

```
WOLFSSL_METHOD * wolfSSLv3_server_method(
    void
)
```

The wolfSSLv3_server_method() function is used to indicate that the application is a server and will only support the SSL 3.0 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().

Parameters:

- **none** No parameters.

See:

- wolfTLSv1_server_method
- wolfTLSv1_1_server_method
- wolfTLSv1_2_server_method
- wolfTLSv1_3_server_method
- wolfDTLSv1_server_method
- wolfSSLv23_server_method
- wolfSSL_CTX_new

Return:

- – If successful, the call will return a pointer to the newly created WOLFSSL_METHOD structure.
- FAIL If memory allocation fails when calling XMALLOC, the failure value of the underlying malloc() implementation will be returned (typically NULL with errno will be set to ENOMEM).

Example

```
#include <wolfssl/ssl.h>

WOLFSSL_METHOD* method;
WOLFSSL_CTX* ctx;

method = wolfSSLv3_server_method();
if (method == NULL) {
    unable to get method
}

ctx = wolfSSL_CTX_new(method);
...
```

C.58.4.4 function wolfSSLv3_client_method

```
WOLFSSL_METHOD * wolfSSLv3_client_method(
    void
)
```

The wolfSSLv3_client_method() function is used to indicate that the application is a client and will only support the SSL 3.0 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().

Parameters:

- **none** No parameters.

See:

- wolfTLSv1_client_method
- wolfTLSv1_1_client_method
- wolfTLSv1_2_client_method
- wolfTLSv1_3_client_method
- wolfDTLSv1_client_method
- wolfSSLv23_client_method
- wolfSSL_CTX_new

Return:

- – If successful, the call will return a pointer to the newly created WOLFSSL_METHOD structure.
- FAIL If memory allocation fails when calling XMALLOC, the failure value of the underlying malloc() implementation will be returned (typically NULL with errno will be set to ENOMEM).

Example

```
#include <wolfssl/ssl.h>

WOLFSSL_METHOD* method;
WOLFSSL_CTX* ctx;

method = wolfSSLv3_client_method();
if (method == NULL) {
    unable to get method
}

ctx = wolfSSL_CTX_new(method);
...
```

C.58.4.5 function wolfTLSv1_server_method

```
WOLFSSL_METHOD * wolfTLSv1_server_method(
    void
)
```

The wolfTLSv1_server_method() function is used to indicate that the application is a server and will only support the TLS 1.0 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().

Parameters:

- **none** No parameters.

See:

- wolfSSLv3_server_method
- wolfTLSv1_1_server_method
- wolfTLSv1_2_server_method
- wolfTLSv1_3_server_method
- wolfDTLSv1_server_method
- wolfSSLv23_server_method
- wolfSSL_CTX_new

Return:

- – If successful, the call will return a pointer to the newly created WOLFSSL_METHOD structure.
- FAIL If memory allocation fails when calling XMALLOC, the failure value of the underlying malloc() implementation will be returned (typically NULL with errno will be set to ENOMEM).

Example

```
#include <wolfssl/ssl.h>

WOLFSSL_METHOD* method;
WOLFSSL_CTX* ctx;

method = wolfTLSv1_server_method();
if (method == NULL) {
    unable to get method
}

ctx = wolfSSL_CTX_new(method);
...
```

C.58.4.6 function wolfTLSv1_client_method

```
WOLFSSL_METHOD * wolfTLSv1_client_method(
    void
)
```

The wolfTLSv1_client_method() function is used to indicate that the application is a client and will only support the TLS 1.0 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().

Parameters:

- **none** No parameters.

See:

- wolfSSLv3_client_method
- wolfTLSv1_1_client_method
- wolfTLSv1_2_client_method
- wolfTLSv1_3_client_method
- wolfDTLSv1_client_method
- wolfSSLv23_client_method
- wolfSSL_CTX_new

Return:

- – If successful, the call will return a pointer to the newly created WOLFSSL_METHOD structure.
- FAIL If memory allocation fails when calling XMALLOC, the failure value of the underlying malloc() implementation will be returned (typically NULL with errno will be set to ENOMEM).

Example

```
#include <wolfssl/ssl.h>

WOLFSSL_METHOD* method;
WOLFSSL_CTX* ctx;

method = wolfTLSv1_client_method();
if (method == NULL) {
    unable to get method
}

ctx = wolfSSL_CTX_new(method);
...
```

C.58.4.7 function wolfTLSv1_1_server_method

```
WOLFSSL_METHOD * wolfTLSv1_1_server_method(
    void
)
```

The wolfTLSv1_1_server_method() function is used to indicate that the application is a server and will only support the TLS 1.1 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().

Parameters:

- **none** No parameters.

See:

- wolfSSLv3_server_method
- wolfTLSv1_server_method
- wolfTLSv1_2_server_method
- wolfTLSv1_3_server_method
- wolfDTLSv1_server_method
- wolfSSLv23_server_method
- wolfSSL_CTX_new

Return:

- – If successful, the call will return a pointer to the newly created WOLFSSL_METHOD structure.
- FAIL If memory allocation fails when calling XMALLOC, the failure value of the underlying malloc() implementation will be returned (typically NULL with errno will be set to ENOMEM).

Example

```
#include <wolfssl/ssl.h>

WOLFSSL_METHOD* method;
WOLFSSL_CTX* ctx;

method = wolfTLSv1_1_server_method();
if (method == NULL) {
    // unable to get method
}

ctx = wolfSSL_CTX_new(method);
...
```

C.58.4.8 function wolfTLSv1_1_client_method

```
WOLFSSL_METHOD * wolfTLSv1_1_client_method(
    void
)
```

The wolfTLSv1_1_client_method() function is used to indicate that the application is a client and will only support the TLS 1.0 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().

Parameters:

- **none** No parameters.

See:

- wolfSSLv3_client_method
- wolfTLSv1_client_method
- wolfTLSv1_2_client_method
- wolfTLSv1_3_client_method
- wolfDTLSv1_client_method
- wolfSSLv23_client_method
- wolfSSL_CTX_new

Return:

- – If successful, the call will return a pointer to the newly created WOLFSSL_METHOD structure.
- FAIL If memory allocation fails when calling XMALLOC, the failure value of the underlying malloc() implementation will be returned (typically NULL with errno will be set to ENOMEM).

Example

```
#include <wolfssl/ssl.h>

WOLFSSL_METHOD* method;
WOLFSSL_CTX* ctx;

method = wolfTLSv1_1_client_method();
if (method == NULL) {
    // unable to get method
}

ctx = wolfSSL_CTX_new(method);
...
```

C.58.4.9 function wolfTLSv1_2_server_method

```
WOLFSSL_METHOD * wolfTLSv1_2_server_method(
    void
)
```

The wolfTLSv1_2_server_method() function is used to indicate that the application is a server and will only support the TLS 1.2 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().

Parameters:

- **none** No parameters.

See:

- wolfSSLv3_server_method
- wolfTLSv1_server_method
- wolfTLSv1_1_server_method
- wolfTLSv1_3_server_method
- wolfDTLSv1_server_method
- wolfSSLv23_server_method
- wolfSSL_CTX_new

Return:

- – If successful, the call will return a pointer to the newly created WOLFSSL_METHOD structure.
- FAIL If memory allocation fails when calling XMALLOC, the failure value of the underlying malloc() implementation will be returned (typically NULL with errno will be set to ENOMEM).

Example

```
#include <wolfssl/ssl.h>

WOLFSSL_METHOD* method;
WOLFSSL_CTX* ctx;

method = wolfTLSv1_2_server_method();
if (method == NULL) {
    // unable to get method
}

ctx = wolfSSL_CTX_new(method);
...
```

C.58.4.10 function wolfTLSv1_2_client_method

```
WOLFSSL_METHOD * wolfTLSv1_2_client_method(
    void
)
```

The wolfTLSv1_2_client_method() function is used to indicate that the application is a client and will only support the TLS 1.2 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().

Parameters:

- **none** No parameters.

See:

- wolfSSLv3_client_method
- wolfTLSv1_client_method
- wolfTLSv1_1_client_method
- wolfTLSv1_3_client_method
- wolfDTLSv1_client_method
- wolfSSLv23_client_method
- wolfSSL_CTX_new

Return:

- – If successful, the call will return a pointer to the newly created WOLFSSL_METHOD structure.
- FAIL If memory allocation fails when calling XMALLOC, the failure value of the underlying malloc() implementation will be returned (typically NULL with errno will be set to ENOMEM).

Example

```
#include <wolfssl/ssl.h>

WOLFSSL_METHOD* method;
WOLFSSL_CTX* ctx;

method = wolfTLSv1_2_client_method();
if (method == NULL) {
    // unable to get method
}

ctx = wolfSSL_CTX_new(method);
...
```

C.58.4.11 function wolfDTLSv1_client_method

```
WOLFSSL_METHOD * wolfDTLSv1_client_method(
    void
)
```

The wolfDTLSv1_client_method() function is used to indicate that the application is a client and will only support the DTLS 1.0 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new(). This function is only available when wolfSSL has been compiled with DTLS support (–enable_dtls, or by defining wolfSSL_DTLS).

Parameters:

- **none** No parameters.

See:

- wolfSSLv3_client_method
- wolfTLSv1_client_method
- wolfTLSv1_1_client_method
- wolfTLSv1_2_client_method
- wolfTLSv1_3_client_method
- wolfSSLv23_client_method
- wolfSSL_CTX_new

Return:

- – If successful, the call will return a pointer to the newly created WOLFSSL_METHOD structure.

- FAIL If memory allocation fails when calling XMALLOC, the failure value of the underlying malloc() implementation will be returned (typically NULL with errno will be set to ENOMEM).

Example

```
WOLFSSL_METHOD* method;
WOLFSSL_CTX* ctx;

method = wolfDTLSv1_client_method();
if (method == NULL) {
    // unable to get method
}

ctx = wolfSSL_CTX_new(method);
...
```

C.58.4.12 function wolfDTLSv1_server_method

```
WOLFSSL_METHOD * wolfDTLSv1_server_method(
    void
)
```

The wolfDTLSv1_server_method() function is used to indicate that the application is a server and will only support the DTLS 1.0 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new(). This function is only available when wolfSSL has been compiled with DTLS support (–enable_dtls, or by defining wolfSSL_DTLS).

Parameters:

- **none** No parameters.

See:

- wolfSSLv3_server_method
- wolfTLSv1_server_method
- wolfTLSv1_1_server_method
- wolfTLSv1_2_server_method
- wolfTLSv1_3_server_method
- wolfSSLv23_server_method
- wolfSSL_CTX_new

Return:

- – If successful, the call will return a pointer to the newly created WOLFSSL_METHOD structure.
- FAIL If memory allocation fails when calling XMALLOC, the failure value of the underlying malloc() implementation will be returned (typically NULL with errno will be set to ENOMEM).

Example

```
WOLFSSL_METHOD* method;
WOLFSSL_CTX* ctx;

method = wolfDTLSv1_server_method();
if (method == NULL) {
    // unable to get method
}
```

```
ctx = wolfSSL_CTX_new(method);
...
```

C.58.4.13 function wolfDTLSv1_3_server_method

```
WOLFSSL_METHOD * wolfDTLSv1_3_server_method(
    void
)
```

The wolfDTLSv1_3_server_method() function is used to indicate that the application is a server and will only support the DTLS 1.3 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new(). This function is only available when wolfSSL has been compiled with DTLSv1.3 support (–enable_dtls13, or by defining wolfSSL_DTLS13).

Parameters:

- **none** No parameters.

See: wolfDTLSv1_3_client_method

Return:

- – If successful, the call will return a pointer to the newly created WOLFSSL_METHOD structure.
- FAIL If memory allocation fails when calling XMALLOC, the failure value of the underlying malloc() implementation will be returned (typically NULL with errno will be set to ENOMEM).

Example

```
WOLFSSL_METHOD* method;
WOLFSSL_CTX* ctx;

method = wolfDTLSv1_3_server_method();
if (method == NULL) {
    // unable to get method
}

ctx = wolfSSL_CTX_new(method);
...
```

C.58.4.14 function wolfDTLSv1_3_client_method

```
WOLFSSL_METHOD * wolfDTLSv1_3_client_method(
    void
)
```

The wolfDTLSv1_3_client_method() function is used to indicate that the application is a client and will only support the DTLS 1.3 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new(). This function is only available when wolfSSL has been compiled with DTLSv1.3 support (–enable_dtls13, or by defining wolfSSL_DTLS13).

Parameters:

- **none** No parameters.

See: wolfDTLSv1_3_server_method

Return:

- – If successful, the call will return a pointer to the newly created WOLFSSL_METHOD structure.

- FAIL If memory allocation fails when calling XMALLOC, the failure value of the underlying malloc() implementation will be returned (typically NULL with errno will be set to ENOMEM).

Example

```
WOLFSSL_METHOD* method;
WOLFSSL_CTX* ctx;

method = wolfDTLSv1_3_client_method();
if (method == NULL) {
    // unable to get method
}

ctx = wolfSSL_CTX_new(method);
...
```

C.58.4.15 function wolfDTLS_server_method

```
WOLFSSL_METHOD * wolfDTLS_server_method(
    void
)
```

The wolfDTLS_server_method() function is used to indicate that the application is a server and will support the highest version of DTLS available and all the version up to the minimum version allowed. The default minimum version allowed is based on the define WOLFSSL_MIN_DTLS_DOWNGRADE and can be changed at runtime using wolfSSL_SetMinVersion(). This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new(). This function is only available when wolfSSL has been compiled with DTLS support (–enable_dtls, or by defining wolfSSL_DTLS).

Parameters:

- **none** No parameters.

See:

- wolfDTLS_client_method
- wolfSSL_SetMinVersion

Return:

- – If successful, the call will return a pointer to the newly created WOLFSSL_METHOD structure.
- FAIL If memory allocation fails when calling XMALLOC, the failure value of the underlying malloc() implementation will be returned (typically NULL with errno will be set to ENOMEM).

Example

```
WOLFSSL_METHOD* method;
WOLFSSL_CTX* ctx;

method = wolfDTLS_server_method();
if (method == NULL) {
    // unable to get method
}

ctx = wolfSSL_CTX_new(method);
...
```

C.58.4.16 function wolfDTLS_client_method

```
WOLFSSL_METHOD * wolfDTLS_client_method(
    void
)
```

The wolfDTLS_client_method() function is used to indicate that the application is a client and will support the highest version of DTLS available and all the version up to the minimum version allowed. The default minimum version allowed is based on the define WOLFSSL_MIN_DTLS_DOWNGRADE and can be changed at runtime using wolfSSL_SetMinVersion(). This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new(). This function is only available when wolfSSL has been compiled with DTLS support (–enable_dtls, or by defining wolfSSL_DTLS).

Parameters:

- **none** No parameters.

See:

- wolfDTLS_server_method
- wolfSSL_SetMinVersion

Return:

- – If successful, the call will return a pointer to the newly created WOLFSSL_METHOD structure.
- FAIL If memory allocation fails when calling XMALLOC, the failure value of the underlying malloc() implementation will be returned (typically NULL with errno will be set to ENOMEM).

Example

```
WOLFSSL_METHOD* method;
WOLFSSL_CTX* ctx;

method = wolfDTLS_client_method();
if (method == NULL) {
    // unable to get method
}

ctx = wolfSSL_CTX_new(method);
...
```

C.58.4.17 function wolfDTLSv1_2_server_method

```
WOLFSSL_METHOD * wolfDTLSv1_2_server_method(
    void
)
```

This function creates and initializes a WOLFSSL_METHOD for the server side.

Parameters:

- **none** No parameters.

See: wolfSSL_CTX_new

Return: This function returns a WOLFSSL_METHOD pointer.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new(wolfDTLSv1_2_server_method());
WOLFSSL* ssl = WOLFSSL_new(ctx);
…
```

C.58.4.18 function wolfSSL_use_old_poly

```
int wolfSSL_use_old_poly(
    WOLFSSL * ssl,
    int value
)
```

Since there is some differences between the first release and newer versions of chacha-poly AEAD construction we have added an option to communicate with servers/clients using the older version. By default wolfSSL uses the new version.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **value** whether or not to use the older version of setting up the information for poly1305. Passing a flag value of 1 indicates yes use the old poly AEAD, to switch back to using the new version pass a flag value of 0.

See: none

Return: 0 upon success

Example

```
int ret = 0;
WOLFSSL* ssl;
...

ret = wolfSSL_use_old_poly(ssl, 1);
if (ret != 0) {
    // failed to set poly1305 AEAD version
}
```

C.58.4.19 function wolfSSL_dtls_import

```
int wolfSSL_dtls_import(
    WOLFSSL * ssl,
    const unsigned char * buf,
    unsigned int sz
)
```

The wolfSSL_dtls_import() function is used to parse in a serialized session state. This allows for picking up the connection after the handshake has been completed. Post-handshake authentication is not available on an imported connection.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **buf** serialized session to import.
- **sz** size of serialized session buffer.

See:

- wolfSSL_new
- wolfSSL_CTX_new
- wolfSSL_CTX_dtls_set_export

Return:

- Success If successful, the amount of the buffer read will be returned.
- Failure All unsuccessful return values will be less than 0.
- VERSION_ERROR If a version mismatch is found ie DTLS v1 and ctx was set up for DTLS v1.2 then VERSION_ERROR is returned.

Example

```
WOLFSSL* ssl;
int ret;
unsigned char buf[MAX];
bufSz = MAX;
...
//get information sent from wc_dtls_export function and place it in buf
fread(buf, 1, bufSz, input);
ret = wolfSSL_dtls_import(ssl, buf, bufSz);
if (ret < 0) {
// handle error case
}
// no wolfSSL_accept needed since handshake was already done
...
ret = wolfSSL_write(ssl) and wolfSSL_read(ssl);
...
```

C.58.4.20 function wolfSSL_tls_import

```
int wolfSSL_tls_import(
    WOLFSSL * ssl,
    const unsigned char * buf,
    unsigned int sz
)
```

Used to import a serialized TLS session. This function is for importing the state of the connection. A TLS 1.3 session serialized with export version 7 or later carries its traffic and resumption secrets, so a KeyUpdate and the issuing of a NewSessionTicket work on the imported connection; an older serialization restores the record layer alone. WARNING: buf contains sensitive information about the state and is best to be encrypted before storing if stored. Additional debug info can be displayed with the macro WOLFSSL_SESSION_EXPORT_DEBUG defined.

Parameters:

- **ssl** WOLFSSL structure to import the session into
- **buf** serialized session
- **sz** size of buffer 'buf'

See:

- wolfSSL_dtls_import
- wolfSSL_tls_export

Return: the number of bytes read from buffer 'buf'

C.58.4.21 function wolfSSL_CTX_dtls_set_export

```
int wolfSSL_CTX_dtls_set_export(
    WOLFSSL_CTX * ctx,
    wc_dtls_export func
)
```

The wolfSSL_CTX_dtls_set_export() function is used to set the callback function for exporting a session. It is allowed to pass in NULL as the parameter func to clear the export function previously stored. Used on the server side and is called immediately after handshake is completed, for DTLS 1.2 only; a DTLS 1.3 session is exported with wolfSSL_dtls_export().

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created with wolfSSL_CTX_new().
- **func** wc_dtls_export function to use when exporting a session.

See:

- wolfSSL_new
- wolfSSL_CTX_new
- wolfSSL_dtls_set_export
- Static buffer use

Return:

- SSL_SUCCESS upon success.
- BAD_FUNC_ARG If null or not expected arguments are passed in

Example

```
int send_session(WOLFSSL* ssl, byte* buf, word32 sz, void* userCtx);
// body of send session (wc_dtls_export) that passes
// buf (serialized session) to destination
WOLFSSL_CTX* ctx;
int ret;
...
ret = wolfSSL_CTX_dtls_set_export(ctx, send_session);
if (ret != SSL_SUCCESS) {
    // handle error case
}
...
ret = wolfSSL_accept(ssl);
...
```

C.58.4.22 function wolfSSL_dtls_set_export

```
int wolfSSL_dtls_set_export(
    WOLFSSL * ssl,
    wc_dtls_export func
)
```

The wolfSSL_dtls_set_export() function is used to set the callback function for exporting a session. It is allowed to pass in NULL as the parameter func to clear the export function previously stored. Used on the server side and is called immediately after handshake is completed, for DTLS 1.2 only; a DTLS 1.3 session is exported with wolfSSL_dtls_export().

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **func** wc_dtls_export function to use when exporting a session.

See:

- wolfSSL_new
- wolfSSL_CTX_new
- wolfSSL_CTX_dtls_set_export

Return:

- SSL_SUCCESS upon success.
- BAD_FUNC_ARG If null or not expected arguments are passed in

Example

```
int send_session(WOLFSSL* ssl, byte* buf, word32 sz, void* userCtx);
// body of send session (wc_dtls_export) that passes
// buf (serialized session) to destination
WOLFSSL* ssl;
int ret;
...
ret = wolfSSL_dtls_set_export(ssl, send_session);
if (ret != SSL_SUCCESS) {
    // handle error case
}
...
ret = wolfSSL_accept(ssl);
...
```

C.58.4.23 function wolfSSL_dtls_export

```
int wolfSSL_dtls_export(
    WOLFSSL * ssl,
    unsigned char * buf,
    unsigned int * sz
)
```

The wolfSSL_dtls_export() function is used to serialize a WOLFSSL session into the provided buffer. Allows for less memory overhead than using a function callback for sending a session and choice over when the session is serialized. If buffer is NULL when passed to function then sz will be set to the size of buffer needed for serializing the WOLFSSL session. The export is refused with a negative return before a DTLS 1.3 handshake is done, while a KeyUpdate is in progress, a fragmented message is half sent, a handshake message other than NewSessionTicket is waiting for the peer's ACK, a post-handshake CertificateRequest is unanswered, or a write dup of the object exists. A NewSessionTicket still waiting for its ACK is not exported and is lost. The session tickets themselves are not serialized: any ticket already issued or received is discarded by the export. For a DTLS 1.3 session the blob carries the resumption secret and the ticket nonce, so an imported server can still issue a NewSessionTicket that resumes; use wolfSSL_get1_session before exporting to keep a received ticket.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **buf** buffer to hold serialized session.
- **sz** size of buffer.

See:

- wolfSSL_new
- wolfSSL_CTX_new
- wolfSSL_CTX_dtls_set_export
- wolfSSL_dtls_import

Return:

- Success If successful, the amount of the buffer used will be returned.
- Failure All unsuccessful return values will be less than 0.

Example

```
WOLFSSL* ssl;
int ret;
unsigned char buf[MAX];
bufSz = MAX;
...
ret = wolfSSL_dtls_export(ssl, buf, bufSz);
if (ret < 0) {
    // handle error case
}
...
```

C.58.4.24 function wolfSSL_tls_export

```
int wolfSSL_tls_export(
    WOLFSSL * ssl,
    unsigned char * buf,
    unsigned int * sz
)
```

Used to export a serialized TLS session. This function is for exporting a serialized state of the connection. In most cases wolfSSL_get1_session should be used instead of wolfSSL_tls_export. The export of a TLS 1.3 session is refused with a negative return before the handshake is done or while a KeyUpdate response is pending. The session tickets themselves are not serialized: any ticket already issued or received is discarded by the export. A TLS 1.3 blob carries the resumption secret and the ticket nonce, so an imported server can still issue a NewSessionTicket that resumes; use wolfSSL_get1_session before exporting to keep a received ticket. Additional debug info can be displayed with the macro WOLFSSL_SESSION_EXPORT_DEBUG defined. WARNING: buf contains sensitive information about the state and is best to be encrypted before storing if stored.

Parameters:

- **ssl** WOLFSSL structure to export the session from
- **buf** output of serialized session
- **sz** size in bytes set in 'buf'

See:

- wolfSSL_dtls_import
- wolfSSL_tls_import

Return: the number of bytes written into buffer 'buf'

C.58.4.25 function wolfSSL_CTX_load_static_memory

```
int wolfSSL_CTX_load_static_memory(
    WOLFSSL_CTX ** ctx,
    wolfSSL_method_func method,
    unsigned char * buf,
    unsigned int sz,
    int flag,
    int max
)
```

This function is used to set aside static memory for a CTX. Memory set aside is then used for the CTX's lifetime and for any SSL objects created from the CTX. By passing in a NULL ctx pointer and a wolfSSL_method_func function the creation of the CTX itself will also use static memory. wolfSSL_method_func has the function signature of WOLFSSL_METHOD* (*wolfSSL_method_func)(void* heap);. Passing in 0 for max makes it behave as if not set and no max concurrent use restrictions is

in place. The flag value passed in determines how the memory is used and behavior while operating. Available flags are the following: 0 - default general memory, WOLFMEM_IO_POOL - used for input/output buffer when sending receiving messages and overrides general memory, so all memory in buffer passed in is used for IO, WOLFMEM_IO_FIXED - same as WOLFMEM_IO_POOL but each SSL now keeps two buffers to themselves for their lifetime, WOLFMEM_TRACK_STATS - each SSL keeps track of memory stats while running.

Parameters:

- **ctx** address of pointer to a WOLFSSL_CTX structure.
- **method** function to create protocol. (should be NULL if ctx is not also NULL)
- **buf** memory to use for all operations.
- **sz** size of memory buffer being passed in.
- **flag** type of memory.
- **max** max concurrent operations.

See:

- wolfSSL_CTX_new
- wolfSSL_CTX_is_static_memory
- wolfSSL_is_static_memory

Return:

- SSL_SUCCESS upon success.
- SSL_FAILURE upon failure.

Example

```
WOLFSSL_CTX* ctx;
WOLFSSL* ssl;
int ret;
unsigned char memory[MAX];
int memorySz = MAX;
unsigned char IO[MAX];
int IOSz = MAX;
int flag = WOLFMEM_IO_FIXED | WOLFMEM_TRACK_STATS;
...
// create ctx also using static memory, start with general memory to use
ctx = NULL:
ret = wolfSSL_CTX_load_static_memory(&ctx, wolfSSLv23_server_method_ex,
memory, memorySz, 0,    MAX_CONCURRENT_HANDSHAKES);
if (ret != SSL_SUCCESS) {
// handle error case
}
// load in memory for use with IO
ret = wolfSSL_CTX_load_static_memory(&ctx, NULL, IO, IOSz, flag,
MAX_CONCURRENT_IO);
if (ret != SSL_SUCCESS) {
// handle error case
}
...
```

C.58.4.26 function wolfSSL_CTX_is_static_memory

```
int wolfSSL_CTX_is_static_memory(
    WOLFSSL_CTX * ctx,
```

```
    WOLFSSL_MEM_STATS * mem_stats
)
```

This function does not change any of the connections behavior and is used only for gathering information about the static memory usage.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().
- **mem_stats** structure to hold information about static memory usage.

See:

- wolfSSL_CTX_new
- wolfSSL_CTX_load_static_memory
- wolfSSL_is_static_memory

Return:

- 1 is returned if using static memory for the CTX is true.
- 0 is returned if not using static memory.

Example

```
WOLFSSL_CTX* ctx;
int ret;
WOLFSSL_MEM_STATS mem_stats;
...
//get information about static memory with CTX
ret = wolfSSL_CTX_is_static_memory(ctx, &mem_stats);
if (ret == 1) {
    // handle case of is using static memory
    // print out or inspect elements of mem_stats
}
if (ret == 0) {
    //handle case of ctx not using static memory
}
…
```

C.58.4.27 function wolfSSL_is_static_memory

```
int wolfSSL_is_static_memory(
    WOLFSSL * ssl,
    WOLFSSL_MEM_CONN_STATS * mem_stats
)
```

wolfSSL_is_static_memory is used to gather information about a SSL's static memory usage. The return value indicates if static memory is being used and WOLFSSL_MEM_CONN_STATS will be filled out if and only if the flag WOLFMEM_TRACK_STATS was passed to the parent CTX when loading in static memory.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **mem_stats** structure to contain static memory usage.

See:

- wolfSSL_new
- wolfSSL_CTX_is_static_memory

Return:

- 1 is returned if using static memory for the CTX is true.
- 0 is returned if not using static memory.

Example

```
WOLFSSL* ssl;
int ret;
WOLFSSL_MEM_CONN_STATS mem_stats;
...
ret = wolfSSL_is_static_memory(ssl, mem_stats);
if (ret == 1) {
    // handle case when is static memory
    // investigate elements in mem_stats if WOLFMEM_TRACK_STATS flag
}
...
```

C.58.4.28 function wolfSSL_CTX_use_certificate_file

```
int wolfSSL_CTX_use_certificate_file(
    WOLFSSL_CTX * ctx,
    const char * file,
    int format
)
```

This function loads a certificate file into the SSL context (WOLFSSL_CTX). The file is provided by the file argument. The format argument specifies the format type of the file, either SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM. Please see the examples for proper usage.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new()
- **file** a pointer to the name of the file containing the certificate to be loaded into the wolfSSL SSL context.
- **format** - format of the certificates pointed to by file. Possible options are SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM.

See:

- wolfSSL_CTX_use_certificate_buffer
- wolfSSL_use_certificate_file
- wolfSSL_use_certificate_buffer

Return:

- SSL_SUCCESS upon success.
- SSL_FAILURE If the function call fails, possible causes might include the file is in the wrong format, or the wrong format has been given using the “format” argument, file doesn’t exist, can’t be read, or is corrupted, an out of memory condition occurs, Base16 decoding fails on the file.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx;
...
ret = wolfSSL_CTX_use_certificate_file(ctx, “./client-cert.pem”,
                                       SSL_FILETYPE_PEM);
if (ret != SSL_SUCCESS) {
    // error loading cert file
}
...
```

C.58.4.29 function wolfSSL_CTX_use_PrivateKey_file

```
int wolfSSL_CTX_use_PrivateKey_file(
    WOLFSSL_CTX * ctx,
    const char * file,
    int format
)
```

This function loads a private key file into the SSL context (WOLFSSL_CTX). The file is provided by the file argument. The format argument specifies the format type of the file - SSL_FILETYPE_ASN1or SSL_FILETYPE_PEM. Please see the examples for proper usage.

Parameters:

- **ctx** pointer to a WOLFSSL_CTX structure.
- **file** path to the private key file.
- **format** format of the key file (SSL_FILETYPE_PEM or SSL_FILETYPE_ASN1).

See:

- wolfSSL_CTX_use_PrivateKey_buffer
- wolfSSL_use_PrivateKey_file
- wolfSSL_use_PrivateKey_buffer
- wc_CryptoCb_RegisterDevice
- wolfSSL_CTX_SetDevId

Return:

- SSL_SUCCESS upon success.
- SSL_FAILURE The file is in the wrong format, or the wrong format has been given using the "format" argument. The file doesn't exist, can't be read, or is corrupted. An out of memory condition occurs. Base16 decoding fails on the file. The key file is encrypted but no password is provided.

If using an external key store and do not have the private key you can instead provide the public key and register the crypro callback to handle the signing. For this you can build with either build with crypto callbacks or PK callbacks. To enable crypto callbacks use –enable-cryptocb or WOLF_CRYPTO_CB and register a crypto callback using wc_CryptoCb_RegisterDevice and set the associated devId using wolfSSL_CTX_SetDevId.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx;
...
ret = wolfSSL_CTX_use_PrivateKey_file(ctx, "./server-key.pem",
                                      SSL_FILETYPE_PEM);
if (ret != SSL_SUCCESS) {
    // error loading key file
}
...
```

C.58.4.30 function wolfSSL_CTX_load_verify_locations

```
int wolfSSL_CTX_load_verify_locations(
    WOLFSSL_CTX * ctx,
    const char * file,
    const char * path
)
```

This function loads PEM-formatted CA certificate files into the SSL context (WOLFSSL_CTX). These certificates will be treated as trusted root certificates and used to verify certs received from peers during the SSL handshake. The root certificate file, provided by the file argument, may be a single certificate or a file containing multiple certificates. If multiple CA certs are included in the same file, wolfSSL will load them in the same order they are presented in the file. The path argument is a pointer to the name of a directory that contains certificates of trusted root CAs. If the value of file is not NULL, path may be specified as NULL if not needed. If path is specified and NO_WOLFSSL_DIR was not defined when building the library, wolfSSL will load all CA certificates located in the given directory. This function will attempt to load all files in the directory. This function expects PEM formatted CERT_TYPE file with header "—–BEGIN CERTIFICATE—–".

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **file** pointer to name of the file containing PEM-formatted CA certificates.
- **path** pointer to the name of a directory to load PEM-formatted certificates from.

See:

- wolfSSL_CTX_load_verify_locations_ex
- wolfSSL_CTX_load_verify_buffer
- wolfSSL_CTX_use_certificate_file
- wolfSSL_CTX_use_PrivateKey_file
- wolfSSL_CTX_use_certificate_chain_file
- wolfSSL_use_certificate_file
- wolfSSL_use_PrivateKey_file
- wolfSSL_use_certificate_chain_file

Return:

- SSL_SUCCESS up success.
- SSL_FAILURE will be returned if ctx is NULL, or if both file and path are NULL.
- SSL_BAD_FILETYPE will be returned if the file is the wrong format.
- SSL_BAD_FILE will be returned if the file doesn't exist, can't be read, or is corrupted.
- MEMORY_E will be returned if an out of memory condition occurs.
- ASN_INPUT_E will be returned if Base16 decoding fails on the file.
- ASN_BEFORE_DATE_E will be returned if the current date is before the before date.
- ASN_AFTER_DATE_E will be returned if the current date is after the after date.
- BUFFER_E will be returned if a chain buffer is bigger than the receiving buffer.
- BAD_PATH_ERROR will be returned if opendir() fails when trying to open path.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx;
...
ret = wolfSSL_CTX_load_verify_locations(ctx, "./ca-cert.pem", NULL);
if (ret != WOLFSSL_SUCCESS) {
    // error loading CA certs
}
...
```

C.58.4.31 function wolfSSL_CTX_load_verify_locations_ex

```
int wolfSSL_CTX_load_verify_locations_ex(
    WOLFSSL_CTX * ctx,
    const char * file,
    const char * path,
```

```
    word32 flags
)
```

This function loads PEM-formatted CA certificate files into the SSL context (WOLFSSL_CTX). These certificates will be treated as trusted root certificates and used to verify certs received from peers during the SSL handshake. The root certificate file, provided by the file argument, may be a single certificate or a file containing multiple certificates. If multiple CA certs are included in the same file, wolfSSL will load them in the same order they are presented in the file. The path argument is a pointer to the name of a directory that contains certificates of trusted root CAs. If the value of file is not NULL, path may be specified as NULL if not needed. If path is specified and NO_WOLFSSL_DIR was not defined when building the library, wolfSSL will load all CA certificates located in the given directory. This function will attempt to load all files in the directory based on flags specified. This function expects PEM formatted CERT_TYPE files with header "—–BEGIN CERTIFICATE—–".

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **file** pointer to name of the file containing PEM-formatted CA certificates.
- **path** pointer to the name of a directory to load PEM-formatted certificates from.
- **flags** possible mask values are: WOLFSSL_LOAD_FLAG_IGNORE_ERR, WOLFSSL_LOAD_FLAG_DATE_ERR_OKAY and WOLFSSL_LOAD_FLAG_PEM_CA_ONLY

See:

- wolfSSL_CTX_load_verify_locations
- wolfSSL_CTX_load_verify_buffer
- wolfSSL_CTX_use_certificate_file
- wolfSSL_CTX_use_PrivateKey_file
- wolfSSL_CTX_use_certificate_chain_file
- wolfSSL_use_certificate_file
- wolfSSL_use_PrivateKey_file
- wolfSSL_use_certificate_chain_file

Return:

- SSL_SUCCESS up success.
- SSL_FAILURE will be returned if ctx is NULL, or if both file and path are NULL. This will also be returned if at least one cert is loaded successfully but there is one or more that failed. Check error stack for reason.
- SSL_BAD_FILETYPE will be returned if the file is the wrong format.
- SSL_BAD_FILE will be returned if the file doesn't exist, can't be read, or is corrupted.
- MEMORY_E will be returned if an out of memory condition occurs.
- ASN_INPUT_E will be returned if Base16 decoding fails on the file.
- BUFFER_E will be returned if a chain buffer is bigger than the receiving buffer.
- BAD_PATH_ERROR will be returned if opendir() fails when trying to open path.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx;
...
ret = wolfSSL_CTX_load_verify_locations_ex(ctx, NULL, "./certs/external",
    WOLFSSL_LOAD_FLAG_PEM_CA_ONLY);
if (ret != WOLFSSL_SUCCESS) {
    // error loading CA certs
}
...
```

C.58.4.32 function wolfSSL_get_system_CA_dirs

```
const char ** wolfSSL_get_system_CA_dirs(
    word32 * num
)
```

This function returns a pointer to an array of strings representing directories wolfSSL will search for system CA certs when wolfSSL_CTX_load_system_CA_certs is called. On systems that don't store certificates in an accessible system directory (such as Apple platforms), this function will always return NULL.

Parameters:

- **num** pointer to a word32 that will be populated with the length of the array of strings.

See:

- wolfSSL_CTX_load_system_CA_certs
- wolfSSL_CTX_load_verify_locations
- wolfSSL_CTX_load_verify_locations_ex

Return:

- Valid pointer on success.
- NULL pointer on failure.

Example

```
WOLFSSL_CTX* ctx;
const char** dirs;
word32 numDirs;

dirs = wolfSSL_get_system_CA_dirs(&numDirs);
for (int i = 0; i < numDirs; ++i) {
    printf("Potential system CA dir: %s\n", dirs[i]);
}
...
```

C.58.4.33 function wolfSSL_CTX_load_system_CA_certs

```
int wolfSSL_CTX_load_system_CA_certs(
    WOLFSSL_CTX * ctx
)
```

On most platforms (including Linux and Windows), this function attempts to load CA certificates into a WOLFSSL_CTX from an OS-dependent CA certificate store. Loaded certificates will be trusted.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().

See:

- wolfSSL_get_system_CA_dirs
- wolfSSL_CTX_load_verify_locations
- wolfSSL_CTX_load_verify_locations_ex

Return:

- WOLFSSL_SUCCESS on success.
- WOLFSSL_BAD_PATH if no system CA certs were loaded.
- WOLFSSL_FAILURE for other failure types (e.g. Windows cert store wasn't properly closed).

On Apple platforms (excluding macOS), certificates can't be obtained from the system, and therefore cannot be loaded into the wolfSSL certificate manager. For these platforms, this function enables TLS connections bound to the WOLFSSL_CTX to use the native system trust APIs to verify authenticity of the peer certificate chain if the authenticity of the peer cannot first be authenticated against certificates loaded by the user.

The platforms supported and tested are: Linux (Debian, Ubuntu, Gentoo, Fedora, RHEL), Windows 10/11, Android, macOS, and iOS.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx;
...
ret = wolfSSL_CTX_load_system_CA_certs(ctx,);
if (ret != WOLFSSL_SUCCESS) {
    // error loading system CA certs
}
...
```

C.58.4.34 function wolfSSL_CTX_trust_peer_cert

```
int wolfSSL_CTX_trust_peer_cert(
    WOLFSSL_CTX * ctx,
    const char * file,
    int type
)
```

This function loads a certificate to use for verifying a peer when performing a TLS/SSL handshake. The peer certificate sent during the handshake is compared by using the SKID when available and the signature. If these two things do not match then any loaded CAs are used. Feature is enabled by defining the macro WOLFSSL_TRUST_PEER_CERT. Please see the examples for proper usage.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **file** pointer to name of the file containing certificates
- **type** type of certificate being loaded ie SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM.

See:

- wolfSSL_CTX_load_verify_buffer
- wolfSSL_CTX_use_certificate_file
- wolfSSL_CTX_use_PrivateKey_file
- wolfSSL_CTX_use_certificate_chain_file
- wolfSSL_CTX_trust_peer_buffer
- wolfSSL_CTX_Unload_trust_peers
- wolfSSL_use_certificate_file
- wolfSSL_use_PrivateKey_file
- wolfSSL_use_certificate_chain_file

Return:

- SSL_SUCCES upon success.
- SSL_FAILURE will be returned if ctx is NULL, or if both file and type are invalid.
- SSL_BAD_FILETYPE will be returned if the file is the wrong format.
- SSL_BAD_FILE will be returned if the file doesn't exist, can't be read, or is corrupted.
- MEMORY_E will be returned if an out of memory condition occurs.
- ASN_INPUT_E will be returned if Base16 decoding fails on the file.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
...

ret = wolfSSL_CTX_trust_peer_cert(ctx, "./peer-cert.pem",
SSL_FILETYPE_PEM);
if (ret != SSL_SUCCESS) {
    // error loading trusted peer cert
}
...
```

C.58.4.35 function wolfSSL_CTX_use_certificate_chain_file

```
int wolfSSL_CTX_use_certificate_chain_file(
    WOLFSSL_CTX * ctx,
    const char * file
)
```

This function loads a chain of certificates into the SSL context (WOLFSSL_CTX). The file containing the certificate chain is provided by the file argument, and must contain PEM-formatted certificates. This function will process up to MAX_CHAIN_DEPTH (default = 9, defined in internal.h) certificates, plus the subject cert.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new()
- **file** a pointer to the name of the file containing the chain of certificates to be loaded into the wolfSSL SSL context. Certificates must be in PEM format.

See:

- wolfSSL_CTX_use_certificate_file
- wolfSSL_CTX_use_certificate_buffer
- wolfSSL_use_certificate_file
- wolfSSL_use_certificate_buffer

Return:

- SSL_SUCCESS upon success
- SSL_FAILURE If the function call fails, possible causes might include the file is in the wrong format, or the wrong format has been given using the "format" argument, file doesn't exist, can't be read, or is corrupted, an out of memory condition occurs.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx;
...
ret = wolfSSL_CTX_use_certificate_chain_file(ctx, "./cert-chain.pem");
if (ret != SSL_SUCCESS) {
    // error loading cert file
}
...
```

C.58.4.36 function wolfSSL_CTX_use_RSAPrivateKey_file

```
int wolfSSL_CTX_use_RSAPrivateKey_file(
    WOLFSSL_CTX * ctx,
    const char * file,
    int format
)
```

This function loads the private RSA key used in the SSL connection into the SSL context (WOLFSSL_CTX). This function is only available when wolfSSL has been compiled with the OpenSSL compatibility layer enabled (–enable-opensslExtra, #define OPENSSL_EXTRA), and is identical to the more-typically used wolfSSL_CTX_use_PrivateKey_file() function. The file argument contains a pointer to the RSA private key file, in the format specified by format.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new()
- **file** a pointer to the name of the file containing the RSA private key to be loaded into the wolfSSL SSL context, with format as specified by format.
- **format** the encoding type of the RSA private key specified by file. Possible values include SSL_FILETYPE_PEM and SSL_FILETYPE_ASN1.

See:

- wolfSSL_CTX_use_PrivateKey_buffer
- wolfSSL_CTX_use_PrivateKey_file
- wolfSSL_use_RSAPrivateKey_file
- wolfSSL_use_PrivateKey_buffer
- wolfSSL_use_PrivateKey_file

Return:

- SSL_SUCCESS upon success.
- SSL_FAILURE If the function call fails, possible causes might include: The input key file is in the wrong format, or the wrong format has been given using the “format” argument, file doesn’t exist, can’t be read, or is corrupted, an out of memory condition occurs.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx;
...
ret = wolfSSL_CTX_use_RSAPrivateKey_file(ctx, “./server-key.pem”,
                                         SSL_FILETYPE_PEM);
if (ret != SSL_SUCCESS) {
    // error loading private key file
}
...
```

C.58.4.37 function wolfSSL_get_verify_depth

```
long wolfSSL_get_verify_depth(
    WOLFSSL * ssl
)
```

This function returns the maximum chain depth allowed, which is 9 by default, for a valid session i.e. there is a non-null session object (ssl).

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See: wolfSSL_CTX_get_verify_depth

Return:

- MAX_CHAIN_DEPTH returned if the WOLFSSL structure is not NULL. By default the value is 9.
- BAD_FUNC_ARG returned if the WOLFSSL structure is NULL.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
WOLFSSL* ssl = wolfSSL_new(ctx);
...
long sslDep = wolfSSL_get_verify_depth(ssl);

if(sslDep > EXPECTED){
    // The verified depth is greater than what was expected
} else {
    // The verified depth is smaller or equal to the expected value
}
```

C.58.4.38 function wolfSSL_CTX_get_verify_depth

```
long wolfSSL_CTX_get_verify_depth(
    WOLFSSL_CTX * ctx
)
```

This function gets the certificate chaining depth using the CTX structure.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().

See:

- wolfSSL_CTX_use_certificate_chain_file
- wolfSSL_get_verify_depth

Return:

- MAX_CHAIN_DEPTH returned if the CTX struct is not NULL. The constant representation of the max certificate chain peer depth.
- BAD_FUNC_ARG returned if the CTX structure is NULL.

Example

```
WOLFSSL_METHOD method; // protocol method
WOLFSSL_CTX* ctx = WOLFSSL_CTX_new(method);
…
long ret = wolfSSL_CTX_get_verify_depth(ctx);

if(ret == EXPECTED){
    //  You have the expected value
} else {
    //  Handle an unexpected depth
}
```

C.58.4.39 function wolfSSL_use_certificate_file

```
int wolfSSL_use_certificate_file(
    WOLFSSL * ssl,
    const char * file,
```

```
    int format
)
```

This function loads a certificate file into the SSL session (WOLFSSL structure). The certificate file is provided by the file argument. The format argument specifies the format type of the file - either SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created with wolfSSL_new().
- **file** a pointer to the name of the file containing the certificate to be loaded into the wolfSSL SSL session, with format as specified by format.
- **format** the encoding type of the certificate specified by file. Possible values include SSL_FILETYPE_PEM and SSL_FILETYPE_ASN1.

See:

- wolfSSL_CTX_use_certificate_buffer
- wolfSSL_CTX_use_certificate_file
- wolfSSL_use_certificate_buffer

Return:

- SSL_SUCCESS upon success
- SSL_FAILURE If the function call fails, possible causes might include: The file is in the wrong format, or the wrong format has been given using the “format” argument, file doesn’t exist, can’t be read, or is corrupted, an out of memory condition occurs, Base16 decoding fails on the file

Example

```
int ret = 0;
WOLFSSL* ssl;
...
ret = wolfSSL_use_certificate_file(ssl, “./client-cert.pem”,
                                SSL_FILETYPE_PEM);
if (ret != SSL_SUCCESS) {
    // error loading cert file
}
...
```

C.58.4.40 function wolfSSL_use_PrivateKey_file

```
int wolfSSL_use_PrivateKey_file(
    WOLFSSL * ssl,
    const char * file,
    int format
)
```

This function loads a private key file into the SSL session (WOLFSSL structure). The key file is provided by the file argument. The format argument specifies the format type of the file - SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created with wolfSSL_new().
- **file** a pointer to the name of the file containing the key file to be loaded into the wolfSSL SSL session, with format as specified by format.
- **format** the encoding type of the key specified by file. Possible values include SSL_FILETYPE_PEM and SSL_FILETYPE_ASN1.

See:

- wolfSSL_CTX_use_PrivateKey_buffer
- wolfSSL_CTX_use_PrivateKey_file
- wolfSSL_use_PrivateKey_buffer
- wc_CryptoCb_RegisterDevice
- wolfSSL_SetDevId

Return:

- SSL_SUCCESS upon success.
- SSL_FAILURE If the function call fails, possible causes might include: The file is in the wrong format, or the wrong format has been given using the "format" argument, The file doesn't exist, can't be read, or is corrupted, An out of memory condition occurs, Base16 decoding fails on the file, The key file is encrypted but no password is provided

If using an external key store and do not have the private key you can instead provide the public key and register the crypro callback to handle the signing. For this you can build with either build with crypto callbacks or PK callbacks. To enable crypto callbacks use –enable-cryptocb or WOLF_CRYPTO_CB and register a crypto callback using wc_CryptoCb_RegisterDevice and set the associated devId using wolfSSL_SetDevId.

Example

```
int ret = 0;
WOLFSSL* ssl;
...
ret = wolfSSL_use_PrivateKey_file(ssl, "./server-key.pem",
                                  SSL_FILETYPE_PEM);
if (ret != SSL_SUCCESS) {
    // error loading key file
}
...
```

C.58.4.41 function wolfSSL_use_certificate_chain_file

```
int wolfSSL_use_certificate_chain_file(
    WOLFSSL * ssl,
    const char * file
)
```

This function loads a chain of certificates into the SSL session (WOLFSSL structure). The file containing the certificate chain is provided by the file argument, and must contain PEM-formatted certificates. This function will process up to MAX_CHAIN_DEPTH (default = 9, defined in internal.h) certificates, plus the subject certificate.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new()
- **file** a pointer to the name of the file containing the chain of certificates to be loaded into the wolfSSL SSL session. Certificates must be in PEM format.

See:

- wolfSSL_CTX_use_certificate_chain_file
- wolfSSL_CTX_use_certificate_chain_buffer
- wolfSSL_use_certificate_chain_buffer

Return:

- SSL_SUCCESS upon success.

- SSL_FAILURE If the function call fails, possible causes might include: The file is in the wrong format, or the wrong format has been given using the “format” argument, file doesn’t exist, can’t be read, or is corrupted, an out of memory condition occurs

Example

```
int ret = 0;
WOLFSSL* ctx;
...
ret = wolfSSL_use_certificate_chain_file(ssl, “./cert-chain.pem”);
if (ret != SSL_SUCCESS) {
    // error loading cert file
}
...
```

C.58.4.42 function wolfSSL_use_RSAPrivateKey_file

```
int wolfSSL_use_RSAPrivateKey_file(
    WOLFSSL * ssl,
    const char * file,
    int format
)
```

This function loads the private RSA key used in the SSL connection into the SSL session (WOLFSSL structure). This function is only available when wolfSSL has been compiled with the OpenSSL compatibility layer enabled (–enable-opensslExtra, #define OPENSSL_EXTRA), and is identical to the more-typically used wolfSSL_use_PrivateKey_file() function. The file argument contains a pointer to the RSA private key file, in the format specified by format.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new()
- **file** a pointer to the name of the file containing the RSA private key to be loaded into the wolfSSL SSL session, with format as specified by format.
- **format** the encoding type of the RSA private key specified by file. Possible values include SSL_FILETYPE_PEM and SSL_FILETYPE_ASN1.

See:

- wolfSSL_CTX_use_RSAPrivateKey_file
- wolfSSL_CTX_use_PrivateKey_buffer
- wolfSSL_CTX_use_PrivateKey_file
- wolfSSL_use_PrivateKey_buffer
- wolfSSL_use_PrivateKey_file

Return:

- SSL_SUCCESS upon success
- SSL_FAILURE If the function call fails, possible causes might include: The input key file is in the wrong format, or the wrong format has been given using the “format” argument, file doesn’t exist, can’t be read, or is corrupted, an out of memory condition occurs

Example

```
int ret = 0;
WOLFSSL* ssl;
...
ret = wolfSSL_use_RSAPrivateKey_file(ssl, “./server-key.pem”,
                                     SSL_FILETYPE_PEM);
if (ret != SSL_SUCCESS) {
```

```
    // error loading private key file
}
...
```

C.58.4.43 function wolfSSL_CTX_der_load_verify_locations

```
int wolfSSL_CTX_der_load_verify_locations(
    WOLFSSL_CTX * ctx,
    const char * file,
    int format
)
```

This function is similar to wolfSSL_CTX_load_verify_locations, but allows the loading of DER-formatted CA files into the SSL context (WOLFSSL_CTX). It may still be used to load PEM-formatted CA files as well. These certificates will be treated as trusted root certificates and used to verify certs received from peers during the SSL handshake. The root certificate file, provided by the file argument, may be a single certificate or a file containing multiple certificates. If multiple CA certs are included in the same file, wolfSSL will load them in the same order they are presented in the file. The format argument specifies the format which the certificates are in either, SSL_FILETYPE_PEM or SSL_FILETYPE_ASN1 (DER). Unlike wolfSSL_CTX_load_verify_locations, this function does not allow the loading of CA certificates from a given directory path. Note that this function is only available when the wolfSSL library was compiled with WOLFSSL_DER_LOAD defined.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new()
- **file** a pointer to the name of the file containing the CA certificates to be loaded into the wolfSSL SSL context, with format as specified by format.
- **format** the encoding type of the certificates specified by file. Possible values include SSL_FILETYPE_PEM and SSL_FILETYPE_ASN1.

See:

- wolfSSL_CTX_load_verify_locations
- wolfSSL_CTX_load_verify_buffer

Return:

- SSL_SUCCESS upon success.
- SSL_FAILURE upon failure.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx;
...
ret = wolfSSL_CTX_der_load_verify_locations(ctx, "./ca-cert.der",
                                            SSL_FILETYPE_ASN1);
if (ret != SSL_SUCCESS) {
    // error loading CA certs
}
...
```

C.58.4.44 function wolfSSL_CTX_new

```
WOLFSSL_CTX * wolfSSL_CTX_new(
    WOLFSSL_METHOD *
)
```

This function creates a new SSL context, taking a desired SSL/TLS protocol method for input.

Parameters:

- **method** pointer to the desired WOLFSSL_METHOD to use for the SSL context. This is created using one of the wolfSSLvXX_XXXX_method() functions to specify SSL/TLS/DTLS protocol level. This function frees the passed in WOLFSSL_METHOD struct on failure.

See: wolfSSL_new

Return:

- pointer If successful the call will return a pointer to the newly-created WOLFSSL_CTX.
- NULL upon failure.

Example

```
WOLFSSL_CTX*    ctx    = 0;
WOLFSSL_METHOD* method = 0;

method = wolfSSLv3_client_method();
if (method == NULL) {
    // unable to get method
}

ctx = wolfSSL_CTX_new(method);
if (ctx == NULL) {
    // context creation failed
}
```

C.58.4.45 function wolfSSL_new

```
WOLFSSL * wolfSSL_new(
    WOLFSSL_CTX *
)
```

This function creates a new SSL session, taking an already created SSL context as input.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().

See: wolfSSL_CTX_new

Return:

- – If successful the call will return a pointer to the newly-created wolfSSL structure.
- NULL Upon failure.

Example

```
#include <wolfssl/ssl.h>

WOLFSSL*     ssl = NULL;
WOLFSSL_CTX* ctx = 0;

ctx = wolfSSL_CTX_new(method);
if (ctx == NULL) {
    // context creation failed
}
```

```
ssl = wolfSSL_new(ctx);
if (ssl == NULL) {
    // SSL object creation failed
}
```

C.58.4.46 function wolfSSL_set_fd

```
int wolfSSL_set_fd(
    WOLFSSL * ssl,
    int fd
)
```

This function assigns a file descriptor (fd) as the input/output facility for the SSL connection. Typically this will be a socket file descriptor.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **fd** file descriptor to use with SSL/TLS connection.

See:

- wolfSSL_CTX_SetIOSend
- wolfSSL_CTX_SetIORecv
- wolfSSL_SetIOReadCtx
- wolfSSL_SetIOWriteCtx

Return:

- SSL_SUCCESS upon success.
- BAD_FUNC_ARG upon failure.

Example

```
int sockfd;
WOLFSSL* ssl = 0;
...

ret = wolfSSL_set_fd(ssl, sockfd);
if (ret != SSL_SUCCESS) {
    // failed to set SSL file descriptor
}
```

C.58.4.47 function wolfSSL_set_dtls_fd_connected

```
int wolfSSL_set_dtls_fd_connected(
    WOLFSSL * ssl,
    int fd
)
```

This function assigns a file descriptor (fd) as the input/output facility for the SSL connection. Typically this will be a socket file descriptor. This is a DTLS specific API because it marks that the socket is connected. recvfrom and sendto calls on this fd will have the addr and addr_len parameters set to NULL.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **fd** file descriptor to use with SSL/TLS connection.

See:

- wolfSSL_CTX_SetIOSend
- wolfSSL_CTX_SetIORecv
- wolfSSL_SetIOReadCtx
- wolfSSL_SetIOWriteCtx
- wolfDTLS_SetChGoodCb

Return:

- SSL_SUCCESS upon success.
- BAD_FUNC_ARG upon failure.

Example

```
int sockfd;
WOLFSSL* ssl = 0;
...
if (connect(sockfd, peer_addr, peer_addr_len) != 0) {
    // handle connect error
}
...
ret = wolfSSL_set_dtls_fd_connected(ssl, sockfd);
if (ret != SSL_SUCCESS) {
    // failed to set SSL file descriptor
}
```

C.58.4.48 function wolfDTLS_SetChGoodCb

```
int wolfDTLS_SetChGoodCb(
    WOLFSSL * ssl,
    ClientHelloGoodCb cb,
    void * user_ctx
)
```

Allows setting a callback for a correctly processed and verified DTLS client hello. When using a cookie exchange mechanism (either the HelloVerifyRequest in DTLS 1.2 or the HelloRetryRequest with a cookie extension in DTLS 1.3) this callback is called after the cookie exchange has succeeded. This is useful to use one WOLFSSL object as the listener for new connections and being able to isolate the WOLFSSL object once the ClientHello is verified (either through a cookie exchange or just checking if the ClientHello had the correct format). With DTLS cookies disabled, the callback is invoked once per ClientHello, only after complete successful ClientHello processing, not on its first fragment. Retries, retransmitted fragments and a second ClientHello after a key-share HelloRetryRequest do not repeat the notification. The object is already stateful before input is read, but the peer's return-routability has not been verified. Returning 0 accepts the ClientHello and the handshake continues. Any negative return stops the accept call with that error and leaves the accept state machine at the ClientHello, so nothing is sent to the peer and the next accept call asks the callback again instead of continuing the handshake. All negative returns behave this way; the value only decides what wolfSSL_get_error() reports, so what it means is the application's choice. A callback that is not ready to decide can return WANT_READ or WANT_WRITE and be asked again as many times as it needs, and one that refuses the peer returns its own error and keeps the server silent by refusing again on every later accept call. The cookie mode cannot be changed from the callback; see wolfSSL_disable_cookie(). DTLS 1.2: https://datatracker.ietf.org/doc/html/rfc6347#section_4.2.1 DTLS 1.3: https://www.rfc_editor.org/rfc/rfc8446#section_4.2.2.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **cb** ClientHelloGoodCb callback function pointer.
- **user_ctx** pointer to user context to be passed to callback.

See: wolfSSL_set_dtls_fd_connected

Return:

- SSL_SUCCESS upon success.
- BAD_FUNC_ARG upon failure.

Example

```
// Called when we have verified a connection
static int chGoodCb(WOLFSSL* ssl, void* arg)
{
    // setup peer and file descriptors

}

if (wolfDTLS_SetChGoodCb(ssl, chGoodCb, NULL) != WOLFSSL_SUCCESS) {
     // error setting callback
}
```

C.58.4.49 function wolfSSL_get_cipher_list

```
char * wolfSSL_get_cipher_list(
    int priority
)
```

Get the name of cipher at priority level passed in.

Parameters:

- **priority** Integer representing the priority level of a cipher.

See:

- wolfSSL_CIPHER_get_name
- wolfSSL_get_current_cipher

Return:

- string Success
- 0 Priority is either out of bounds or not valid.

Example

```
printf("The cipher at 1 is %s", wolfSSL_get_cipher_list(1));
```

C.58.4.50 function wolfSSL_get_ciphers

```
int wolfSSL_get_ciphers(
    char * buf,
    int len
)
```

This function gets the ciphers enabled in wolfSSL.

Parameters:

- **buf** a char pointer representing the buffer.
- **len** the length of the buffer.

See:

- GetCipherNames

- wolfSSL_get_cipher_list
- ShowCiphers

Return:

- SSL_SUCCESS returned if the function executed without error.
- BAD_FUNC_ARG returned if the buf parameter was NULL or if the len argument was less than or equal to zero.
- BUFFER_E returned if the buffer is not large enough and will overflow.

Example

```
static void ShowCiphers(void){
char* ciphers;
int ret = wolfSSL_get_ciphers(ciphers, (int)sizeof(ciphers));

if(ret == SSL_SUCCES){
        printf("%s\n", ciphers);
    }
}
```

C.58.4.51 function wolfSSL_get_cipher_name

```
const char * wolfSSL_get_cipher_name(
    WOLFSSL * ssl
)
```

This function gets the cipher name in the format DHE-RSA by passing through argument to wolfSSL_get_cipher_name_internal.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_CIPHER_get_name
- wolfSSL_get_current_cipher
- wolfSSL_get_cipher_name_internal

Return:

- string This function returns the string representation of the cipher suite that was matched.
- NULL error or cipher not found.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
WOLFSSL* ssl = wolfSSL_new(ctx);
…
char* cipherS = wolfSSL_get_cipher_name(ssl);

if(cipher == NULL){
    // There was not a cipher suite matched
} else {
    // There was a cipher suite matched
    printf("%s\n", cipherS);
}
```

C.58.4.52 function wolfSSL_get_fd

```
int wolfSSL_get_fd(
    const WOLFSSL * ssl
)
```

This function returns the read file descriptor (fd) used as the input facility for the SSL connection. Typically this will be a socket file descriptor.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().

See:

- wolfSSL_set_fd
- wolfSSL_set_read_fd
- wolfSSL_set_write_fd

Return: fd If successful the call will return the SSL session file descriptor.

Example

```
int sockfd;
WOLFSSL* ssl = 0;
...
sockfd = wolfSSL_get_fd(ssl);
...
```

C.58.4.53 function wolfSSL_get_wfd

```
int wolfSSL_get_wfd(
    const WOLFSSL * ssl
)
```

This function returns the write file descriptor (fd) used as the output facility for the SSL connection. Typically this will be a socket file descriptor.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().

See:

- wolfSSL_set_fd
- wolfSSL_set_read_fd
- wolfSSL_set_write_fd

Return: fd If successful the call will return the SSL session file descriptor.

Example

```
int sockfd;
WOLFSSL* ssl = 0;
...
sockfd = wolfSSL_get_wfd(ssl);
...
```

C.58.4.54 function wolfSSL_set_using_nonblock

```
void wolfSSL_set_using_nonblock(
    WOLFSSL * ssl,
```

```
    int nonblock
)
```

This function informs the WOLFSSL object that the underlying I/O is non-blocking. After an application creates a WOLFSSL object, if it will be used with a non-blocking socket, call wolfSSL_set_using_nonblock() on it. This lets the WOLFSSL object know that receiving EWOULDBLOCK means that the recvfrom call would block rather than that it timed out.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **nonblock** value used to set non-blocking flag on WOLFSSL object. Use 1 to specify non-blocking, otherwise 0.

See:

- wolfSSL_get_using_nonblock
- wolfSSL_dtls_got_timeout
- wolfSSL_dtls_get_current_timeout

Return: none No return.

Example

```
WOLFSSL* ssl = 0;
...
wolfSSL_set_using_nonblock(ssl, 1);
```

C.58.4.55 function wolfSSL_get_using_nonblock

```
int wolfSSL_get_using_nonblock(
    WOLFSSL *
)
```

This function allows the application to determine if wolfSSL is using non-blocking I/O. If wolfSSL is using non-blocking I/O, this function will return 1, otherwise 0. After an application creates a WOLFSSL object, if it will be used with a non-blocking socket, call wolfSSL_set_using_nonblock() on it. This lets the WOLFSSL object know that receiving EWOULDBLOCK means that the recvfrom call would block rather than that it timed out.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().

See: wolfSSL_set_session

Return:

- 0 underlying I/O is blocking.
- 1 underlying I/O is non-blocking.

Example

```
int ret = 0;
WOLFSSL* ssl = 0;
...
ret = wolfSSL_get_using_nonblock(ssl);
if (ret == 1) {
    // underlying I/O is non-blocking
}
...
```

C.58.4.56 function wolfSSL_write

```
int wolfSSL_write(
    WOLFSSL * ssl,
    const void * data,
    int sz
)
```

This function writes sz bytes from the buffer, data, to the SSL connection, ssl. If necessary, wolfSSL_write() will negotiate an SSL/TLS session if the handshake has not already been performed yet by wolfSSL_connect() or wolfSSL_accept(). When using (D)TLSv1.3 and early data feature is compiled in, this function progresses the handshake only up to the point when it is possible to send data. Next invocations of wolfSSL_Connect()/wolfSSL_Accept()/wolfSSL_read() will complete the handshake. wolfSSL_write() works with both blocking and non_blocking I/O. When the underlying I/O is non_blocking, wolfSSL_write() will return when the underlying I/O could not satisfy the needs of wolfSSL_write() to continue. In this case, a call to wolfSSL_get_error() will yield either SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE. The calling process must then repeat the call to wolfSSL_write() when the underlying I/O is ready. If the underlying I/O is blocking, wolfSSL_write() will only return once the buffer data of size sz has been completely written or an error occurred.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **data** data buffer which will be sent to peer.
- **sz** size, in bytes, of data to send to the peer (data).

See:

- wolfSSL_send
- wolfSSL_read
- wolfSSL_recv

Return:

- 0 the number of bytes written upon success.
- 0 will be returned upon failure. Call wolfSSL_get_error() for the specific error code.
- SSL_FATAL_ERROR will be returned upon failure when either an error occurred or, when using non-blocking sockets, the SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE error was received and and the application needs to call wolfSSL_write() again. Use wolfSSL_get_error() to get a specific error code.
- BAD_FUNC_ARG will be returned when ssl or data is NULL, or sz is negative.

Example

```
WOLFSSL* ssl = 0;
char msg[64] = “hello wolfssl!”;
int msgSz = (int)strlen(msg);
int flags;
int ret;
...

ret = wolfSSL_write(ssl, msg, msgSz);
if (ret <= 0) {
    // wolfSSL_write() failed, call wolfSSL_get_error()
}
```

C.58.4.57 function wolfSSL_write_ex

```
int wolfSSL_write_ex(
    WOLFSSL * ssl,
    const void * data,
    size_t sz,
    size_t * wr
)
```

This function writes sz bytes from the buffer, data, to the SSL connection, ssl, and reports the number of bytes written. It is equivalent to wolfSSL_write() except that the length written is returned through wr and the return value only indicates success or failure. Whether a partial write counts as success depends on WOLFSSL_MODE_ENABLE_PARTIAL_WRITE having been set with wolfSSL_CTX_set_mode(); without it, anything short of the full length is a failure.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **data** data buffer to write to the SSL connection.
- **sz** number of bytes to write.
- **wr** pointer that receives the number of bytes written. May be NULL. Set to zero before anything else is done, so it reads as zero even when the call fails. This differs from wolfSSL_read_ex(), which leaves its count alone unless data was read.

See:

- wolfSSL_write
- wolfSSL_read_ex
- wolfSSL_get_error

Return:

- 1 on success.
- 0 on failure. Call wolfSSL_get_error() for the reason.
- BAD_FUNC_ARG when ssl is NULL.

Example

```
WOLFSSL* ssl = 0;
char msg[] = "hello wolfssl!";
size_t written = 0;
...

if (wolfSSL_write_ex(ssl, msg, sizeof(msg), &written) != 1) {
    // handle the failure, see wolfSSL_get_error()
}
```

C.58.4.58 function wolfSSL_read

```
int wolfSSL_read(
    WOLFSSL * ssl,
    void * data,
    int sz
)
```

This function reads sz bytes from the SSL session (ssl) internal read buffer into the buffer data. The bytes read are removed from the internal receive buffer. If necessary wolfSSL_read() will negotiate an SSL/TLS session if the handshake has not already been performed yet by wolfSSL_connect() or wolfSSL_accept(). The SSL/TLS protocol uses SSL records which have a maximum size of 16kB (the max

record size can be controlled by the MAX_RECORD_SIZE define in /wolfssl/internal.h). As such, wolfSSL needs to read an entire SSL record internally before it is able to process and decrypt the record. Because of this, a call to wolfSSL_read() will only be able to return the maximum buffer size which has been decrypted at the time of calling. There may be additional not_yet_decrypted data waiting in the internal wolfSSL receive buffer which will be retrieved and decrypted with the next call to wolfSSL_read(). If sz is larger than the number of bytes in the internal read buffer, SSL_read() will return the bytes available in the internal read buffer. If no bytes are buffered in the internal read buffer yet, a call to wolfSSL_read() will trigger processing of the next record.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **data** buffer where wolfSSL_read() will place data read.
- **sz** number of bytes to read into data.

See:

- wolfSSL_recv
- wolfSSL_write
- wolfSSL_peek
- wolfSSL_pending

Return:

- 0 the number of bytes read upon success.
- 0 will be returned upon failure. This may be caused by a either a clean (close notify alert) shutdown or just that the peer closed the connection. Call wolfSSL_get_error() for the specific error code.
- SSL_FATAL_ERROR will be returned upon failure when either an error occurred or, when using non-blocking sockets, the SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE error was received and and the application needs to call wolfSSL_read() again. Use wolfSSL_get_error() to get a specific error code.
- BAD_FUNC_ARG will be returned when ssl or data is NULL, or sz is negative.

Example

```
WOLFSSL* ssl = 0;
char reply[1024];
...

input = wolfSSL_read(ssl, reply, sizeof(reply));
if (input > 0) {
    // “input” number of bytes returned into buffer “reply”
}

See wolfSSL examples (client, server, echoclient, echoserver) for more
complete examples of wolfSSL_read().
```

C.58.4.59 function wolfSSL_read_ex

```
int wolfSSL_read_ex(
    WOLFSSL * ssl,
    void * data,
    size_t sz,
    size_t * rd
)
```

This function reads up to sz bytes of decrypted application data from the SSL connection, ssl, into the buffer, data, and reports the number of bytes read. It is equivalent to wolfSSL_read() except that the length read is returned through rd and the return value only indicates whether any application data was read.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **data** buffer to hold the data read.
- **sz** size of the buffer in bytes.
- **rd** pointer that receives the number of bytes read. May be NULL and is only set when data was read, so it keeps whatever the caller left in it when the call fails. This differs from wolfSSL_write_ex(), which clears its count first.

See:

- wolfSSL_read
- wolfSSL_write_ex
- wolfSSL_pending
- wolfSSL_get_error

Return:

- 1 when application data was read.
- 0 when no application data was read. Call wolfSSL_get_error() for the reason.
- BAD_FUNC_ARG when ssl is NULL.

Example

```
WOLFSSL* ssl = 0;
char reply[1024];
size_t bytesRead = 0;
...

if (wolfSSL_read_ex(ssl, reply, sizeof(reply), &bytesRead) == 1) {
    // "bytesRead" bytes returned into buffer "reply"
}
```

C.58.4.60 function wolfSSL_peek

```
int wolfSSL_peek(
    WOLFSSL * ssl,
    void * data,
    int sz
)
```

This function copies sz bytes from the SSL session (ssl) internal read buffer into the buffer data. This function is identical to wolfSSL_read() except that the data in the internal SSL session receive buffer is not removed or modified. If necessary, like wolfSSL_read(), wolfSSL_peek() will negotiate an SSL/TLS session if the handshake has not already been performed yet by wolfSSL_connect() or wolfSSL_accept(). The SSL/TLS protocol uses SSL records which have a maximum size of 16kB (the max record size can be controlled by the MAX_RECORD_SIZE define in /wolfssl/internal.h). As such, wolfSSL needs to read an entire SSL record internally before it is able to process and decrypt the record. Because of this, a call to wolfSSL_peek() will only be able to return the maximum buffer size which has been decrypted at the time of calling. There may be additional not_yet_decrypted data waiting in the internal wolfSSL receive buffer which will be retrieved and decrypted with the next call to wolfSSL_peek() / wolfSSL_read(). If sz is larger than the number of bytes in the internal read buffer, SSL_peek() will return the bytes available in the internal read buffer. If no bytes are buffered in the internal read buffer yet, a call to wolfSSL_peek() will trigger processing of the next record.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **data** buffer where wolfSSL_peek() will place data read.
- **sz** number of bytes to read into data.

See: wolfSSL_read

Return:

- 0 the number of bytes read upon success.
- 0 will be returned upon failure. This may be caused by a either a clean (close notify alert) shutdown or just that the peer closed the connection. Call wolfSSL_get_error() for the specific error code.
- SSL_FATAL_ERROR will be returned upon failure when either an error occurred or, when using nonblocking sockets, the SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE error was received and and the application needs to call wolfSSL_peek() again. Use wolfSSL_get_error() to get a specific error code.
- BAD_FUNC_ARG will be returned when ssl or data is NULL, or sz is negative.

Example

```
WOLFSSL* ssl = 0;
char reply[1024];
...

input = wolfSSL_peek(ssl, reply, sizeof(reply));
if (input > 0) {
    // “input” number of bytes returned into buffer “reply”
}
```

C.58.4.61 function wolfSSL_accept

```
int wolfSSL_accept(
    WOLFSSL * ssl
)
```

This function is called on the server side and waits for an SSL client to initiate the SSL/TLS handshake. When this function is called, the underlying communication channel has already been set up. wolfSSL_accept() works with both blocking and non_blocking I/O. When the underlying I/O is non_blocking, wolfSSL_accept() will return when the underlying I/O could not satisfy the needs of wolfSSL_accept to continue the handshake. In this case, a call to wolfSSL_get_error() will yield either SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE. The calling process must then repeat the call to wolfSSL_accept when data is available to read and wolfSSL will pick up where it left off. When using a non_blocking socket, nothing needs to be done, but select() can be used to check for the required condition. If the underlying I/O is blocking, wolfSSL_accept() will only return once the handshake has been finished or an error occurred.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_get_error
- wolfSSL_connect

Return:

- SSL_SUCCESS upon success.
- SSL_FATAL_ERROR will be returned if an error occurred. To get a more detailed error code, call wolfSSL_get_error().

If decrypted application data is waiting to be read, for example early data that has not been read yet or data received during a secure renegotiation, the handshake is not continued and wolfSSL_get_error() returns APP_DATA_READY. Read the data with wolfSSL_read() and then call wolfSSL_accept() again.

Example

```
int ret = 0;
int err = 0;
WOLFSSL* ssl;
char buffer[80];
...

ret = wolfSSL_accept(ssl);
if (ret != SSL_SUCCESS) {
    err = wolfSSL_get_error(ssl, ret);
    printf("error = %d, %s\n", err, wolfSSL_ERR_error_string(err, buffer));
}
```

C.58.4.62 function wolfDTLS_accept_stateless

```
int wolfDTLS_accept_stateless(
    WOLFSSL * ssl
)
```

This function statelessly listens for an SSL client to initiate the DTLS handshake. Cookies must be enabled. A cookie-disabled DTLS object is rejected before I/O or callback changes: WOLFSSL_FATAL_ERROR is returned and wolfSSL_get_error() reports BAD_STATE_E. Use wolfSSL_accept() for cookie-disabled connections instead.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_accept
- wolfSSL_get_error
- wolfSSL_connect

Return:

- WOLFSSL_SUCCESS ClientHello containing a valid cookie was received. The connection can be continued with wolfSSL_accept().
- WOLFSSL_FAILURE The I/O layer returned WANT_READ. This is either because there is no data to read and we are using non-blocking sockets or we sent a cookie request and we are waiting for a reply. The user should call wolfDTLS_accept_stateless again after data becomes available in the I/O layer.
- WOLFSSL_FATAL_ERROR A fatal error occurred. The ssl object should be free'd and allocated again to continue. wolfSSL_get_error() reports SIDE_ERROR when called on a client object, and BAD_STATE_E when cookies are disabled on this object.

Example

```
int ret = 0;
int err = 0;
WOLFSSL* ssl;
```

```
...
do {
    ret = wolfDTLS_accept_stateless(ssl);
    if (ret == WOLFSSL_FATAL_ERROR)
        // re-allocate the ssl object with wolfSSL_free() and wolfSSL_new()
} while (ret != WOLFSSL_SUCCESS);
ret = wolfSSL_accept(ssl);
if (ret != SSL_SUCCESS) {
    err = wolfSSL_get_error(ssl, ret);
    printf("error = %d, %s\n", err, wolfSSL_ERR_error_string(err, buffer));
}
```

C.58.4.63 function wolfSSL_disable_cookie

```
int wolfSSL_disable_cookie(
    WOLFSSL * ssl
)
```

Disable server cookies for DTLS 1.2, DTLS 1.3 and TLS 1.3, including DTLS 1.2 fallback from DTLS 1.3. Cookies are enabled by default for DTLS. For DTLS, ordinary wolfSSL_accept() or wolfSSL_accept_TLSv13() commits it to stateful processing before the first read, even if a nonblocking accept has no input available. The application must isolate/demultiplex the peer before accepting; disabling cookies removes return_routability verification and exposes the server to DoS/amplification attacks. wolfDTLS_accept_stateless() cannot be used.

Parameters:

- **ssl** DTLS or TLS 1.3 server session created with wolfSSL_new(). A general-purpose session that has not chosen a side yet is accepted: the policy set here is what the promotion to the server side finds.

See:

- wolfSSL_enable_cookie
- wolfDTLS_SetChGoodCb

Return:

- WOLFSSL_SUCCESS on success (including an unchanged mode).
- BAD_FUNC_ARG if ssl is NULL or uses an unsupported protocol (TLS 1.2).
- SIDE_ERROR if ssl is a client.
- BAD_STATE_E if the DTLS handshake already committed to stateful processing.

Primary and secondary cookie secrets for the applicable protocols are securely erased and freed.

Without cookies a DTLS 1.3 server can process a first ClientHello that arrives fragmented, but only when ClientHello fragment reassembly is available: wolfSSL must be built with WOLFSSL_DTLS_CH_FRAG (–enable-dtls-frag-ch, turned on automatically with ML-KEM and DTLS 1.3) and it must be enabled on the object with wolfSSL_dtls13_allow_ch_frag(), which is done by default only in builds with ML-KEM. Otherwise the fragments are dropped and the handshake does not progress.

The DTLS cookie mode is fixed once the handshake commits to stateful processing, which the accept functions do before the first read and stateless processing does when a cookie verifies. After that this call fails instead of reporting a change that cannot take effect, so it cannot be used from a ClientHello good callback.

C.58.4.64 function wolfSSL_enable_cookie

```
int wolfSSL_enable_cookie(
    WOLFSSL * ssl
)
```

Enable server cookies for DTLS 1.2, DTLS 1.3 and TLS 1.3. Like wolfSSL_disable_cookie(), this does not change stateful processing. It can undo a disable before accept begins, including wolfSSL_disable_hrr_cookie(). Missing primary cookie secrets are randomly generated immediately; existing primary and secondary secrets are preserved.

Parameters:

- **ssl** DTLS or TLS 1.3 server session created with wolfSSL_new(). A general-purpose session that has not chosen a side yet is accepted: the policy set here is what the promotion to the server side finds.

See: wolfSSL_disable_cookie

Return:

- WOLFSSL_SUCCESS on success (including an unchanged mode).
- BAD_FUNC_ARG if ssl is NULL or uses an unsupported protocol (TLS 1.2).
- SIDE_ERROR if ssl is a client.
- BAD_STATE_E if the DTLS handshake already committed to stateful processing, as for wolfSSL_disable_cookie(), or if a missing secret must be generated and the session's RNG has been released (as happens when its handshake resources are freed).
- MEMORY_ERROR if secret allocation fails, or another negative error if random secret generation fails. A failure is all or nothing: no secret is installed and the cookie policy is left as it was found, even when the session needs both a DTLS 1.2 and a DTLS 1.3 secret.

C.58.4.65 function wolfSSL_CTX_free

```
void wolfSSL_CTX_free(
    WOLFSSL_CTX * ctx
)
```

This function frees an allocated WOLFSSL_CTX object. This function decrements the CTX reference count and only frees the context when the reference count has reached 0.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().

See:

- wolfSSL_CTX_new
- wolfSSL_new
- wolfSSL_free

Return: none No return.

Example

```
WOLFSSL_CTX* ctx = 0;
...
wolfSSL_CTX_free(ctx);
```

C.58.4.66 function wolfSSL_free

```
void wolfSSL_free(
    WOLFSSL * ssl
)
```

This function frees an allocated wolfSSL object.

Parameters:

- **ssl** pointer to the SSL object, created with wolfSSL_new().

See:

- wolfSSL_CTX_new
- wolfSSL_new
- wolfSSL_CTX_free

Return: none No return.

Example

```
#include <wolfssl/ssl.h>

WOLFSSL* ssl = 0;
...
wolfSSL_free(ssl);
```

C.58.4.67 function wolfSSL_shutdown

```
int wolfSSL_shutdown(
    WOLFSSL * ssl
)
```

This function shuts down an active SSL/TLS connection using the SSL session, ssl. This function will try to send a "close notify" alert to the peer. The calling application can choose to wait for the peer to send its "close notify" alert in response or just go ahead and shut down the underlying connection after directly calling wolfSSL_shutdown (to save resources). Either option is allowed by the TLS specification. If the underlying connection will be used again in the future, the complete two-directional shutdown procedure must be performed to keep synchronization intact between the peers. wolfSSL_shutdown() works with both blocking and non_blocking I/O. When the underlying I/O is non_blocking, wolfSSL_shutdown() will return an error if the underlying I/O could not satisfy the needs of wolfSSL_shutdown() to continue. In this case, a call to wolfSSL_get_error() will yield either SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE. The calling process must then repeat the call to wolfSSL_shutdown() when the underlying I/O is ready.

Parameters:

- **ssl** pointer to the SSL session created with wolfSSL_new().

See:

- wolfSSL_free
- wolfSSL_CTX_free

Return:

- SSL_SUCCESS will be returned upon success.
- SSL_SHUTDOWN_NOT_DONE will be returned when shutdown has not finished, and the function should be called again.
- SSL_FATAL_ERROR will be returned upon failure. Call wolfSSL_get_error() for a more specific error code.

When the connection is already closed or reset and no close notify was ever sent, the exchange can never complete and SSL_FATAL_ERROR is returned, so a loop that calls this function until the shutdown completes terminates. wolfSSL_get_error() then reports SOCKET_PEER_CLOSED_E, unless a more specific error has already been recorded. That code is used whatever closed the connection, including this side sending a fatal alert, so under OPENSSL_EXTRA, where wolfSSL_get_error() reports it as

SSL_ERROR_SYSCALL, a locally aborted connection can surface as a syscall error. Recording it also puts an entry on the OpenSSL error queue in builds that have one, so an application that inspects the queue after tearing down an already_aborted connection finds an entry where it previously found none; call wolfSSL_ERR_clear_error() if leftover entries matter.

Example

```
#include <wolfssl/ssl.h>

int ret = 0;
WOLFSSL* ssl = 0;
...
ret = wolfSSL_shutdown(ssl);
if (ret != 0) {
    // failed to shut down SSL connection
}
```

C.58.4.68 function wolfSSL_SendUserCanceled

```
int wolfSSL_SendUserCanceled(
    WOLFSSL * ssl
)
```

This function sends a user_canceled alert to the peer and then shuts the connection down by calling wolfSSL_shutdown(). It is used when the application abandons a connection for its own reasons rather than because of a protocol failure.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().

See:

- wolfSSL_shutdown
- wolfSSL_get_error

Return:

- WOLFSSL_SUCCESS on successful shutdown.
- WOLFSSL_SHUTDOWN_NOT_DONE when the peer has yet to send its close notify alert. Call wolfSSL_shutdown() again to complete the bidirectional shutdown. Under WOLFSSL_ERROR_CODE_OPENSSL this value is 0, which is also WOLFSSL_FAILURE, so in that configuration the return value alone does not separate this case from the one below.
- WOLFSSL_FAILURE when ssl is NULL or the alert could not be sent. Call wolfSSL_get_error() for the reason.
- WOLFSSL_FATAL_ERROR when the shutdown that follows the alert fails. Call wolfSSL_get_error() for the reason.
- SSL_SHUTDOWN_ALREADY_DONE_E when the connection was already shut down and WOLFSSL_SHUTDOWNONCE is defined.

Note: RFC 9846, Section 6.1 requires this alert to be followed by a close notify, which is why the shutdown is part of this call. On the receiving side the alert is not itself an error: a TLS 1.3 peer keeps reading until the close notify arrives, whatever AlertLevel was used.

Example

```
int ret = 0;
WOLFSSL* ssl = 0;
...
```

```
ret = wolfSSL_SendUserCanceled(ssl);
if (ret != WOLFSSL_SUCCESS) {
    // failed to shut the connection down, see wolfSSL_get_error()
}
```

C.58.4.69 function wolfSSL_send

```
int wolfSSL_send(
    WOLFSSL * ssl,
    const void * data,
    int sz,
    int flags
)
```

This function writes sz bytes from the buffer, data, to the SSL connection, ssl, using the specified flags for the underlying write operation. If necessary wolfSSL_send() will negotiate an SSL/TLS session if the handshake has not already been performed yet by wolfSSL_connect() or wolfSSL_accept(). wolfSSL_send() works with both blocking and non_blocking I/O. When the underlying I/O is non_blocking, wolfSSL_send() will return when the underlying I/O could not satisfy the needs of wolfSSL_send to continue. In this case, a call to wolfSSL_get_error() will yield either SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE. The calling process must then repeat the call to wolfSSL_send() when the underlying I/O is ready. If the underlying I/O is blocking, wolfSSL_send() will only return once the buffer data of size sz has been completely written or an error occurred.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **data** data buffer to send to peer.
- **sz** size, in bytes, of data to be sent to peer.
- **flags** the send flags to use for the underlying send operation.

See:

- wolfSSL_write
- wolfSSL_read
- wolfSSL_recv

Return:

- 0 the number of bytes written upon success.
- 0 will be returned upon failure. Call wolfSSL_get_error() for the specific error code.
- SSL_FATAL_ERROR will be returned upon failure when either an error occurred or, when using non-blocking sockets, the SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE error was received and and the application needs to call wolfSSL_send() again. Use wolfSSL_get_error() to get a specific error code.
- BAD_FUNC_ARG will be returned when ssl or data is NULL, or sz is negative.

Example

```
WOLFSSL* ssl = 0;
char msg[64] = “hello wolfssl!”;
int msgSz = (int)strlen(msg);
int flags = ... ;
...

input = wolfSSL_send(ssl, msg, msgSz, flags);
if (input != msgSz) {
```

```
    // wolfSSL_send() failed
}
```

C.58.4.70 function wolfSSL_recv

```
int wolfSSL_recv(
    WOLFSSL * ssl,
    void * data,
    int sz,
    int flags
)
```

This function reads sz bytes from the SSL session (ssl) internal read buffer into the buffer data using the specified flags for the underlying recv operation. The bytes read are removed from the internal receive buffer. This function is identical to wolfSSL_read() except that it allows the application to set the recv flags for the underlying read operation. If necessary wolfSSL_recv() will negotiate an SSL/TLS session if the handshake has not already been performed yet by wolfSSL_connect() or wolfSSL_accept(). The SSL/TLS protocol uses SSL records which have a maximum size of 16kB (the max record size can be controlled by the MAX_RECORD_SIZE define in /wolfssl/internal.h). As such, wolfSSL needs to read an entire SSL record internally before it is able to process and decrypt the record. Because of this, a call to wolfSSL_recv() will only be able to return the maximum buffer size which has been decrypted at the time of calling. There may be additional not_yet_decrypted data waiting in the internal wolfSSL receive buffer which will be retrieved and decrypted with the next call to wolfSSL_recv(). If sz is larger than the number of bytes in the internal read buffer, SSL_recv() will return the bytes available in the internal read buffer. If no bytes are buffered in the internal read buffer yet, a call to wolfSSL_recv() will trigger processing of the next record.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **data** buffer where wolfSSL_recv() will place data read.
- **sz** number of bytes to read into data.
- **flags** the recv flags to use for the underlying recv operation.

See:

- wolfSSL_read
- wolfSSL_write
- wolfSSL_peek
- wolfSSL_pending

Return:

- 0 the number of bytes read upon success.
- 0 will be returned upon failure. This may be caused by a either a clean (close notify alert) shutdown or just that the peer closed the connection. Call wolfSSL_get_error() for the specific error code.
- SSL_FATAL_ERROR will be returned upon failure when either an error occurred or, when using non-blocking sockets, the SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE error was received and and the application needs to call wolfSSL_recv() again. Use wolfSSL_get_error() to get a specific error code.
- BAD_FUNC_ARG will be returned when ssl or data is NULL, or sz is negative.

Example

```
WOLFSSL* ssl = 0;
char reply[1024];
```

```
int flags = ... ;
...

input = wolfSSL_recv(ssl, reply, sizeof(reply), flags);
if (input > 0) {
    // “input” number of bytes returned into buffer “reply”
}
```

C.58.4.71 function wolfSSL_get_error

```
int wolfSSL_get_error(
    WOLFSSL * ssl,
    int ret
)
```

This function returns a unique error code describing why the previous API function call (wolfSSL_connect, wolfSSL_accept, wolfSSL_read, wolfSSL_write, etc.) resulted in an error return code (SSL_FAILURE). The return value of the previous function is passed to wolfSSL_get_error through ret. After wolfSSL_get_error is called and returns the unique error code, wolfSSL_ERR_error_string() may be called to get a human_readable error string. See wolfSSL_ERR_error_string() for more information.

Parameters:

- **ssl** pointer to the SSL object, created with wolfSSL_new().
- **ret** return value of the previous function that resulted in an error return code.

See:

- wolfSSL_ERR_error_string
- wolfSSL_ERR_error_string_n
- wolfSSL_ERR_print_errors_fp
- wolfSSL_load_error_strings

Return:

- On successful completion, this function will return the unique error code describing why the previous API function failed.
- SSL_ERROR_NONE will be returned if ret > 0. For ret <= 0, there are some cases when this value can also be returned when a previous API appeared to return an error code but no error actually occurred. An example is calling wolfSSL_read() with a zero sz parameter. A 0 return from wolfSSL_read() usually indicates an error but in this case no error occurred. If wolfSSL_get_error() is called afterwards, SSL_ERROR_NONE will be returned.

Example

```
int err = 0;
WOLFSSL* ssl;
char buffer[80];
...
err = wolfSSL_get_error(ssl, 0);
wolfSSL_ERR_error_string(err, buffer);
printf(“err = %d, %s\n”, err, buffer);
```

C.58.4.72 function wolfSSL_get_alert_history

```
int wolfSSL_get_alert_history(
    WOLFSSL * ssl,
    WOLFSSL_ALERT_HISTORY * h
)
```

This function gets the alert history.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **h** a pointer to a WOLFSSL_ALERT_HISTORY structure that will hold the WOLFSSL struct's alert_history member's value.

See: wolfSSL_get_error

Return: SSL_SUCCESS returned when the function completed successfully. Either there was alert history or there wasn't, either way, the return value is SSL_SUCCESS.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new(protocol method);
WOLFSSL* ssl = wolfSSL_new(ctx);
WOLFSSL_ALERT_HISTORY* h;
...
wolfSSL_get_alert_history(ssl, h);
// h now has a copy of the ssl->alert_history  contents
```

C.58.4.73 function wolfSSL_set_session

```
int wolfSSL_set_session(
    WOLFSSL * ssl,
    WOLFSSL_SESSION * session
)
```

This function sets the session to be used when the SSL object, ssl, is used to establish a SSL/TLS connection. For session resumption, before calling wolfSSL_shutdown() with your session object, an application should save the session ID from the object with a call to wolfSSL_get1_session(), which returns a pointer to the session. Later, the application should create a new WOLFSSL object and assign the saved session with wolfSSL_set_session(). At this point, the application may call wolfSSL_connect() and wolfSSL will try to resume the session. The wolfSSL server code allows session resumption by default. The object returned by wolfSSL_get1_session() needs to be freed after the application is done with it by calling wolfSSL_SESSION_free() on it.

Parameters:

- **ssl** pointer to the SSL object, created with wolfSSL_new().
- **session** pointer to the WOLFSSL_SESSION used to set the session for ssl.

See: wolfSSL_get1_session

Return:

- SSL_SUCCESS will be returned upon successfully setting the session.
- SSL_FAILURE will be returned on failure. This could be caused by the session cache being disabled, the session having timed out, or an EMS session being declined because EMS is disabled.
- When OPENSSL_EXTRA and WOLFSSL_ERROR_CODE_OPENSSL are defined, SSL_SUCCESS will be returned even if the session has timed out.

Example

```
int ret;
WOLFSSL* ssl;
WOLFSSL_SESSION* session;
...
session = wolfSSL_get1_session(ssl);
if (session == NULL) {
```

```
    // failed to get session object from ssl object
}
...
ret = wolfSSL_set_session(ssl, session);
if (ret != SSL_SUCCESS) {
    // failed to set the SSL session
}
wolfSSL_SESSION_free(session);
...
```

C.58.4.74 function wolfSSL_get_session

```
WOLFSSL_SESSION * wolfSSL_get_session(
    WOLFSSL * ssl
)
```

Returns a pointer to the current session (WOLFSSL_SESSION) used in ssl. This is a non-persistent pointer to the WOLFSSL_SESSION object, freed when wolfSSL_free is called, so the call should only be used to inspect or modify the current session. For session resumption use wolfSSL_get1_session(), which returns a reference the caller owns and releases with wolfSSL_SESSION_free().

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().

See:

- wolfSSL_get1_session
- wolfSSL_set_session

Return:

- pointer If successful the call will return a pointer to the the current SSL session object.
- NULL will be returned if ssl is NULL, the SSL session cache is disabled, wolfSSL doesn't have the Session ID available, or mutex functions fail.

This is the default behaviour: settings.h defines NO_SESSION_CACHE_REF unless WOLFSSL_SESSION_CACHE_REF is defined, so every build selects it without asking. The deprecated behaviour remains available by defining WOLFSSL_SESSION_CACHE_REF, or through –enable-session-cache-ref and -DWOLFSSL_SESSION_CACHE_REF=yes, and such a build warns at compile time, both when building the library and at every call to this function; define WOLFSSL_SESSION_CACHE_REF_WARNED to silence both.

Under WOLFSSL_SESSION_CACHE_REF this function instead returns a persistent session object pointer stored in the local cache. The cache size is finite and there is a risk that the session object will be overwritten by another ssl connection by the time the application calls wolfSSL_set_session() on it. Note the lifetime difference when migrating: the deprecated pointer stayed valid after wolfSSL_free(), the default one does not.

Example

```
WOLFSSL* ssl;
WOLFSSL_SESSION* session;
...
session = wolfSSL_get_session(ssl);
if (session == NULL) {
    // failed to get session pointer
}
...
```

C.58.4.75 function wolfSSL_flush_sessions

```
void wolfSSL_flush_sessions(
    WOLFSSL_CTX * ctx,
    long tm
)
```

This function flushes session from the session cache which have expired. The time, tm, is used for the time comparison. Note that wolfSSL currently uses a static table for sessions, so no flushing is needed. As such, this function is currently just a stub. This function provides OpenSSL compatibility (SSL_flush_sessions) when wolfSSL is compiled with the OpenSSL compatibility layer.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().
- **tm** time used in session expiration comparison.

See:

- wolfSSL_get1_session
- wolfSSL_set_session

Return: none No returns.

Example

```
WOLFSSL_CTX* ssl;
...
wolfSSL_flush_sessions(ctx, time(0));
```

C.58.4.76 function wolfSSL_SetServerID

```
int wolfSSL_SetServerID(
    WOLFSSL * ssl,
    const unsigned char * id,
    int len,
    int newSession
)
```

This function associates the client session with the server id. If the newSession flag is on, an existing session won't be reused.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **id** a constant byte pointer that will be copied to the serverID member of the WOLFSSL_SESSION structure.
- **len** an int type representing the length of the session id parameter.
- **newSession** an int type representing the flag to denote whether to reuse a session or not.

See: wolfSSL_set_session

Return:

- SSL_SUCCESS returned if the function executed without error.
- BAD_FUNC_ARG returned if the WOLFSSL struct or id parameter is NULL or if len is not greater than zero.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol );
WOLFSSL* ssl = WOLFSSL_new(ctx);
const byte id[MAX_SIZE];  // or dynamically create space
```

```
int len = 0; // initialize length
int newSession = 0; // flag to allow
…
int ret = wolfSSL_SetServerID(ssl, id, len, newSession);

if (ret == WOLFSSL_SUCCESS) {
    // The Id was successfully set
}
```

C.58.4.77 function wolfSSL_GetSessionIndex

```
int wolfSSL_GetSessionIndex(
    WOLFSSL * ssl
)
```

This function gets the session index of the WOLFSSL structure.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See: wolfSSL_GetSessionAtIndex

Return: int The function returns an int type representing the sessionIndex within the WOLFSSL struct.

Example

```
WOLFSSL_CTX_new( protocol method );
WOLFSSL* ssl = WOLFSSL_new(ctx);
...
int sesIdx = wolfSSL_GetSessionIndex(ssl);

if(sesIdx < 0 || sesIdx > sizeof(ssl->sessionIndex)/sizeof(int)){
    // You have an out of bounds index number and something is not right.
}
```

C.58.4.78 function wolfSSL_GetSessionAtIndex

```
int wolfSSL_GetSessionAtIndex(
    int index,
    WOLFSSL_SESSION * session
)
```

This function gets the session at specified index of the session cache and copies it into memory. The WOLFSSL_SESSION structure holds the session information. The copy is independent of the cache entry: it does not share the ticket buffer, peer certificate or ex_data with the cache, and it stays valid after the cache entry is overwritten or evicted. The caller owns the copy and releases it with wolfSSL_SESSION_free().

Parameters:

- **index** an int type representing the session index.
- **session** a pointer to a WOLFSSL_SESSION structure to copy into, obtained from wolfSSL_SESSION_new().

See:

- UnLockMutex
- LockMutex
- wolfSSL_GetSessionIndex

Return:

- SSL_SUCCESS returned if the function executed successfully and no errors were thrown.
- BAD_MUTEX_E returned if there was an unlock or lock mutex error.
- SSL_FAILURE returned if the function did not execute successfully.

Example

```
int idx; // The index to locate the session.
WOLFSSL_SESSION* session = wolfSSL_SESSION_new();  // Buffer to copy to.
...
if(wolfSSL_GetSessionAtIndex(idx, session) != SSL_SUCCESS){
    // Failure case.
}
...
wolfSSL_SESSION_free(session);
```

C.58.4.79 function wolfSSL_SESSION_get_peer_chain

```
WOLFSSL_X509_CHAIN * wolfSSL_SESSION_get_peer_chain(
    WOLFSSL_SESSION * session
)
```

Returns the peer certificate chain from the WOLFSSL_SESSION struct.

Parameters:

- **session** a pointer to a WOLFSSL_SESSION structure.

See:

- wolfSSL_GetSessionAtIndex
- wolfSSL_GetSessionIndex
- AddSession

Return: pointer A pointer to a WOLFSSL_X509_CHAIN structure that contains the peer certification chain.

Example

```
WOLFSSL_SESSION* session;
WOLFSSL_X509_CHAIN* chain;
...
chain = wolfSSL_SESSION_get_peer_chain(session);
if(!chain){
    // There was no chain. Failure case.
}
```

C.58.4.80 function wolfSSL_CTX_set_verify

```
void wolfSSL_CTX_set_verify(
    WOLFSSL_CTX * ctx,
    int mode,
    VerifyCallback verify_callback
)
```

This function sets the verification method for remote peers and also allows a verify callback to be registered with the SSL context. The verify callback will be called only when a verification failure has occurred. If no verify callback is desired, the NULL pointer can be used for verify_callback. The verification mode of peer certificates is a logically OR'd list of flags. The possible flag values include:

SSL_VERIFY_NONE Client mode: the client will not verify the certificate received from the server and the handshake will continue as normal. Server mode: the server will not send a certificate request to the client. As such, client verification will not be enabled. SSL_VERIFY_PEER Client mode: the client will verify the certificate received from the server during the handshake. This is turned on by default in wolfSSL, therefore, using this option has no effect. Server mode: the server will send a certificate request to the client and verify the client certificate received. SSL_VERIFY_FAIL_IF_NO_PEER_CERT Client mode: no effect when used on the client side. Server mode: the verification will fail on the server side if the client fails to send a certificate when requested to do so (when using SSL_VERIFY_PEER on the SSL server). SSL_VERIFY_FAIL_EXCEPT_PSK Client mode: no effect when used on the client side. Server mode: the verification is the same as SSL_VERIFY_FAIL_IF_NO_PEER_CERT except in the case of a PSK connection. If a PSK connection is being made then the connection will go through without a peer cert. SSL_VERIFY_CLIENT_ONCE Accepted and ignored. It is present so that OpenSSL-derived code compiles unchanged; wolfSSL does not act on it, does not store it, and wolfSSL_get_verify_mode() / wolfSSL_CTX_get_verify_mode() will not report it back. Including it in mode has no effect on any of the other flags.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **mode** flags indicating verification mode for peer's cert.
- **verify_callback** callback to be called when verification fails. If no callback is desired, the NULL pointer can be used for verify_callback.

See: wolfSSL_set_verify

Return: none No return.

Example

```
WOLFSSL_CTX*    ctx    = 0;
...
wolfSSL_CTX_set_verify(ctx, (WOLFSSL_VERIFY_PEER |
                       WOLFSSL_VERIFY_FAIL_IF_NO_PEER_CERT), NULL);
```

C.58.4.81 function wolfSSL_set_verify

```
void wolfSSL_set_verify(
    WOLFSSL * ssl,
    int mode,
    VerifyCallback verify_callback
)
```

This function sets the verification method for remote peers and also allows a verify callback to be registered with the SSL session. The verify callback will be called only when a verification failure has occurred. If no verify callback is desired, the NULL pointer can be used for verify_callback. The verification mode of peer certificates is a logically OR'd list of flags. The possible flag values include: SSL_VERIFY_NONE Client mode: the client will not verify the certificate received from the server and the handshake will continue as normal. Server mode: the server will not send a certificate request to the client. As such, client verification will not be enabled. SSL_VERIFY_PEER Client mode: the client will verify the certificate received from the server during the handshake. This is turned on by default in wolfSSL, therefore, using this option has no effect. Server mode: the server will send a certificate request to the client and verify the client certificate received. SSL_VERIFY_FAIL_IF_NO_PEER_CERT Client mode: no effect when used on the client side. Server mode: the verification will fail on the server side if the client fails to send a certificate when requested to do so (when using SSL_VERIFY_PEER on the SSL server). SSL_VERIFY_FAIL_EXCEPT_PSK Client mode: no effect when used on the client side. Server mode: the verification is the same as SSL_VERIFY_FAIL_IF_NO_PEER_CERT except in the case of a PSK connection. If a PSK connection is being made then the connection will go through without a peer cert. SSL_VERIFY_CLIENT_ONCE Accepted and ignored. It is present so that OpenSSL-derived code

compiles unchanged; wolfSSL does not act on it, does not store it, and wolfSSL_get_verify_mode() / wolfSSL_CTX_get_verify_mode() will not report it back. Including it in mode has no effect on any of the other flags.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **mode** flags indicating verification mode for peer's cert.
- **verify_callback** callback to be called when verification fails. If no callback is desired, the NULL pointer can be used for verify_callback.

See: wolfSSL_CTX_set_verify

Return: none No return.

Example

```
WOLFSSL* ssl = 0;
...
wolfSSL_set_verify(ssl, SSL_VERIFY_PEER | SSL_VERIFY_FAIL_IF_NO_PEER_CERT, 0);
```

C.58.4.82 function wolfSSL_SetCertCbCtx

```
void wolfSSL_SetCertCbCtx(
    WOLFSSL * ssl,
    void * ctx
)
```

This function stores user CTX object information for verify callback.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **ctx** a void pointer that is set to WOLFSSL structure's verifyCbCtx member's value.

See:

- wolfSSL_CTX_save_cert_cache
- wolfSSL_CTX_restore_cert_cache
- wolfSSL_CTX_set_verify

Return: none No return.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
(void*)ctx;
...
if(ssl != NULL){
wolfSSL_SetCertCbCtx(ssl, ctx);
} else {
    // Error case, the SSL is not initialized properly.
}
```

C.58.4.83 function wolfSSL_CTX_SetCertCbCtx

```
void wolfSSL_CTX_SetCertCbCtx(
    WOLFSSL_CTX * ctx,
    void * userCtx
)
```

This function stores user CTX object information for verify callback.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure.
- **userCtx** a void pointer that is used to set WOLFSSL_CTX structure's verifyCbCtx member's value.

See:

- wolfSSL_CTX_save_cert_cache
- wolfSSL_CTX_restore_cert_cache
- wolfSSL_CTX_set_verify

Return: none No return.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
void* userCtx = NULL; // Assign some user defined context
...
if(ctx != NULL){
    wolfSSL_SetCertCbCtx(ctx, userCtx);
} else {
    // Error case, the SSL is not initialized properly.
}
```

C.58.4.84 function wolfSSL_CTX_SetChainVerifyCb

```
int wolfSSL_CTX_SetChainVerifyCb(
    WOLFSSL_CTX * ctx,
    ChainVerifyCb cb
)
```

Replaces wolfSSL's verification of the peer's certificate chain with an application callback, for every SSL/TLS object created from the context. When a callback is set, wolfSSL decodes the certificates from the Certificate message and hands them to the callback as raw DER, the peer's own certificate first. It builds no chain, verifies no signature and checks no date, revocation status, key usage or host name, and the verify callback set with wolfSSL_CTX_set_verify() is not called; the callback is consulted for any certificate the peer sends, even under WOLFSSL_VERIFY_NONE. A server only requests a client certificate under WOLFSSL_VERIFY_PEER and only requires one with WOLFSSL_VERIFY_FAIL_IF_NO_PEER_CERT, so a server that relies on the callback for client authentication must set both. Malformed DER, a certificate the parser refuses regardless of the verify mode such as one with a zero serial number, or one whose decoding stops part way such as one with an unsupported key algorithm, still fails the handshake before the callback is called. An unknown critical extension or a key usage inconsistent with the basic constraints is left for the callback to judge. The callback returns 0 to accept, CHAIN_VERIFY_WANT_E to suspend the handshake until the application re_enters wolfSSL_connect(), wolfSSL_accept(), wolfSSL_read() or wolfSSL_write() (a certificate received after the handshake is resumed by wolfSSL_read() only, and wolfSSL_write() fails with CHAIN_VERIFY_WANT_E until then), or any other value to reject with CHAIN_VERIFY_CB_E and a fatal bad_certificate alert; 0 is the only accepting value, so returning WOLFSSL_SUCCESS rejects. Because wolfSSL checks nothing itself, wolfSSL_get_verify_result() reports WOLFSSL_X509_V_OK once the callback accepts, recording its verdict rather than a verification wolfSSL performed. DTLS, raw public keys and verifying a stapled OCSP response are not supported with the callback: setting it on a context configured for one of them fails, and so does the handshake of a connection using one of them, with CHAIN_VERIFY_UNSUPPORTED_E. The stapling check covers the client, the side that verifies a stapled response; a server may still staple its own status. Requires WOLFSSL_CHAIN_VERIFY_CB (–enable_chain_verify_cb).

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **cb** the callback, or NULL to clear it.

See:

- wolfSSL_SetChainVerifyCb
- wolfSSL_CTX_SetChainVerifyCtx
- wolfSSL_SetChainVerifyCtx
- wolfSSL_GetChainVerifyCtx

Return:

- WOLFSSL_SUCCESS on success.
- BAD_FUNC_ARG when ctx is NULL.
- CHAIN_VERIFY_UNSUPPORTED_E when the context uses a DTLS method, raw public keys or client-side OCSP stapling.

Example

```
static int myChainVerify(WOLFSSL* ssl, const WOLFSSL_BUFFER_INFO* certs,
                         int certsSz, void* ctx)
{
    // certs[0] is the peer's certificate, the rest is the chain it sent
    if (!hsmVerifyStarted(certs, certsSz))
        return CHAIN_VERIFY_WANT_E; // ask again later
    return hsmVerifyPassed() ? 0 : -1;
}
...
WOLFSSL_CTX* ctx = wolfSSL_CTX_new(method);
if (wolfSSL_CTX_SetChainVerifyCb(ctx, myChainVerify) != WOLFSSL_SUCCESS) {
    // context uses DTLS, raw public keys or client-side stapling
}
```

C.58.4.85 function wolfSSL_SetChainVerifyCb

```
int wolfSSL_SetChainVerifyCb(
    WOLFSSL * ssl,
    ChainVerifyCb cb
)
```

Sets the chain verification callback for one SSL/TLS object. It takes precedence over the callback set on the context with wolfSSL_CTX_SetChainVerifyCb(), which documents the callback's contract.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **cb** the callback, or NULL to fall back to the context's.

See:

- wolfSSL_CTX_SetChainVerifyCb
- wolfSSL_SetChainVerifyCtx

Return:

- WOLFSSL_SUCCESS on success.
- BAD_FUNC_ARG when ssl is NULL.
- CHAIN_VERIFY_UNSUPPORTED_E when the object uses DTLS, raw public keys or client-side OCSP stapling.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
if (wolfSSL_SetChainVerifyCb(ssl, myChainVerify) != WOLFSSL_SUCCESS) {
    // object uses DTLS, raw public keys or client-side stapling
}
```

C.58.4.86 function wolfSSL_CTX_SetChainVerifyCtx

```
void wolfSSL_CTX_SetChainVerifyCtx(
    WOLFSSL_CTX * ctx,
    void * userCtx
)
```

Sets the user context passed to the chain verification callback for every SSL/TLS object created from the context.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **userCtx** the value the callback receives as its ctx argument.

See:

- wolfSSL_CTX_SetChainVerifyCb
- wolfSSL_SetChainVerifyCtx
- wolfSSL_GetChainVerifyCtx

Return: none No return.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new(method);
wolfSSL_CTX_SetChainVerifyCb(ctx, myChainVerify);
wolfSSL_CTX_SetChainVerifyCtx(ctx, &myHsm);
```

C.58.4.87 function wolfSSL_SetChainVerifyCtx

```
void wolfSSL_SetChainVerifyCtx(
    WOLFSSL * ssl,
    void * ctx
)
```

Sets the user context passed to the chain verification callback for one SSL/TLS object. It takes precedence over the value set on the context with wolfSSL_CTX_SetChainVerifyCtx().

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **ctx** the value the callback receives as its ctx argument, or NULL to fall back to the context's.

See:

- wolfSSL_CTX_SetChainVerifyCtx
- wolfSSL_GetChainVerifyCtx

Return: none No return.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
wolfSSL_SetChainVerifyCtx(ssl, &myConnectionState);
```

C.58.4.88 function wolfSSL_GetChainVerifyCtx

```
void * wolfSSL_GetChainVerifyCtx(
    const WOLFSSL * ssl
)
```

Returns the user context the chain verification callback is called with for this SSL/TLS object: the value set with wolfSSL_SetChainVerifyCtx() when there is one, otherwise the context's.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().

See:

- wolfSSL_SetChainVerifyCtx
- wolfSSL_CTX_SetChainVerifyCtx

Return: void* the user context, or NULL when none is set or ssl is NULL.

Example

```
struct myState* st = (struct myState*)wolfSSL_GetChainVerifyCtx(ssl);
```

C.58.4.89 function wolfSSL_pending

```
int wolfSSL_pending(
    WOLFSSL * ssl
)
```

This function returns the number of bytes which are buffered and available in the SSL object to be read by wolfSSL_read().

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().

See:

- wolfSSL_recv
- wolfSSL_read
- wolfSSL_peek

Return:

- int This function returns the number of bytes pending.
- SSL_FAILURE will be returned when ssl is NULL.

Example

```
int pending = 0;
WOLFSSL* ssl = 0;
...

pending = wolfSSL_pending(ssl);
printf("There are %d bytes buffered and available for reading", pending);
```

C.58.4.90 function wolfSSL_load_error_strings

```
void wolfSSL_load_error_strings(
    void
)
```

This function is for OpenSSL compatibility (SSL_load_error_string) only and takes no action.

Parameters:

- **none** No parameters.

See:

- wolfSSL_get_error
- wolfSSL_ERR_error_string
- wolfSSL_ERR_error_string_n
- wolfSSL_ERR_print_errors_fp
- wolfSSL_load_error_strings

Return: none No returns.

Example

```
wolfSSL_load_error_strings();
```

C.58.4.91 function wolfSSL_library_init

```
int wolfSSL_library_init(
    void
)
```

This function is called internally in wolfSSL_CTX_new(). This function is a wrapper around wolfSSL_Init() and exists for OpenSSL compatibility (SSL_library_init) when wolfSSL has been compiled with OpenSSL compatibility layer. wolfSSL_Init() is the more typically-used wolfSSL initialization function.

Parameters:

- **none** No parameters.

See:

- wolfSSL_Init
- wolfSSL_Cleanup

Return:

- SSL_SUCCESS If successful the call will return.
- SSL_FATAL_ERROR is returned upon failure.

Example

```
int ret = 0;
ret = wolfSSL_library_init();
if (ret != SSL_SUCCESS) {
    failed to initialize wolfSSL
}
...
```

C.58.4.92 function wolfSSL_SetDevId

```
int wolfSSL_SetDevId(
    WOLFSSL * ssl,
    int devId
)
```

This function sets the Device Id at the WOLFSSL session level.

Parameters:

- **ssl** pointer to a SSL object, created with wolfSSL_new().
- **devId** ID to use with crypto callbacks or async hardware. Set to INVALID_DEVID (-2) if not used

See:

- wolfSSL_CTX_SetDevId
- wolfSSL_CTX_GetDevId

Return:

- WOLFSSL_SUCCESS upon success.
- BAD_FUNC_ARG if ssl is NULL.

Example

```
WOLFSSL* ssl;
int DevId = -2;

wolfSSL_SetDevId(ssl, devId);
```

C.58.4.93 function wolfSSL_CTX_SetDevId

```
int wolfSSL_CTX_SetDevId(
    WOLFSSL_CTX * ctx,
    int devId
)
```

This function sets the Device Id at the WOLFSSL_CTX context level.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **devId** ID to use with crypto callbacks or async hardware. Set to INVALID_DEVID (-2) if not used

See:

- wolfSSL_SetDevId
- wolfSSL_CTX_GetDevId

Return:

- WOLFSSL_SUCCESS upon success.
- BAD_FUNC_ARG if ssl is NULL.

Example

```
WOLFSSL_CTX* ctx;
int DevId = -2;

wolfSSL_CTX_SetDevId(ctx, devId);
```

C.58.4.94 function wolfSSL_CTX_GetDevId

```
int wolfSSL_CTX_GetDevId(
    WOLFSSL_CTX * ctx,
    WOLFSSL * ssl
)
```

This function retrieves the Device Id.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().

- **ssl** pointer to a SSL object, created with wolfSSL_new().

See:

- wolfSSL_SetDevId
- wolfSSL_CTX_SetDevId

Return:

- devId upon success.
- INVALID_DEVID if both ssl and ctx are NULL.

Example

```
WOLFSSL_CTX* ctx;

wolfSSL_CTX_GetDevId(ctx, ssl);
```

C.58.4.95 function wolfSSL_CTX_set_session_cache_mode

```
long wolfSSL_CTX_set_session_cache_mode(
    WOLFSSL_CTX * ctx,
    long mode
)
```

This function enables or disables SSL session caching. Behavior depends on the value used for mode. The following values for mode are available: SSL_SESS_CACHE_OFF- disable session caching. Session caching is turned on by default. SSL_SESS_CACHE_NO_AUTO_CLEAR - Disable auto-flushing of the session cache. Auto-flushing is turned on by default.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **mode** modifier used to change behavior of the session cache.

See:

- wolfSSL_flush_sessions
- wolfSSL_get1_session
- wolfSSL_set_session
- wolfSSL_get_sessionID
- wolfSSL_CTX_set_timeout

Return: SSL_SUCCESS will be returned upon success.

Example

```
WOLFSSL_CTX* ctx = 0;
...
ret = wolfSSL_CTX_set_session_cache_mode(ctx, SSL_SESS_CACHE_OFF);
if (ret != SSL_SUCCESS) {
    // failed to turn SSL session caching off
}
```

C.58.4.96 function wolfSSL_CTX_sess_set_get_cb

```
void wolfSSL_CTX_sess_set_get_cb(
    WOLFSSL_CTX * ctx,
    WOLFSSL_SESSION *(*)(WOLFSSL *ssl, const unsigned char *, int, int *) f
)
```

This function registers the callback wolfSSL uses to look a session up in an application managed (external) session cache. It is called on the server side when a peer offers a session id to resume, before the internal cache is consulted. Compatibility layer equivalent of SSL_CTX_sess_set_get_cb().

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **f** the lookup callback, or NULL to remove a previously registered one. It is passed the WOLFSSL object being negotiated, the session id to look up and its length, and a pointer to a copy flag. It returns the matching WOLFSSL_SESSION, or NULL when the cache holds no session for that id. wolfSSL sets the copy flag to 1 before the call. Left at 1, the callback keeps its reference and wolfSSL never releases it, so the session must stay valid while wolfSSL processes the lookup. For TLS 1.3 stateful ticket resumption, which keeps the session longer, wolfSSL takes a reference of its own and releases it when done; a session it cannot take a reference on is then treated as no session found. Set to 0, the callback hands its reference to wolfSSL, which releases it once done with the session.

See:

- wolfSSL_CTX_set_session_cache_mode
- wolfSSL_get1_session
- wolfSSL_SESSION_free
- wolfSSL_flush_sessions

Return: none No return.

Example

```
WOLFSSL_SESSION* myGetSession(WOLFSSL* ssl, const unsigned char* id,
                              int idLen, int* copy)
{
    (void)ssl;
    // The cache keeps its session, so leave copy alone.
    return myCacheLookup(id, idLen);
}
...
WOLFSSL_CTX* ctx = wolfSSL_CTX_new(method);
wolfSSL_CTX_sess_set_get_cb(ctx, myGetSession);
```

C.58.4.97 function wolfSSL_set_session_secret_cb

```
int wolfSSL_set_session_secret_cb(
    WOLFSSL * ssl,
    SessionSecretCb cb,
    void * ctx
)
```

This function sets the session secret callback function. The SessionSecretCb type has the signature: int (*SessionSecretCb)(WOLFSSL* ssl, void* secret, int* secretSz, void* ctx). The sessionSecretCb member of the WOLFSSL struct is set to the parameter cb.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **cb** a SessionSecretCb type that is a function pointer with the above signature.
- **ctx** a pointer to the user context to be stored

See: SessionSecretCb

Return:

- SSL_SUCCESS returned if the execution of the function did not return an error.
- SSL_FATAL_ERROR returned if the WOLFSSL structure is NULL.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
// Signature of SessionSecretCb
int SessionSecretCB (WOLFSSL* ssl, void* secret, int* secretSz,
void* ctx) = SessionSecretCb;
…
int wolfSSL_set_session_secret_cb(ssl, SessionSecretCB, (void*)ssl->ctx){
    // Function body.
}
```

C.58.4.98 function wolfSSL_save_session_cache

```
int wolfSSL_save_session_cache(
    const char * fname
)
```

This function persists the session cache to file. It doesn't use memsave because of additional memory use.

Parameters:

- **fname** is a constant char pointer that points to a file for writing.

See:

- XFWRITE
- wolfSSL_restore_session_cache
- wolfSSL_memrestore_session_cache

Return:

- SSL_SUCCESS returned if the function executed without error. The session cache has been written to a file.
- SSL_BAD_FILE returned if fname cannot be opened or is otherwise corrupt.
- FWRITE_ERROR returned if XFWRITE failed to write to the file.
- BAD_MUTEX_E returned if there was a mutex lock failure.

Warning: The file holds session master secrets and resumption credentials in the clear. On POSIX systems it is created with mode 0600; on other platforms the permissions are whatever the port's XFOPEN produces, so the caller must place the file where only the intended user can read it. An existing file is additionally tightened with fchmod, which fails on filesystems without permission bits (FAT); define WOLFSSL_NO_FCHMOD to skip that step on such targets.

Example

```
const char* fname;
...
if(wolfSSL_save_session_cache(fname) != SSL_SUCCESS){
    // Fail to write to file.
}
```

C.58.4.99 function wolfSSL_restore_session_cache

```
int wolfSSL_restore_session_cache(
    const char * fname
)
```

This function restores the persistent session cache from file. It does not use memstore because of additional memory use.

Parameters:

- **fname** a constant char pointer file input that will be read.

See:

- XFREAD
- XFOPEN

Return:

- SSL_SUCCESS returned if the function executed without error.
- SSL_BAD_FILE returned if the file passed into the function was corrupted and could not be opened by XFOPEN.
- FREAD_ERROR returned if the file had a read error from XFREAD.
- CACHE_MATCH_ERROR returned if the session cache header match failed.
- BAD_MUTEX_E returned if there was a mutex lock failure.

Example

```
const char *fname;
...
if(wolfSSL_restore_session_cache(fname) != SSL_SUCCESS){
    // Failure case. The function did not return SSL_SUCCESS.
}
```

C.58.4.100 function wolfSSL_memsave_session_cache

```
int wolfSSL_memsave_session_cache(
    void * mem,
    int sz
)
```

This function persists session cache to memory.

Parameters:

- **mem** a void pointer representing the destination for the memory copy, XMEMCPY().
- **sz** an int type representing the size of mem.

See:

- XMEMCPY
- wolfSSL_get_session_cache_memsize

Return:

- SSL_SUCCESS returned if the function executed without error. The session cache has been successfully persisted to memory.
- BAD_MUTEX_E returned if there was a mutex lock error.
- BUFFER_E returned if the buffer size was too small.

Example

```
void* mem;
int sz; // Max size of the memory buffer.
```

```
…
if(wolfSSL_memsave_session_cache(mem, sz) != SSL_SUCCESS){
    // Failure case, you did not persist the session cache to memory
}
```

C.58.4.101 function wolfSSL_memrestore_session_cache

```
int wolfSSL_memrestore_session_cache(
    const void * mem,
    int sz
)
```

This function restores the persistent session cache from memory.

Parameters:

- **mem** a constant void pointer containing the source of the restoration.
- **sz** an integer representing the size of the memory buffer.

See: wolfSSL_save_session_cache

Return:

- SSL_SUCCESS returned if the function executed without an error.
- BUFFER_E returned if the memory buffer is too small.
- BAD_MUTEX_E returned if the session cache mutex lock failed.
- CACHE_MATCH_ERROR returned if the session cache header match failed.

Example

```
const void* memoryFile;
int szMf;
...
if(wolfSSL_memrestore_session_cache(memoryFile, szMf) != SSL_SUCCESS){
    // Failure case. SSL_SUCCESS was not returned.
}
```

C.58.4.102 function wolfSSL_get_session_cache_memsize

```
int wolfSSL_get_session_cache_memsize(
    void
)
```

This function returns how large the session cache save buffer should be.

Parameters:

- **none** No parameters.

See: wolfSSL_memrestore_session_cache

Return: int This function returns an integer that represents the size of the session cache save buffer.

Example

```
int sz = // Minimum size for error checking;
...
if(sz < wolfSSL_get_session_cache_memsize()){
    // Memory buffer is too small
}
```

C.58.4.103 function wolfSSL_CTX_save_cert_cache

```
int wolfSSL_CTX_save_cert_cache(
    WOLFSSL_CTX * ctx,
    const char * fname
)
```

This function writes the cert cache from memory to file.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, holding the certificate information.
- **fname** a constant char pointer that points to a file for writing.

See:

- CM_SaveCertCache
- DoMemSaveCertCache

Return:

- SSL_SUCCESS if CM_SaveCertCache exits normally.
- BAD_FUNC_ARG is returned if either of the arguments are NULL.
- SSL_BAD_FILE if the cert cache save file could not be opened.
- BAD_MUTEX_E if the lock mutex failed.
- MEMORY_E the allocation of memory failed.
- FWRITE_ERROR Certificate cache file write failed.

Example

```
WOLFSSL_CTX* ctx = WOLFSSL_CTX_new( protocol def );
const char* fname;
...
if(wolfSSL_CTX_save_cert_cache(ctx, fname)){
    // file was written.
}
```

C.58.4.104 function wolfSSL_CTX_restore_cert_cache

```
int wolfSSL_CTX_restore_cert_cache(
    WOLFSSL_CTX * ctx,
    const char * fname
)
```

This function persistes certificate cache from a file.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, holding the certificate information.
- **fname** a constant char pointer that points to a file for reading.

See:

- CM_RestoreCertCache
- XFOPEN

Return:

- SSL_SUCCESS returned if the function, CM_RestoreCertCache, executes normally.
- SSL_BAD_FILE returned if XFOPEN returns XBADFILE. The file is corrupted.
- MEMORY_E returned if the allocated memory for the temp buffer fails.
- BAD_FUNC_ARG returned if fname or ctx have a NULL value.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
WOLFSSL* ssl = wolfSSL_new(ctx);
const char* fname = "path to file";
...
if(wolfSSL_CTX_restore_cert_cache(ctx, fname)){
    // check to see if the execution was successful
}
```

C.58.4.105 function wolfSSL_CTX_memsave_cert_cache

```
int wolfSSL_CTX_memsave_cert_cache(
    WOLFSSL_CTX * ctx,
    void * mem,
    int sz,
    int * used
)
```

This function persists the certificate cache to memory.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().
- **mem** a void pointer to the destination (output buffer).
- **sz** the size of the output buffer.
- **used** a pointer to size of the cert cache header.

See:

- DoMemSaveCertCache
- GetCertCacheMemSize
- CM_MemRestoreCertCache
- CM_GetCertCacheMemSize

Return:

- SSL_SUCCESS returned on successful execution of the function. No errors were thrown.
- BAD_MUTEX_E mutex error where the WOLFSSL_CERT_MANAGER member caLock was not 0 (zero).
- BAD_FUNC_ARG returned if ctx, mem, or used is NULL or if sz is less than or equal to 0 (zero).
- BUFFER_E output buffer mem was too small.

Example

```
WOLFSSL_CTX* ctx = WOLFSSL_CTX_new( protocol );
void* mem;
int sz;
int* used;
...
if(wolfSSL_CTX_memsave_cert_cache(ctx, mem, sz, used) != SSL_SUCCESS){
    // The function returned with an error
}
```

C.58.4.106 function wolfSSL_CTX_memrestore_cert_cache

```
int wolfSSL_CTX_memrestore_cert_cache(
    WOLFSSL_CTX * ctx,
    const void * mem,
```

```
    int sz
)
```

This function restores the certificate cache from memory.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().
- **mem** a void pointer with a value that will be restored to the certificate cache.
- **sz** an int type that represents the size of the mem parameter.

See: CM_MemRestoreCertCache

Return:

- SSL_SUCCESS returned if the function and subroutines executed without an error.
- BAD_FUNC_ARG returned if the ctx or mem parameters are NULL or if the sz parameter is less than or equal to zero.
- BUFFER_E returned if the cert cache memory buffer is too small.
- CACHE_MATCH_ERROR returned if there was a cert cache header mismatch.
- BAD_MUTEX_E returned if the lock mutex on failed.

Example

```
WOLFSSL_CTX* ctx = WOLFSSL_CTX_new( protocol method );
WOLFSSL* ssl = WOLFSSL_new(ctx);
void* mem;
int sz = (*int) sizeof(mem);
…
if(wolfSSL_CTX_memrestore_cert_cache(ssl->ctx, mem, sz)){
    // The success case
}
```

C.58.4.107 function wolfSSL_CTX_get_cert_cache_memsize

```
int wolfSSL_CTX_get_cert_cache_memsize(
    WOLFSSL_CTX * ctx
)
```

Returns the size the certificate cache save buffer needs to be.

Parameters:

- **ctx** a pointer to a wolfSSL_CTX structure, created using wolfSSL_CTX_new().

See: CM_GetCertCacheMemSize

Return:

- int integer value returned representing the memory size upon success.
- BAD_FUNC_ARG is returned if the WOLFSSL_CTX struct is NULL.
- BAD_MUTEX_E - returned if there was a mutex lock error.

Example

```
WOLFSSL_CTX* ctx = WOLFSSL_CTX_new(protocol);
...
int certCacheSize = wolfSSL_CTX_get_cert_cache_memsize(ctx);

if(certCacheSize != BAD_FUNC_ARG || certCacheSize != BAD_MUTEX_E){
// Successfully retrieved the memory size.
}
```

C.58.4.108 function wolfSSL_CTX_set_cipher_list

```
int wolfSSL_CTX_set_cipher_list(
    WOLFSSL_CTX * ctx,
    const char * list
)
```

This function sets the cipher suite list for a given WOLFSSL_CTX. The list becomes the default cipher suite list for any new WOLFSSL sessions created from the context, and the order in the string is the local preference order from highest to lowest. Each call replaces the previous list. The list is a null-terminated, colon-delimited text string of suite names and/or OpenSSL-style group keywords, for example "TLS13-AES128-GCM-SHA256:ECDHE-RSA-AES128-GCM-SHA256:DHE-RSA-AES256-SHA256".

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **list** null-terminated text string and a colon-delimited list of cipher suites and/or keywords to use with the specified SSL context.

See:

- wolfSSL_set_cipher_list
- wolfSSL_get_ciphers
- wolfSSL_get_cipher_list
- wolfSSL_CTX_new

Return:

- WOLFSSL_SUCCESS will be returned upon successful function completion.
- WOLFSSL_FAILURE will be returned on failure.

Each token in the colon-delimited list is one of the following:

1. A specific cipher suite name. wolfSSL accepts both its own short name and the IANA name (when WOLFSSL_NO_ERROR_STRINGS is not defined). For example "ECDHE-RSA-AES128-GCM-SHA256" and "TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256" are equivalent. The complete authoritative list of accepted names lives in the cipher_names[] array in src/internal.c; programs may also enumerate the suites compiled into the current build at runtime via wolfSSL_get_ciphers().
2. An OpenSSL-compatible keyword that selects a family of suites or toggles a class on/off (see the keyword table below). Some keywords require OPENSSL_EXTRA or OPENSSL_ALL to be defined.
3. A negated keyword "!keyword" to disallow a class (requires OPENSSL_EXTRA or OPENSSL_ALL). For example "HIGH:!aNULL".

A "+" operator (e.g. "ECDHE+AESGCM") is recognized only to extract the leading public-key family token ("ECDHE", "RSA" or "DHE"); trailing parts after "+" are ignored by wolfSSL. To intersect with a specific cipher use the explicit suite name instead.

OpenSSL-compatible group keywords:

Keyword	Effect	Required build option
DEFAULT / ALL	Include all built suites; "ALL" also enables anonymous (aNULL)	OPENSSL_EXTRA / OPENSSL_ALL (also accepted as the entire string with no other tokens)
HIGH	All suites except static, anonymous, and NULL ciphers	OPENSSL_EXTRA / OPENSSL_ALL (also accepted as the entire string with no other tokens)

Keyword	Effect	Required build option
LOW / MEDIUM	Accepted but do not restrict by bit size; behave as “RSA”	OPENSSL_EXTRA / OPENSSL_ALL
aNULL	Anonymous (no authentication) suites	OPENSSL_EXTRA / OPENSSL_ALL; suites require HAVE_ANON
eNULL / NULL	Null encryption suites	OPENSSL_EXTRA / OPENSSL_ALL; suites require HAVE_NULL_CIPHER
kDH	Static DH key exchange	OPENSSL_EXTRA / OPENSSL_ALL
DHE / EDH	Ephemeral DH key exchange	OPENSSL_EXTRA / OPENSSL_ALL; suites require !NO_DH
ECDHE / EECDH	Ephemeral ECDH key exchange	OPENSSL_EXTRA / OPENSSL_ALL; suites require HAVE_ECC
kRSA / RSA	Static RSA key exchange	OPENSSL_EXTRA / OPENSSL_ALL; suites require !NO_RSA
PSK	Pre-shared-key suites	OPENSSL_EXTRA / OPENSSL_ALL; suites require !NO_PSK
DSS	Silently ignored — wolfSSL has no DSA ciphersuites	OPENSSL_EXTRA / OPENSSL_ALL
EXP / EXPORT	Silently ignored — export-grade ciphers are not supported	OPENSSL_EXTRA / OPENSSL_ALL
AES128 / SHA1 / RC4	When negated (“!AES128”, etc.), disable that class	WOLFSSL_SYS_CRYPTO_POLICY
@SECLEVEL=n	Set OpenSSL-compatible security level	WOLFSSL_SYS_CRYPTO_POLICY

Representative TLS 1.3 cipher suite names (each guarded by its own BUILD_* macro; most are enabled automatically by –enable-tls13):

Name (wolfSSL)	IANA name	Required build option
TLS13-AES128-GCM-SHA256	TLS_AES_128_GCM_SHA256	BUILD_TLS_AES_128_GCM_SHA256 (default with TLS 1.3)
TLS13-AES256-GCM-SHA384	TLS_AES_256_GCM_SHA384	BUILD_TLS_AES_256_GCM_SHA384
TLS13-CHACHA20-POLY1305-SHA256	TLS_CHACHA20_POLY1305_SHA256	BUILD_TLS_CHACHA20_POLY1305_SHA256 (HAVE_CHACHA + HAVE_POLY1305)
TLS13-AES128-CCM-SHA256	TLS_AES_128_CCM_SHA256	BUILD_TLS_AES_128_CCM_SHA256 (HAVE_AESCCM)
TLS13-AES128-CCM-8-SHA256	TLS_AES_128_CCM_8_SHA256	BUILD_TLS_AES_128_CCM_8_SHA256 (HAVE_AESCCM)
TLS13-SM4-GCM-SM3	TLS_SM4_GCM_SM3	BUILD_TLS_SM4_GCM_SM3 (WOLFSSL_SM4_GCM + WOLFSSL_SM3)

COPYRIGHT ©2024 wolfSSL Inc.

Name (wolfSSL)	IANA name	Required build option
TLS13-SM4-CCM-SM3	TLS_SM4_CCM_SM3	BUILD_TLS_SM4_CCM_SM3 (WOLFSSL_SM4_CCM + WOLFSSL_SM3)
TLS13-SHA256-SHA256	TLS_SHA256_SHA256	BUILD_TLS_SHA256_SHA256 (integrity-only)
TLS13-SHA384-SHA384	TLS_SHA384_SHA384	BUILD_TLS_SHA384_SHA384

Representative TLS 1.2 cipher suite name families (each individual suite is guarded by its own BUILD_* macro derived from the IANA name; the common build-option requirements are summarized below):

Name family / example	Typical requirements
ECDHE-ECDSA-AES128-GCM-SHA256, ECDHE-ECDSA-AES256-GCM-SHA384, ECDHE-ECDSA-CHACHA20-POLY1305	HAVE_ECC, HAVE_AESGCM (or HAVE_CHACHA + HAVE_POLY1305)
ECDHE-RSA-AES128-GCM-SHA256, ECDHE-RSA-AES256-GCM-SHA384, ECDHE-RSA-CHACHA20-POLY1305	HAVE_ECC, !NO_RSA, HAVE_AESGCM (or HAVE_CHACHA + HAVE_POLY1305)
DHE-RSA-AES128-GCM-SHA256, DHE-RSA-AES256-GCM-SHA384, DHE-RSA-CHACHA20-POLY1305	!NO_DH, !NO_RSA, HAVE_AESGCM (or HAVE_CHACHA + HAVE_POLY1305)
AES128-SHA, AES256-SHA, AES128-SHA256, AES256-SHA256, AES128-GCM-SHA256, AES256-GCM-SHA384 (static-RSA)	!NO_RSA, !NO_AES_CBC and/or HAVE_AESGCM
DES-CBC3-SHA, RC4-SHA, RC4-MD5	Legacy: !NO_DES3 / !NO_RC4, !NO_OLD_TLS
NULL-SHA, NULL-SHA256, NULL-MD5	HAVE_NULL_CIPHER
PSK-AES128-CBC-SHA256, PSK-AES256-GCM-SHA384, ECDHE-PSK-AES128-CBC-SHA256, DHE-PSK-AES256-GCM-SHA384	!NO_PSK (HAVE_ECC for ECDHE-PSK, !NO_DH for DHE-PSK)
ADH-AES128-SHA, ADH-AES256-SHA	HAVE_ANON
ECDHE-ECDSA-SM4-GCM-SM3, ECDHE-ECDSA-SM4-CCM-SM3	WOLFSSL_SM2, WOLFSSL_SM3, WOLFSSL_SM4_GCM/WOLFSSL_SM4_CCM

Notes:

- TLS 1.3 suite names and TLS 1.2 suite names may be mixed in the same list; wolfSSL groups them by version internally.
- For DTLS, RC4-based stream ciphers in the list are silently dropped.
- When set as the literal whole-string “DEFAULT”, “ALL”, “HIGH”, or the empty string, wolfSSL installs its built-in default suite list and returns success without parsing further tokens.

Example

```
WOLFSSL_CTX* ctx = 0;
...
ret = wolfSSL_CTX_set_cipher_list(ctx,
    "TLS13-AES128-GCM-SHA256:ECDHE-RSA-AES128-GCM-SHA256:"
    "DHE-RSA-AES256-SHA256");
if (ret != WOLFSSL_SUCCESS) {
    // failed to set cipher suite list
}
```

C.58.4.109 function wolfSSL_set_cipher_list

```
int wolfSSL_set_cipher_list(
    WOLFSSL * ssl,
    const char * list
)
```

This function sets the cipher suite list for a given WOLFSSL session. The list format and the set of recognized suite names and keywords are identical to those documented for wolfSSL_CTX_set_cipher_list(); refer to that function for the full keyword/suite tables and required build options. Each call replaces the previous list on the session.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **list** null-terminated text string and a colon-delimited list of cipher suites and/or keywords to use with the specified SSL session.

See:

- wolfSSL_CTX_set_cipher_list
- wolfSSL_get_ciphers
- wolfSSL_get_cipher_list
- wolfSSL_new

Return:

- WOLFSSL_SUCCESS will be returned upon successful function completion.
- WOLFSSL_FAILURE will be returned on failure.

Example

```
int ret = 0;
WOLFSSL* ssl = 0;
...
ret = wolfSSL_set_cipher_list(ssl,
    "TLS13-AES128-GCM-SHA256:ECDHE-RSA-AES128-GCM-SHA256:"
    "DHE-RSA-AES256-SHA256");
if (ret != WOLFSSL_SUCCESS) {
    // failed to set cipher suite list
}
```

C.58.4.110 function wolfSSL_dtls_set_using_nonblock

```
void wolfSSL_dtls_set_using_nonblock(
    WOLFSSL * ssl,
    int nonblock
)
```

This function informs the WOLFSSL DTLS object that the underlying UDP I/O is non-blocking. After an application creates a WOLFSSL object, if it will be used with a non-blocking UDP socket, call wolfSSL_dtls_set_using_nonblock() on it. This lets the WOLFSSL object know that receiving EWOULDBLOCK means that the recvfrom call would block rather than that it timed out.

Parameters:

- **ssl** pointer to the DTLS session, created with wolfSSL_new().
- **nonblock** value used to set non-blocking flag on WOLFSSL object. Use 1 to specify non-blocking, otherwise 0.

See:

- wolfSSL_dtls_get_using_nonblock
- wolfSSL_dtls_got_timeout
- wolfSSL_dtls_get_current_timeout

Return: none No return.

Example

```
WOLFSSL* ssl = 0;
...
wolfSSL_dtls_set_using_nonblock(ssl, 1);
```

C.58.4.111 function wolfSSL_dtls_get_using_nonblock

```
int wolfSSL_dtls_get_using_nonblock(
    WOLFSSL * ssl
)
```

This function allows the application to determine if wolfSSL is using non-blocking I/O with UDP. If wolfSSL is using non-blocking I/O, this function will return 1, otherwise 0. After an application creates a WOLFSSL object, if it will be used with a non-blocking UDP socket, call wolfSSL_dtls_set_using_nonblock() on it. This lets the WOLFSSL object know that receiving EWOULDBLOCK means that the recvfrom call would block rather than that it timed out. This function is only meaningful to DTLS sessions.

Parameters:

- **ssl** pointer to the DTLS session, created with wolfSSL_new().

See:

- wolfSSL_dtls_set_using_nonblock
- wolfSSL_dtls_got_timeout
- wolfSSL_dtls_set_using_nonblock

Return:

- 0 underlying I/O is blocking.
- 1 underlying I/O is non-blocking.

Example

```
int ret = 0;
WOLFSSL* ssl = 0;
...
ret = wolfSSL_dtls_get_using_nonblock(ssl);
if (ret == 1) {
    // underlying I/O is non-blocking
}
...
```

C.58.4.112 function wolfSSL_dtls_get_current_timeout

```
int wolfSSL_dtls_get_current_timeout(
    WOLFSSL * ssl
)
```

This function returns the current timeout value in seconds for the WOLFSSL object. When using non-blocking sockets, something in the user code needs to decide when to check for available recv data and how long it has been waiting. The value returned by this function indicates how long the application should wait.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_dtls
- wolfSSL_dtls_get_peer
- wolfSSL_dtls_got_timeout
- wolfSSL_dtls_set_peer

Return:

- seconds The current DTLS timeout value in seconds
- NOT_COMPILED_IN if wolfSSL was not built with DTLS support.

Example

```
int timeout = 0;
WOLFSSL* ssl;
...
timeout = wolfSSL_get_dtls_current_timeout(ssl);
printf("DTLS timeout (sec) = %d\n", timeout);
```

C.58.4.113 function wolfSSL_dtls13_use_quick_timeout

```
int wolfSSL_dtls13_use_quick_timeout(
    WOLFSSL * ssl
)
```

This function returns true if the application should setup a quicker timeout. When using non-blocking sockets, something in the user code needs to decide when to check for available data and how long it needs to wait. If this function returns true, it means that the library already detected some disruption in the communication, but it wants to wait for a little longer in case some messages from the other peers are still in flight. Is up to the application to fine tune the value of this timer, a good one may be dtls_get_current_timeout() / 4.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_dtls
- wolfSSL_dtls_get_peer
- wolfSSL_dtls_got_timeout
- wolfSSL_dtls_set_peer
- wolfSSL_dtls13_set_send_more_acks

Return: true if the application code should setup a quicker timeout

C.58.4.114 function wolfSSL_dtls13_set_send_more_acks

```
void wolfSSL_dtls13_set_send_more_acks(
    WOLFSSL * ssl,
    int value
)
```

This function sets whether the library should send ACKs to the other peer immediately when detecting disruption or not. Sending ACKs immediately assures minimum latency but it may consume more bandwidth than necessary. If the application manages the timer by itself and this option is set to 0

then application code can use wolfSSL_dtls13_use_quick_timeout() to determine if it should setup a quicker timeout to send those delayed ACKs.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **value** 1 to set the option, 0 to disable the option

See:

- wolfSSL_dtls
- wolfSSL_dtls_get_peer
- wolfSSL_dtls_got_timeout
- wolfSSL_dtls_set_peer
- wolfSSL_dtls13_use_quick_timeout

C.58.4.115 function wolfSSL_dtls_set_timeout_init

```
int wolfSSL_dtls_set_timeout_init(
    WOLFSSL * ssl,
    int timeout
)
```

This function sets the dtls timeout.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **timeout** an int type that will be set to the dtls_timeout_init member of the WOLFSSL structure.

See:

- wolfSSL_dtls_set_timeout_max
- wolfSSL_dtls_got_timeout

Return:

- SSL_SUCCESS returned if the function executes without an error. The dtls_timeout_init and the dtls_timeout members of SSL have been set.
- BAD_FUNC_ARG returned if the WOLFSSL struct is NULL or if the timeout is not greater than 0. It will also return if the timeout argument exceeds the maximum value allowed.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
int timeout = TIMEOUT;
...
if(wolfSSL_dtls_set_timeout_init(ssl, timeout)){
    // the dtls timeout was set
} else {
    // Failed to set DTLS timeout.
}
```

C.58.4.116 function wolfSSL_dtls_set_timeout_max

```
int wolfSSL_dtls_set_timeout_max(
    WOLFSSL * ssl,
    int timeout
)
```

This function sets the maximum dtls timeout.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **timeout** an int type representing the dtls maximum timeout.

See:

- wolfSSL_dtls_set_timeout_init
- wolfSSL_dtls_got_timeout

Return:

- SSL_SUCCESS returned if the function executed without an error.
- BAD_FUNC_ARG returned if the WOLFSSL struct is NULL or if the timeout argument is not greater than zero or is less than the dtls_timeout_init member of the WOLFSSL structure.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
int timeout = TIMEOUTVAL;
...
int ret = wolfSSL_dtls_set_timeout_max(ssl);
if(!ret){
    // Failed to set the max timeout
}
```

C.58.4.117 function wolfSSL_dtls_got_timeout

```
int wolfSSL_dtls_got_timeout(
    WOLFSSL * ssl
)
```

When using non-blocking sockets with DTLS, this function should be called on the WOLFSSL object when the controlling code thinks the transmission has timed out. It performs the actions needed to retry the last transmit, including adjusting the timeout value. If it has been too long, this will return a failure.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_dtls_get_current_timeout
- wolfSSL_dtls_get_peer
- wolfSSL_dtls_set_peer
- wolfSSL_dtls

Return:

- SSL_SUCCESS will be returned upon success
- SSL_FATAL_ERROR will be returned if there have been too many retransmissions/timeouts without getting a response from the peer.
- NOT_COMPILED_IN will be returned if wolfSSL was not compiled with DTLS support.

Example

```
See the following files for usage examples:
<wolfssl_root>/examples/client/client.c
<wolfssl_root>/examples/server/server.c
```

C.58.4.118 function wolfSSL_dtls_retransmit

```
int wolfSSL_dtls_retransmit(
    WOLFSSL * ssl
)
```

When using non-blocking sockets with DTLS, this function retransmits the last handshake flight ignoring the expected timeout value and retransmit count. It is useful for applications that are using DTLS and need to manage even the timeout and retry count.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_dtls_get_current_timeout
- wolfSSL_dtls_got_timeout
- wolfSSL_dtls

Return:

- SSL_SUCCESS will be returned upon success
- SSL_FATAL_ERROR will be returned if there have been too many retransmissions/timeouts without getting a response from the peer.

Example

```
int ret = 0;
WOLFSSL* ssl;
...
ret = wolfSSL_dtls_retransmit(ssl);
```

C.58.4.119 function wolfSSL_dtls13_do_scheduled_work

```
int wolfSSL_dtls13_do_scheduled_work(
    WOLFSSL * ssl
)
```

Sends the DTLS 1.3 work that was scheduled while reading. With WOLFSSL_RW_THREADED the read path never transmits, because that would race the write thread over the output buffer and the sending key schedule, so ACKs, retransmissions and a KeyUpdate the peer asked for are only sent from the write side. An application that reads without writing must call this, from the same thread it uses for writing, or those messages are never sent and the peer keeps retransmitting what it is waiting to have acknowledged. Not for write-dup applications, which drain through wolfSSL_write().

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_dtls13_pending_work
- wolfSSL_dtls_retransmit

Return:

- WOLFSSL_SUCCESS on success, including when there was nothing to do.
- WOLFSSL_FATAL_ERROR if ssl is NULL, is not a DTLS 1.3 object, is part of a write-dup pair, or the send failed. Call wolfSSL_get_error() to tell a retryable SSL_ERROR_WANT_WRITE from a real failure.

A KeyUpdate is only sent while none of ours is still unacknowledged, since DTLS must not have two in flight. Completing one we started needs the peer's acknowledgement processed, which rotates the sending keys and so does not happen here, so in a WOLFSSL_RW_THREADED build a peer request arriving after that point is held rather than answered.

A send that could only write part of a record returns WOLFSSL_FATAL_ERROR with wolfSSL_get_error() reporting SSL_ERROR_WANT_WRITE. That is not a failure of the connection: the record is held and the next call sends the rest, so wolfSSL_dtls13_pending_work() keeps reporting work until it is out. Treat it as a retry rather than as a reason to stop draining.

Example

```
WOLFSSL* ssl;
...
while (wolfSSL_dtls13_pending_work(ssl)) {
    if (wolfSSL_dtls13_do_scheduled_work(ssl) != WOLFSSL_SUCCESS) {
        if (wolfSSL_get_error(ssl, 0) == SSL_ERROR_WANT_WRITE) {
            // the socket is full, wait for it and call again
            break;
        }
        // a real error
        break;
    }
}
```

C.58.4.120 function wolfSSL_dtls13_pending_work

```
int wolfSSL_dtls13_pending_work(
    WOLFSSL * ssl
)
```

Reports whether the object has DTLS 1.3 work waiting to be sent by wolfSSL_dtls13_do_scheduled_work(). Only meaningful with WOLFSSL_RW_THREADED. The answer is advisory and can change as soon as it is returned. Only work the pump can actually carry out is reported, so a drain loop over the pair terminates; waiting for the peer to acknowledge a key update we sent is not reported, as there is nothing to send for it. A record the pump could only write in part is reported, so that the retry it owes is not lost.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See: wolfSSL_dtls13_do_scheduled_work

Return:

- 1 if there is work to send, or if it could not be determined.
- 0 if there is nothing to do, or ssl is not supported here.

Example

```
WOLFSSL* ssl;
...
if (wolfSSL_dtls13_pending_work(ssl))
    wolfSSL_dtls13_do_scheduled_work(ssl);
```

C.58.4.121 function wolfSSL_dtls

```
int wolfSSL_dtls(
    WOLFSSL * ssl
)
```

This function is used to determine if the SSL session has been configured to use DTLS.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_dtls_get_current_timeout
- wolfSSL_dtls_get_peer
- wolfSSL_dtls_got_timeout
- wolfSSL_dtls_set_peer

Return:

- 1 If the SSL session (ssl) has been configured to use DTLS, this function will return 1.
- 0 otherwise.

Example

```
int ret = 0;
WOLFSSL* ssl;
...
ret = wolfSSL_dtls(ssl);
if (ret) {
    // SSL session has been configured to use DTLS
}
```

C.58.4.122 function wolfSSL_dtls_set_peer

```
int wolfSSL_dtls_set_peer(
    WOLFSSL * ssl,
    void * peer,
    unsigned int peerSz
)
```

This function sets the DTLS peer, peer (sockaddr_in) with size of peerSz.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **peer** pointer to peer's sockaddr_in structure. If NULL then the peer information in ssl is cleared.
- **peerSz** size of the sockaddr_in structure pointed to by peer. If 0 then the peer information in ssl is cleared.

See:

- wolfSSL_dtls_get_current_timeout
- wolfSSL_dtls_set_pending_peer
- wolfSSL_dtls_get_peer
- wolfSSL_dtls_got_timeout
- wolfSSL_dtls

Return:

- SSL_SUCCESS will be returned upon success.
- SSL_FAILURE will be returned upon failure.
- SSL_NOT_IMPLEMENTED will be returned if wolfSSL was not compiled with DTLS support.

Example

```
int ret = 0;
WOLFSSL* ssl;
sockaddr_in addr;
...
ret = wolfSSL_dtls_set_peer(ssl, &addr, sizeof(addr));
if (ret != SSL_SUCCESS) {
    // failed to set DTLS peer
}
```

C.58.4.123 function wolfSSL_dtls_set_pending_peer

```
int wolfSSL_dtls_set_pending_peer(
    WOLFSSL * ssl,
    void * peer,
    unsigned int peerSz
)
```

This function sets the pending DTLS peer, peer (sockaddr_in) with size of peerSz. This sets the pending peer that will be upgraded to a regular peer when we successfully de-protect the next record. This is useful in scenarios where the peer's address can change to avoid off-path attackers from changing the peer address. This should be used with Connection ID's to allow seamless and safe transition to a new peer address.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **peer** pointer to peer's sockaddr_in structure. If NULL then the peer information in ssl is cleared.
- **peerSz** size of the sockaddr_in structure pointed to by peer. If 0 then the peer information in ssl is cleared.

See:

- wolfSSL_dtls_get_current_timeout
- wolfSSL_dtls_set_peer
- wolfSSL_dtls_get_peer
- wolfSSL_dtls_got_timeout
- wolfSSL_dtls

Return:

- SSL_SUCCESS will be returned upon success.
- SSL_FAILURE will be returned upon failure.
- SSL_NOT_IMPLEMENTED will be returned if wolfSSL was not compiled with DTLS support.

Example

```
int ret = 0;
WOLFSSL* ssl;
sockaddr_in addr;
...
ret = wolfSSL_dtls_set_pending_peer(ssl, &addr, sizeof(addr));
if (ret != SSL_SUCCESS) {
    // failed to set DTLS peer
}
```

C.58.4.124 function wolfSSL_dtls_get_peer

```
int wolfSSL_dtls_get_peer(
    WOLFSSL * ssl,
    void * peer,
    unsigned int * peerSz
)
```

This function gets the sockaddr_in (of size peerSz) of the current DTLS peer. The function will compare peerSz to the actual DTLS peer size stored in the SSL session. If the peer will fit into peer, the peer's sockaddr_in will be copied into peer, with peerSz set to the size of peer.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **peer** pointer to memory location to store peer's sockaddr_in structure.
- **peerSz** input/output size. As input, the size of the allocated memory pointed to by peer. As output, the size of the actual sockaddr_in structure pointed to by peer.

See:

- wolfSSL_dtls_get_current_timeout
- wolfSSL_dtls_got_timeout
- wolfSSL_dtls_set_peer
- wolfSSL_dtls

Return:

- SSL_SUCCESS will be returned upon success.
- SSL_FAILURE will be returned upon failure.
- SSL_NOT_IMPLEMENTED will be returned if wolfSSL was not compiled with DTLS support.

Example

```
int ret = 0;
WOLFSSL* ssl;
sockaddr_in addr;
...
ret = wolfSSL_dtls_get_peer(ssl, &addr, sizeof(addr));
if (ret != SSL_SUCCESS) {
    // failed to get DTLS peer
}
```

C.58.4.125 function wolfSSL_dtls_get0_peer

```
int wolfSSL_dtls_get0_peer(
    WOLFSSL * ssl,
    const void ** peer,
    unsigned int * peerSz
)
```

This function gets the sockaddr_in (of size peerSz) of the current DTLS peer. This is a zero-copy alternative to wolfSSL_dtls_get_peer().

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **peer** pointer to return the internal buffer holding the peer address
- **peerSz** output the size of the actual sockaddr_in structure pointed to by peer.

See:

- wolfSSL_dtls_get_current_timeout

- wolfSSL_dtls_got_timeout
- wolfSSL_dtls_set_peer
- wolfSSL_dtls

Return:

- SSL_SUCCESS will be returned upon success.
- SSL_FAILURE will be returned upon failure.
- SSL_NOT_IMPLEMENTED will be returned if wolfSSL was not compiled with DTLS support.

Example

```
int ret = 0;
WOLFSSL* ssl;
sockaddr_in* addr;
unsigned int addrSz;
...
ret = wolfSSL_dtls_get_peer(ssl, &addr, &addrSz);
if (ret != SSL_SUCCESS) {
    // failed to get DTLS peer
}
```

C.58.4.126 function wolfSSL_ERR_error_string

```
char * wolfSSL_ERR_error_string(
    unsigned long errNumber,
    char * data
)
```

This function converts an error code returned by wolfSSL_get_error() into a more human_readable error string. errNumber is the error code returned by wolfSSL_get_error() and data is the storage buffer which the error string will be placed in. The maximum length of data is 80 characters by default, as defined by MAX_ERROR_SZ is wolfssl/wolfcrypt/error.h.

Parameters:

- **errNumber** error code returned by wolfSSL_get_error().
- **data** output buffer containing human-readable error string matching errNumber.

See:

- wolfSSL_get_error
- wolfSSL_ERR_error_string_n
- wolfSSL_ERR_print_errors_fp
- wolfSSL_load_error_strings

Return:

- success On successful completion, this function returns the same string as is returned in data.
- failure Upon failure, this function returns a string with the appropriate failure reason, msg.

Example

```
int err = 0;
WOLFSSL* ssl;
char buffer[80];
...
err = wolfSSL_get_error(ssl, 0);
wolfSSL_ERR_error_string(err, buffer);
printf("err = %d, %s\n", err, buffer);
```

C.58.4.127 function wolfSSL_ERR_error_string_n

```
void wolfSSL_ERR_error_string_n(
    unsigned long e,
    char * buf,
    unsigned long len
)
```

This function is a version of wolfSSL_ERR_error_string() where len specifies the maximum number of characters that may be written to buf. Like wolfSSL_ERR_error_string(), this function converts an error code returned from wolfSSL_get_error() into a more human-readable error string. The human-readable string is placed in buf.

Parameters:

- **e** error code returned by wolfSSL_get_error().
- **buff** output buffer containing human-readable error string matching e.
- **len** maximum length in characters which may be written to buf.

See:

- wolfSSL_get_error
- wolfSSL_ERR_error_string
- wolfSSL_ERR_print_errors_fp
- wolfSSL_load_error_strings

Return: none No returns.

Example

```
int err = 0;
WOLFSSL* ssl;
char buffer[80];
...
err = wolfSSL_get_error(ssl, 0);
wolfSSL_ERR_error_string_n(err, buffer, 80);
printf("err = %d, %s\n", err, buffer);
```

C.58.4.128 function wolfSSL_get_shutdown

```
int wolfSSL_get_shutdown(
    const WOLFSSL * ssl
)
```

This function checks the shutdown conditions in closeNotify or connReset or sentNotify members of the Options structure. The Options structure is within the WOLFSSL structure.

Parameters:

- **ssl** a constant pointer to a WOLFSSL structure, created using wolfSSL_new().

See: wolfSSL_SESSION_free

Return:

- 1 SSL_SENT_SHUTDOWN is returned.
- 2 SSL_RECEIVED_SHUTDOWN is returned.

Example

```
#include <wolfssl/ssl.h>

WOLFSSL_CTX* ctx = WOLFSSL_CTX_new( protocol method );
```

```
WOLFSSL* ssl = WOLFSSL_new(ctx);
…
int ret;
ret = wolfSSL_get_shutdown(ssl);

if(ret == 1){
    SSL_SENT_SHUTDOWN
} else if(ret == 2){
    SSL_RECEIVED_SHUTDOWN
} else {
    Fatal error.
}
```

C.58.4.129 function wolfSSL_session_reused

```
int wolfSSL_session_reused(
    WOLFSSL * ssl
)
```

This function returns the resuming member of the options struct. The flag indicates whether or not to reuse a session. If not, a new session must be established.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_SESSION_free
- wolfSSL_GetSessionIndex
- wolfSSL_memsave_session_cache

Return: This function returns an int type held in the Options structure representing the flag for session reuse.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
…
if(!wolfSSL_session_reused(sslResume)){
    // No session reuse allowed.
}
```

C.58.4.130 function wolfSSL_is_init_finished

```
int wolfSSL_is_init_finished(
    const WOLFSSL * ssl
)
```

This function checks to see if the connection is established.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_set_accept_state
- wolfSSL_get_keys
- wolfSSL_set_shutdown

Return:

- 0 returned if the connection is not established, i.e. the WOLFSSL struct is NULL or the handshake is not done.
- 1 returned if the connection is established i.e. the WOLFSSL handshake is done.

EXAMPLE

```
#include <wolfssl/ssl.h>

WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
WOLFSSL* ssl = wolfSSL_new(ctx);
...
if(wolfSSL_is_init_finished(ssl)){
    Handshake is done and connection is established
}
```

C.58.4.131 function wolfSSL_get_version

```
const char * wolfSSL_get_version(
    WOLFSSL * ssl
)
```

Returns the SSL version being used as a string.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See: wolfSSL_lib_version

Return:

- “SSLv3” Using SSLv3
- “TLSv1” Using TLSv1
- “TLSv1.1” Using TLSv1.1
- “TLSv1.2” Using TLSv1.2
- “TLSv1.3” Using TLSv1.3
- “DTLS”: Using DTLS
- “DTLSv1.2” Using DTLSv1.2
- “unknown” There was a problem determining which version of TLS being used.

Example

```
wolfSSL_Init();
WOLFSSL_CTX* ctx;
WOLFSSL* ssl;
WOLFSSL_METHOD method = // Some wolfSSL method
ctx = wolfSSL_CTX_new(method);
ssl = wolfSSL_new(ctx);
printf(wolfSSL_get_version("Using version: %s", ssl));
```

C.58.4.132 function wolfSSL_get_current_cipher_suite

```
int wolfSSL_get_current_cipher_suite(
    WOLFSSL * ssl
)
```

Returns the current cipher suit an ssl session is using.

Parameters:

- **ssl** The SSL session to check.

See:

- wolfSSL_CIPHER_get_name
- wolfSSL_get_current_cipher
- wolfSSL_get_cipher_list

Return:

- ssl->options.cipherSuite An integer representing the current cipher suite.
- 0 The ssl session provided is null.

Example

```
wolfSSL_Init();
WOLFSSL_CTX* ctx;
WOLFSSL* ssl;
WOLFSSL_METHOD method = // Some wolfSSL method
ctx = wolfSSL_CTX_new(method);
ssl = wolfSSL_new(ctx);

if(wolfSSL_get_current_cipher_suite(ssl) == 0)
{
    // Error getting cipher suite
}
```

C.58.4.133 function wolfSSL_get_current_cipher

```
WOLFSSL_CIPHER * wolfSSL_get_current_cipher(
    WOLFSSL * ssl
)
```

This function returns a pointer to the current cipher in the ssl session. The cipher is filled in from the session on each call, so call it again after the session changes, e.g. after the handshake.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_get_cipher
- wolfSSL_get_cipher_name_internal
- wolfSSL_get_cipher_name

Return:

- The function returns the address of the cipher member of the WOLFSSL struct. This is a pointer to the WOLFSSL_CIPHER structure.
- NULL returned if the WOLFSSL structure is NULL.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
WOLFSSL* ssl = wolfSSL_new(ctx);
…
WOLFSSL_CIPHER* cipherCurr = wolfSSL_get_current_cipher;

if(!cipherCurr){
    // Failure case.
} else {
```

```
    // The cipher was returned to cipherCurr
}
```

C.58.4.134 function wolfSSL_CIPHER_get_name

```
const char * wolfSSL_CIPHER_get_name(
    const WOLFSSL_CIPHER * cipher
)
```

This function matches the cipher suite in the SSL object with the available suites and returns the string representation.

Parameters:

- **cipher** a constant pointer to a WOLFSSL_CIPHER structure.

See:

- wolfSSL_get_cipher
- wolfSSL_get_current_cipher
- wolfSSL_get_cipher_name_internal
- wolfSSL_get_cipher_name

Return:

- string This function returns the string representation of the matched cipher suite.
- none It will return “None” if there are no suites matched.

Example

```
// gets cipher name in the format DHE_RSA ...
const char* wolfSSL_get_cipher_name_internal(WOLFSSL* ssl){
WOLFSSL_CIPHER* cipher;
const char* fullName;
…
cipher = wolfSSL_get_curent_cipher(ssl);
fullName = wolfSSL_CIPHER_get_name(cipher);

if(fullName){
    // sanity check on returned cipher
}
```

C.58.4.135 function wolfSSL_get_cipher

```
const char * wolfSSL_get_cipher(
    WOLFSSL *
)
```

This function matches the cipher suite in the SSL object with the available suites.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_CIPHER_get_name
- wolfSSL_get_current_cipher

Return: This function returns the string value of the suite matched. It will return “None” if there are no suites matched.

Example

```
#ifdef WOLFSSL_DTLS
…
// make sure a valid suite is used
if(wolfSSL_get_cipher(ssl) == NULL){
    WOLFSSL_MSG("Can not match cipher suite imported");
    return MATCH_SUITE_ERROR;
}
…
#endif // WOLFSSL_DTLS
```

C.58.4.136 function wolfSSL_get1_session

```
WOLFSSL_SESSION * wolfSSL_get1_session(
    WOLFSSL * ssl
)
```

This function returns the WOLFSSL_SESSION from the WOLFSSL structure as a reference type. This requires calling wolfSSL_SESSION_free to release the session reference. The WOLFSSL_SESSION pointed to contains all the necessary information required to perform a session resumption and reestablish the connection without a new handshake. For session resumption, before calling wolfSSL_shutdown() with your session object, an application should save the session ID from the object with a call to wolfSSL_get1_session(), which returns a pointer to the session. Later, the application should create a new WOLFSSL object and assign the saved session with wolfSSL_set_session(). At this point, the application may call wolfSSL_connect() and wolfSSL will try to resume the session. The wolfSSL server code allows session resumption by default. The object returned by wolfSSL_get1_session() needs to be freed after the application is done with it by calling wolfSSL_SESSION_free() on it.

Parameters:

- **ssl** WOLFSSL structure to get session from.

See:

- wolfSSL_new
- wolfSSL_free
- wolfSSL_SESSION_free

Return:

- WOLFSSL_SESSION On success return session pointer.
- NULL will be returned if ssl is NULL, the SSL session cache is disabled, wolfSSL doesn't have the Session ID available, or mutex functions fail.

Example

```
WOLFSSL* ssl;
WOLFSSL_SESSION* ses;
// attempt/complete handshake
wolfSSL_connect(ssl);
ses  = wolfSSL_get1_session(ssl);
// check ses information
// disconnect / setup new SSL instance
wolfSSL_set_session(ssl, ses);
// attempt/resume handshake
wolfSSL_SESSION_free(ses);
```

C.58.4.137 function wolfSSLv23_client_method

```
WOLFSSL_METHOD * wolfSSLv23_client_method(
    void
)
```

The wolfSSLv23_client_method() function is used to indicate that the application is a client and will support the highest protocol version supported by the server between SSL 3.0 _ TLS 1.3. This function allocates memory for and initializes a new WOLFSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new(). Both wolfSSL clients and servers have robust version downgrade capability. If a specific protocol version method is used on either side, then only that version will be negotiated or an error will be returned. For example, a client that uses TLSv1 and tries to connect to a SSLv3 only server will fail, likewise connecting to a TLSv1.1 will fail as well. To resolve this issue, a client that uses the wolfSSLv23_client_method() function will use the highest protocol version supported by the server and downgrade to SSLv3 if needed. In this case, the client will be able to connect to a server running SSLv3 - TLSv1.3.

Parameters:

- **none** No parameters

See:

- wolfSSLv3_client_method
- wolfTLSv1_client_method
- wolfTLSv1_1_client_method
- wolfTLSv1_2_client_method
- wolfTLSv1_3_client_method
- wolfDTLSv1_client_method
- wolfSSL_CTX_new

Return:

- pointer upon success a pointer to a WOLFSSL_METHOD.
- Failure If memory allocation fails when calling XMALLOC, the failure value of the underlying malloc() implementation will be returned (typically NULL with errno will be set to ENOMEM).

Example

```
WOLFSSL_METHOD* method;
WOLFSSL_CTX* ctx;
method = wolfSSLv23_client_method();
if (method == NULL) {
// unable to get method
}

ctx = wolfSSL_CTX_new(method);
...
```

C.58.4.138 function wolfSSL_BIO_get_mem_data

```
int wolfSSL_BIO_get_mem_data(
    WOLFSSL_BIO * bio,
    void * p
)
```

This is used to set a byte pointer to the start of the internal memory buffer.

Parameters:

- **bio** WOLFSSL_BIO structure to get memory buffer of.

- **p** byte pointer to set to memory buffer.

See:

- wolfSSL_BIO_new
- wolfSSL_BIO_s_mem
- wolfSSL_BIO_set_fp
- wolfSSL_BIO_free

Return:

- size On success the size of the buffer is returned
- SSL_FATAL_ERROR If an error case was encountered.

Example

```
WOLFSSL_BIO* bio;
const byte* p;
int ret;
bio  = wolfSSL_BIO_new(wolfSSL_BIO_s_mem());
ret  = wolfSSL_BIO_get_mem_data(bio, &p);
// check ret value
```

C.58.4.139 function wolfSSL_BIO_set_init

```
void wolfSSL_BIO_set_init(
    WOLFSSL_BIO * bio,
    int init
)
```

This is used to set the init flag of a BIO, indicating whether the BIO has been initialised and is ready for use. Typically called from a custom BIO create callback.

Parameters:

- **bio** WOLFSSL_BIO structure to set the init flag on.
- **init** value to set (0 = not initialised, 1 = initialised).

See:

- wolfSSL_BIO_get_init
- wolfSSL_BIO_new

Example

```
WOLFSSL_BIO* bio;
// inside a custom BIO create callback
wolfSSL_BIO_set_init(bio, 1);
```

C.58.4.140 function wolfSSL_BIO_get_init

```
int wolfSSL_BIO_get_init(
    WOLFSSL_BIO * bio
)
```

This is used to retrieve the init flag of a BIO, indicating whether the BIO has been initialised and is ready for use.

Parameters:

- **bio** WOLFSSL_BIO structure to query.

See:

- wolfSSL_BIO_set_init
- wolfSSL_BIO_new

Return:

- 1 if the BIO has been initialised.
- 0 if the BIO has not been initialised or bio is NULL.

Example

```
WOLFSSL_BIO* bio;
// create bio with custom method
if (wolfSSL_BIO_get_init(bio)) {
    // bio is ready
}
```

C.58.4.141 function wolfSSL_BIO_set_fd

```
long wolfSSL_BIO_set_fd(
    WOLFSSL_BIO * b,
    int fd,
    int flag
)
```

Sets the file descriptor for bio to use.

Parameters:

- **b** WOLFSSL_BIO structure to set fd.
- **fd** file descriptor to use.
- **flag** flag for behavior when closing fd.

See:

- wolfSSL_BIO_new
- wolfSSL_BIO_free

Return: SSL_SUCCESS(1) upon success.

Example

```
WOLFSSL_BIO* bio;
int fd;
// setup bio
wolfSSL_BIO_set_fd(bio, fd, BIO_NOCLOSE);
```

C.58.4.142 function wolfSSL_BIO_set_close

```
int wolfSSL_BIO_set_close(
    WOLFSSL_BIO * b,
    long flag
)
```

Sets the close flag, used to indicate that the i/o stream should be closed when the BIO is freed.

Parameters:

- **b** WOLFSSL_BIO structure.
- **flag** flag for behavior when closing i/o stream.

See:

- wolfSSL_BIO_new

- wolfSSL_BIO_free

Return: SSL_SUCCESS(1) upon success.

Example

```
WOLFSSL_BIO* bio;
// setup bio
wolfSSL_BIO_set_close(bio, BIO_NOCLOSE);
```

C.58.4.143 function wolfSSL_BIO_s_socket

```
WOLFSSL_BIO_METHOD * wolfSSL_BIO_s_socket(
    void
)
```

This is used to get a BIO_SOCKET type WOLFSSL_BIO_METHOD.

Parameters:

- **none** No parameters.

See:

- wolfSSL_BIO_new
- wolfSSL_BIO_s_mem

Return: WOLFSSL_BIO_METHOD pointer to a WOLFSSL_BIO_METHOD structure that is a socket type

Example

```
WOLFSSL_BIO* bio;
bio = wolfSSL_BIO_new(wolfSSL_BIO_s_socket);
```

C.58.4.144 function wolfSSL_BIO_set_write_buf_size

```
int wolfSSL_BIO_set_write_buf_size(
    WOLFSSL_BIO * b,
    long size
)
```

This is used to set the size of write buffer for a WOLFSSL_BIO. If write buffer has been previously set this function will free it when resetting the size. It is similar to wolfSSL_BIO_reset in that it resets read and write indexes to 0.

Parameters:

- **b** WOLFSSL_BIO structure to set write buffer size.
- **size** size of buffer to allocate.

See:

- wolfSSL_BIO_new
- wolfSSL_BIO_s_mem
- wolfSSL_BIO_free

Return:

- SSL_SUCCESS On successfully setting the write buffer.
- SSL_FAILURE If an error case was encountered.

Example

```
WOLFSSL_BIO* bio;
int ret;
bio = wolfSSL_BIO_new(wolfSSL_BIO_s_mem());
ret = wolfSSL_BIO_set_write_buf_size(bio, 15000);
// check return value
```

C.58.4.145 function wolfSSL_BIO_make_bio_pair

```
int wolfSSL_BIO_make_bio_pair(
    WOLFSSL_BIO * b1,
    WOLFSSL_BIO * b2
)
```

This is used to pair two bios together. A pair of bios acts similar to a two way pipe writing to one can be read by the other and vice versa. It is expected that both bios be in the same thread, this function is not thread safe. Freeing one of the two bios removes both from being paired. If a write buffer size was not previously set for either of the bios it is set to a default size of 17000 (WOLFSSL_BIO_SIZE) before being paired.

Parameters:

- **b1** WOLFSSL_BIO structure to set pair.
- **b2** second WOLFSSL_BIO structure to complete pair.

See:

- wolfSSL_BIO_new
- wolfSSL_BIO_s_mem
- wolfSSL_BIO_free

Return:

- SSL_SUCCESS On successfully pairing the two bios.
- SSL_FAILURE If an error case was encountered.

Example

```
WOLFSSL_BIO* bio;
WOLFSSL_BIO* bio2;
int ret;
bio  = wolfSSL_BIO_new(wolfSSL_BIO_s_bio());
bio2 = wolfSSL_BIO_new(wolfSSL_BIO_s_bio());
ret = wolfSSL_BIO_make_bio_pair(bio, bio2);
// check ret value
```

C.58.4.146 function wolfSSL_BIO_ctrl_reset_read_request

```
int wolfSSL_BIO_ctrl_reset_read_request(
    WOLFSSL_BIO * b
)
```

This is used to set the read request flag back to 0.

Parameters:

- **b** WOLFSSL_BIO structure to set read request flag.

See:

- wolfSSL_BIO_new, wolfSSL_BIO_s_mem
- wolfSSL_BIO_new, wolfSSL_BIO_free

Return:

- SSL_SUCCESS On successfully setting value.
- SSL_FAILURE If an error case was encountered.

Example

```
WOLFSSL_BIO* bio;
int ret;
...
ret = wolfSSL_BIO_ctrl_reset_read_request(bio);
// check ret value
```

C.58.4.147 function wolfSSL_BIO_nread0

```
int wolfSSL_BIO_nread0(
    WOLFSSL_BIO * bio,
    char ** buf
)
```

This is used to get a buffer pointer for reading from. Unlike wolfSSL_BIO_nread the internal read index is not advanced by the number returned from the function call. Reading past the value returned can result in reading out of array bounds.

Parameters:

- **bio** WOLFSSL_BIO structure to read from.
- **buf** pointer to set at beginning of read array.

See: wolfSSL_BIO_new

Return: >=0 on success return the number of bytes to read

Example

```
WOLFSSL_BIO* bio;
char* bufPt;
int ret;
// set up bio
ret = wolfSSL_BIO_nread0(bio, &bufPt); // read as many bytes as possible
// handle negative ret check
// read ret bytes from bufPt
```

C.58.4.148 function wolfSSL_BIO_nread

```
int wolfSSL_BIO_nread(
    WOLFSSL_BIO * bio,
    char ** buf,
    int num
)
```

This is used to get a buffer pointer for reading from. The internal read index is advanced by the number returned from the function call with buf being pointed to the beginning of the buffer to read from. In the case that less bytes are in the read buffer than the value requested with num the lesser value is returned. Reading past the value returned can result in reading out of array bounds.

Parameters:

- **bio** WOLFSSL_BIO structure to read from.
- **buf** pointer to set at beginning of read array.
- **num** number of bytes to try and read.

See:

- wolfSSL_BIO_new
- wolfSSL_BIO_nwrite

Return:

- =0 on success return the number of bytes to read
- WOLFSSL_BIO_ERROR(-1) on error case with nothing to read return -1

Example

```
WOLFSSL_BIO* bio;
char* bufPt;
int ret;

// set up bio
ret = wolfSSL_BIO_nread(bio, &bufPt, 10); // try to read 10 bytes
// handle negative ret check
// read ret bytes from bufPt
```

C.58.4.149 function wolfSSL_BIO_nwrite

```
int wolfSSL_BIO_nwrite(
    WOLFSSL_BIO * bio,
    char ** buf,
    int num
)
```

Gets a pointer to the buffer for writing as many bytes as returned by the function. Writing more bytes to the pointer returned then the value returned can result in writing out of bounds.

Parameters:

- **bio** WOLFSSL_BIO structure to write to.
- **buf** pointer to buffer to write to.
- **num** number of bytes desired to be written.

See:

- wolfSSL_BIO_new
- wolfSSL_BIO_free
- wolfSSL_BIO_nread

Return:

- int Returns the number of bytes that can be written to the buffer pointer returned.
- WOLFSSL_BIO_UNSET(-2) in the case that is not part of a bio pair
- WOLFSSL_BIO_ERROR(-1) in the case that there is no more room to write to

Example

```
WOLFSSL_BIO* bio;
char* bufPt;
int ret;
// set up bio
ret = wolfSSL_BIO_nwrite(bio, &bufPt, 10); // try to write 10 bytes
// handle negative ret check
// write ret bytes to bufPt
```

C.58.4.150 function wolfSSL_BIO_reset

```
int wolfSSL_BIO_reset(
    WOLFSSL_BIO * bio
)
```

Resets bio to an initial state. As an example for type BIO_BIO this resets the read and write index.

Parameters:

- **bio** WOLFSSL_BIO structure to reset.

See:

- wolfSSL_BIO_new
- wolfSSL_BIO_free

Return:

- 0 On successfully resetting the bio.
- WOLFSSL_BIO_ERROR(-1) Returned on bad input or unsuccessful reset.

Example

```
WOLFSSL_BIO* bio;
// setup bio
wolfSSL_BIO_reset(bio);
//use pt
```

C.58.4.151 function wolfSSL_BIO_seek

```
int wolfSSL_BIO_seek(
    WOLFSSL_BIO * bio,
    int ofs
)
```

This function adjusts the file pointer to the offset given. This is the offset from the head of the file.

Parameters:

- **bio** WOLFSSL_BIO structure to set.
- **ofs** offset into file.

See:

- wolfSSL_BIO_new
- wolfSSL_BIO_s_mem
- wolfSSL_BIO_set_fp
- wolfSSL_BIO_free

Return:

- 0 On successfully seeking.
- -1 If an error case was encountered.

Example

```
WOLFSSL_BIO* bio;
XFILE fp;
int ret;
bio  = wolfSSL_BIO_new(wolfSSL_BIO_s_file());
ret  = wolfSSL_BIO_set_fp(bio, &fp);
// check ret value
```

```
ret  = wolfSSL_BIO_seek(bio, 3);
// check ret value
```

C.58.4.152 function wolfSSL_BIO_write_filename

```
int wolfSSL_BIO_write_filename(
    WOLFSSL_BIO * bio,
    char * name
)
```

This is used to set and write to a file. WIll overwrite any data currently in the file and is set to close the file when the bio is freed.

Parameters:

- **bio** WOLFSSL_BIO structure to set file.
- **name** name of file to write to.

See:

- wolfSSL_BIO_new
- wolfSSL_BIO_s_file
- wolfSSL_BIO_set_fp
- wolfSSL_BIO_free

Return:

- SSL_SUCCESS On successfully opening and setting file.
- SSL_FAILURE If an error case was encountered.

Example

```
WOLFSSL_BIO* bio;
int ret;
bio  = wolfSSL_BIO_new(wolfSSL_BIO_s_file());
ret  = wolfSSL_BIO_write_filename(bio, “test.txt”);
// check ret value
```

C.58.4.153 function wolfSSL_BIO_set_mem_eof_return

```
long wolfSSL_BIO_set_mem_eof_return(
    WOLFSSL_BIO * bio,
    int v
)
```

This is used to set the end of file value. Common value is -1 so as not to get confused with expected positive values.

Parameters:

- **bio** WOLFSSL_BIO structure to set end of file value.
- **v** value to set in bio.

See:

- wolfSSL_BIO_new
- wolfSSL_BIO_s_mem
- wolfSSL_BIO_set_fp
- wolfSSL_BIO_free

Return: 0 returned on completion

Example

```
WOLFSSL_BIO* bio;
int ret;
bio  = wolfSSL_BIO_new(wolfSSL_BIO_s_mem());
ret  = wolfSSL_BIO_set_mem_eof_return(bio, -1);
// check ret value
```

C.58.4.154 function wolfSSL_BIO_get_mem_ptr

```
long wolfSSL_BIO_get_mem_ptr(
    WOLFSSL_BIO * bio,
    WOLFSSL_BUF_MEM ** m
)
```

This is a getter function for WOLFSSL_BIO memory pointer.

Parameters:

- **bio** pointer to the WOLFSSL_BIO structure for getting memory pointer.
- **m** pointer to WOLFSSL_BUF_MEM structure. Is set to point to bio's memory.

See:

- wolfSSL_BIO_new
- wolfSSL_BIO_s_mem

Return:

- SSL_SUCCESS On successfully getting the pointer SSL_SUCCESS is returned (currently value of 1).
- SSL_FAILURE Returned if NULL arguments are passed in (currently value of 0).

Example

```
WOLFSSL_BIO* bio;
WOLFSSL_BUF_MEM* pt;
// setup bio
wolfSSL_BIO_get_mem_ptr(bio, &pt);
//use pt
```

C.58.4.155 function wolfSSL_X509_NAME_oneline

```
char * wolfSSL_X509_NAME_oneline(
    WOLFSSL_X509_NAME * name,
    char * in,
    int sz
)
```

This function copies the name of the x509 into a buffer.

Parameters:

- **name** a pointer to a WOLFSSL_X509 structure.
- **in** a buffer to hold the name copied from the WOLFSSL_X509_NAME structure.
- **sz** the maximum size of the buffer.

See:

- wolfSSL_X509_get_subject_name
- wolfSSL_X509_get_issuer_name

- wolfSSL_X509_get_isCA
- wolfSSL_get_peer_certificate
- wolfSSL_X509_version

Return: A char pointer to the buffer with the WOLFSSL_X509_NAME structures name member's data is returned if the function executed normally.

Example

```
WOLFSSL_X509 x509;
char* name;
...
name = wolfSSL_X509_NAME_oneline(wolfSSL_X509_get_issuer_name(x509), 0, 0);

if(name <= 0){
    // There's nothing in the buffer.
}
```

C.58.4.156 function wolfSSL_X509_get_issuer_name

```
WOLFSSL_X509_NAME * wolfSSL_X509_get_issuer_name(
    WOLFSSL_X509 * cert
)
```

This function returns the name of the certificate issuer.

Parameters:

- **cert** a pointer to a WOLFSSL_X509 structure.

See:

- wolfSSL_X509_get_subject_name
- wolfSSL_X509_get_isCA
- wolfSSL_get_peer_certificate
- wolfSSL_X509_NAME_oneline

Return:

- point a pointer to the WOLFSSL_X509 struct's issuer member is returned.
- NULL if the cert passed in is NULL.

Example

```
WOLFSSL_X509* x509;
WOLFSSL_X509_NAME issuer;
...
issuer = wolfSSL_X509_NAME_oneline(wolfSSL_X509_get_issuer_name(x509), 0, 0);

if(!issuer){
    // NULL was returned
} else {
    // issuer hods the name of the certificate issuer.
}
```

C.58.4.157 function wolfSSL_X509_get_subject_name

```
WOLFSSL_X509_NAME * wolfSSL_X509_get_subject_name(
    WOLFSSL_X509 * cert
)
```

This function returns the subject member of the WOLFSSL_X509 structure.

Parameters:

- **cert** a pointer to a WOLFSSL_X509 structure.

See:

- wolfSSL_X509_get_issuer_name
- wolfSSL_X509_get_isCA
- wolfSSL_get_peer_certificate

Return: pointer a pointer to the WOLFSSL_X509_NAME structure. The pointer may be NULL if the WOLFSSL_X509 struct is NULL or if the subject member of the structure is NULL.

Example

```
WOLFSSL_X509* cert;
WOLFSSL_X509_NAME name;
…
name = wolfSSL_X509_get_subject_name(cert);
if(name == NULL){
    // Deal with the NULL cacse
}
```

C.58.4.158 function wolfSSL_X509_get_isCA

```
int wolfSSL_X509_get_isCA(
    WOLFSSL_X509 * x509
)
```

Checks the isCa member of the WOLFSSL_X509 structure and returns the value.

Parameters:

- **x509** a pointer to a WOLFSSL_X509 structure.

See:

- wolfSSL_X509_get_issuer_name
- wolfSSL_X509_get_isCA

Return:

- isCA returns the value in the isCA member of the WOLFSSL_X509 structure is returned.
- 0 returned if there is not a valid x509 structure passed in.

Example

```
WOLFSSL* ssl;
...
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
...
if(wolfSSL_X509_get_isCA(ssl)){
    // This is the CA
}else {
    // Failure case
}
```

C.58.4.159 function wolfSSL_X509_NAME_get_text_by_NID

```
int wolfSSL_X509_NAME_get_text_by_NID(
    const WOLFSSL_X509_NAME * name,
    int nid,
    char * buf,
    int len
)
```

This function gets the text related to the passed in NID value.

Parameters:

- **name** WOLFSSL_X509_NAME to search for text.
- **nid** NID to search for.
- **buf** buffer to hold text when found.
- **len** length of buffer.

See: none

Return: int returns the size of the text buffer.

Example

```
WOLFSSL_X509_NAME* name;
char buffer[100];
int bufferSz;
int ret;
// get WOLFSSL_X509_NAME
ret = wolfSSL_X509_NAME_get_text_by_NID(name, NID_commonName,
buffer, bufferSz);

//check ret value
```

C.58.4.160 function wolfSSL_X509_get_signature_type

```
int wolfSSL_X509_get_signature_type(
    WOLFSSL_X509 * x509
)
```

This function returns the value stored in the sigOID member of the WOLFSSL_X509 structure.

Parameters:

- **x509** a pointer to a WOLFSSL_X509 structure.

See:

- wolfSSL_X509_get_signature
- wolfSSL_X509_version
- wolfSSL_X509_get_der
- wolfSSL_X509_get_serial_number
- wolfSSL_X509_notBefore
- wolfSSL_X509_notAfter
- wolfSSL_X509_free

Return:

- 0 returned if the WOLFSSL_X509 structure is NULL.
- int an integer value is returned which was retrieved from the x509 object.

Example

```
WOLFSSL_X509 x509 = (WOLFSSL_X509*)XMALLOC(sizeof(WOLFSSL_X509), NULL,
                        DYNAMIC_TYPE_X509);
...
int x509SigType = wolfSSL_X509_get_signature_type(x509);

if(x509SigType != EXPECTED){
// Deal with an unexpected value
}
```

C.58.4.161 function wolfSSL_X509_free

```
void wolfSSL_X509_free(
    WOLFSSL_X509 * x509
)
```

This function frees a WOLFSSL_X509 structure.

Parameters:

- **x509** a pointer to the WOLFSSL_X509 struct.

See:

- wolfSSL_X509_get_signature
- wolfSSL_X509_version
- wolfSSL_X509_get_der
- wolfSSL_X509_get_serial_number
- wolfSSL_X509_notBefore
- wolfSSL_X509_notAfter

Example

```
WOLFSSL_X509* x509 = (WOLFSSL_X509*)XMALOC(sizeof(WOLFSSL_X509), NULL,
DYNAMIC_TYPE_X509) ;

wolfSSL_X509_free(x509);
```

C.58.4.162 function wolfSSL_X509_get_signature

```
int wolfSSL_X509_get_signature(
    WOLFSSL_X509 * x509,
    unsigned char * buf,
    int * bufSz
)
```

Gets the X509 signature and stores it in the buffer.

Parameters:

- **x509** pointer to a WOLFSSL_X509 structure.
- **buf** a char pointer to the buffer.
- **bufSz** an integer pointer to the size of the buffer.

See:

- wolfSSL_X509_get_serial_number
- wolfSSL_X509_get_signature_type
- wolfSSL_X509_get_device_type

Return:

- SSL_SUCCESS returned if the function successfully executes. The signature is loaded into the buffer.
- SSL_FATAL_ERRROR returns if the x509 struct or the bufSz member is NULL. There is also a check for the length member of the sig structure (sig is a member of x509).

Example

```
WOLFSSL_X509* x509 = (WOLFSSL_X509)XMALOC(sizeof(WOLFSSL_X509), NULL,
DYNAMIC_TYPE_X509);
unsigned char* buf; // Initialize
int* bufSz = sizeof(buf)/sizeof(unsigned char);
...
if(wolfSSL_X509_get_signature(x509, buf, bufSz) != SSL_SUCCESS){
    // The function did not execute successfully.
} else{
    // The buffer was written to correctly.
}
```

C.58.4.163 function wolfSSL_X509_STORE_add_cert

```
int wolfSSL_X509_STORE_add_cert(
    WOLFSSL_X509_STORE * store,
    WOLFSSL_X509 * x509
)
```

This function adds a certificate to the WOLFSSL_X509_STRE structure.

Parameters:

- **store** certificate store to add the certificate to.
- **x509** certificate to add.

See: wolfSSL_X509_free

Return:

- SSL_SUCCESS If certificate is added successfully.
- SSL_FATAL_ERROR: If certificate is not added successfully.

Example

```
WOLFSSL_X509_STORE* str;
WOLFSSL_X509* x509;
int ret;
ret = wolfSSL_X509_STORE_add_cert(str, x509);
//check ret value
```

C.58.4.164 function wolfSSL_X509_STORE_CTX_get_chain

```
WOLFSSL_STACK * wolfSSL_X509_STORE_CTX_get_chain(
    WOLFSSL_X509_STORE_CTX * ctx
)
```

This function is a getter function for chain variable in WOLFSSL_X509_STORE_CTX structure. Currently chain is not populated.

Parameters:

- **ctx** certificate store ctx to get parse chain from.

See: wolfSSL_sk_X509_free

Return:

- pointer if successful returns WOLFSSL_STACK (same as STACK_OF(WOLFSSL_X509)) pointer
- Null upon failure

Example

```
WOLFSSL_STACK* sk;
WOLFSSL_X509_STORE_CTX* ctx;
sk = wolfSSL_X509_STORE_CTX_get_chain(ctx);
//check sk for NULL and then use it. sk needs freed after done.
```

C.58.4.165 function wolfSSL_X509_STORE_set_flags

```
int wolfSSL_X509_STORE_set_flags(
    WOLFSSL_X509_STORE * store,
    unsigned long flag
)
```

This function takes in a flag to change the behavior of the WOLFSSL_X509_STORE structure passed in. An example of a flag used is WOLFSSL_CRL_CHECK. X509_V_FLAG_CRL_CHECK and X509_V_FLAG_CRL_CHECK_ALL enable CRL checking like WOLFSSL_CRL_CHECK and WOLFSSL_CRL_CHECKALL.

Parameters:

- **str** certificate store to set flag in.
- **flag** flag for behavior.

See:

- wolfSSL_X509_STORE_new
- wolfSSL_X509_STORE_free

Return:

- SSL_SUCCESS If no errors were encountered when setting the flag.
- <0 a negative value will be returned upon failure.

Example

```
WOLFSSL_X509_STORE* str;
int ret;
// create and set up str
ret = wolfSSL_X509_STORE_set_flags(str, WOLFSSL_CRL_CHECKALL);
If (ret != SSL_SUCCESS) {
    //check ret value and handle error case
}
```

C.58.4.166 function wolfSSL_X509_notBefore

```
const byte * wolfSSL_X509_notBefore(
    WOLFSSL_X509 * x509
)
```

This function the certificate “not before” validity encoded as a byte array.

Parameters:

- **x509** pointer to a WOLFSSL_X509 structure.

See:

- wolfSSL_X509_get_signature
- wolfSSL_X509_version
- wolfSSL_X509_get_der
- wolfSSL_X509_get_serial_number
- wolfSSL_X509_notAfter
- wolfSSL_X509_free

Return:

- NULL returned if the WOLFSSL_X509 structure is NULL.
- byte is returned that contains the notBeforeData.

Example

```
WOLFSSL_X509* x509 = (WOLFSSL_X509*)XMALLOC(sizeof(WOLFSSL_X509), NULL,
                        DYNAMIC_TYPE_X509);
...
byte* notBeforeData = wolfSSL_X509_notBefore(x509);
```

C.58.4.167 function wolfSSL_X509_notAfter

```
const byte * wolfSSL_X509_notAfter(
    WOLFSSL_X509 * x509
)
```

This function the certificate “not after” validity encoded as a byte array.

Parameters:

- **x509** pointer to a WOLFSSL_X509 structure.

See:

- wolfSSL_X509_get_signature
- wolfSSL_X509_version
- wolfSSL_X509_get_der
- wolfSSL_X509_get_serial_number
- wolfSSL_X509_notBefore
- wolfSSL_X509_free

Return:

- NULL returned if the WOLFSSL_X509 structure is NULL.
- byte is returned that contains the notAfterData.

Example

```
WOLFSSL_X509* x509 = (WOLFSSL_X509*)XMALLOC(sizeof(WOLFSSL_X509), NULL,
                        DYNAMIC_TYPE_X509);
...
byte* notAfterData = wolfSSL_X509_notAfter(x509);
```

C.58.4.168 function wolfSSL_ASN1_INTEGER_to_BN

```
WOLFSSL_BIGNUM * wolfSSL_ASN1_INTEGER_to_BN(
    const WOLFSSL_ASN1_INTEGER * ai,
    WOLFSSL_BIGNUM * bn
)
```

This function is used to copy a WOLFSSL_ASN1_INTEGER value to a WOLFSSL_BIGNUM structure.

Parameters:

- **ai** WOLFSSL_ASN1_INTEGER structure to copy from.
- **bn** if wanting to copy into an already existing WOLFSSL_BIGNUM struct then pass in a pointer to it. Optionally this can be NULL and a new WOLFSSL_BIGNUM structure will be created.

See: none

Return:

- pointer On successfully copying the WOLFSSL_ASN1_INTEGER value a WOLFSSL_BIGNUM pointer is returned.
- Null upon failure.

Example

```
WOLFSSL_ASN1_INTEGER* ai;
WOLFSSL_BIGNUM* bn;
// create ai
bn = wolfSSL_ASN1_INTEGER_to_BN(ai, NULL);

// or if having already created bn and wanting to reuse structure
// wolfSSL_ASN1_INTEGER_to_BN(ai, bn);
// check bn is or return value is not NULL
```

C.58.4.169 function wolfSSL_CTX_add_extra_chain_cert

```
long wolfSSL_CTX_add_extra_chain_cert(
    WOLFSSL_CTX * ctx,
    WOLFSSL_X509 * x509
)
```

This function adds the certificate to the internal chain being built in the WOLFSSL_CTX structure.

Parameters:

- **ctx** WOLFSSL_CTX structure to add certificate to.
- **x509** certificate to add to the chain.

See:

- wolfSSL_CTX_new
- wolfSSL_CTX_free

Return:

- SSL_SUCCESS after successfully adding the certificate.
- SSL_FAILURE if failing to add the certificate to the chain.

Example

```
WOLFSSL_CTX* ctx;
WOLFSSL_X509* x509;
int ret;
// create ctx
ret = wolfSSL_CTX_add_extra_chain_cert(ctx, x509);
// check ret value
```

C.58.4.170 function wolfSSL_CTX_get_read_ahead

```
int wolfSSL_CTX_get_read_ahead(
    WOLFSSL_CTX * ctx
)
```

This function returns the get read ahead flag from a WOLFSSL_CTX structure.

Parameters:

- **ctx** WOLFSSL_CTX structure to get read ahead flag from.

See:

- wolfSSL_CTX_new
- wolfSSL_CTX_free
- wolfSSL_CTX_set_read_ahead

Return:

- flag On success returns the read ahead flag.
- SSL_FAILURE If ctx is NULL then SSL_FAILURE is returned.

Example

```
WOLFSSL_CTX* ctx;
int flag;
// setup ctx
flag = wolfSSL_CTX_get_read_ahead(ctx);
//check flag
```

C.58.4.171 function wolfSSL_CTX_set_read_ahead

```
int wolfSSL_CTX_set_read_ahead(
    WOLFSSL_CTX * ctx,
    int v
)
```

This function sets the read ahead flag in the WOLFSSL_CTX structure. When enabled, the record-header read pulls in up to a full TLS record in a single recv(), so the body (and any following buffered records) is obtained without a second syscall. The flag only changes I/O behaviour when the library is built with read-ahead support (–enable-readahead / WOLFSSL_TLS_READ_AHEAD); otherwise it is stored but inert.

Parameters:

- **ctx** WOLFSSL_CTX structure to set read ahead flag.
- **v** read ahead flag

See:

- wolfSSL_CTX_new
- wolfSSL_CTX_free
- wolfSSL_CTX_get_read_ahead
- wolfSSL_has_pending

Return:

- SSL_SUCCESS If ctx read ahead flag set.
- SSL_FAILURE If ctx is NULL then SSL_FAILURE is returned.

Note: With read-ahead enabled, undecrypted data can remain buffered internally while the socket has no more data to read. wolfSSL_has_pending() reports whether any such data is buffered, but a non-zero return does not guarantee a full record is available: wolfSSL_read() may still return WANT_READ when only a partial record is buffered. Event_driven applications should therefore drain the connection by calling wolfSSL_read() until it returns WANT_READ (or an error) before returning to select()/poll(), rather than looping on wolfSSL_has_pending() alone; otherwise buffered data could be missed or the loop could spin.

Example

```
WOLFSSL_CTX* ctx;
int flag;
int ret;
// setup ctx
ret = wolfSSL_CTX_set_read_ahead(ctx, flag);
// check return value
```

C.58.4.172 function wolfSSL_CTX_set_default_read_buffer_len

```
int wolfSSL_CTX_set_default_read_buffer_len(
    WOLFSSL_CTX * ctx,
    size_t len
)
```

This function sets the read-ahead receive window size for contexts created from this WOLFSSL_CTX. When read-ahead is enabled (wolfSSL_CTX_set_read_ahead()), a single recv() pulls in up to `len` bytes:

Parameters:

- **ctx** WOLFSSL_CTX structure to set the read-ahead buffer length on.
- **len** read-ahead coalescing buffer size in bytes (0 = one record).

See:

- wolfSSL_CTX_set_read_ahead
- wolfSSL_set_default_read_buffer_len
- wolfSSL_has_pending

Return:

- SSL_SUCCESS If the buffer length was set.
- SSL_FAILURE If ctx is NULL.

Note: This is a memory-vs-syscall trade-off. While read-ahead is enabled the input buffer is retained (bounded to `len`) for the connection's lifetime, so a large `len` multiplied by many concurrent connections is persistent memory, while a small `len` bounds per-connection footprint at the cost of more syscalls for records that exceed it.

- `len` of 0 resets the window to the one-record default. This is also the window a freshly created context already carries, so the record body is read together with its header without a second syscall.
- A `len` larger than one record lets a single recv() coalesce several back-to-back records, one syscall instead of one per record.
- A `len` smaller than one record caps the receive buffer's footprint when the peer's records are known to be small (e.g. 4 KB), saving heap versus the one-record default. `len` is only a speculative read window, not a hard limit: a record larger than `len` is still received correctly, with the input buffer grown to the record's actual size on demand (costing an extra syscall and reallocation for that record) and then reallocated back down to the window once the oversized record is consumed, so the retained footprint stays bounded by `len` rather than by the largest record seen. The setting only affects I/O when the library is built with read-ahead support (–enable-readahead / WOLFSSL_TLS_READ_AHEAD); otherwise it is stored but inert. This is the wolfSSL equivalent of OpenSSL's SSL_CTX_set_default_read_buffer_len(); unlike OpenSSL it returns a status code (callers that ignore the return remain source-compatible) and it honours sizes below one record, whereas OpenSSL only ever enlarges the buffer. A `len` above WOLFSSL_MAX_READ_AHEAD_SZ (16 MB) is clamped to that maximum. Because 0 and oversized values are both normalised, wolfSSL_CTX_get_default_read_buffer_len() reports the effective window (the one_record default rather than 0 when unset), not the raw argument.

Example

```
WOLFSSL_CTX* ctx;
// setup ctx
wolfSSL_CTX_set_read_ahead(ctx, 1);
// coalesce up to four max-size records per recv()
wolfSSL_CTX_set_default_read_buffer_len(ctx, 4 * 16384);
```

C.58.4.173 function wolfSSL_set_default_read_buffer_len

```
int wolfSSL_set_default_read_buffer_len(
    WOLFSSL * ssl,
    size_t len
)
```

This function sets the read-ahead coalescing buffer size on a single WOLFSSL session, overriding the value inherited from its WOLFSSL_CTX. See wolfSSL_CTX_set_default_read_buffer_len() for the full description, the one-record default, and the memory-vs-syscall trade-off.

Parameters:

- **ssl** WOLFSSL structure to set the read-ahead buffer length on.
- **len** read-ahead coalescing buffer size in bytes (0 = one record).

See:

- wolfSSL_CTX_set_default_read_buffer_len
- wolfSSL_set_read_ahead
- wolfSSL_has_pending

Return:

- SSL_SUCCESS If the buffer length was set.
- SSL_FAILURE If ssl is NULL.

C.58.4.174 function wolfSSL_CTX_get_default_read_buffer_len

```
long wolfSSL_CTX_get_default_read_buffer_len(
    WOLFSSL_CTX * ctx
)
```

This function returns the read-ahead coalescing buffer size configured on a WOLFSSL_CTX by wolfSSL_CTX_set_default_read_buffer_len(). Because a length of 0 and oversized values are normalised when set, the value reported is the effective window actually in use (the one_record default rather than 0 when the length was never changed), not the raw argument last passed.

Parameters:

- **ctx** WOLFSSL_CTX structure to get the read-ahead buffer length from.

See:

- wolfSSL_CTX_set_default_read_buffer_len
- wolfSSL_get_default_read_buffer_len
- wolfSSL_CTX_set_read_ahead

Return:

- len On success returns the read-ahead buffer length in bytes.
- SSL_FAILURE If ctx is NULL.

Example

```
WOLFSSL_CTX* ctx;
long len;
// setup ctx
len = wolfSSL_CTX_get_default_read_buffer_len(ctx);
// check len
```

C.58.4.175 function wolfSSL_get_default_read_buffer_len

```
long wolfSSL_get_default_read_buffer_len(
    const WOLFSSL * ssl
)
```

This function returns the read-ahead coalescing buffer size in effect for a single WOLFSSL session, whether inherited from its WOLFSSL_CTX or overridden by wolfSSL_set_default_read_buffer_len(). As with the WOLFSSL_CTX getter, the value reported is the effective window in use, not the raw argument last passed.

Parameters:

- **ssl** WOLFSSL structure to get the read-ahead buffer length from.

See:

- wolfSSL_set_default_read_buffer_len
- wolfSSL_CTX_get_default_read_buffer_len
- wolfSSL_set_read_ahead

Return:

- len On success returns the read-ahead buffer length in bytes.
- SSL_FAILURE If ssl is NULL.

Example

```
WOLFSSL* ssl;
long len;
// setup ssl
len = wolfSSL_get_default_read_buffer_len(ssl);
// check len
```

C.58.4.176 function wolfSSL_CTX_set_max_send_fragment

```
int wolfSSL_CTX_set_max_send_fragment(
    WOLFSSL_CTX * ctx,
    long max_fragment
)
```

This function caps the plaintext carried in each record sent by WOLFSSL objects created from the context afterwards. It is the wolfSSL equivalent of OpenSSL's SSL_CTX_set_max_send_fragment(). The cap is local and send only: the peer is not told and records received are not limited. Unset, there is no cap. wolfSSL_new() copies the value, so a later call does not change existing objects, as in OpenSSL. With a negotiated max_fragment_length the smaller of the two limits applies, where OpenSSL uses the negotiated length instead. A DTLS write larger than the cap fails with DTLS_SIZE_ERROR, like one larger than the MTU, unless WOLFSSL_NO_DTLS_SIZE_CHECK is defined. In TLS 1.3 only Certificate and CertificateVerify are split to the cap. Other handshake messages, such as ClientHello, ServerHello, EncryptedExtensions, CertificateRequest and NewSessionTicket, are sent in one record each, as they are with a negotiated max_fragment_length. Application data is always split.

Parameters:

- **ctx** WOLFSSL_CTX structure to set the cap on.
- **max_fragment** most plaintext bytes in a record sent.

See:

- wolfSSL_set_max_send_fragment
- wolfSSL_CTX_UseMaxFragment
- wolfSSL_GetMaxOutputSize

Return:

- WOLFSSL_SUCCESS (1) If the cap was set.
- WOLFSSL_FAILURE (0) If ctx is NULL or max_fragment is not in the range 512 to 16384.

Example

```
WOLFSSL_CTX* ctx;
// setup ctx
if (wolfSSL_CTX_set_max_send_fragment(ctx, 1024) != WOLFSSL_SUCCESS) {
    // value out of range
}
```

C.58.4.177 function wolfSSL_set_max_send_fragment

```
int wolfSSL_set_max_send_fragment(
    WOLFSSL * ssl,
    long max_fragment
)
```

This function caps the plaintext carried in each record sent by a single WOLFSSL object, replacing the value copied from its WOLFSSL_CTX. It is the wolfSSL equivalent of OpenSSL's SSL_set_max_send_fragment() and takes effect from the next record sent. See wolfSSL_CTX_set_max_send_fragment() for the full description.

Parameters:

- **ssl** WOLFSSL structure to set the cap on.
- **max_fragment** most plaintext bytes in a record sent.

See:

- wolfSSL_CTX_set_max_send_fragment
- wolfSSL_UseMaxFragment
- wolfSSL_GetMaxOutputSize

Return:

- WOLFSSL_SUCCESS (1) If the cap was set.
- WOLFSSL_FAILURE (0) If ssl is NULL or max_fragment is not in the range 512 to 16384.

Example

```
WOLFSSL* ssl;
// setup ssl
if (wolfSSL_set_max_send_fragment(ssl, 512) != WOLFSSL_SUCCESS) {
    // value out of range
}
```

C.58.4.178 function wolfSSL_CTX_set_tlsext_status_arg

```
long wolfSSL_CTX_set_tlsext_status_arg(
    WOLFSSL_CTX * ctx,
    void * arg
)
```

This function sets the argument to be passed to the OCSP status callback.

Parameters:

- **ctx** WOLFSSL_CTX structure to set user argument.
- **arg** user argument.

See:

- wolfSSL_CTX_set_tlsext_status_cb
- wolfSSL_CTX_new
- wolfSSL_CTX_free

Return:

- SSL_FAILURE If ctx or it's cert manager is NULL, or stapling is not set up.
- SSL_SUCCESS If successfully set.

Example

```
WOLFSSL_CTX* ctx;
void* data;
int ret;
// setup ctx
ret = wolfSSL_CTX_set_tlsext_status_arg(ctx, data);

//check ret value
```

C.58.4.179 function wolfSSL_CTX_set_client_cert_cb

```
void wolfSSL_CTX_set_client_cert_cb(
    WOLFSSL_CTX * ctx,
    client_cert_cb cb
)
```

Sets a callback to select the client certificate and private key.

Parameters:

- **ctx** The WOLFSSL_CTX object.
- **cb** The callback function to select the client certificate and key.

See: wolfSSL_CTX_set_cert_cb

Return: void

This function allows the application to register a callback that will be invoked when a client certificate is requested during the handshake. The callback can select and provide the certificate and key to use.

Example

```
int my_client_cert_cb(WOLFSSL *ssl, WOLFSSL_X509 **x509, WOLFSSL_EVP_PKEY
 ↪  **pkey) { ... }
wolfSSL_CTX_set_client_cert_cb(ctx, my_client_cert_cb);
```

C.58.4.180 function wolfSSL_CTX_set_cert_cb

```
void wolfSSL_CTX_set_cert_cb(
    WOLFSSL_CTX * ctx,
    CertSetupCallback cb,
    void * arg
)
```

Sets a generic certificate setup callback.

Parameters:

- **ctx** The WOLFSSL_CTX object.
- **cb** The callback function for certificate setup.
- **arg** User argument to pass to the callback.

See:

- wolfSSL_CTX_set_client_cert_cb
- wolfSSL_get0_peer_CA_list
- wolfSSL_get_client_CA_list

Return: void

The callback is called whenever a certificate is about to be used, so the application can inspect, set or clear certificates - for example to react to a CA list sent by the peer.

Example

```
int my_cert_setup_cb(WOLFSSL* ssl, void* arg) { ... }
wolfSSL_CTX_set_cert_cb(ctx, my_cert_setup_cb, NULL);
```

C.58.4.181 function wolfSSL_CTX_set_tlsext_status_cb

```
int wolfSSL_CTX_set_tlsext_status_cb(
    WOLFSSL_CTX * ctx,
    tlsextStatusCb cb
)
```

Sets the callback to be used for handling OCSP status requests (OCSP stapling).

Parameters:

- **ctx** The WOLFSSL_CTX object.
- **cb** The callback function to handle OCSP status requests. NULL clears any callback already set.

See:

- wolfSSL_CTX_get_tlsext_status_cb
- wolfSSL_CTX_set_tlsext_status_arg

Return:

- SSL_SUCCESS on success, SSL_FAILURE otherwise.
- SSL_FAILURE will be returned when ctx or its certificate manager is NULL, or stapling is not set up. A NULL cb is not a failure.

This function allows the application to register a callback that will be invoked when an OCSP status request is received during the TLS handshake. The callback can provide an OCSP response to be stapled to the handshake. This API is only useful on the server side.

Example

```
int my_ocsp_status_cb(WOLFSSL* ssl, void* arg) { ... }
wolfSSL_CTX_set_tlsext_status_cb(ctx, my_ocsp_status_cb);
```

C.58.4.182 function wolfSSL_CTX_get_tlsext_status_cb

```
int wolfSSL_CTX_get_tlsext_status_cb(
    WOLFSSL_CTX * ctx,
    tlsextStatusCb * cb
)
```

Gets the currently set OCSP status callback for the context.

Parameters:

- **ctx** The WOLFSSL_CTX object.
- **cb** Pointer to receive the callback function. Required.

See: wolfSSL_CTX_set_tlsext_status_cb

Return:

- SSL_SUCCESS on success, SSL_FAILURE otherwise.
- SSL_FAILURE will be returned when ctx, its certificate manager or cb is NULL, or stapling is not set up.

C.58.4.183 function wolfSSL_get_tlsext_status_ocsp_resp

```
long wolfSSL_get_tlsext_status_ocsp_resp(
    WOLFSSL * ssl,
    unsigned char ** resp
)
```

Gets the OCSP response that will be sent (stapled) to the peer.

Parameters:

- **ssl** The WOLFSSL session.
- **resp** Pointer to receive the response buffer.

See: wolfSSL_set_tlsext_status_ocsp_resp

Return: Length of the response, or negative value on error.

C.58.4.184 function wolfSSL_set_tlsext_status_ocsp_resp

```
long wolfSSL_set_tlsext_status_ocsp_resp(
    WOLFSSL * ssl,
    unsigned char * resp,
    int len
)
```

Sets the OCSP response to be sent (stapled) to the peer.

Parameters:

- **ssl** The WOLFSSL session.
- **resp** Pointer to the response buffer.
- **len** Length of the response buffer.

See: wolfSSL_get_tlsext_status_ocsp_resp

Return:

- SSL_SUCCESS on success, SSL_FAILURE otherwise.
- SSL_FAILURE will be returned when ssl is NULL or the response and length disagree.

The buffer in resp becomes owned by wolfSSL and will be freed by wolfSSL. The application must not free the buffer after calling this function.

C.58.4.185 function wolfSSL_set_tlsext_status_ocsp_resp_multi

```
int wolfSSL_set_tlsext_status_ocsp_resp_multi(
    WOLFSSL * ssl,
    unsigned char * resp,
    int len,
    word32 idx
)
```

Sets multiple OCSP responses for TLS multi-certificate chains.

Parameters:

- **ssl** The WOLFSSL session.
- **resp** Pointer to the response buffer.
- **len** Length of the response buffer.
- **idx** Index of the certificate chain.

Return:

- SSL_SUCCESS on success, SSL_FAILURE otherwise.
- SSL_FAILURE will be returned when ssl is NULL, idx is out of range, or the response and length disagree.

The buffer in resp becomes owned by wolfSSL and will be freed by wolfSSL. The application must not free the buffer after calling this function.

Each stapled response (one per certificate) must carry exactly one SingleResponse. A BasicOCSPResponse bundling more than one SingleResponse is rejected by the peer, so responders must supply a separate response per certificate rather than combining statuses into a single response.

C.58.4.186 function wolfSSL_CTX_set_ocsp_status_verify_cb

```
void wolfSSL_CTX_set_ocsp_status_verify_cb(
    WOLFSSL_CTX * ctx,
    ocspVerifyStatusCb cb,
    void * cbArg
)
```

Sets a callback to verify the OCSP status response.

Parameters:

- **ctx** The WOLFSSL_CTX object.
- **cb** The callback function.
- **cbArg** User argument to pass to the callback.

Return: void

It is recommended to enable SESSION_CERTS in order to have access to the peer's certificate chain during OCSP verification.

Example

```
void my_ocsp_verify_cb(WOLFSSL* ssl, int err, byte* resp, word32 respSz, word32
 ↪  idx, void* arg)
{
    (void)arg;
    if (err == 0 && staple && stapleSz > 0) {
        printf("Client: OCSP staple received, size=%u\n", stapleSz);
        return 0;
    }
    // Manual OCSP staple verification if err != 0
    if (err != 0 && staple && stapleSz > 0) {
        WOLFSSL_CERT_MANAGER* cm = NULL;
        DecodedCert cert;
        byte certInit = 0;
        WOLFSSL_OCSP* ocsp = NULL;
        WOLFSSL_X509_CHAIN* peerCerts;
        int i;

        cm = wolfSSL_CertManagerNew();
        if (cm == NULL)
            goto cleanup;
        if (wolfSSL_CertManagerLoadCA(cm, CA_CERT, NULL) != WOLFSSL_SUCCESS)
            goto cleanup;

        peerCerts = wolfSSL_get_peer_chain(ssl);
        if (peerCerts == NULL || wolfSSL_get_chain_count(peerCerts) <= (int)idx
                || wolfSSL_get_chain_length(peerCerts, (int)idx) == 0)
            goto cleanup;

        for (i = idx + 1; i < wolfSSL_get_chain_count(peerCerts); i++) {
            if (wolfSSL_get_chain_length(peerCerts, i) == 0)
                continue;   // a certificate too large to store leaves its slot
                 ↪  empty
            if (wolfSSL_CertManagerLoadCABuffer(cm,
                 ↪  wolfSSL_get_chain_cert(peerCerts, i),
                    wolfSSL_get_chain_length(peerCerts, i),
 ↪  WOLFSSL_FILETYPE_ASN1) != WOLFSSL_SUCCESS)
                goto cleanup;
        }

        wc_InitDecodedCert(&cert, wolfSSL_get_chain_cert(peerCerts, idx),
 ↪  wolfSSL_get_chain_length(peerCerts, idx), NULL);
        certInit = 1;
        if (wc_ParseCert(&cert, CERT_TYPE, VERIFY, cm) != 0)
            goto cleanup;
        if ((ocsp = wc_NewOCSP(cm)) == NULL)
            goto cleanup;
        if (wc_CheckCertOcspResponse(ocsp, &cert, staple, stapleSz, NULL) != 0)
            goto cleanup;

        printf("Client: Manual OCSP staple verification succeeded for
 ↪  idx=%u\n", idx);
        err = 0;
cleanup:
        wc_FreeOCSP(ocsp);
```

```
        if (certInit)
            wc_FreeDecodedCert(&cert);
        wolfSSL_CertManagerFree(cm);
        if (err == 0)
            return 0;
        printf("Client: Manual OCSP staple verification failed for idx=%u\n",
 ↪  idx);
    }
    printf("Client: OCSP staple verify error=%d\n", err);
    return err;
}
wolfSSL_CTX_set_ocsp_status_verify_cb(ctx, my_ocsp_verify_cb, NULL);
```

C.58.4.187 function wolfSSL_CTX_set_tlsext_opaque_prf_input_callback_arg

```
long wolfSSL_CTX_set_tlsext_opaque_prf_input_callback_arg(
    WOLFSSL_CTX * ctx,
    void * arg
)
```

This function sets the optional argument to be passed to the PRF callback.

Parameters:

- **ctx** WOLFSSL_CTX structure to set user argument.
- **arg** user argument.

See:

- wolfSSL_CTX_new
- wolfSSL_CTX_free

Return:

- SSL_FAILURE If ctx is NULL.
- SSL_SUCCESS If successfully set.

Example

```
WOLFSSL_CTX* ctx;
void* data;
int ret;
// setup ctx
ret = wolfSSL_CTX_set_tlsext_opaques_prf_input_callback_arg(ctx, data);
//check ret value
```

C.58.4.188 function wolfSSL_CTX_set_options

```
long wolfSSL_CTX_set_options(
    WOLFSSL_CTX * ctx,
    long opt
)
```

This function ORs the bits in opt into the options mask of the given WOLFSSL_CTX. The options mask is inherited by every WOLFSSL session later created from this context. Bits are accumulated — to remove an option, use wolfSSL_CTX_clear_options(). The OpenSSL-style "SSL_OP_" *macros are aliases for the corresponding "WOLFSSL_OP_"* values; either spelling may be used.

Parameters:

- **ctx** WOLFSSL_CTX structure on which to set the options mask.
- **opt** the bitmask of SSL_OP_* / WOLFSSL_OP_* flags to OR into the current mask.

See:

- wolfSSL_CTX_clear_options
- wolfSSL_CTX_get_options
- wolfSSL_set_options
- wolfSSL_get_options

Return:

- BAD_FUNC_ARG if `ctx` is NULL.
- The updated options mask value stored in `ctx` on success.

Effective options:

Macro	Effect
SSL_OP_NO_SSLv2	Disable SSLv2 (wolfSSL never supports SSLv2; flag is accepted for OpenSSL compatibility)
SSL_OP_NO_SSLv3	Disable SSLv3
SSL_OP_NO_TLSv1	Disable TLS 1.0
SSL_OP_NO_TLSv1_1	Disable TLS 1.1
SSL_OP_NO_TLSv1_2	Disable TLS 1.2
SSL_OP_NO_TLSv1_3	Disable TLS 1.3 (requires WOLFSSL_TLS13)
SSL_OP_NO_COMPRESSION	Disable record-layer compression (no-op unless HAVE_LIBZ)
SSL_OP_NO_TICKET	Disable RFC 5077 session tickets (TLS 1.2 only; TLS 1.3 ignores this flag); requires HAVE_SESSION_TICKET and (OPENSSL_EXTRA or HAVE_WEBSERVER or WOLFSSL_WPAS_SMALL)
SSL_OP_NO_RENEGOTIATION	Reject peer-initiated renegotiation
SSL_OP_NO_SESSION_RESUMPTION_ON_RENEGOTIATION	Disable session resumption on renegotiation
SSL_OP_COOKIE_EXCHANGE	Enable HelloVerifyRequest cookie exchange (default-on for DTLS)
SSL_OP_NO_QUERY_MTU	DTLS: do not query the path MTU
SSL_OP_CIPHER_SERVER_PREFERENCE	Server uses its own cipher preference order rather than the client's
SSL_OP_SINGLE_DH_USE	Generate a fresh DH key for every handshake
SSL_OP_SINGLE_ECDH_USE	Generate a fresh ECDH key for every handshake
SSL_OP_EPHEMERAL_RSA	Use ephemeral RSA (legacy, accepted for OpenSSL compatibility)
SSL_OP_DONT_INSERT_EMPTY_FRAGMENTS	Do not insert empty fragments before a record (CBC BEAST workaround)
SSL_OP_PKCS1_CHECK_1 / _2	Accepted for OpenSSL compatibility
SSL_OP_LEGACY_SERVER_CONNECT	Always allow legacy (unsafe) initial connect; defined as 0 — no effect (requires the openssl/ssl.h compatibility header)

Convenience macros and bug-workaround flags (all members of SSL_OP_ALL, accepted for OpenSSL compatibility but otherwise no-ops in wolfSSL):

- SSL_OP_ALL (bitwise OR of all bug-workaround flags below)
- SSL_OP_MICROSOFT_SESS_ID_BUG

- SSL_OP_NETSCAPE_CHALLENGE_BUG
- SSL_OP_NETSCAPE_REUSE_CIPHER_CHANGE_BUG
- SSL_OP_SSLREF2_REUSE_CERT_TYPE_BUG
- SSL_OP_MICROSOFT_BIG_SSLV3_BUFFER
- SSL_OP_MSIE_SSLV2_RSA_PADDING
- SSL_OP_SSLEAY_080_CLIENT_DH_BUG
- SSL_OP_TLS_D5_BUG
- SSL_OP_TLS_BLOCK_PADDING_BUG
- SSL_OP_TLS_ROLLBACK_BUG
- SSL_OP_NETSCAPE_CA_DN_BUG
- SSL_OP_NETSCAPE_DEMO_CIPHER_CHANGE_BUG

Convenience composite:

- SSL_OP_NO_SSL_MASK = SSL_OP_NO_SSLv3 | SSL_OP_NO_TLSv1 | SSL_OP_NO_TLSv1_1 | SSL_OP_NO_TLSv1_2 | SSL_OP_NO_TLSv1_3

Example

```
WOLFSSL_CTX* ctx;
long mask;
mask = wolfSSL_CTX_set_options(ctx,
    SSL_OP_NO_SSLv3 | SSL_OP_NO_TLSv1 | SSL_OP_NO_TLSv1_1 |
    SSL_OP_NO_COMPRESSION | SSL_OP_CIPHER_SERVER_PREFERENCE);
// 'mask' now reflects the accumulated options stored in ctx
```

C.58.4.189 function wolfSSL_set_options

```
long wolfSSL_set_options(
    WOLFSSL * s,
    long op
)
```

This function ORs the bits in op into the options mask of the given WOLFSSL session. The set of recognized "SSL_OP_" / "WOLFSSL_OP_" flags is identical to that documented for wolfSSL_CTX_set_options(); refer to that function for the full options table and the build-option requirements of individual flags. Flags inherited from the parent WOLFSSL_CTX remain set; setting SSL_OP_NO_TLSv1_3 here lowers the session's negotiated minor version to TLS 1.2.

Parameters:

- **s** WOLFSSL session on which to set the options mask.
- **op** the bitmask of SSL_OP_* / WOLFSSL_OP_* flags to OR into the current mask.

See:

- wolfSSL_CTX_set_options
- wolfSSL_clear_options
- wolfSSL_get_options
- wolfSSL_new
- wolfSSL_free

Return: The updated options mask value stored in s on success, or 0 if s is NULL.

Example

```
WOLFSSL* ssl;
long mask;
mask = wolfSSL_set_options(ssl, SSL_OP_NO_TLSv1_3);
// 'mask' now reflects the accumulated options stored in ssl
```

C.58.4.190 function wolfSSL_get_options

```
long wolfSSL_get_options(
    const WOLFSSL * s
)
```

This function returns the current options mask.

Parameters:

- **s** WOLFSSL structure to get options mask from.

See:

- wolfSSL_new
- wolfSSL_free
- wolfSSL_set_options

Return: val Returns the mask value stored in ssl.

Example

```
WOLFSSL* ssl;
unsigned long mask;
mask  = wolfSSL_get_options(ssl);
// check mask
```

C.58.4.191 function wolfSSL_set_tlsext_debug_arg

```
long wolfSSL_set_tlsext_debug_arg(
    WOLFSSL * s,
    void * arg
)
```

This is used to set the debug argument passed around.

Parameters:

- **s** WOLFSSL structure to set argument in.
- **arg** argument to use.

See:

- wolfSSL_new
- wolfSSL_free

Return:

- SSL_SUCCESS On successful setting argument.
- SSL_FAILURE If an NULL ssl passed in.

Example

```
WOLFSSL* ssl;
void* args;
int ret;
// create ssl object
ret  = wolfSSL_set_tlsext_debug_arg(ssl, args);
// check ret value
```

C.58.4.192 function wolfSSL_set_tlsext_debug_callback

```
long wolfSSL_set_tlsext_debug_callback(
    WOLFSSL * s,
    WOLFSSL_TLSEXT_DEBUG_CB cb
)
```

This is used to set the TLS extension debug callback on the object.

Parameters:

- **s** WOLFSSL structure to set the callback in.
- **cb** Callback to invoke for each received TLS extension, or NULL to disable it.

See: wolfSSL_set_tlsext_debug_arg

Return:

- WOLFSSL_SUCCESS On successful setting of the callback.
- WOLFSSL_FAILURE If a NULL ssl is passed in.

The callback (type WOLFSSL_TLSEXT_DEBUG_CB) is invoked once for every TLS extension received during the handshake, in wire order, before the extension is processed. It reports the side of the connection, the extension type, the raw extension content and the argument set with wolfSSL_set_tlsext_debug_arg(). Passing a NULL callback disables it.

Example

```
WOLFSSL* ssl;
long ret;
// create ssl object
ret = wolfSSL_set_tlsext_debug_callback(ssl, my_tlsext_debug_cb);
// check ret value
```

C.58.4.193 function wolfSSL_set_tlsext_status_type

```
long wolfSSL_set_tlsext_status_type(
    WOLFSSL * s,
    int type
)
```

This function is called when the client application request that a server send back an OCSP status response (also known as OCSP stapling).Currently, the only supported type is TLSEXT_STATUSTYPE_ocsp.

Parameters:

- **s** pointer to WOLFSSL struct which is created by SSL_new() function
- **type** ssl extension type which TLSEXT_STATUSTYPE_ocsp is only supported.

See:

- wolfSSL_new
- wolfSSL_CTX_new
- wolfSSL_free
- wolfSSL_CTX_free

Return:

- 1 upon success.
- 0 upon error.
- BAD_FUNC_ARG will be returned when s is NULL.
- SSL_FAILURE will be returned when the type is not OCSP.

Example

```
WOLFSSL *ssl;
WOLFSSL_CTX *ctx;
int ret;
ctx = wolfSSL_CTX_new(wolfSSLv23_server_method());
ssl = wolfSSL_new(ctx);
ret = WolfSSL_set_tlsext_status_type(ssl,TLSEXT_STATUSTYPE_ocsp);
wolfSSL_free(ssl);
wolfSSL_CTX_free(ctx);
```

C.58.4.194 function wolfSSL_get_verify_result

```
long wolfSSL_get_verify_result(
    const WOLFSSL * ssl
)
```

This is used to get the results after trying to verify the peer's certificate.

Parameters:

- **ssl** WOLFSSL structure to get verification results from.

See:

- wolfSSL_new
- wolfSSL_free

Return:

- X509_V_OK On successful verification.
- SSL_FAILURE If an NULL ssl passed in.

Example

```
WOLFSSL* ssl;
long ret;
// attempt/complete handshake
ret  = wolfSSL_get_verify_result(ssl);
// check ret value
```

C.58.4.195 function wolfSSL_ERR_print_errors_fp

```
void wolfSSL_ERR_print_errors_fp(
    XFILE fp,
    int err
)
```

This function converts an error code returned by wolfSSL_get_error() into a more human_readable error string and prints that string to the output file _ fp. err is the error code returned by wolfSSL_get_error() and fp is the file which the error string will be placed in.

Parameters:

- **fp** output file for human-readable error string to be written to.
- **err** error code returned by wolfSSL_get_error().

See:

- wolfSSL_get_error
- wolfSSL_ERR_error_string
- wolfSSL_ERR_error_string_n

- wolfSSL_load_error_strings

Return: none No returns.

Example

```
int err = 0;
WOLFSSL* ssl;
FILE* fp = ...
...
err = wolfSSL_get_error(ssl, 0);
wolfSSL_ERR_print_errors_fp(fp, err);
```

C.58.4.196 function wolfSSL_ERR_print_errors_cb

```
void wolfSSL_ERR_print_errors_cb(
    int(*)(const char *str, size_t len, void *u) cb,
    void * u
)
```

This function uses the provided callback to handle error reporting. The callback function is executed for each error line. The string, length, and userdata are passed into the callback parameters.

Parameters:

- **cb** the callback function.
- **u** userdata to pass into the callback function.

See:

- wolfSSL_get_error
- wolfSSL_ERR_error_string
- wolfSSL_ERR_error_string_n
- wolfSSL_load_error_strings

Return: none No returns.

Example

```
int error_cb(const char *str, size_t len, void *u)
{ fprintf((FILE*)u, "%-*.*s\n", (int)len, (int)len, str); return 0; }
...
FILE* fp = ...
wolfSSL_ERR_print_errors_cb(error_cb, fp);
```

C.58.4.197 function wolfSSL_CTX_set_psk_client_callback

```
void wolfSSL_CTX_set_psk_client_callback(
    WOLFSSL_CTX * ctx,
    wc_psk_client_callback cb
)
```

The function sets the client_psk_cb member of the WOLFSSL_CTX structure.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().
- **cb** wc_psk_client_callback is a function pointer that will be stored in the WOLFSSL_CTX structure. Return value is the key length on success or zero on error. unsigned int *(wc_psk_client_callback) PSK client callback parameters: WOLFSSL* ssl - Pointer to the wolfSSL structure const char* hint - A stored string that could be displayed to provide a hint to the user. char* identity - The ID will be

stored here. unsigned int id_max_len - Size of the ID buffer. unsigned char* key - The key will be stored here. unsigned int key_max_len - The max size of the key.

See:

- wolfSSL_set_psk_client_callback
- wolfSSL_set_psk_server_callback
- wolfSSL_CTX_set_psk_server_callback
- wolfSSL_CTX_set_psk_client_callback

Return: none No returns.

Example

```
WOLFSSL_CTX* ctx = WOLFSSL_CTX_new( protocol def );
…
static WC_INLINE unsigned int my_psk_client_cb(WOLFSSL* ssl, const char* hint,
char* identity, unsigned int id_max_len, unsigned char* key,
Unsigned int key_max_len){
…
wolfSSL_CTX_set_psk_client_callback(ctx, my_psk_client_cb);
```

C.58.4.198 function wolfSSL_set_psk_client_callback

```
void wolfSSL_set_psk_client_callback(
    WOLFSSL * ssl,
    wc_psk_client_callback cb
)
```

Sets the PSK client side callback.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **cb** a function pointer to type wc_psk_client_callback. Return value is the key length on success or zero on error. unsigned int (*wc_psk_client_callback) PSK client callback parameters: WOLFSSL ssl - Pointer to the wolfSSL structure const char* hint - A stored string that could be displayed to provide a hint to the user. char* identity - The ID will be stored here. unsigned int id_max_len - Size of the ID buffer. unsigned char* key - The key will be stored here. unsigned int key_max_len - The max size of the key.

See:

- wolfSSL_CTX_set_psk_client_callback
- wolfSSL_CTX_set_psk_server_callback
- wolfSSL_set_psk_server_callback

Return: none No returns.

Example

```
WOLFSSL* ssl;
static WC_INLINE unsigned int my_psk_client_cb(WOLFSSL* ssl, const char* hint,
char* identity, unsigned int id_max_len, unsigned char* key,
Unsigned int key_max_len){
…
if(ssl){
wolfSSL_set_psk_client_callback(ssl, my_psk_client_cb);
} else {
    // could not set callback
}
```

C.58.4.199 function wolfSSL_get_psk_identity_hint

```
const char * wolfSSL_get_psk_identity_hint(
    const WOLFSSL *
)
```

This function returns the psk identity hint.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See: wolfSSL_get_psk_identity

Return:

- pointer a const char pointer to the value that was stored in the arrays member of the WOLFSSL structure is returned.
- NULL returned if the WOLFSSL or Arrays structures are NULL.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
char* idHint;
...
idHint = wolfSSL_get_psk_identity_hint(ssl);
if(idHint){
    // The hint was retrieved
    return idHint;
} else {
    // Hint wasn't successfully retrieved
}
```

C.58.4.200 function wolfSSL_get_psk_identity

```
const char * wolfSSL_get_psk_identity(
    const WOLFSSL *
)
```

The function returns a constant pointer to the client_identity member of the Arrays structure.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_get_psk_identity_hint
- wolfSSL_use_psk_identity_hint

Return:

- string the string value of the client_identity member of the Arrays structure.
- NULL if the WOLFSSL structure is NULL or if the Arrays member of the WOLFSSL structure is NULL.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
const char* pskID;
...
pskID = wolfSSL_get_psk_identity(ssl);
```

```
if(pskID == NULL){
    // There is not a value in pskID
}
```

C.58.4.201 function wolfSSL_CTX_use_psk_identity_hint

```
int wolfSSL_CTX_use_psk_identity_hint(
    WOLFSSL_CTX * ctx,
    const char * hint
)
```

This function stores the hint argument in the server_hint member of the WOLFSSL_CTX structure.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().
- **hint** a constant char pointer that will be copied to the WOLFSSL_CTX structure.

See: wolfSSL_use_psk_identity_hint

Return: SSL_SUCCESS returned for successful execution of the function.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
const char* hint;
int ret;
…
ret = wolfSSL_CTX_use_psk_identity_hint(ctx, hint);
if(ret == SSL_SUCCESS){
    // Function was successful.
return ret;
} else {
    // Failure case.
}
```

C.58.4.202 function wolfSSL_use_psk_identity_hint

```
int wolfSSL_use_psk_identity_hint(
    WOLFSSL * ssl,
    const char * hint
)
```

This function stores the hint argument in the server_hint member of the Arrays structure within the WOLFSSL structure.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **hint** a constant character pointer that holds the hint to be saved in memory.

See: wolfSSL_CTX_use_psk_identity_hint

Return:

- SSL_SUCCESS returned if the hint was successfully stored in the WOLFSSL structure.
- SSL_FAILURE returned if the WOLFSSL or Arrays structures are NULL.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
const char* hint;
...
if(wolfSSL_use_psk_identity_hint(ssl, hint) != SSL_SUCCESS){
    // Handle failure case.
}
```

C.58.4.203 function wolfSSL_CTX_set_psk_server_callback

```
void wolfSSL_CTX_set_psk_server_callback(
    WOLFSSL_CTX * ctx,
    wc_psk_server_callback cb
)
```

This function sets the psk callback for the server side in the WOLFSSL_CTX structure.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **cb** a function pointer for the callback and will be stored in the WOLFSSL_CTX structure. Return value is the key length on success or zero on error. unsigned int *(wc_psk_server_callback) PSK server callback parameters WOLFSSL* ssl - Pointer to the wolfSSL structure char* identity - The ID will be stored here. unsigned char* key - The key will be stored here. unsigned int key_max_len - The max size of the key.

See:

- wc_psk_server_callback
- wolfSSL_set_psk_client_callback
- wolfSSL_set_psk_server_callback
- wolfSSL_CTX_set_psk_client_callback

Return: none No returns.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
WOLFSSL* ssl = wolfSSL_new(ctx);
…
static unsigned int my_psk_server_cb(WOLFSSL* ssl, const char* identity,
                        unsigned char* key, unsigned int key_max_len)
{
    // Function body.
}
…
if(ctx != NULL){
    wolfSSL_CTX_set_psk_server_callback(ctx, my_psk_server_cb);
} else {
    // The CTX object was not properly initialized.
}
```

C.58.4.204 function wolfSSL_set_psk_server_callback

```
void wolfSSL_set_psk_server_callback(
    WOLFSSL * ssl,
    wc_psk_server_callback cb
)
```

Sets the psk callback for the server side by setting the WOLFSSL structure options members.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **cb** a function pointer for the callback and will be stored in the WOLFSSL structure. Return value is the key length on success or zero on error. unsigned int (*wc_psk_server_callback) PSK server callback parameters WOLFSSL* ssl - Pointer to the wolfSSL structure char* identity - The ID will be stored here. unsigned char* key - The key will be stored here. unsigned int key_max_len - The max size of the key.

See:

- wolfSSL_set_psk_client_callback
- wolfSSL_CTX_set_psk_server_callback
- wolfSSL_CTX_set_psk_client_callback
- wolfSSL_get_psk_identity_hint
- wc_psk_server_callback
- InitSuites

Return: none No returns.

Example

```
WOLFSSL_CTX* ctx;
WOLFSSL* ssl;
…
static unsigned int my_psk_server_cb(WOLFSSL* ssl, const char* identity,
                        unsigned char* key, unsigned int key_max_len)
{
    // Function body.
}
…
if(ssl != NULL && cb != NULL){
    wolfSSL_set_psk_server_callback(ssl, my_psk_server_cb);
}
```

C.58.4.205 function wolfSSL_set_psk_callback_ctx

```
int wolfSSL_set_psk_callback_ctx(
    WOLFSSL * ssl,
    void * psk_ctx
)
```

Sets a PSK user context in the WOLFSSL structure options member.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **psk_ctx** void pointer to user PSK context

See:

- wolfSSL_get_psk_callback_ctx
- wolfSSL_CTX_set_psk_callback_ctx
- wolfSSL_CTX_get_psk_callback_ctx

Return: WOLFSSL_SUCCESS or WOLFSSL_FAILURE

C.58.4.206 function wolfSSL_CTX_set_psk_callback_ctx

```
int wolfSSL_CTX_set_psk_callback_ctx(
    WOLFSSL_CTX * ctx,
    void * psk_ctx
)
```

Sets a PSK user context in the WOLFSSL_CTX structure.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().
- **psk_ctx** void pointer to user PSK context

See:

- wolfSSL_set_psk_callback_ctx
- wolfSSL_get_psk_callback_ctx
- wolfSSL_CTX_get_psk_callback_ctx

Return: WOLFSSL_SUCCESS or WOLFSSL_FAILURE

C.58.4.207 function wolfSSL_get_psk_callback_ctx

```
void * wolfSSL_get_psk_callback_ctx(
    WOLFSSL * ssl
)
```

Get a PSK user context in the WOLFSSL structure options member.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_set_psk_callback_ctx
- wolfSSL_CTX_set_psk_callback_ctx
- wolfSSL_CTX_get_psk_callback_ctx

Return: void pointer to user PSK context

C.58.4.208 function wolfSSL_CTX_get_psk_callback_ctx

```
void * wolfSSL_CTX_get_psk_callback_ctx(
    WOLFSSL_CTX * ctx
)
```

Get a PSK user context in the WOLFSSL_CTX structure.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().

See:

- wolfSSL_CTX_set_psk_callback_ctx
- wolfSSL_set_psk_callback_ctx
- wolfSSL_get_psk_callback_ctx

Return: void pointer to user PSK context

C.58.4.209 function wolfSSL_CTX_allow_anon_cipher

```
int wolfSSL_CTX_allow_anon_cipher(
    WOLFSSL_CTX * ctx
)
```

This function enables the havAnon member of the CTX structure if HAVE_ANON is defined during compilation.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().

See: none

Return:

- SSL_SUCCESS returned if the function executed successfully and the haveAnnon member of the CTX is set to 1.
- SSL_FAILURE returned if the CTX structure was NULL.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
WOLFSSL* ssl = wolfSSL_new(ctx);
...
#ifdef HAVE_ANON
if(cipherList == NULL){
    wolfSSL_CTX_allow_anon_cipher(ctx);
    if(wolfSSL_CTX_set_cipher_list(ctx, “ADH_AES128_SHA”) != SSL_SUCCESS){
        // failure case
    }
}
#endif
```

C.58.4.210 function wolfSSLv23_server_method

```
WOLFSSL_METHOD * wolfSSLv23_server_method(
    void
)
```

The wolfSSLv23_server_method() function is used to indicate that the application is a server and will support clients connecting with protocol version from SSL 3.0 _ TLS 1.3. This function allocates memory for and initializes a new WOLFSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().

Parameters:

- **none** No parameters

See:

- wolfSSLv3_server_method
- wolfTLSv1_server_method
- wolfTLSv1_1_server_method
- wolfTLSv1_2_server_method
- wolfTLSv1_3_server_method
- wolfDTLSv1_server_method
- wolfSSL_CTX_new

Return:

- pointer If successful, the call will return a pointer to the newly created WOLFSSL_METHOD structure.
- Failure If memory allocation fails when calling XMALLOC, the failure value of the underlying malloc() implementation will be returned (typically NULL with errno will be set to ENOMEM).

Example

```
WOLFSSL_METHOD* method;
WOLFSSL_CTX* ctx;

method = wolfSSLv23_server_method();
if (method == NULL) {
    // unable to get method
}

ctx = wolfSSL_CTX_new(method);
...
```

C.58.4.211 function wolfSSL_state

```
int wolfSSL_state(
    WOLFSSL * ssl
)
```

This is used to get the internal error state of the WOLFSSL structure.

See:

- wolfSSL_new
- wolfSSL_free

Return:

- wolfssl_error returns ssl error state, usually a negative
- BAD_FUNC_ARG if ssl is NULL.
- ssl WOLFSSL structure to get state from.

Example

```
WOLFSSL* ssl;
int ret;
// create ssl object
ret  = wolfSSL_state(ssl);
// check ret value
```

C.58.4.212 function wolfSSL_get_peer_certificate

```
WOLFSSL_X509 * wolfSSL_get_peer_certificate(
    WOLFSSL * ssl
)
```

This function gets the peer's certificate.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_X509_get_issuer_name
- wolfSSL_X509_get_subject_name

- wolfSSL_X509_get_isCA

Return:

- pointer a pointer to the peerCert member of the WOLFSSL_X509 structure if it exists.
- 0 returned if the peer certificate issuer size is not defined.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
...
WOLFSSL_X509* peerCert = wolfSSL_get_peer_certificate(ssl);

if(peerCert){
    // You have a pointer peerCert to the peer certification
}
```

C.58.4.213 function wolfSSL_want_read

```
int wolfSSL_want_read(
    WOLFSSL * ssl
)
```

This function is similar to calling wolfSSL_get_error() and getting SSL_ERROR_WANT_READ in return. If the underlying error state is SSL_ERROR_WANT_READ, this function will return 1, otherwise, 0.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().

See:

- wolfSSL_want_write
- wolfSSL_get_error

Return:

- 1 wolfSSL_get_error() would return SSL_ERROR_WANT_READ, the underlying I/O has data available for reading.
- 0 There is no SSL_ERROR_WANT_READ error state.

Example

```
int ret;
WOLFSSL* ssl = 0;
...

ret = wolfSSL_want_read(ssl);
if (ret == 1) {
    // underlying I/O has data available for reading (SSL_ERROR_WANT_READ)
}
```

C.58.4.214 function wolfSSL_want_write

```
int wolfSSL_want_write(
    WOLFSSL * ssl
)
```

This function is similar to calling wolfSSL_get_error() and getting SSL_ERROR_WANT_WRITE in return. If the underlying error state is SSL_ERROR_WANT_WRITE, this function will return 1, otherwise, 0.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().

See:

- wolfSSL_want_read
- wolfSSL_get_error

Return:

- 1 wolfSSL_get_error() would return SSL_ERROR_WANT_WRITE, the underlying I/O needs data to be written in order for progress to be made in the underlying SSL connection.
- 0 There is no SSL_ERROR_WANT_WRITE error state.

Example

```
int ret;
WOLFSSL* ssl = 0;
...
ret = wolfSSL_want_write(ssl);
if (ret == 1) {
    // underlying I/O needs data to be written (SSL_ERROR_WANT_WRITE)
}
```

C.58.4.215 function wolfSSL_want

```
int wolfSSL_want(
    WOLFSSL * ssl
)
```

This function reports which I/O operation, if any, the SSL session is waiting on. It reflects the same state that wolfSSL_want_read() and wolfSSL_want_write() report individually. Unlike those two, which are always available, this function is only built when OPENSSL_EXTRA is defined.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().

See:

- wolfSSL_want_read
- wolfSSL_want_write
- wolfSSL_get_error

Return:

- WOLFSSL_READING when the underlying I/O needs data to be read before progress can be made.
- WOLFSSL_WRITING when the underlying I/O needs data to be written before progress can be made.
- WOLFSSL_NOTHING when the session is not waiting on the underlying I/O, or ssl is NULL.

Example

```
WOLFSSL* ssl = 0;
...

if (wolfSSL_want(ssl) == WOLFSSL_READING) {
    // wait for the socket to become readable, then retry
}
```

C.58.4.216 function wolfSSL_check_domain_name

```
int wolfSSL_check_domain_name(
    WOLFSSL * ssl,
    const char * dn
)
```

wolfSSL by default checks the peer certificate for a valid date range and a verified signature. Calling this function before wolfSSL_connect() or wolfSSL_accept() will add a domain name check to the list of checks to perform. dn holds the domain name to check against the peer certificate when it's received.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **dn** domain name to check against the peer certificate when received.

See: none

Return:

- SSL_SUCCESS upon success.
- SSL_FAILURE will be returned if a memory error was encountered.

Example

```
int ret = 0;
WOLFSSL* ssl;
char* domain = (char*) "www.yassl.com";
...

ret = wolfSSL_check_domain_name(ssl, domain);
if (ret != SSL_SUCCESS) {
   // failed to enable domain name check
}
```

C.58.4.217 function wolfSSL_check_ip_address

```
int wolfSSL_check_ip_address(
    WOLFSSL * ssl,
    const char * ipaddr
)
```

Calling this function before wolfSSL_connect() or wolfSSL_accept() adds an IP-address identity check against the peer certificate SAN iPAddress entries.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **ipaddr** NULL-terminated ASCII IP address string to verify against the peer certificate.

See: wolfSSL_check_domain_name

Return:

- SSL_SUCCESS upon success.
- SSL_FAILURE if parameters are invalid or memory allocation fails.

Example

```
int ret = 0;
WOLFSSL* ssl;
const char* ip = "127.0.0.1";
...
```

```
ret = wolfSSL_check_ip_address(ssl, ip);
if (ret != SSL_SUCCESS) {
   // failed to enable IP check
}
```

C.58.4.218 function wolfSSL_Init

```
int wolfSSL_Init(
    void
)
```

Initializes the wolfSSL library for use. Must be called once per application and before any other call to the library.

See: wolfSSL_Cleanup

Return:

- SSL_SUCCESS If successful the call will return.
- BAD_MUTEX_E is an error that may be returned.
- WC_INIT_E wolfCrypt initialization error returned.

Example

```
int ret = 0;
ret = wolfSSL_Init();
if (ret != SSL_SUCCESS) {
    failed to initialize wolfSSL library
}
```

C.58.4.219 function wolfSSL_Cleanup

```
int wolfSSL_Cleanup(
    void
)
```

Un-initializes the wolfSSL library from further use. Doesn't have to be called, though it will free any resources used by the library.

See: wolfSSL_Init

Return:

- SSL_SUCCESS return no errors.
- BAD_MUTEX_E a mutex error return.]

Example

```
wolfSSL_Cleanup();
```

C.58.4.220 function wolfSSL_lib_version

```
const char * wolfSSL_lib_version(
    void
)
```

This function returns the current library version.

Parameters:

- **none** No parameters.

See: word32_wolfSSL_lib_version_hex

Return: LIBWOLFSSL_VERSION_STRING a const char pointer defining the version.

Example

```
char version[MAXSIZE];
version = wolfSSL_KeepArrays();
…
if(version != ExpectedVersion){
    // Handle the mismatch case
}
```

C.58.4.221 function wolfSSL_lib_version_hex

```
word32 wolfSSL_lib_version_hex(
    void
)
```

This function returns the current library version in hexadecimal notation.

Parameters:

- **none** No parameters.

See: wolfSSL_lib_version

Return: LILBWOLFSSL_VERSION_HEX returns the hexadecimal version defined in wolfssl/version.h.

Example

```
word32 libV;
libV = wolfSSL_lib_version_hex();

if(libV != EXPECTED_HEX){
    // How to handle an unexpected value
} else {
    // The expected result for libV
}
```

C.58.4.222 function wolfSSL_negotiate

```
int wolfSSL_negotiate(
    WOLFSSL * ssl
)
```

Performs the actual connect or accept based on the side of the SSL method. If called from the client side then an wolfSSL_connect() is done while a wolfSSL_accept() is performed if called from the server side.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().

See:

- SSL_connect
- SSL_accept

Return:

- SSL_SUCCESS will be returned if successful. (Note, older versions will return 0.)

- SSL_FATAL_ERROR will be returned if the underlying call resulted in an error. Use wolfSSL_get_error() to get a specific error code.

If decrypted application data is waiting to be read, the handshake is not continued and wolfSSL_get_error() returns APP_DATA_READY. Read the data with wolfSSL_read() and then call wolfSSL_negotiate() again.

Example

```
int ret = SSL_FATAL_ERROR;
WOLFSSL* ssl = 0;
...
ret = wolfSSL_negotiate(ssl);
if (ret == SSL_FATAL_ERROR) {
    // SSL establishment failed
int error_code = wolfSSL_get_error(ssl);
...
}
...
```

C.58.4.223 function wolfSSL_set_compression

```
int wolfSSL_set_compression(
    WOLFSSL * ssl
)
```

Turns on the ability to use compression for the SSL connection. Both sides must have compression turned on otherwise compression will not be used. The zlib library performs the actual data compression. To compile into the library use –with-libz for the configure system and define HAVE_LIBZ otherwise. Keep in mind that while compressing data before sending decreases the actual size of the messages being sent and received, the amount of data saved by compression usually takes longer in time to analyze than it does to send it raw on all but the slowest of networks.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().

See: none

Return:

- SSL_SUCCESS upon success.
- NOT_COMPILED_IN will be returned if compression support wasn't built into the library.
- BAD_FUNC_ARG will be returned if ssl is NULL or is a DTLS session.

Record layer compression was removed in TLS 1.3 (RFC 8446 section 5.2). A connection that negotiates TLS 1.3 or DTLS 1.3 therefore completes uncompressed and this request is silently dropped; the call still returns SSL_SUCCESS, so check the negotiated protocol version rather than this return value to learn whether compression is actually in use. For the same reason a ClientHello that offers TLS 1.3 never advertises zlib.

Compression is not available over DTLS at all. zlib keeps one deflate stream running across records, so a datagram that is lost, duplicated or reordered would desync the peer for the rest of the connection. Since the transport is known when the WOLFSSL object is created, this is reported rather than dropped.

Example

```
int ret = 0;
WOLFSSL* ssl = 0;
...
ret = wolfSSL_set_compression(ssl);
```

```
if (ret == SSL_SUCCESS) {
    // successfully enabled compression for SSL session
}
```

C.58.4.224 function wolfSSL_set_timeout

```
int wolfSSL_set_timeout(
    WOLFSSL * ssl,
    unsigned int to
)
```

This function sets the SSL session timeout value in seconds.

Parameters:

- **ssl** pointer to the SSL object, created with wolfSSL_new().
- **to** value, in seconds, used to set the SSL session timeout.

See:

- wolfSSL_get1_session
- wolfSSL_set_session

Return:

- SSL_SUCCESS will be returned upon successfully setting the session.
- BAD_FUNC_ARG will be returned if ssl is NULL.

Example

```
int ret = 0;
WOLFSSL* ssl = 0;
...

ret = wolfSSL_set_timeout(ssl, 500);
if (ret != SSL_SUCCESS) {
    // failed to set session timeout value
}
...
```

C.58.4.225 function wolfSSL_CTX_set_timeout

```
int wolfSSL_CTX_set_timeout(
    WOLFSSL_CTX * ctx,
    unsigned int to
)
```

This function sets the timeout value for SSL sessions, in seconds, for the specified SSL context.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **to** session timeout value in seconds.

See:

- wolfSSL_flush_sessions
- wolfSSL_get1_session
- wolfSSL_set_session
- wolfSSL_get_sessionID
- wolfSSL_CTX_set_session_cache_mode

Return:

- the previous timeout value, if WOLFSSL_ERROR_CODE_OPENSSL is
- defined on success. If not defined, SSL_SUCCESS will be returned.
- BAD_FUNC_ARG will be returned when the input context (ctx) is null.

Example

```
WOLFSSL_CTX*    ctx    = 0;
...
ret = wolfSSL_CTX_set_timeout(ctx, 500);
if (ret != SSL_SUCCESS) {
    // failed to set session timeout value
}
```

C.58.4.226 function wolfSSL_get_peer_chain

```
WOLFSSL_X509_CHAIN * wolfSSL_get_peer_chain(
    WOLFSSL * ssl
)
```

Retrieves the peer's certificate chain.

Parameters:

- **ssl** pointer to a valid WOLFSSL structure.

See:

- wolfSSL_get_chain_count
- wolfSSL_get_chain_length
- wolfSSL_get_chain_cert
- wolfSSL_get_chain_cert_pem

Return:

- chain If successful the call will return the peer's certificate chain.
- 0 will be returned if an invalid WOLFSSL pointer is passed to the function.

Example

none

C.58.4.227 function wolfSSL_get_chain_count

```
int wolfSSL_get_chain_count(
    WOLFSSL_X509_CHAIN * chain
)
```

Retrieve's the peers certificate chain count.

Parameters:

- **chain** pointer to a valid WOLFSSL_X509_CHAIN structure.

See:

- wolfSSL_get_peer_chain
- wolfSSL_get_chain_length
- wolfSSL_get_chain_cert
- wolfSSL_get_chain_cert_pem

Return:

- Success If successful the call will return the peer's certificate chain count.
- 0 will be returned if an invalid chain pointer is passed to the function.

Example

none

C.58.4.228 function wolfSSL_get_chain_length

```
int wolfSSL_get_chain_length(
    WOLFSSL_X509_CHAIN * chain,
    int idx
)
```

Retrieves the peer's ASN1.DER certificate length in bytes at index (idx).

Parameters:

- **chain** pointer to a valid WOLFSSL_X509_CHAIN structure.
- **idx** index to start of chain.

See:

- wolfSSL_get_peer_chain
- wolfSSL_get_chain_count
- wolfSSL_get_chain_cert
- wolfSSL_get_chain_cert_pem

Return:

- Success If successful the call will return the peer's certificate length in bytes by index.
- 0 will be returned if an invalid chain pointer is passed to the function, or if the slot at idx holds no certificate because the one presented there was too large to store.

Example

none

C.58.4.229 function wolfSSL_get_chain_cert

```
unsigned char * wolfSSL_get_chain_cert(
    WOLFSSL_X509_CHAIN * chain,
    int idx
)
```

Retrieves the peer's ASN1.DER certificate at index (idx).

Parameters:

- **chain** pointer to a valid WOLFSSL_X509_CHAIN structure.
- **idx** index to start of chain.

See:

- wolfSSL_get_peer_chain
- wolfSSL_get_chain_count
- wolfSSL_get_chain_length
- wolfSSL_get_chain_cert_pem

Return:

- Success If successful the call will return the peer's certificate by index.

- 0 will be returned if an invalid chain pointer is passed to the function, or if the slot at idx holds no certificate because the one presented there was too large to store. Indices inside wolfSSL_get_chain_count() can be empty, so check wolfSSL_get_chain_length() before using the result.

Example

none

C.58.4.230 function wolfSSL_get_chain_X509

```
WOLFSSL_X509 * wolfSSL_get_chain_X509(
    WOLFSSL_X509_CHAIN * chain,
    int idx
)
```

This function gets the peer's wolfSSL_X509_certificate at index (idx) from the chain of certificates.

Parameters:

- **chain** a pointer to the WOLFSSL_X509_CHAIN used for no dynamic memory SESSION_CACHE.
- **idx** the index of the WOLFSSL_X509 certificate.

See:

- InitDecodedCert
- ParseCertRelative
- CopyDecodedToX509

Return: pointer returns a pointer to a WOLFSSL_X509 structure.

Note that it is the user's responsibility to free the returned memory by calling wolfSSL_FreeX509(). NULL is also returned when the slot at idx holds no certificate because the one presented there was too large to store, which can happen for an index inside wolfSSL_get_chain_count().

Example

```
WOLFSSL_X509_CHAIN* chain = &session->chain;
int idx = 999; // set idx
...
WOLFSSL_X509_CHAIN ptr;
prt = wolfSSL_get_chain_X509(chain, idx);

if(ptr != NULL){
    // ptr contains the cert at the index specified
    wolfSSL_FreeX509(ptr);
} else {
    // ptr is NULL
}
```

C.58.4.231 function wolfSSL_get_chain_cert_pem

```
int wolfSSL_get_chain_cert_pem(
    WOLFSSL_X509_CHAIN * chain,
    int idx,
    unsigned char * buf,
    int inLen,
    int * outLen
)
```

Retrieves the peer's PEM certificate at index (idx).

Parameters:

- **chain** pointer to a valid WOLFSSL_X509_CHAIN structure.
- **idx** index to start of chain.
- **buf** buffer to hold the PEM certificate. May be NULL to ask for the required length only.
- **inLen** length of buf in bytes.
- **outLen** length of the PEM data in bytes.

See:

- wolfSSL_get_peer_chain
- wolfSSL_get_chain_count
- wolfSSL_get_chain_length
- wolfSSL_get_chain_cert

Return:

- SSL_SUCCESS will be returned on success.
- SSL_FAILURE will be returned when the certificate cannot be converted.
- BAD_FUNC_ARG will be returned when chain is NULL, idx is out of range, outLen is NULL, or inLen is negative. An idx inside wolfSSL_get_chain_count() whose slot holds no certificate, because the one presented there was too large to store, is reported the same way.
- BUFFER_E will be returned when inLen is too small to hold the PEM output, in a build that converts with wc_DerToPem(). A build that has only WOLFSSL_PEM_TO_DER reports that case as BAD_FUNC_ARG, so a caller growing its buffer on a short write should accept either.
- LENGTH_ONLY_E will be returned when buf is NULL, with the required length returned through outLen.

Example

none

C.58.4.232 function wolfSSL_get_sessionID

```
const unsigned char * wolfSSL_get_sessionID(
    const WOLFSSL_SESSION * s
)
```

Retrieves the session's ID. The session ID is always 32 bytes long.

Parameters:

- **session** pointer to a valid wolfssl session.

See: SSL_get_session

Return: id The session ID.

Example

none

C.58.4.233 function wolfSSL_X509_get_serial_number

```
int wolfSSL_X509_get_serial_number(
    WOLFSSL_X509 * x509,
    unsigned char * in,
    int * inOutSz
)
```

Retrieves the peer's certificate serial number. The serial number buffer (in) should be at least 32 bytes long and be provided as the *inOutSz argument as input. After calling the function* inOutSz will hold the actual length in bytes written to the in buffer.

Parameters:

- **in** The serial number buffer and should be at least 32 bytes long
- **inOutSz** will hold the actual length in bytes written to the in buffer.

See: SSL_get_peer_certificate

Return:

- SSL_SUCCESS upon success.
- BAD_FUNC_ARG will be returned if a bad function argument was encountered.

Example

none

C.58.4.234 function wolfSSL_X509_get_subjectCN

```
char * wolfSSL_X509_get_subjectCN(
    WOLFSSL_X509 *
)
```

Returns the common name of the subject from the certificate.

Parameters:

- **x509** a pointer to a WOLFSSL_X509 structure containing certificate information.

See:

- wolfSSL_X509_Name_get_entry
- wolfSSL_X509_get_next_altname
- wolfSSL_X509_get_issuer_name
- wolfSSL_X509_get_subject_name

Return:

- NULL returned if the x509 structure is null
- string a string representation of the subject's common name is returned upon success

Example

```
WOLFSSL_X509 x509 = (WOLFSSL_X509*)XMALLOC(sizeof(WOLFSSL_X509), NULL,
                        DYNAMIC_TYPE_X509);
...
int x509Cn = wolfSSL_X509_get_subjectCN(x509);
if(x509Cn == NULL){
    // Deal with NULL case
} else {
    // x509Cn contains the common name
}
```

C.58.4.235 function wolfSSL_X509_get_der

```
const unsigned char * wolfSSL_X509_get_der(
    WOLFSSL_X509 * x509,
    int * outSz
)
```

This function gets the DER encoded certificate in the WOLFSSL_X509 struct.

Parameters:

- **x509** a pointer to a WOLFSSL_X509 structure containing certificate information.
- **outSz** length of the derBuffer member of the WOLFSSL_X509 struct.

See:

- wolfSSL_X509_version
- wolfSSL_X509_Name_get_entry
- wolfSSL_X509_get_next_altname
- wolfSSL_X509_get_issuer_name
- wolfSSL_X509_get_subject_name

Return:

- buffer This function returns the DerBuffer structure's buffer member, which is of type byte.
- NULL returned if the x509 or outSz parameter is NULL.

Example

```
WOLFSSL_X509 x509 = (WOLFSSL_X509*)XMALLOC(sizeof(WOLFSSL_X509), NULL,
                        DYNAMIC_TYPE_X509);
int* outSz; // initialize
...
byte* x509Der = wolfSSL_X509_get_der(x509, outSz);
if(x509Der == NULL){
    // Failure case one of the parameters was NULL
}
```

C.58.4.236 function wolfSSL_X509_get_notAfter

```
WOLFSSL_ASN1_TIME * wolfSSL_X509_get_notAfter(
    WOLFSSL_X509 *
)
```

This function checks to see if x509 is NULL and if it's not, it returns the notAfter member of the x509 struct.

Parameters:

- **x509** a pointer to the WOLFSSL_X509 struct.

See: wolfSSL_X509_get_notBefore

Return:

- pointer to struct with ASN1_TIME to the notAfter member of the x509 struct.
- NULL returned if the x509 object is NULL.

Example

```
WOLFSSL_X509* x509 = (WOLFSSL_X509)XMALOC(sizeof(WOLFSSL_X509), NULL,
DYNAMIC_TYPE_X509) ;
...
const WOLFSSL_ASN1_TIME* notAfter = wolfSSL_X509_get_notAfter(x509);
if(notAfter == NULL){
    // Failure case, the x509 object is null.
}
```

C.58.4.237 function wolfSSL_X509_version

```
int wolfSSL_X509_version(
    WOLFSSL_X509 * x509
)
```

This function retrieves the version of the X509 certificate.

Parameters:

- **x509** a pointer to a WOLFSSL_X509 structure.

See:

- wolfSSL_X509_get_subject_name
- wolfSSL_X509_get_issuer_name
- wolfSSL_X509_get_isCA
- wolfSSL_get_peer_certificate

Return:

- 0 returned if the x509 structure is NULL.
- version the version stored in the x509 structure will be returned.

Example

```
WOLFSSL_X509* x509;
int version;
...
version = wolfSSL_X509_version(x509);
if(!version){
    // The function returned 0, failure case.
}
```

C.58.4.238 function wolfSSL_X509_d2i_fp

```
WOLFSSL_X509 * wolfSSL_X509_d2i_fp(
    WOLFSSL_X509 ** x509,
    FILE * file
)
```

If NO_STDIO_FILESYSTEM is defined this function will allocate heap memory, initialize a WOLFSSL_X509 structure and return a pointer to it.

Parameters:

- **x509** a pointer to a WOLFSSL_X509 pointer.
- **file** a defined type that is a pointer to a FILE.

See:

- wolfSSL_X509_d2i
- XFTELL
- XREWIND
- XFSEEK

Return:

- *WOLFSSL_X509 WOLFSSL_X509 structure pointer is returned if the function executes successfully.
- NULL if the call to XFTELL macro returns a negative value.

Example

```
WOLFSSL_X509* x509a = (WOLFSSL_X509*)XMALLOC(sizeof(WOLFSSL_X509), NULL,
DYNAMIC_TYPE_X509);
WOLFSSL_X509** x509 = x509a;
XFILE file;  (mapped to struct fs_file*)
...
WOLFSSL_X509* newX509 = wolfSSL_X509_d2i_fp(x509, file);
if(newX509 == NULL){
    // The function returned NULL
}
```

C.58.4.239 function wolfSSL_X509_load_certificate_file

```
WOLFSSL_X509 * wolfSSL_X509_load_certificate_file(
    const char * fname,
    int format
)
```

The function loads the x509 certificate into memory.

Parameters:

- **fname** the certificate file to be loaded.
- **format** the format of the certificate.

See:

- InitDecodedCert
- PemToDer
- wolfSSL_get_certificate
- AssertNotNull

Return:

- pointer a successful execution returns pointer to a WOLFSSL_X509 structure.
- NULL returned if the certificate was not able to be written.

Example

```
#define cliCert    "certs/client-cert.pem"
…
X509* x509;
…
x509 = wolfSSL_X509_load_certificate_file(cliCert, SSL_FILETYPE_PEM);
AssertNotNull(x509);
```

C.58.4.240 function wolfSSL_X509_get_device_type

```
unsigned char * wolfSSL_X509_get_device_type(
    WOLFSSL_X509 * x509,
    unsigned char * in,
    int * inOutSz
)
```

This function copies the device type from the x509 structure to the buffer.

Parameters:

- **x509** pointer to a WOLFSSL_X509 structure, created with WOLFSSL_X509_new().
- **in** a pointer to a byte type that will hold the device type (the buffer).

- **inOutSz** the minimum of either the parameter inOutSz or the deviceTypeSz member of the x509 structure.

See:

- wolfSSL_X509_get_hw_type
- wolfSSL_X509_get_hw_serial_number
- wolfSSL_X509_d2i

Return:

- pointer returns a byte pointer holding the device type from the x509 structure.
- NULL returned if the buffer size is NULL.

Example

```
WOLFSSL_X509* x509 = (WOLFSSL_X509)XMALOC(sizeof(WOLFSSL_X509), NULL,
DYNAMIC_TYPE_X509);
byte* in;
int* inOutSz;
...
byte* deviceType = wolfSSL_X509_get_device_type(x509, in, inOutSz);

if(!deviceType){
    // Failure case, NULL was returned.
}
```

C.58.4.241 function wolfSSL_X509_get_hw_type

```
unsigned char * wolfSSL_X509_get_hw_type(
    WOLFSSL_X509 * x509,
    unsigned char * in,
    int * inOutSz
)
```

The function copies the hwType member of the WOLFSSL_X509 structure to the buffer.

Parameters:

- **x509** a pointer to a WOLFSSL_X509 structure containing certificate information.
- **in** pointer to type byte that represents the buffer.
- **inOutSz** pointer to type int that represents the size of the buffer.

See:

- wolfSSL_X509_get_hw_serial_number
- wolfSSL_X509_get_device_type

Return:

- byte The function returns a byte type of the data previously held in the hwType member of the WOLFSSL_X509 structure.
- NULL returned if inOutSz is NULL.

Example

```
WOLFSSL_X509* x509;  // X509 certificate
byte* in;  // initialize the buffer
int* inOutSz;  // holds the size of the buffer
...
byte* hwType = wolfSSL_X509_get_hw_type(x509, in, inOutSz);
```

```
if(hwType == NULL){
    // Failure case function returned NULL.
}
```

C.58.4.242 function wolfSSL_X509_get_hw_serial_number

```
unsigned char * wolfSSL_X509_get_hw_serial_number(
    WOLFSSL_X509 * x509,
    unsigned char * in,
    int * inOutSz
)
```

This function returns the hwSerialNum member of the x509 object.

Parameters:

- **x509** pointer to a WOLFSSL_X509 structure containing certificate information.
- **in** a pointer to the buffer that will be copied to.
- **inOutSz** a pointer to the size of the buffer.

See:

- wolfSSL_X509_get_subject_name
- wolfSSL_X509_get_issuer_name
- wolfSSL_X509_get_isCA
- wolfSSL_get_peer_certificate
- wolfSSL_X509_version

Return: pointer the function returns a byte pointer to the in buffer that will contain the serial number loaded from the x509 object.

Example

```
char* serial;
byte* in;
int* inOutSz;
WOLFSSL_X509 x509;
...
serial = wolfSSL_X509_get_hw_serial_number(x509, in, inOutSz);

if(serial == NULL || serial <= 0){
    // Failure case
}
```

C.58.4.243 function wolfSSL_connect_cert

```
int wolfSSL_connect_cert(
    WOLFSSL * ssl
)
```

This function is called on the client side and initiates an SSL/TLS handshake with a server only long enough to get the peer's certificate chain. When this function is called, the underlying communication channel has already been set up. wolfSSL_connect_cert() works with both blocking and non_blocking I/O. When the underlying I/O is non_blocking, wolfSSL_connect_cert() will return when the underlying I/O could not satisfy the needs of wolfSSL_connect_cert() to continue the handshake. In this case, a call to wolfSSL_get_error() will yield either SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE. The calling process must then repeat the call to wolfSSL_connect_cert() when the underlying I/O is ready and wolfSSL will pick up where it left off. When using a non_blocking socket, nothing needs to be

done, but select() can be used to check for the required condition. If the underlying I/O is blocking, wolfSSL_connect_cert() will only return once the peer's certificate chain has been received.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_get_error
- wolfSSL_connect
- wolfSSL_accept

Return:

- SSL_SUCCESS upon success.
- SSL_FAILURE will be returned if the SSL session parameter is NULL.
- SSL_FATAL_ERROR will be returned if an error occurred. To get a more detailed error code, call wolfSSL_get_error().

Example

```
int ret = 0;
int err = 0;
WOLFSSL* ssl;
char buffer[80];
...
ret = wolfSSL_connect_cert(ssl);
if (ret != SSL_SUCCESS) {
    err = wolfSSL_get_error(ssl, ret);
    printf("error = %d, %s\n", err, wolfSSL_ERR_error_string(err, buffer));
}
```

C.58.4.244 function wolfSSL_d2i_PKCS12_bio

```
WC_PKCS12 * wolfSSL_d2i_PKCS12_bio(
    WOLFSSL_BIO * bio,
    WC_PKCS12 ** pkcs12
)
```

wolfSSL_d2i_PKCS12_bio (d2i_PKCS12_bio) copies in the PKCS12 information from WOLFSSL_BIO to the structure WC_PKCS12. The information is divided up in the structure as a list of Content Infos along with a structure to hold optional MAC information. After the information has been divided into chunks (but not decrypted) in the structure WC_PKCS12, it can then be parsed and decrypted by calling.

Parameters:

- **bio** WOLFSSL_BIO structure to read PKCS12 buffer from.
- **pkcs12** WC_PKCS12 structure pointer for new PKCS12 structure created. Can be NULL

See:

- wolfSSL_PKCS12_parse
- wc_PKCS12_free

Return:

- WC_PKCS12 pointer to a WC_PKCS12 structure.
- Failure If function failed it will return NULL.

Example

```
WC_PKCS12* pkcs;
WOLFSSL_BIO* bio;
WOLFSSL_X509* cert;
WOLFSSL_EVP_PKEY* pkey;
STACK_OF(X509) certs;
//bio loads in PKCS12 file
wolfSSL_d2i_PKCS12_bio(bio, &pkcs);
wolfSSL_PKCS12_parse(pkcs, “a password”, &pkey, &cert, &certs)
wc_PKCS12_free(pkcs)
//use cert, pkey, and optionally certs stack
```

C.58.4.245 function wolfSSL_i2d_PKCS12_bio

```
WC_PKCS12 * wolfSSL_i2d_PKCS12_bio(
    WOLFSSL_BIO * bio,
    WC_PKCS12 * pkcs12
)
```

wolfSSL_i2d_PKCS12_bio (i2d_PKCS12_bio) copies in the cert information from the structure WC_PKCS12 to WOLFSSL_BIO.

Parameters:

- **bio** WOLFSSL_BIO structure to write PKCS12 buffer to.
- **pkcs12** WC_PKCS12 structure for PKCS12 structure as input.

See:

- wolfSSL_PKCS12_parse
- wc_PKCS12_free

Return:

- 1 for success.
- Failure 0.

Example

```
WC_PKCS12 pkcs12;
FILE *f;
byte buffer[5300];
char file[] = "./test.p12";
int bytes;
WOLFSSL_BIO* bio;
pkcs12 = wc_PKCS12_new();
f = fopen(file, "rb");
bytes = (int)fread(buffer, 1, sizeof(buffer), f);
fclose(f);
//convert the DER file into an internal structure
wc_d2i_PKCS12(buffer, bytes, pkcs12);
bio = wolfSSL_BIO_new(wolfSSL_BIO_s_mem());
//convert PKCS12 structure into bio
wolfSSL_i2d_PKCS12_bio(bio, pkcs12);
wc_PKCS12_free(pkcs)
//use bio
```

C.58.4.246 function wolfSSL_PKCS12_parse

```
int wolfSSL_PKCS12_parse(
    WC_PKCS12 * pkcs12,
    const char * psw,
    WOLFSSL_EVP_PKEY ** pkey,
    WOLFSSL_X509 ** cert,
    WOLF_STACK_OF(WOLFSSL_X509) ** ca
)
```

PKCS12 can be enabled with adding –enable-opensslextra to the configure command. It can use triple DES and RC4 for decryption so would recommend also enabling these features when enabling opensslextra (–enable-des3 –enable-arc4). wolfSSL does not currently support RC2 so decryption with RC2 is currently not available. This may be noticeable with default encryption schemes used by OpenSSL command line to create .p12 files. wolfSSL_PKCS12_parse (PKCS12_parse). The first thing this function does is check the MAC is correct if present. If the MAC fails then the function returns and does not try to decrypt any of the stored Content Infos. This function then parses through each Content Info looking for a bag type, if the bag type is known it is decrypted as needed and either stored in the list of certificates being built or as a key found. After parsing through all bags the key found is then compared with the certificate list until a matching pair is found. This matching pair is then returned as the key and certificate, optionally the certificate list found is returned as a STACK_OF certificates. At the moment a CRL, Secret or SafeContents bag will be skipped over and not parsed. It can be seen if these or other “Unknown” bags are skipped over by viewing the debug print out. Additional attributes such as friendly name are skipped over when parsing a PKCS12 file.

Parameters:

- **pkcs12** WC_PKCS12 structure to parse.
- **paswd** password for decrypting PKCS12.
- **pkey** structure to hold private key decoded from PKCS12.
- **cert** structure to hold certificate decoded from PKCS12.
- **stack** optional stack of extra certificates.

See:

- wolfSSL_d2i_PKCS12_bio
- wc_PKCS12_free

Return:

- SSL_SUCCESS On successfully parsing PKCS12.
- SSL_FAILURE If an error case was encountered.

Example

```
WC_PKCS12* pkcs;
WOLFSSL_BIO* bio;
WOLFSSL_X509* cert;
WOLFSSL_EVP_PKEY* pkey;
STACK_OF(X509) certs;
//bio loads in PKCS12 file
wolfSSL_d2i_PKCS12_bio(bio, &pkcs);
wolfSSL_PKCS12_parse(pkcs, “a password”, &pkey, &cert, &certs)
wc_PKCS12_free(pkcs)
//use cert, pkey, and optionally certs stack
```

C.58.4.247 function wolfSSL_SetTmpDH

```
int wolfSSL_SetTmpDH(
    WOLFSSL * ssl,
    const unsigned char * p,
```

```
    int pSz,
    const unsigned char * g,
    int gSz
)
```

Server Diffie-Hellman Ephemeral parameters setting. This function sets up the group parameters to be used if the server negotiates a cipher suite that uses DHE.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **p** Diffie-Hellman prime number parameter.
- **pSz** size of p.
- **g** Diffie-Hellman "generator" parameter.
- **gSz** size of g.

See: SSL_accept

Return:

- SSL_SUCCESS upon success.
- MEMORY_ERROR will be returned if a memory error was encountered.
- SIDE_ERROR will be returned if this function is called on an SSL client instead of an SSL server.

Example

```
WOLFSSL* ssl;
static unsigned char p[] = {...};
static unsigned char g[] = {...};
...
wolfSSL_SetTmpDH(ssl, p, sizeof(p), g, sizeof(g));
```

C.58.4.248 function wolfSSL_SetTmpDH_buffer

```
int wolfSSL_SetTmpDH_buffer(
    WOLFSSL * ssl,
    const unsigned char * b,
    long sz,
    int format
)
```

The function calls the wolfSSL_SetTMpDH_buffer_wrapper, which is a wrapper for Diffie-Hellman parameters.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **buf** allocated buffer passed in from wolfSSL_SetTMpDH_file_wrapper.
- **sz** a long int that holds the size of the file (fname within wolfSSL_SetTmpDH_file_wrapper).
- **format** an integer type passed through from wolfSSL_SetTmpDH_file_wrapper() that is a representation of the certificate format.

See:

- wolfSSL_SetTmpDH_buffer_wrapper
- wc_DhParamsLoad
- wolfSSL_SetTmpDH
- PemToDer
- wolfSSL_CTX_SetTmpDH
- wolfSSL_CTX_SetTmpDH_file

Return:

- SSL_SUCCESS on successful execution.
- SSL_BAD_FILETYPE if the file type is not PEM and is not ASN.1. It will also be returned if the wc_DhParamsLoad does not return normally.
- SSL_NO_PEM_HEADER returns from PemToDer if there is not a PEM header.
- SSL_BAD_FILE returned if there is a file error in PemToDer.
- SSL_FATAL_ERROR returned from PemToDer if there was a copy error.
- MEMORY_E - if there was a memory allocation error.
- BAD_FUNC_ARG returned if the WOLFSSL struct is NULL or if there was otherwise a NULL argument passed to a subroutine.
- DH_KEY_SIZE_E is returned if their is a key size error in wolfSSL_SetTmpDH() or in wolfSSL_CTX_SetTmpDH().
- SIDE_ERROR returned if it is not the server side in wolfSSL_SetTmpDH.

Example

```
Static int wolfSSL_SetTmpDH_file_wrapper(WOLFSSL_CTX* ctx, WOLFSSL* ssl,
Const char* fname, int format);
long sz = 0;
byte* myBuffer = staticBuffer[FILE_BUFFER_SIZE];
…
if(ssl)
ret = wolfSSL_SetTmpDH_buffer(ssl, myBuffer, sz, format);
```

C.58.4.249 function wolfSSL_SetTmpDH_file

```
int wolfSSL_SetTmpDH_file(
    WOLFSSL * ssl,
    const char * f,
    int format
)
```

This function calls wolfSSL_SetTmpDH_file_wrapper to set server Diffie-Hellman parameters.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **fname** a constant char pointer holding the certificate.
- **format** an integer type that holds the format of the certification.

See:

- wolfSSL_CTX_SetTmpDH_file
- wolfSSL_SetTmpDH_file_wrapper
- wolfSSL_SetTmpDH_buffer
- wolfSSL_CTX_SetTmpDH_buffer
- wolfSSL_SetTmpDH_buffer_wrapper
- wolfSSL_SetTmpDH
- wolfSSL_CTX_SetTmpDH

Return:

- SSL_SUCCESS returned on successful completion of this function and its subroutines.
- MEMORY_E returned if a memory allocation failed in this function or a subroutine.
- SIDE_ERROR if the side member of the Options structure found in the WOLFSSL struct is not the server side.
- SSL_BAD_FILETYPE returns if the certificate fails a set of checks.

- DH_KEY_SIZE_E returned if the DH parameter's key size is less than the value of the minDhKeySz member in the WOLFSSL struct.
- DH_KEY_SIZE_E returned if the DH parameter's key size is greater than the value of the maxDhKeySz member in the WOLFSSL struct.
- BAD_FUNC_ARG returns if an argument value is NULL that is not permitted such as, the WOLFSSL structure.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
const char* dhParam;
…
AssertIntNE(SSL_SUCCESS,
wolfSSL_SetTmpDH_file(ssl, dhParam, SSL_FILETYPE_PEM));
```

C.58.4.250 function wolfSSL_CTX_SetTmpDH

```
int wolfSSL_CTX_SetTmpDH(
    WOLFSSL_CTX * ctx,
    const unsigned char * p,
    int pSz,
    const unsigned char * g,
    int gSz
)
```

Sets the parameters for the server CTX Diffie-Hellman.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().
- **p** a constant unsigned char pointer loaded into the buffer member of the serverDH_P struct.
- **pSz** an int type representing the size of p, initialized to MAX_DH_SIZE.
- **g** a constant unsigned char pointer loaded into the buffer member of the serverDH_G struct.
- **gSz** an int type representing the size of g, initialized to MAX_DH_SIZE.

See:

- wolfSSL_SetTmpDH
- wc_DhParamsLoad

Return:

- SSL_SUCCESS returned if the function and all subroutines return without error.
- BAD_FUNC_ARG returned if the CTX, p or g parameters are NULL.
- DH_KEY_SIZE_E returned if the DH parameter's key size is less than the value of the minDhKeySz member of the WOLFSSL_CTX struct.
- DH_KEY_SIZE_E returned if the DH parameter's key size is greater than the value of the maxDhKeySz member of the WOLFSSL_CTX struct.
- MEMORY_E returned if the allocation of memory failed in this function or a subroutine.

Exmaple

```
WOLFSSL_CTX* ctx =  WOLFSSL_CTX_new( protocol );
byte* p;
byte* g;
word32 pSz = (word32)sizeof(p)/sizeof(byte);
word32 gSz = (word32)sizeof(g)/sizeof(byte);
…
int ret =  wolfSSL_CTX_SetTmpDH(ctx, p, pSz, g, gSz);
```

```
if(ret != SSL_SUCCESS){
    // Failure case
}
```

C.58.4.251 function wolfSSL_CTX_SetTmpDH_buffer

```
int wolfSSL_CTX_SetTmpDH_buffer(
    WOLFSSL_CTX * ctx,
    const unsigned char * b,
    long sz,
    int format
)
```

A wrapper function that calls wolfSSL_SetTmpDH_buffer_wrapper.

Parameters:

- **ctx** a pointer to a WOLFSSL structure, created using wolfSSL_CTX_new().
- **buf** a pointer to a constant unsigned char type that is allocated as the buffer and passed through to wolfSSL_SetTmpDH_buffer_wrapper.
- **sz** a long integer type that is derived from the fname parameter in wolfSSL_SetTmpDH_file_wrapper().
- **format** an integer type passed through from wolfSSL_SetTmpDH_file_wrapper().

See:

- wolfSSL_SetTmpDH_buffer_wrapper
- wolfSSL_SetTMpDH_buffer
- wolfSSL_SetTmpDH_file_wrapper
- wolfSSL_CTX_SetTmpDH_file

Return:

- 0 returned for a successful execution.
- BAD_FUNC_ARG returned if the ctx or buf parameters are NULL.
- MEMORY_E if there is a memory allocation error.
- SSL_BAD_FILETYPE returned if format is not correct.

Example

```
static int wolfSSL_SetTmpDH_file_wrapper(WOLFSSL_CTX* ctx, WOLFSSL* ssl,
Const char* fname, int format);
#ifdef WOLFSSL_SMALL_STACK
byte staticBuffer[1]; // force heap usage
#else
byte* staticBuffer;
long sz = 0;
…
if(ssl){
    ret = wolfSSL_SetTmpDH_buffer(ssl, myBuffer, sz, format);
} else {
ret = wolfSSL_CTX_SetTmpDH_buffer(ctx, myBuffer, sz, format);
}
```

C.58.4.252 function wolfSSL_CTX_SetTmpDH_file

```
int wolfSSL_CTX_SetTmpDH_file(
    WOLFSSL_CTX * ctx,
    const char * f,
```

```
    int format
)
```

The function calls wolfSSL_SetTmpDH_file_wrapper to set the server Diffie-Hellman parameters.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().
- **fname** a constant character pointer to a certificate file.
- **format** an integer type passed through from wolfSSL_SetTmpDH_file_wrapper() that is a representation of the certificate format.

See:

- wolfSSL_SetTmpDH_buffer_wrapper
- wolfSSL_SetTmpDH
- wolfSSL_CTX_SetTmpDH
- wolfSSL_SetTmpDH_buffer
- wolfSSL_CTX_SetTmpDH_buffer
- wolfSSL_SetTmpDH_file_wrapper
- AllocDer
- PemToDer

Return:

- SSL_SUCCESS returned if the wolfSSL_SetTmpDH_file_wrapper or any of its subroutines return successfully.
- MEMORY_E returned if an allocation of dynamic memory fails in a subroutine.
- BAD_FUNC_ARG returned if the ctx or fname parameters are NULL or if a subroutine is passed a NULL argument.
- SSL_BAD_FILE returned if the certificate file is unable to open or if the a set of checks on the file fail from wolfSSL_SetTmpDH_file_wrapper.
- SSL_BAD_FILETYPE returned if the format is not PEM or ASN.1 from wolfSSL_SetTmpDH_buffer_wrapper().
- DH_KEY_SIZE_E returned if the DH parameter's key size is less than the value of the minDhKeySz member of the WOLFSSL_CTX struct.
- DH_KEY_SIZE_E returned if the DH parameter's key size is greater than the value of the maxDhKeySz member of the WOLFSSL_CTX struct.
- SIDE_ERROR returned in wolfSSL_SetTmpDH() if the side is not the server end.
- SSL_NO_PEM_HEADER returned from PemToDer if there is no PEM header.
- SSL_FATAL_ERROR returned from PemToDer if there is a memory copy failure.

Example

```
#define dhParam     "certs/dh2048.pem"
#DEFINE aSSERTiNTne(x, y)     AssertInt(x, y, !=, ==)
WOLFSSL_CTX* ctx;
…
AssertNotNull(ctx = wolfSSL_CTX_new(wolfSSLv23_client_method()))
…
AssertIntNE(SSL_SUCCESS, wolfSSL_CTX_SetTmpDH_file(NULL, dhParam,
SSL_FILETYPE_PEM));
```

C.58.4.253 function wolfSSL_CTX_SetMinDhKey_Sz

```
int wolfSSL_CTX_SetMinDhKey_Sz(
    WOLFSSL_CTX * ctx,
    word16 keySz_bits
)
```

This function sets the minimum size (in bits) of the Diffie Hellman key size by accessing the minDhKeySz member in the WOLFSSL_CTX structure.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().
- **keySz_bits** a word16 type used to set the minimum DH key size in bits. The WOLFSSL_CTX struct holds this information in the minDhKeySz member.

See:

- wolfSSL_SetMinDhKey_Sz
- wolfSSL_CTX_SetMaxDhKey_Sz
- wolfSSL_SetMaxDhKey_Sz
- wolfSSL_GetDhKey_Sz
- wolfSSL_CTX_SetTMpDH_file

Return:

- SSL_SUCCESS returned if the function completes successfully.
- BAD_FUNC_ARG returned if the WOLFSSL_CTX struct is NULL or if the keySz_bits is greater than 16,000 or not divisible by 8.

Example

```
public static int CTX_SetMinDhKey_Sz(IntPtr ctx, short minDhKey){
…
return wolfSSL_CTX_SetMinDhKey_Sz(local_ctx, minDhKeyBits);
```

C.58.4.254 function wolfSSL_SetMinDhKey_Sz

```
int wolfSSL_SetMinDhKey_Sz(
    WOLFSSL * ssl,
    word16 keySz_bits
)
```

Sets the minimum size (in bits) for a Diffie-Hellman key in the WOLFSSL structure.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **keySz_bits** a word16 type used to set the minimum DH key size in bits. The WOLFSSL_CTX struct holds this information in the minDhKeySz member.

See:

- wolfSSL_CTX_SetMinDhKey_Sz
- wolfSSL_GetDhKey_Sz

Return:

- SSL_SUCCESS the minimum size was successfully set.
- BAD_FUNC_ARG the WOLFSSL structure was NULL or if the keySz_bits is greater than 16,000 or not divisible by 8.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
word16 keySz_bits;
...
if(wolfSSL_SetMinDhKey_Sz(ssl, keySz_bits) != SSL_SUCCESS){
    // Failed to set.
}
```

C.58.4.255 function wolfSSL_CTX_SetMaxDhKey_Sz

```
int wolfSSL_CTX_SetMaxDhKey_Sz(
    WOLFSSL_CTX * ctx,
    word16 keySz_bits
)
```

This function sets the maximum size (in bits) of the Diffie Hellman key size by accessing the maxDhKeySz member in the WOLFSSL_CTX structure.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().
- **keySz_bits** a word16 type used to set the maximum DH key size in bits. The WOLFSSL_CTX struct holds this information in the maxDhKeySz member.

See:

- wolfSSL_SetMinDhKey_Sz
- wolfSSL_CTX_SetMinDhKey_Sz
- wolfSSL_SetMaxDhKey_Sz
- wolfSSL_GetDhKey_Sz
- wolfSSL_CTX_SetTMpDH_file

Return:

- SSL_SUCCESS returned if the function completes successfully.
- BAD_FUNC_ARG returned if the WOLFSSL_CTX struct is NULL or if the keySz_bits is greater than 16,000 or not divisible by 8.

Example

```
public static int CTX_SetMaxDhKey_Sz(IntPtr ctx, short maxDhKey){
…
return wolfSSL_CTX_SetMaxDhKey_Sz(local_ctx, keySz_bits);
```

C.58.4.256 function wolfSSL_SetMaxDhKey_Sz

```
int wolfSSL_SetMaxDhKey_Sz(
    WOLFSSL * ssl,
    word16 keySz_bits
)
```

Sets the maximum size (in bits) for a Diffie-Hellman key in the WOLFSSL structure.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **keySz** a word16 type representing the bit size of the maximum DH key.

See:

- wolfSSL_CTX_SetMaxDhKey_Sz
- wolfSSL_GetDhKey_Sz

Return:

- SSL_SUCCESS the maximum size was successfully set.
- BAD_FUNC_ARG the WOLFSSL structure was NULL or the keySz parameter was greater than the allowable size or not divisible by 8.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
word16 keySz;
...
if(wolfSSL_SetMaxDhKey(ssl, keySz) != SSL_SUCCESS){
    // Failed to set.
}
```

C.58.4.257 function wolfSSL_GetDhKey_Sz

```
int wolfSSL_GetDhKey_Sz(
    WOLFSSL * ssl
)
```

Returns the value of dhKeySz (in bits) that is a member of the options structure. This value represents the Diffie-Hellman key size in bytes.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_SetMinDhKey_sz
- wolfSSL_CTX_SetMinDhKey_Sz
- wolfSSL_CTX_SetTmpDH
- wolfSSL_SetTmpDH
- wolfSSL_CTX_SetTmpDH_file

Return:

- dhKeySz returns the value held in ssl->options.dhKeySz which is an integer value representing a size in bits.
- BAD_FUNC_ARG returns if the WOLFSSL struct is NULL.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
WOLFSSL* ssl = wolfSSL_new(ctx);
int dhKeySz;
...
dhKeySz = wolfSSL_GetDhKey_Sz(ssl);

if(dhKeySz == BAD_FUNC_ARG || dhKeySz <= 0){
    // Failure case
} else {
    // dhKeySz holds the size of the key.
}
```

C.58.4.258 function wolfSSL_CTX_SetMinRsaKey_Sz

```
int wolfSSL_CTX_SetMinRsaKey_Sz(
    WOLFSSL_CTX * ctx,
    short keySz
)
```

Sets the minimum RSA key size in both the WOLFSSL_CTX structure and the WOLFSSL_CERT_MANAGER structure.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().
- **keySz** a short integer type stored in minRsaKeySz in the ctx structure and the cm structure converted to bytes.

See: wolfSSL_SetMinRsaKey_Sz

Return:

- SSL_SUCCESS returned on successful execution of the function.
- BAD_FUNC_ARG returned if the ctx structure is NULL or the keySz is less than zero or not divisible by 8.

Example

```
WOLFSSL_CTX* ctx = SSL_CTX_new(method);
(void)minDhKeyBits;
ourCert = myoptarg;
…
minDhKeyBits = atoi(myoptarg);
…
if(wolfSSL_CTX_SetMinRsaKey_Sz(ctx, minRsaKeyBits) != SSL_SUCCESS){
…
```

C.58.4.259 function wolfSSL_SetMinRsaKey_Sz

```
int wolfSSL_SetMinRsaKey_Sz(
    WOLFSSL * ssl,
    short keySz
)
```

Sets the minimum allowable key size in bits for RSA located in the WOLFSSL structure.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **keySz** a short integer value representing the the minimum key in bits.

See: wolfSSL_CTX_SetMinRsaKey_Sz

Return:

- SSL_SUCCESS the minimum was set successfully.
- BAD_FUNC_ARG returned if the ssl structure is NULL or if the ksySz is less than zero or not divisible by 8.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
short keySz;
…

int isSet =  wolfSSL_SetMinRsaKey_Sz(ssl, keySz);
if(isSet != SSL_SUCCESS){
    Failed to set.
}
```

C.58.4.260 function wolfSSL_CTX_SetMinEccKey_Sz

```
int wolfSSL_CTX_SetMinEccKey_Sz(
    WOLFSSL_CTX * ctx,
```

```
    short keySz
)
```

Sets the minimum size in bits for the ECC key in the WOLF_CTX structure and the WOLFSSL_CERT_MANAGER structure.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().
- **keySz** a short integer type that represents the minimum ECC key size in bits.

See: wolfSSL_SetMinEccKey_Sz

Return:

- SSL_SUCCESS returned for a successful execution and the minEccKeySz member is set.
- BAD_FUNC_ARG returned if the WOLFSSL_CTX struct is NULL or if the keySz is negative or not divisible by 8.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
short keySz; // minimum key size
…
if(wolfSSL_CTX_SetMinEccKey(ctx, keySz) != SSL_SUCCESS){
    // Failed to set min key size
}
```

C.58.4.261 function wolfSSL_SetMinEccKey_Sz

```
int wolfSSL_SetMinEccKey_Sz(
    WOLFSSL * ssl,
    short keySz
)
```

Sets the value of the minEccKeySz member of the options structure. The options struct is a member of the WOLFSSL structure and is accessed through the ssl parameter.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **keySz** value used to set the minimum ECC key size. Sets value in the options structure.

See:

- wolfSSL_CTX_SetMinEccKey_Sz
- wolfSSL_CTX_SetMinRsaKey_Sz
- wolfSSL_SetMinRsaKey_Sz

Return:

- SSL_SUCCESS if the function successfully set the minEccKeySz member of the options structure.
- BAD_FUNC_ARG if the WOLFSSL_CTX structure is NULL or if the key size (keySz) is less than 0 (zero) or not divisible by 8.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx); // New session
short keySz = 999; // should be set to min key size allowable
...
if(wolfSSL_SetMinEccKey_Sz(ssl, keySz) != SSL_SUCCESS){
    // Failure case.
}
```

C.58.4.262 function wolfSSL_make_eap_keys

```
int wolfSSL_make_eap_keys(
    WOLFSSL * ssl,
    void * key,
    unsigned int len,
    const char * label
)
```

This function is used by EAP_TLS and EAP-TTLS to derive keying material from the master secret.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **key** a void pointer variable that will hold the result of the p_hash function.
- **len** an unsigned integer that represents the length of the key variable.
- **label** a constant char pointer that is copied from in wc_PRF().

See:

- wc_PRF
- wc_HmacFinal
- wc_HmacUpdate

Return:

- BUFFER_E returned if the actual size of the buffer exceeds the maximum size allowable.
- MEMORY_E returned if there is an error with memory allocation.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);;
void* key;
unsigned int len;
const char* label;
…
return wolfSSL_make_eap_keys(ssl, key, len, label);
```

C.58.4.263 function wolfSSL_writev

```
int wolfSSL_writev(
    WOLFSSL * ssl,
    const struct iovec * iov,
    int iovcnt
)
```

Simulates writev semantics but doesn't actually do block at a time because of SSL_write() behavior and because front adds may be small. Makes porting into software that uses writev easier.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **iov** array of I/O vectors to write
- **iovcnt** number of vectors in iov array.

See: wolfSSL_write

Return:

- 0 the number of bytes written upon success.
- 0 will be returned upon failure. Call wolfSSL_get_error() for the specific error code.

- MEMORY_ERROR will be returned if a memory error was encountered.
- BAD_FUNC_ARG will be returned when ssl is NULL, iovcnt is negative, or iov is NULL with a non-zero iovcnt.
- SSL_FATAL_ERROR will be returned upon failure when either an error occurred or, when using non-blocking sockets, the SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE error was received and and the application needs to call wolfSSL_write() again. Use wolfSSL_get_error() to get a specific error code.
- BUFFER_E will be returned when the total length of the segments overflows.

Example

```
WOLFSSL* ssl = 0;
char *bufA = “hello\n”;
char *bufB = “hello world\n”;
int iovcnt;
struct iovec iov[2];

iov[0].iov_base = buffA;
iov[0].iov_len = strlen(buffA);
iov[1].iov_base = buffB;
iov[1].iov_len = strlen(buffB);
iovcnt = 2;
...
ret = wolfSSL_writev(ssl, iov, iovcnt);
// wrote “ret” bytes, or error if <= 0.
```

C.58.4.264 function wolfSSL_CTX_UnloadCAs

```
int wolfSSL_CTX_UnloadCAs(
    WOLFSSL_CTX * ctx
)
```

This function unloads the CA signer list and frees the whole signer table.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().

See:

- wolfSSL_CertManagerUnloadCAs
- LockMutex
- UnlockMutex

Return:

- SSL_SUCCESS returned on successful execution of the function.
- BAD_FUNC_ARG returned if the WOLFSSL_CTX struct is NULL or there are otherwise unpermitted argument values passed in a subroutine.
- BAD_MUTEX_E returned if there was a mutex error. The LockMutex() did not return 0.

Example

```
WOLFSSL_METHOD method = wolfTLSv1_2_client_method();
WOLFSSL_CTX* ctx = WOLFSSL_CTX_new(method);
…
if(wolfSSL_CTX_UnloadCAs(ctx) != SSL_SUCCESS){
```

```
    // The function did not unload CAs
}
```

C.58.4.265 function wolfSSL_CTX_UnloadIntermediateCerts

```
int wolfSSL_CTX_UnloadIntermediateCerts(
    WOLFSSL_CTX * ctx
)
```

This function unloads intermediate certificates added to the CA signer list and frees them.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().

See:

- wolfSSL_CTX_UnloadCAs
- wolfSSL_CertManagerUnloadIntermediateCerts

Return:

- SSL_SUCCESS returned on successful execution of the function.
- BAD_FUNC_ARG returned if the WOLFSSL_CTX struct is NULL or there are otherwise unpermitted argument values passed in a subroutine.
- BAD_STATE_E returned if the WOLFSSL_CTX has a reference count > 1.
- BAD_MUTEX_E returned if there was a mutex error. The LockMutex() did not return 0.

Example

```
WOLFSSL_METHOD method = wolfTLSv1_2_client_method();
WOLFSSL_CTX* ctx = WOLFSSL_CTX_new(method);
…
if(wolfSSL_CTX_UnloadIntermediateCerts(ctx) != NULL){
    // The function did not unload CAs
}
```

C.58.4.266 function wolfSSL_CTX_Unload_trust_peers

```
int wolfSSL_CTX_Unload_trust_peers(
    WOLFSSL_CTX * ctx
)
```

This function is used to unload all previously loaded trusted peer certificates. Feature is enabled by defining the macro WOLFSSL_TRUST_PEER_CERT.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().

See:

- wolfSSL_CTX_trust_peer_buffer
- wolfSSL_CTX_trust_peer_cert

Return:

- SSL_SUCCESS upon success.
- BAD_FUNC_ARG will be returned if ctx is NULL.
- SSL_BAD_FILE will be returned if the file doesn't exist, can't be read, or is corrupted.
- MEMORY_E will be returned if an out of memory condition occurs.
- BAD_MUTEX_E will be returned when locking fails.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx;
...
ret = wolfSSL_CTX_Unload_trust_peers(ctx);
if (ret != SSL_SUCCESS) {
    // error unloading trusted peer certs
}
...
```

C.58.4.267 function wolfSSL_CTX_trust_peer_buffer

```
int wolfSSL_CTX_trust_peer_buffer(
    WOLFSSL_CTX * ctx,
    const unsigned char * in,
    long sz,
    int format
)
```

This function loads a certificate to use for verifying a peer when performing a TLS/SSL handshake. The peer certificate sent during the handshake is compared by using the SKID when available and the signature. If these two things do not match then any loaded CAs are used. Is the same functionality as wolfSSL_CTX_trust_peer_cert except is from a buffer instead of a file. Feature is enabled by defining the macro WOLFSSL_TRUST_PEER_CERT Please see the examples for proper usage.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **buffer** pointer to the buffer containing certificates.
- **sz** length of the buffer input.
- **type** type of certificate being loaded i.e. SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM.

See:

- wolfSSL_CTX_load_verify_buffer
- wolfSSL_CTX_use_certificate_file
- wolfSSL_CTX_use_PrivateKey_file
- wolfSSL_CTX_use_certificate_chain_file
- wolfSSL_CTX_trust_peer_cert
- wolfSSL_CTX_Unload_trust_peers
- wolfSSL_use_certificate_file
- wolfSSL_use_PrivateKey_file
- wolfSSL_use_certificate_chain_file

Return:

- SSL_SUCCESS upon success
- SSL_FAILURE will be returned if ctx is NULL, or if both file and type are invalid.
- SSL_BAD_FILETYPE will be returned if the file is the wrong format.
- SSL_BAD_FILE will be returned if the file doesn't exist, can't be read, or is corrupted.
- MEMORY_E will be returned if an out of memory condition occurs.
- ASN_INPUT_E will be returned if Base16 decoding fails on the file.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx;
...
```

```
ret = wolfSSL_CTX_trust_peer_buffer(ctx, bufferPtr, bufferSz,
SSL_FILETYPE_PEM);
if (ret != SSL_SUCCESS) {
// error loading trusted peer cert
}
...
```

C.58.4.268 function wolfSSL_CTX_load_verify_buffer

```
int wolfSSL_CTX_load_verify_buffer(
    WOLFSSL_CTX * ctx,
    const unsigned char * in,
    long sz,
    int format
)
```

This function loads a CA certificate buffer into the WOLFSSL Context. It behaves like the non-buffered version, only differing in its ability to be called with a buffer as input instead of a file. The buffer is provided by the in argument of size sz. format specifies the format type of the buffer; SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM. More than one CA certificate may be loaded per buffer as long as the format is in PEM. Please see the examples for proper usage.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **in** pointer to the CA certificate buffer.
- **sz** size of the input CA certificate buffer, in.
- **format** format of the buffer certificate, either SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM.

See:

- wolfSSL_CTX_load_verify_locations
- wolfSSL_CTX_use_certificate_buffer
- wolfSSL_CTX_use_PrivateKey_buffer
- wolfSSL_CTX_use_certificate_chain_buffer
- wolfSSL_use_certificate_buffer
- wolfSSL_use_PrivateKey_buffer
- wolfSSL_use_certificate_chain_buffer

Return:

- SSL_SUCCESS upon success
- SSL_BAD_FILETYPE will be returned if the file is the wrong format.
- SSL_BAD_FILE will be returned if the file doesn't exist, can't be read, or is corrupted.
- MEMORY_E will be returned if an out of memory condition occurs.
- ASN_INPUT_E will be returned if Base16 decoding fails on the file.
- BUFFER_E will be returned if a chain buffer is bigger than the receiving buffer.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx;
byte certBuff[...];
long sz = sizeof(certBuff);
...

ret = wolfSSL_CTX_load_verify_buffer(ctx, certBuff, sz, SSL_FILETYPE_PEM);
if (ret != SSL_SUCCESS) {
```

```
    // error loading CA certs from buffer
}
...
```

C.58.4.269 function wolfSSL_CTX_load_verify_buffer_ex

```
int wolfSSL_CTX_load_verify_buffer_ex(
    WOLFSSL_CTX * ctx,
    const unsigned char * in,
    long sz,
    int format,
    int userChain,
    word32 flags
)
```

This function loads a CA certificate buffer into the WOLFSSL Context. It behaves like the non-buffered version, only differing in its ability to be called with a buffer as input instead of a file. The buffer is provided by the in argument of size sz. format specifies the format type of the buffer; SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM. More than one CA certificate may be loaded per buffer as long as the format is in PEM. The _ex version was added in PR 2413 and supports additional arguments for userChain and flags.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **in** pointer to the CA certificate buffer.
- **sz** size of the input CA certificate buffer, in.
- **format** format of the buffer certificate, either SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM.
- **userChain** If using format WOLFSSL_FILETYPE_ASN1 this set to non-zero indicates a chain of DER's is being presented.
- **flags** See ssl.h around WOLFSSL_LOAD_VERIFY_DEFAULT_FLAGS.

See:

- wolfSSL_CTX_load_verify_buffer
- wolfSSL_CTX_load_verify_locations
- wolfSSL_CTX_use_certificate_buffer
- wolfSSL_CTX_use_PrivateKey_buffer
- wolfSSL_CTX_use_certificate_chain_buffer
- wolfSSL_use_certificate_buffer
- wolfSSL_use_PrivateKey_buffer
- wolfSSL_use_certificate_chain_buffer

Return:

- SSL_SUCCESS upon success
- SSL_BAD_FILETYPE will be returned if the file is the wrong format.
- SSL_BAD_FILE will be returned if the file doesn't exist, can't be read, or is corrupted.
- MEMORY_E will be returned if an out of memory condition occurs.
- ASN_INPUT_E will be returned if Base16 decoding fails on the file.
- BUFFER_E will be returned if a chain buffer is bigger than the receiving buffer.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx;
byte certBuff[...];
long sz = sizeof(certBuff);
...
```

```
// Example for force loading an expired certificate
ret = wolfSSL_CTX_load_verify_buffer_ex(ctx, certBuff, sz, SSL_FILETYPE_PEM,
    0, (WOLFSSL_LOAD_FLAG_DATE_ERR_OKAY));
if (ret != SSL_SUCCESS) {
    // error loading CA certs from buffer
}
...
```

C.58.4.270 function wolfSSL_CTX_load_verify_chain_buffer_format

```
int wolfSSL_CTX_load_verify_chain_buffer_format(
    WOLFSSL_CTX * ctx,
    const unsigned char * in,
    long sz,
    int format
)
```

This function loads a CA certificate chain buffer into the WOLFSSL Context. It behaves like the non-buffered version, only differing in its ability to be called with a buffer as input instead of a file. The buffer is provided by the in argument of size sz. format specifies the format type of the buffer; SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM. More than one CA certificate may be loaded per buffer as long as the format is in PEM. Please see the examples for proper usage.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **in** pointer to the CA certificate buffer.
- **sz** size of the input CA certificate buffer, in.
- **format** format of the buffer certificate, either SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM.

See:

- wolfSSL_CTX_load_verify_locations
- wolfSSL_CTX_use_certificate_buffer
- wolfSSL_CTX_use_PrivateKey_buffer
- wolfSSL_CTX_use_certificate_chain_buffer
- wolfSSL_use_certificate_buffer
- wolfSSL_use_PrivateKey_buffer
- wolfSSL_use_certificate_chain_buffer

Return:

- SSL_SUCCESS upon success
- SSL_BAD_FILETYPE will be returned if the file is the wrong format.
- SSL_BAD_FILE will be returned if the file doesn't exist, can't be read, or is corrupted.
- MEMORY_E will be returned if an out of memory condition occurs.
- ASN_INPUT_E will be returned if Base16 decoding fails on the file.
- BUFFER_E will be returned if a chain buffer is bigger than the receiving buffer.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx;
byte certBuff[...];
long sz = sizeof(certBuff);
...

ret = wolfSSL_CTX_load_verify_chain_buffer_format(ctx,
```

```
                    certBuff, sz, WOLFSSL_FILETYPE_ASN1);
if (ret != SSL_SUCCESS) {
    // error loading CA certs from buffer
}
...
```

C.58.4.271 function wolfSSL_CTX_use_certificate_buffer

```
int wolfSSL_CTX_use_certificate_buffer(
    WOLFSSL_CTX * ctx,
    const unsigned char * in,
    long sz,
    int format
)
```

This function loads a certificate buffer into the WOLFSSL Context. It behaves like the non-buffered version, only differing in its ability to be called with a buffer as input instead of a file. The buffer is provided by the in argument of size sz. format specifies the format type of the buffer; SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM. Please see the examples for proper usage.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **in** the input buffer containing the certificate to be loaded.
- **sz** the size of the input buffer.
- **format** the format of the certificate located in the input buffer (in). Possible values are SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM.

See:

- wolfSSL_CTX_load_verify_buffer
- wolfSSL_CTX_use_PrivateKey_buffer
- wolfSSL_CTX_use_certificate_chain_buffer
- wolfSSL_use_certificate_buffer
- wolfSSL_use_PrivateKey_buffer
- wolfSSL_use_certificate_chain_buffer

Return:

- SSL_SUCCESS upon success
- SSL_BAD_FILETYPE will be returned if the file is the wrong format.
- SSL_BAD_FILE will be returned if the file doesn't exist, can't be read, or is corrupted.
- MEMORY_E will be returned if an out of memory condition occurs.
- ASN_INPUT_E will be returned if Base16 decoding fails on the file.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx;
byte certBuff[...];
long sz = sizeof(certBuff);
...
ret = wolfSSL_CTX_use_certificate_buffer(ctx, certBuff, sz, SSL_FILETYPE_PEM);
if (ret != SSL_SUCCESS) {
    // error loading certificate from buffer
}
...
```

C.58.4.272 function wolfSSL_CTX_use_PrivateKey_buffer

```
int wolfSSL_CTX_use_PrivateKey_buffer(
    WOLFSSL_CTX * ctx,
    const unsigned char * in,
    long sz,
    int format
)
```

This function loads a private key buffer into the SSL Context. It behaves like the non-buffered version, only differing in its ability to be called with a buffer as input instead of a file. The buffer is provided by the in argument of size sz. format specifies the format type of the buffer; SSL_FILETYPE_ASN1or SSL_FILETYPE_PEM. Please see the examples for proper usage.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **in** the input buffer containing the private key to be loaded.
- **sz** the size of the input buffer.
- **format** the format of the private key located in the input buffer (in). Possible values are SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM.

See:

- wolfSSL_CTX_load_verify_buffer
- wolfSSL_CTX_use_certificate_buffer
- wolfSSL_CTX_use_certificate_chain_buffer
- wolfSSL_use_certificate_buffer
- wolfSSL_use_PrivateKey_buffer
- wolfSSL_use_certificate_chain_buffer

Return:

- SSL_SUCCESS upon success
- SSL_BAD_FILETYPE will be returned if the file is the wrong format.
- SSL_BAD_FILE will be returned if the file doesn't exist, can't be read, or is corrupted.
- MEMORY_E will be returned if an out of memory condition occurs.
- ASN_INPUT_E will be returned if Base16 decoding fails on the file.
- NO_PASSWORD will be returned if the key file is encrypted but no password is provided.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx;
byte keyBuff[...];
long sz = sizeof(certBuff);
...
ret = wolfSSL_CTX_use_PrivateKey_buffer(ctx, keyBuff, sz, SSL_FILETYPE_PEM);
if (ret != SSL_SUCCESS) {
    // error loading private key from buffer
}
...
```

C.58.4.273 function wolfSSL_CTX_use_certificate_chain_buffer

```
int wolfSSL_CTX_use_certificate_chain_buffer(
    WOLFSSL_CTX * ctx,
    const unsigned char * in,
```

```
    long sz
)
```

This function loads a certificate chain buffer into the WOLFSSL Context. It behaves like the non-buffered version, only differing in its ability to be called with a buffer as input instead of a file. The buffer is provided by the in argument of size sz. The buffer must be in PEM format and start with the subject's certificate, ending with the root certificate. Please see the examples for proper usage.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **in** the input buffer containing the PEM-formatted certificate chain to be loaded.
- **sz** the size of the input buffer.

See:

- wolfSSL_CTX_load_verify_buffer
- wolfSSL_CTX_use_certificate_buffer
- wolfSSL_CTX_use_PrivateKey_buffer
- wolfSSL_use_certificate_buffer
- wolfSSL_use_PrivateKey_buffer
- wolfSSL_use_certificate_chain_buffer

Return:

- SSL_SUCCESS upon success
- SSL_BAD_FILETYPE will be returned if the file is the wrong format.
- SSL_BAD_FILE will be returned if the file doesn't exist, can't be read, or is corrupted.
- MEMORY_E will be returned if an out of memory condition occurs.
- ASN_INPUT_E will be returned if Base16 decoding fails on the file.
- BUFFER_E will be returned if a chain buffer is bigger than the receiving buffer.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx;
byte certChainBuff[...];
long sz = sizeof(certBuff);
...
ret = wolfSSL_CTX_use_certificate_chain_buffer(ctx, certChainBuff, sz);
if (ret != SSL_SUCCESS) {
    // error loading certificate chain from buffer
}
...
```

C.58.4.274 function wolfSSL_use_certificate_buffer

```
int wolfSSL_use_certificate_buffer(
    WOLFSSL * ssl,
    const unsigned char * in,
    long sz,
    int format
)
```

This function loads a certificate buffer into the WOLFSSL object. It behaves like the non-buffered version, only differing in its ability to be called with a buffer as input instead of a file. The buffer is provided by the in argument of size sz. format specifies the format type of the buffer; SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM. Please see the examples for proper usage.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **in** buffer containing certificate to load.
- **sz** size of the certificate located in buffer.
- **format** format of the certificate to be loaded. Possible values are SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM.

See:

- wolfSSL_CTX_load_verify_buffer
- wolfSSL_CTX_use_certificate_buffer
- wolfSSL_CTX_use_PrivateKey_buffer
- wolfSSL_CTX_use_certificate_chain_buffer
- wolfSSL_use_PrivateKey_buffer
- wolfSSL_use_certificate_chain_buffer

Return:

- SSL_SUCCESS upon success.
- SSL_BAD_FILETYPE will be returned if the file is the wrong format.
- SSL_BAD_FILE will be returned if the file doesn't exist, can't be read, or is corrupted.
- MEMORY_E will be returned if an out of memory condition occurs.
- ASN_INPUT_E will be returned if Base16 decoding fails on the file.

Example

```
int ret;
byte certBuff[...];
WOLFSSL* ssl = 0;
long buffSz = sizeof(certBuff);
...

ret = wolfSSL_use_certificate_buffer(ssl, certBuff, buffSz, SSL_FILETYPE_PEM);
if (ret != SSL_SUCCESS) {
    // failed to load certificate from buffer
}
```

C.58.4.275 function wolfSSL_use_PrivateKey_buffer

```
int wolfSSL_use_PrivateKey_buffer(
    WOLFSSL * ssl,
    const unsigned char * in,
    long sz,
    int format
)
```

This function loads a private key buffer into the WOLFSSL object. It behaves like the non-buffered version, only differing in its ability to be called with a buffer as input instead of a file. The buffer is provided by the in argument of size sz. format specifies the format type of the buffer; SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM. Please see the examples for proper usage.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **in** buffer containing private key to load.
- **sz** size of the private key located in buffer.
- **format** format of the private key to be loaded. Possible values are SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM.

See:

- wolfSSL_use_PrivateKey
- wolfSSL_CTX_load_verify_buffer
- wolfSSL_CTX_use_certificate_buffer
- wolfSSL_CTX_use_PrivateKey_buffer
- wolfSSL_CTX_use_certificate_chain_buffer
- wolfSSL_use_certificate_buffer
- wolfSSL_use_certificate_chain_buffer

Return:

- SSL_SUCCESS upon success.
- SSL_BAD_FILETYPE will be returned if the file is the wrong format.
- SSL_BAD_FILE will be returned if the file doesn't exist, can't be read, or is corrupted.
- MEMORY_E will be returned if an out of memory condition occurs.
- ASN_INPUT_E will be returned if Base16 decoding fails on the file.
- NO_PASSWORD will be returned if the key file is encrypted but no password is provided.

Example

```
int ret;
byte keyBuff[...];
WOLFSSL* ssl = 0;
long buffSz = sizeof(certBuff);
...
ret = wolfSSL_use_PrivateKey_buffer(ssl, keyBuff, buffSz, SSL_FILETYPE_PEM);
if (ret != SSL_SUCCESS) {
    // failed to load private key from buffer
}
```

C.58.4.276 function wolfSSL_use_certificate_chain_buffer

```
int wolfSSL_use_certificate_chain_buffer(
    WOLFSSL * ssl,
    const unsigned char * in,
    long sz
)
```

This function loads a certificate chain buffer into the WOLFSSL object. It behaves like the non-buffered version, only differing in its ability to be called with a buffer as input instead of a file. The buffer is provided by the in argument of size sz. The buffer must be in PEM format and start with the subject's certificate, ending with the root certificate. Please see the examples for proper usage.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **in** buffer containing certificate to load.
- **sz** size of the certificate located in buffer.

See:

- wolfSSL_CTX_load_verify_buffer
- wolfSSL_CTX_use_certificate_buffer
- wolfSSL_CTX_use_PrivateKey_buffer
- wolfSSL_CTX_use_certificate_chain_buffer
- wolfSSL_use_certificate_buffer
- wolfSSL_use_PrivateKey_buffer

Return:

- SSL_SUCCES upon success.

- SSL_BAD_FILETYPE will be returned if the file is the wrong format.
- SSL_BAD_FILE will be returned if the file doesn't exist, can't be read, or is corrupted.
- MEMORY_E will be returned if an out of memory condition occurs.
- ASN_INPUT_E will be returned if Base16 decoding fails on the file.
- BUFFER_E will be returned if a chain buffer is bigger than the receiving buffer.

Example

```
int ret;
byte certChainBuff[...];
WOLFSSL* ssl = 0;
long buffSz = sizeof(certBuff);
...
ret = wolfSSL_use_certificate_chain_buffer(ssl, certChainBuff, buffSz);
if (ret != SSL_SUCCESS) {
    // failed to load certificate chain from buffer
}
```

C.58.4.277 function wolfSSL_UnloadCertsKeys

```
int wolfSSL_UnloadCertsKeys(
    WOLFSSL * ssl
)
```

This function unloads any certificates or keys that SSL owns.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See: wolfSSL_CTX_UnloadCAs

Return:

- SSL_SUCCESS - returned if the function executed successfully.
- BAD_FUNC_ARG - returned if the WOLFSSL object is NULL.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
...
int unloadKeys = wolfSSL_UnloadCertsKeys(ssl);
if(unloadKeys != SSL_SUCCESS){
    // Failure case.
}
```

C.58.4.278 function wolfSSL_CTX_set_group_messages

```
int wolfSSL_CTX_set_group_messages(
    WOLFSSL_CTX * ctx
)
```

This function turns on grouping of handshake messages where possible.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().

See:

- wolfSSL_set_group_messages
- wolfSSL_CTX_clear_group_messages

- wolfSSL_clear_group_messages
- wolfSSL_CTX_new

Return:

- SSL_SUCCESS will be returned upon success.
- BAD_FUNC_ARG will be returned if the input context is null.

Example

```
WOLFSSL_CTX* ctx = 0;
...
ret = wolfSSL_CTX_set_group_messages(ctx);
if (ret != SSL_SUCCESS) {
    // failed to set handshake message grouping
}
```

C.58.4.279 function wolfSSL_set_group_messages

```
int wolfSSL_set_group_messages(
    WOLFSSL * ssl
)
```

This function turns on grouping of handshake messages where possible.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().

See:

- wolfSSL_CTX_set_group_messages
- wolfSSL_clear_group_messages
- wolfSSL_CTX_clear_group_messages
- wolfSSL_new

Return:

- SSL_SUCCESS will be returned upon success.
- BAD_FUNC_ARG will be returned if the input context is null.

Example

```
WOLFSSL* ssl = 0;
...
ret = wolfSSL_set_group_messages(ssl);
if (ret != SSL_SUCCESS) {
// failed to set handshake message grouping
}
```

C.58.4.280 function wolfSSL_SetFuzzerCb

```
void wolfSSL_SetFuzzerCb(
    WOLFSSL * ssl,
    CallbackFuzzer cbf,
    void * fCtx
)
```

This function sets the fuzzer callback.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **cbf** a CallbackFuzzer type that is a function pointer of the form: int (*CallbackFuzzer)(WOLFSSL* ssl, const unsigned char* buf, int sz, int type, void* fuzzCtx);
- **fCtx** a void pointer type that will be set to the fuzzerCtx member of the WOLFSSL structure.

See: CallbackFuzzer

Return: none No returns.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
void* fCtx;

int callbackFuzzerCB(WOLFSSL* ssl, const unsigned char* buf, int sz,
            int type, void* fuzzCtx){
// function definition
}
…
wolfSSL_SetFuzzerCb(ssl, callbackFuzzerCB, fCtx);
```

C.58.4.281 function wolfSSL_DTLS_SetCookieSecret

```
int wolfSSL_DTLS_SetCookieSecret(
    WOLFSSL * ssl,
    const byte * secret,
    word32 secretSz
)
```

This function sets a new dtls cookie secret.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **secret** a constant byte pointer representing the secret buffer. Passing NULL indicates to generate a new random secret.
- **secretSz** the size of the buffer. Passing 0 with a NULL secret generates a secret of the default size (COOKIE_SECRET_SZ); passing 0 with a non-NULL secret returns BAD_FUNC_ARG.

See:

- ForceZero
- wc_RNG_GenerateBlock

Return:

- 0 returned if the function executed without an error.
- BAD_FUNC_ARG returned if there was an argument passed to the function with an unacceptable value.
- MEMORY_ERROR returned if there was a problem allocating memory for a new cookie secret.
- BAD_STATE_E returned if secret is NULL and the session's RNG has been released, so no secret can be generated.
- Another -ve value when a new secret could not be generated. The rotation does not happen and the secret already in use is kept, so the server carries on issuing and verifying cookies under it.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
const* byte secret;
```

```
word32 secretSz; // size of secret
…
if(!wolfSSL_DTLS_SetCookieSecret(ssl, secret, secretSz)){
    // Code block for failure to set DTLS cookie secret
} else {
    // Success! Cookie secret is set.
}
```

C.58.4.282 function wolfSSL_DTLS_SetCookieSecretSecondary

```
int wolfSSL_DTLS_SetCookieSecretSecondary(
    WOLFSSL * ssl,
    const byte * secret,
    word32 secretSz
)
```

This function sets a secondary DTLS 1.2 cookie secret used only when verifying a received HelloVerifyRequest cookie, and only if the primary secret (set with wolfSSL_DTLS_SetCookieSecret()) fails to verify it. This lets an application rotate the cookie secret on a stateless server without rejecting clients whose cookie was issued under the previous secret: install the new secret as the primary and the previous secret here for an overlap window. The secondary secret is never used to issue cookies. It is the DTLS 1.2 counterpart of wolfSSL_set_hrr_cookie_secret_secondary().

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **secret** a constant byte pointer representing the secret buffer. Passing NULL (or a secretSz of 0) clears any previously set secondary secret.
- **secretSz** the size of the buffer.

See: wolfSSL_DTLS_SetCookieSecret

Return:

- 0 returned if the function executed without an error.
- BAD_FUNC_ARG returned if ssl is NULL.
- MEMORY_ERROR returned if there was a problem allocating memory for the secondary cookie secret. The secondary secret already in use, if any, is kept.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
const byte* oldSecret;
word32 oldSecretSz; // size of oldSecret
...
if(wolfSSL_DTLS_SetCookieSecretSecondary(ssl, oldSecret, oldSecretSz) != 0){
    // Code block for failure to set secondary DTLS cookie secret
} else {
    // Success! Secondary cookie secret is set.
}
```

C.58.4.283 function wolfSSL_GetRNG

```
WC_RNG * wolfSSL_GetRNG(
    WOLFSSL * ssl
)
```

This function retrieves the random number.

Parameters:

- **ssl** pointer to a SSL object, created with wolfSSL_new().

See: wolfSSL_CTX_new_rng

Return:

- rng upon success.
- NULL if ssl is NULL.

Example

```
WOLFSSL* ssl;

wolfSSL_GetRNG(ssl);
```

C.58.4.284 function wolfSSL_CTX_SetMinVersion

```
int wolfSSL_CTX_SetMinVersion(
    WOLFSSL_CTX * ctx,
    int version
)
```

This function sets the minimum downgrade version allowed. Applicable only when the connection allows downgrade using (wolfSSLv23_client_method or wolfSSLv23_server_method).

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().
- **version** an integer representation of the version to be set as the minimum: WOLFSSL_SSLV3 = 0, WOLFSSL_TLSV1 = 1, WOLFSSL_TLSV1_1 = 2 or WOLFSSL_TLSV1_2 = 3.

See: SetMinVersionHelper

Return:

- SSL_SUCCESS returned if the function returned without error and the minimum version is set.
- BAD_FUNC_ARG returned if the WOLFSSL_CTX structure was NULL or if the minimum version is not supported.

Example

```
WOLFSSL_CTX* ctx = WOLFSSL_CTX_new( protocol method );
WOLFSSL* ssl = WOLFSSL_new(ctx);
int version; // macrop representation
…
if(wolfSSL_CTX_SetMinVersion(ssl->ctx, version) != SSL_SUCCESS){
    // Failed to set min version
}
```

C.58.4.285 function wolfSSL_SetMinVersion

```
int wolfSSL_SetMinVersion(
    WOLFSSL * ssl,
    int version
)
```

This function sets the minimum downgrade version allowed. Applicable only when the connection allows downgrade using (wolfSSLv23_client_method or wolfSSLv23_server_method).

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **version** an integer representation of the version to be set as the minimum: WOLFSSL_SSLV3 = 0, WOLFSSL_TLSV1 = 1, WOLFSSL_TLSV1_1 = 2 or WOLFSSL_TLSV1_2 = 3.

See: SetMinVersionHelper

Return:

- SSL_SUCCESS returned if this function and its subroutine executes without error.
- BAD_FUNC_ARG returned if the SSL object is NULL. In the subroutine this error is thrown if there is not a good version match.

Example

```
WOLFSSL_CTX* ctx = WOLFSSL_CTX_new(protocol method);
WOLFSSL* ssl = WOLFSSL_new(ctx);
int version;  macro representation
…
if(wolfSSL_CTX_SetMinVersion(ssl->ctx, version) != SSL_SUCCESS){
    Failed to set min version
}
```

C.58.4.286 function wolfSSL_GetObjectSize

```
int wolfSSL_GetObjectSize(
    void
)
```

This function returns the size of the WOLFSSL object and will be dependent on build options and settings. If SHOW_SIZES has been defined when building wolfSSL, this function will also print the sizes of individual objects within the WOLFSSL object (Suites, Ciphers, etc.) to stdout.

Parameters:

- **none** No parameters.

See: wolfSSL_new

Return: size This function returns the size of the WOLFSSL object.

Example

```
int size = 0;
size = wolfSSL_GetObjectSize();
printf("sizeof(WOLFSSL) = %d\n", size);
```

C.58.4.287 function wolfSSL_GetOutputSize

```
int wolfSSL_GetOutputSize(
    WOLFSSL * ssl,
    int inSz
)
```

Returns the record layer size of the plaintext input. This is helpful when an application wants to know how many bytes will be sent across the Transport layer, given a specified plaintext input size. This function must be called after the SSL/TLS handshake has been completed.

Parameters:

- **ssl** a pointer to a WOLFSSL object, created using wolfSSL_new().
- **inSz** size of plaintext data.

See: wolfSSL_GetMaxOutputSize

Return:

- size Upon success, the requested size will be returned
- INPUT_SIZE_E will be returned if the input size is greater than the maximum TLS fragment size (see wolfSSL_GetMaxOutputSize())
- BAD_FUNC_ARG will be returned upon invalid function argument, or if the SSL/TLS handshake has not been completed yet

Example

none

C.58.4.288 function wolfSSL_GetMaxOutputSize

```
int wolfSSL_GetMaxOutputSize(
    WOLFSSL * ssl
)
```

Returns the maximum record layer size for plaintext data. This will correspond to either the maximum SSL/TLS record size as specified by the protocol standard, the maximum TLS fragment size as set by the TLS Max Fragment Length extension. This function is helpful when the application has called wolfSSL_GetOutputSize() and received a INPUT_SIZE_E error. This function must be called after the SSL/TLS handshake has been completed.

Parameters:

- **ssl** a pointer to a WOLFSSL object, created using wolfSSL_new().

See: wolfSSL_GetOutputSize

Return:

- size Upon success, the maximum output size will be returned
- BAD_FUNC_ARG will be returned upon invalid function argument, or if the SSL/TLS handshake has not been completed yet.

Example

none

C.58.4.289 function wolfSSL_SetVersion

```
int wolfSSL_SetVersion(
    WOLFSSL * ssl,
    int version
)
```

This function sets the SSL/TLS protocol version for the specified SSL session (WOLFSSL object) using the version as specified by version. This will override the protocol setting for the SSL session (ssl) - originally defined and set by the SSL context (wolfSSL_CTX_new()) method type.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **version** SSL/TLS protocol version. Possible values include WOLFSSL_SSLV3, WOLFSSL_TLSV1, WOLFSSL_TLSV1_1, WOLFSSL_TLSV1_2.

See: wolfSSL_CTX_new

Return:

- SSL_SUCCESS upon success.
- BAD_FUNC_ARG will be returned if the input SSL object is NULL or an incorrect protocol version is given for version.

Example

```
int ret = 0;
WOLFSSL* ssl;
...

ret = wolfSSL_SetVersion(ssl, WOLFSSL_TLSV1);
if (ret != SSL_SUCCESS) {
    // failed to set SSL session protocol version
}
```

C.58.4.290 function wolfSSL_CTX_SetMacEncryptCb

```
void wolfSSL_CTX_SetMacEncryptCb(
    WOLFSSL_CTX * ctx,
    CallbackMacEncrypt cb
)
```

Allows caller to set the Atomic User Record Processing Mac/Encrypt Callback. The callback should return 0 for success or < 0 for an error. The ssl and ctx pointers are available for the user's convenience. macOut is the output buffer where the result of the mac should be stored. macIn is the mac input buffer and macInSz notes the size of the buffer. macContent and macVerify are needed for wolfSSL_SetTlsHmacInner() and be passed along as is. encOut is the output buffer where the result on the encryption should be stored. encIn is the input buffer to encrypt while encSz is the size of the input. An example callback can be found wolfssl/test.h myMacEncryptCb().

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **cb** callback function to register for Mac/Encrypt.

See:

- wolfSSL_SetMacEncryptCtx
- wolfSSL_GetMacEncryptCtx

Return: none No return.

Example

none

C.58.4.291 function wolfSSL_SetMacEncryptCtx

```
void wolfSSL_SetMacEncryptCtx(
    WOLFSSL * ssl,
    void * ctx
)
```

Allows caller to set the Atomic User Record Processing Mac/Encrypt Callback Context to ctx.

Parameters:

- **ssl** pointer to a WOLFSSL structure, created using wolfSSL_new().
- **ctx** pointer to the user context to be stored.

See:

- wolfSSL_CTX_SetMacEncryptCb
- wolfSSL_GetMacEncryptCtx

Return: none No return.

Example

none

C.58.4.292 function wolfSSL_GetMacEncryptCtx

```
void * wolfSSL_GetMacEncryptCtx(
    WOLFSSL * ssl
)
```

Allows caller to retrieve the Atomic User Record Processing Mac/Encrypt Callback Context previously stored with wolfSSL_SetMacEncryptCtx().

Parameters:

- **ssl** pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_CTX_SetMacEncryptCb
- wolfSSL_SetMacEncryptCtx

Return:

- pointer If successful the call will return a valid pointer to the context.
- NULL will be returned for a blank context.

Example

none

C.58.4.293 function wolfSSL_CTX_SetDecryptVerifyCb

```
void wolfSSL_CTX_SetDecryptVerifyCb(
    WOLFSSL_CTX * ctx,
    CallbackDecryptVerify cb
)
```

Allows caller to set the Atomic User Record Processing Decrypt/Verify Callback. The callback should return 0 for success or < 0 for an error. The ssl and ctx pointers are available for the user's convenience. decOut is the output buffer where the result of the decryption should be stored. decIn is the encrypted input buffer and decInSz notes the size of the buffer. content and verify are needed for wolfSSL_SetTlsHmacInner() and be passed along as is. padSz is an output variable that should be set with the total value of the padding. That is, the mac size plus any padding and pad bytes. An example callback can be found wolfssl/test.h myDecryptVerifyCb().

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **cb** callback function to register for Decrypt/Verify.

See:

- wolfSSL_SetMacEncryptCtx
- wolfSSL_GetMacEncryptCtx

Return: none No returns.

Example

none

C.58.4.294 function wolfSSL_SetDecryptVerifyCtx

```
void wolfSSL_SetDecryptVerifyCtx(
    WOLFSSL * ssl,
    void * ctx
)
```

Allows caller to set the Atomic User Record Processing Decrypt/Verify Callback Context to ctx.

Parameters:

- **ssl** pointer to a WOLFSSL structure, created using wolfSSL_new().
- **ctx** pointer to the user context to be stored.

See:

- wolfSSL_CTX_SetDecryptVerifyCb
- wolfSSL_GetDecryptVerifyCtx

Return: none No returns.

Example

none

C.58.4.295 function wolfSSL_GetDecryptVerifyCtx

```
void * wolfSSL_GetDecryptVerifyCtx(
    WOLFSSL * ssl
)
```

Allows caller to retrieve the Atomic User Record Processing Decrypt/Verify Callback Context previously stored with wolfSSL_SetDecryptVerifyCtx().

Parameters:

- **ssl** pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_CTX_SetDecryptVerifyCb
- wolfSSL_SetDecryptVerifyCtx

Return:

- pointer If successful the call will return a valid pointer to the context.
- NULL will be returned for a blank context.

Example

none

C.58.4.296 function wolfSSL_GetMacSecret

```
const unsigned char * wolfSSL_GetMacSecret(
    WOLFSSL * ssl,
    int verify
)
```

Allows retrieval of the Hmac/Mac secret from the handshake process. The verify parameter specifies whether this is for verification of a peer message.

Parameters:

- **ssl** a pointer to a WOLFSSL object, created using wolfSSL_new().
- **verify** specifies whether this is for verification of a peer message.

See: wolfSSL_GetHmacSize

Return:

- pointer If successful the call will return a valid pointer to the secret. The size of the secret can be obtained from wolfSSL_GetHmacSize().
- NULL will be returned for an error state.

Example

none

C.58.4.297 function wolfSSL_GetClientWriteKey

```
const unsigned char * wolfSSL_GetClientWriteKey(
    WOLFSSL *
)
```

Allows retrieval of the client write key from the handshake process.

Parameters:

- **ssl** a pointer to a WOLFSSL object, created using wolfSSL_new().

See:

- wolfSSL_GetKeySize
- wolfSSL_GetClientWriteIV

Return:

- pointer If successful the call will return a valid pointer to the key. The size of the key can be obtained from wolfSSL_GetKeySize().
- NULL will be returned for an error state.

Example

none

C.58.4.298 function wolfSSL_GetClientWriteIV

```
const unsigned char * wolfSSL_GetClientWriteIV(
    WOLFSSL *
)
```

Allows retrieval of the client write IV (initialization vector) from the handshake process.

Parameters:

- **ssl** a pointer to a WOLFSSL object, created using wolfSSL_new().

See:

- wolfSSL_GetCipherBlockSize()
- wolfSSL_GetClientWriteKey()

Return:

- pointer If successful the call will return a valid pointer to the IV. The size of the IV can be obtained from wolfSSL_GetCipherBlockSize().
- NULL will be returned for an error state.

Example

none

C.58.4.299 function wolfSSL_GetServerWriteKey

```
const unsigned char * wolfSSL_GetServerWriteKey(
    WOLFSSL *
)
```

Allows retrieval of the server write key from the handshake process.

Parameters:

- **ssl** a pointer to a WOLFSSL object, created using wolfSSL_new().

See:

- wolfSSL_GetKeySize
- wolfSSL_GetServerWriteIV

Return:

- pointer If successful the call will return a valid pointer to the key. The size of the key can be obtained from wolfSSL_GetKeySize().
- NULL will be returned for an error state.

Example

none

C.58.4.300 function wolfSSL_GetServerWriteIV

```
const unsigned char * wolfSSL_GetServerWriteIV(
    WOLFSSL *
)
```

Allows retrieval of the server write IV (initialization vector) from the handshake process.

Parameters:

- **ssl** a pointer to a WOLFSSL object, created using wolfSSL_new().

See:

- wolfSSL_GetCipherBlockSize
- wolfSSL_GetClientWriteKey

Return:

- pointer If successful the call will return a valid pointer to the IV. The size of the IV can be obtained from wolfSSL_GetCipherBlockSize().
- NULL will be returned for an error state.

C.58.4.301 function wolfSSL_GetKeySize

```
int wolfSSL_GetKeySize(
    WOLFSSL * ssl
)
```

Allows retrieval of the key size from the handshake process.

Parameters:

- **ssl** a pointer to a WOLFSSL object, created using wolfSSL_new().

See:

- wolfSSL_GetClientWriteKey
- wolfSSL_GetServerWriteKey

Return:

- size If successful the call will return the key size in bytes.
- BAD_FUNC_ARG will be returned for an error state.

Example

none

C.58.4.302 function wolfSSL_GetIVSize

```
int wolfSSL_GetIVSize(
    WOLFSSL * ssl
)
```

Returns the iv_size member of the specs structure held in the WOLFSSL struct.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_GetKeySize
- wolfSSL_GetClientWriteIV
- wolfSSL_GetServerWriteIV

Return:

- iv_size returns the value held in ssl->specs.iv_size.
- BAD_FUNC_ARG returned if the WOLFSSL structure is NULL.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
int ivSize;
...
ivSize = wolfSSL_GetIVSize(ssl);

if(ivSize > 0){
    // ivSize holds the specs.iv_size value.
}
```

C.58.4.303 function wolfSSL_GetSide

```
int wolfSSL_GetSide(
    WOLFSSL * ssl
)
```

Allows retrieval of the side of this WOLFSSL connection.

Parameters:

- **ssl** a pointer to a WOLFSSL object, created using wolfSSL_new().

See:

- wolfSSL_GetClientWriteKey
- wolfSSL_GetServerWriteKey

Return:

- success If successful the call will return either WOLFSSL_SERVER_END or WOLFSSL_CLIENT_END depending on the side of WOLFSSL object.
- BAD_FUNC_ARG will be returned for an error state.

Example

none

C.58.4.304 function wolfSSL_IsTLSv1_1

```
int wolfSSL_IsTLSv1_1(
    WOLFSSL * ssl
)
```

Allows caller to determine if the negotiated protocol version is at least TLS version 1.1 or greater.

Parameters:

- **ssl** a pointer to a WOLFSSL object, created using wolfSSL_new().

See: wolfSSL_GetSide

Return:

- true/false If successful the call will return 1 for true or 0 for false.
- BAD_FUNC_ARG will be returned for an error state.

Example

none

C.58.4.305 function wolfSSL_GetBulkCipher

```
int wolfSSL_GetBulkCipher(
    WOLFSSL * ssl
)
```

Allows caller to determine the negotiated bulk cipher algorithm from the handshake.

Parameters:

- **ssl** a pointer to a WOLFSSL object, created using wolfSSL_new().

See:

- wolfSSL_GetCipherBlockSize
- wolfSSL_GetKeySize

Return:

- If successful the call will return one of the following: wolfssl_cipher_null, wolfssl_des, wolfssl_triple_des, wolfssl_aes, wolfssl_aes_gcm, wolfssl_aes_ccm, wolfssl_camellia.
- BAD_FUNC_ARG will be returned for an error state.

Example

none

C.58.4.306 function wolfSSL_GetCipherBlockSize

```
int wolfSSL_GetCipherBlockSize(
    WOLFSSL * ssl
)
```

Allows caller to determine the negotiated cipher block size from the handshake.

Parameters:

- **ssl** a pointer to a WOLFSSL object, created using wolfSSL_new().

See:

- wolfSSL_GetBulkCipher
- wolfSSL_GetKeySize

Return:

- size If successful the call will return the size in bytes of the cipher block size.
- BAD_FUNC_ARG will be returned for an error state.

Example

none

C.58.4.307 function wolfSSL_GetAeadMacSize

```
int wolfSSL_GetAeadMacSize(
    WOLFSSL * ssl
)
```

Allows caller to determine the negotiated aead mac size from the handshake. For cipher type WOLFSSL_AEAD_TYPE.

Parameters:

- **ssl** a pointer to a WOLFSSL object, created using wolfSSL_new().

See:

- wolfSSL_GetBulkCipher
- wolfSSL_GetKeySize

Return:

- size If successful the call will return the size in bytes of the aead mac size.
- BAD_FUNC_ARG will be returned for an error state.

Example

none

C.58.4.308 function wolfSSL_GetHmacSize

```
int wolfSSL_GetHmacSize(
    WOLFSSL * ssl
)
```

Allows caller to determine the negotiated (h)mac size from the handshake. For cipher types except WOLFSSL_AEAD_TYPE.

Parameters:

- **ssl** a pointer to a WOLFSSL object, created using wolfSSL_new().

See:

- wolfSSL_GetBulkCipher
- wolfSSL_GetHmacType

Return:

- size If successful the call will return the size in bytes of the (h)mac size.
- BAD_FUNC_ARG will be returned for an error state.

Example

none

C.58.4.309 function wolfSSL_GetHmacType

```
int wolfSSL_GetHmacType(
    WOLFSSL * ssl
)
```

Allows caller to determine the negotiated (h)mac type from the handshake. For cipher types except WOLFSSL_AEAD_TYPE.

Parameters:

- **ssl** a pointer to a WOLFSSL object, created using wolfSSL_new().

See:

- wolfSSL_GetBulkCipher
- wolfSSL_GetHmacSize

Return:

- If successful the call will return one of the following: MD5, SHA, SHA256, SHA384.
- BAD_FUNC_ARG may be returned for an error state.
- SSL_FATAL_ERROR may also be returned for an error state.

Example

none

C.58.4.310 function wolfSSL_GetCipherType

```
int wolfSSL_GetCipherType(
    WOLFSSL * ssl
)
```

Allows caller to determine the negotiated cipher type from the handshake.

Parameters:

- **ssl** a pointer to a WOLFSSL object, created using wolfSSL_new().

See:

- wolfSSL_GetBulkCipher
- wolfSSL_GetHmacType

Return:

- If successful the call will return one of the following: WOLFSSL_BLOCK_TYPE, WOLFSSL_STREAM_TYPE, WOLFSSL_AEAD_TYPE.
- BAD_FUNC_ARG will be returned for an error state.

Example

none

C.58.4.311 function wolfSSL_SetTlsHmacInner

```
int wolfSSL_SetTlsHmacInner(
    WOLFSSL * ssl,
    byte * inner,
    word32 sz,
    int content,
    int verify
)
```

Allows caller to set the Hmac Inner vector for message sending/receiving. The result is written to inner which should be at least wolfSSL_GetHmacSize() bytes. The size of the message is specified by sz, content is the type of message, and verify specifies whether this is a verification of a peer message. Valid for cipher types excluding WOLFSSL_AEAD_TYPE.

Parameters:

- **none** No parameters.

See:

- wolfSSL_GetBulkCipher
- wolfSSL_GetHmacType

Return:

- 1 upon success.
- BAD_FUNC_ARG will be returned for an error state.

Example

none

C.58.4.312 function wolfSSL_CTX_SetEccSignCb

```
void wolfSSL_CTX_SetEccSignCb(
    WOLFSSL_CTX * ctx,
    CallbackEccSign cb
)
```

Allows caller to set the Public Key Callback for ECC Signing. The callback should return 0 for success or < 0 for an error. The ssl and ctx pointers are available for the user's convenience. in is the input buffer to sign while inSz denotes the length of the input. out is the output buffer where the result of the signature should be stored. outSz is an input/output variable that specifies the size of the output buffer upon invocation and the actual size of the signature should be stored there before returning. keyDer is the ECC Private key in ASN1 format and keySz is the length of the key in bytes. An example callback can be found wolfssl/test.h myEccSign().

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **cb** callback function to register for ECC signing.

See:

- wolfSSL_SetEccSignCtx
- wolfSSL_GetEccSignCtx

Return: none No returns.

Example

none

C.58.4.313 function wolfSSL_SetEccSignCtx

```
void wolfSSL_SetEccSignCtx(
    WOLFSSL * ssl,
    void * ctx
)
```

Allows caller to set the Public Key Ecc Signing Callback Context to ctx.

Parameters:

- **ssl** a pointer to a WOLFSSL object, created using wolfSSL_new().
- **ctx** a pointer to the user context to be stored

See:

- wolfSSL_CTX_SetEccSignCb
- wolfSSL_GetEccSignCtx

Return: none No returns.

Example

none

C.58.4.314 function wolfSSL_GetEccSignCtx

```
void * wolfSSL_GetEccSignCtx(
    WOLFSSL * ssl
)
```

Allows caller to retrieve the Public Key Ecc Signing Callback Context previously stored with wolfSSL_SetEccSignCtx().

Parameters:

- **ssl** a pointer to a WOLFSSL object, created using wolfSSL_new().

See:

- wolfSSL_CTX_SetEccSignCb
- wolfSSL_SetEccSignCtx

Return:

- pointer If successful the call will return a valid pointer to the context.
- NULL will be returned for a blank context.

Example

none

C.58.4.315 function wolfSSL_CTX_SetEccSignCtx

```
void wolfSSL_CTX_SetEccSignCtx(
    WOLFSSL_CTX * ctx,
    void * userCtx
)
```

Allows caller to set the Public Key Ecc Signing Callback Context to ctx.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created with wolfSSL_CTX_new().
- **ctx** a pointer to the user context to be stored

See:

- wolfSSL_CTX_SetEccSignCb
- wolfSSL_CTX_GetEccSignCtx

Return: none No returns.

Example

none

C.58.4.316 function wolfSSL_CTX_GetEccSignCtx

```
void * wolfSSL_CTX_GetEccSignCtx(
    WOLFSSL_CTX * ctx
)
```

Allows caller to retrieve the Public Key Ecc Signing Callback Context previously stored with wolfSSL_SetEccSignCtx().

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created with wolfSSL_CTX_new().

See:

- wolfSSL_CTX_SetEccSignCb
- wolfSSL_CTX_SetEccSignCtx

Return:

- pointer If successful the call will return a valid pointer to the context.
- NULL will be returned for a blank context.

Example

none

C.58.4.317 function wolfSSL_CTX_SetEccVerifyCb

```
void wolfSSL_CTX_SetEccVerifyCb(
    WOLFSSL_CTX * ctx,
    CallbackEccVerify cb
)
```

Allows caller to set the Public Key Callback for ECC Verification. The callback should return 0 for success or < 0 for an error. The ssl and ctx pointers are available for the user's convenience. sig is the signature to verify and sigSz denotes the length of the signature. hash is an input buffer containing the digest of the message and hashSz denotes the length in bytes of the hash. result is an output variable where the result of the verification should be stored, 1 for success and 0 for failure. keyDer is the ECC Private key in ASN1 format and keySz is the length of the key in bytes. keyDer is NULL with keySz 0 when only the callback holds the key, so the callback must then supply it. An example callback can be found wolfssl/test.h myEccVerify().

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().

- **cb** callback function to register for ECC verification.

See:

- wolfSSL_SetEccVerifyCtx
- wolfSSL_GetEccVerifyCtx

Return: none No returns.

Example

none

C.58.4.318 function wolfSSL_SetEccVerifyCtx

```
void wolfSSL_SetEccVerifyCtx(
    WOLFSSL * ssl,
    void * ctx
)
```

Allows caller to set the Public Key Ecc Verification Callback Context to ctx.

Parameters:

- **ssl** pointer to a WOLFSSL structure, created using wolfSSL_new().
- **ctx** pointer to the user context to be stored.

See:

- wolfSSL_CTX_SetEccVerifyCb
- wolfSSL_GetEccVerifyCtx

Return: none No returns.

Example

none

C.58.4.319 function wolfSSL_GetEccVerifyCtx

```
void * wolfSSL_GetEccVerifyCtx(
    WOLFSSL * ssl
)
```

Allows caller to retrieve the Public Key Ecc Verification Callback Context previously stored with wolfSSL_SetEccVerifyCtx().

Parameters:

- **ssl** pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_CTX_SetEccVerifyCb
- wolfSSL_SetEccVerifyCtx

Return:

- pointer If successful the call will return a valid pointer to the context.
- NULL will be returned for a blank context.

Example

none

C.58.4.320 function wolfSSL_CTX_SetRsaSignCb

```
void wolfSSL_CTX_SetRsaSignCb(
    WOLFSSL_CTX * ctx,
    CallbackRsaSign cb
)
```

Allows caller to set the Public Key Callback for RSA Signing. The callback should return 0 for success or < 0 for an error. The ssl and ctx pointers are available for the user's convenience. in is the input buffer to sign while inSz denotes the length of the input. out is the output buffer where the result of the signature should be stored. outSz is an input/output variable that specifies the size of the output buffer upon invocation and the actual size of the signature should be stored there before returning. keyDer is the RSA Private key in ASN1 format and keySz is the length of the key in bytes. An example callback can be found wolfssl/test.h myRsaSign().

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **cb** callback function to register for RSA signing.

See:

- wolfSSL_SetRsaSignCtx
- wolfSSL_GetRsaSignCtx

Return: none No returns.

Example

none

C.58.4.321 function wolfSSL_SetRsaSignCtx

```
void wolfSSL_SetRsaSignCtx(
    WOLFSSL * ssl,
    void * ctx
)
```

Allows caller to set the Public Key RSA Signing Callback Context to ctx.

Parameters:

- **ssl** pointer to a WOLFSSL structure, created using wolfSSL_new().
- **ctx** pointer to the user context to be stored.

See:

- wolfSSL_CTX_SetRsaSignCb
- wolfSSL_GetRsaSignCtx

Return: none No Returns.

Example

none

C.58.4.322 function wolfSSL_GetRsaSignCtx

```
void * wolfSSL_GetRsaSignCtx(
    WOLFSSL * ssl
)
```

Allows caller to retrieve the Public Key RSA Signing Callback Context previously stored with wolfSSL_SetRsaSignCtx().

Parameters:

- **ssl** pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_CTX_SetRsaSignCb
- wolfSSL_SetRsaSignCtx

Return:

- pointer If successful the call will return a valid pointer to the context.
- NULL will be returned for a blank context.

Example

none

C.58.4.323 function wolfSSL_CTX_SetRsaVerifyCb

```
void wolfSSL_CTX_SetRsaVerifyCb(
    WOLFSSL_CTX * ctx,
    CallbackRsaVerify cb
)
```

Allows caller to set the Public Key Callback for RSA Verification. The callback should return the number of plaintext bytes for success or < 0 for an error. The ssl and ctx pointers are available for the user's convenience. sig is the signature to verify and sigSz denotes the length of the signature. out should be set to the beginning of the verification buffer after the decryption process and any padding. keyDer is the RSA Public key in ASN1 format and keySz is the length of the key in bytes. An example callback can be found wolfssl/test.h myRsaVerify().

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **cb** callback function to register for RSA verification.

See:

- wolfSSL_SetRsaVerifyCtx
- wolfSSL_GetRsaVerifyCtx

Return: none No returns.

C.58.4.324 function wolfSSL_SetRsaVerifyCtx

```
void wolfSSL_SetRsaVerifyCtx(
    WOLFSSL * ssl,
    void * ctx
)
```

Allows caller to set the Public Key RSA Verification Callback Context to ctx.

Parameters:

- **ssl** pointer to a WOLFSSL structure, created using wolfSSL_new().
- **ctx** pointer to the user context to be stored.

See:

- wolfSSL_CTX_SetRsaVerifyCb

- wolfSSL_GetRsaVerifyCtx

Return: none No returns.

Example

none

C.58.4.325 function wolfSSL_GetRsaVerifyCtx

```
void * wolfSSL_GetRsaVerifyCtx(
    WOLFSSL * ssl
)
```

Allows caller to retrieve the Public Key RSA Verification Callback Context previously stored with wolfSSL_SetRsaVerifyCtx().

Parameters:

- **ssl** pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_CTX_SetRsaVerifyCb
- wolfSSL_SetRsaVerifyCtx

Return:

- pointer If successful the call will return a valid pointer to the context.
- NULL will be returned for a blank context.

Example

none

C.58.4.326 function wolfSSL_CTX_SetRsaEncCb

```
void wolfSSL_CTX_SetRsaEncCb(
    WOLFSSL_CTX * ctx,
    CallbackRsaEnc cb
)
```

Allows caller to set the Public Key Callback for RSA Public Encrypt. The callback should return 0 for success or < 0 for an error. The ssl and ctx pointers are available for the user's convenience. in is the input buffer to encrypt while inSz denotes the length of the input. out is the output buffer where the result of the encryption should be stored. outSz is an input/output variable that specifies the size of the output buffer upon invocation and the actual size of the encryption should be stored there before returning. keyDer is the RSA Public key in ASN1 format and keySz is the length of the key in bytes. An example callback can be found wolfssl/test.h myRsaEnc().

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **cb** callback function to register for RSA public encrypt.

See:

- wolfSSL_SetRsaEncCtx
- wolfSSL_GetRsaEncCtx

Return: none No returns.

Examples

none

C.58.4.327 function wolfSSL_SetRsaEncCtx

```
void wolfSSL_SetRsaEncCtx(
    WOLFSSL * ssl,
    void * ctx
)
```

Allows caller to set the Public Key RSA Public Encrypt Callback Context to ctx.

Parameters:

- **ssl** pointer to a WOLFSSL structure, created using wolfSSL_new().
- **ctx** pointer to the user context to be stored.

See:

- wolfSSL_CTX_SetRsaEncCb
- wolfSSL_GetRsaEncCtx

Return: none No returns.

Example

none

C.58.4.328 function wolfSSL_GetRsaEncCtx

```
void * wolfSSL_GetRsaEncCtx(
    WOLFSSL * ssl
)
```

Allows caller to retrieve the Public Key RSA Public Encrypt Callback Context previously stored with wolfSSL_SetRsaEncCtx().

Parameters:

- **ssl** pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_CTX_SetRsaEncCb
- wolfSSL_SetRsaEncCtx

Return:

- pointer If successful the call will return a valid pointer to the context.
- NULL will be returned for a blank context.

Example

none

C.58.4.329 function wolfSSL_CTX_SetRsaDecCb

```
void wolfSSL_CTX_SetRsaDecCb(
    WOLFSSL_CTX * ctx,
    CallbackRsaDec cb
)
```

Allows caller to set the Public Key Callback for RSA Private Decrypt. The callback should return the number of plaintext bytes for success or < 0 for an error. The ssl and ctx pointers are available for the user's convenience. in is the input buffer to decrypt and inSz denotes the length of the input. out should be set to the beginning of the decryption buffer after the decryption process and any padding. keyDer is the RSA Private key in ASN1 format and keySz is the length of the key in bytes. An example callback can be found wolfssl/test.h myRsaDec().

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **cb** callback function to register for RSA private decrypt.

See:

- wolfSSL_SetRsaDecCtx
- wolfSSL_GetRsaDecCtx

Return: none No returns.

Example

none

C.58.4.330 function wolfSSL_SetRsaDecCtx

```
void wolfSSL_SetRsaDecCtx(
    WOLFSSL * ssl,
    void * ctx
)
```

Allows caller to set the Public Key RSA Private Decrypt Callback Context to ctx.

Parameters:

- **ssl** pointer to a WOLFSSL structure, created using wolfSSL_new().
- **ctx** pointer to the user context to be stored.

See:

- wolfSSL_CTX_SetRsaDecCb
- wolfSSL_GetRsaDecCtx

Return: none No returns.

Example

none

C.58.4.331 function wolfSSL_GetRsaDecCtx

```
void * wolfSSL_GetRsaDecCtx(
    WOLFSSL * ssl
)
```

Allows caller to retrieve the Public Key RSA Private Decrypt Callback Context previously stored with wolfSSL_SetRsaDecCtx().

Parameters:

- **ssl** pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_CTX_SetRsaDecCb

- wolfSSL_SetRsaDecCtx

Return:

- pointer If successful the call will return a valid pointer to the context.
- NULL will be returned for a blank context.

Example

none

C.58.4.332 function wolfSSL_CTX_SetCACb

```
void wolfSSL_CTX_SetCACb(
    WOLFSSL_CTX * ctx,
    CallbackCACache cb
)
```

This function registers a callback with the SSL context (WOLFSSL_CTX) to be called when a new CA certificate is loaded into wolfSSL. The callback is given a buffer with the DER-encoded certificate.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **cb** function to be registered as the CA callback for the wolfSSL context, ctx. The signature of this function must follow that as shown above in the Synopsis section.

See: wolfSSL_CTX_load_verify_locations

Return: none No return.

Example

```
WOLFSSL_CTX* ctx = 0;

// CA callback prototype
int MyCACallback(unsigned char *der, int sz, int type);

// Register the custom CA callback with the SSL context
wolfSSL_CTX_SetCACb(ctx, MyCACallback);

int MyCACallback(unsigned char* der, int sz, int type)
{
    // custom CA callback function, DER-encoded cert
    // located in “der” of size “sz” with type “type”
}
```

C.58.4.333 function wolfSSL_CertManagerNew_ex

```
WOLFSSL_CERT_MANAGER * wolfSSL_CertManagerNew_ex(
    void * heap
)
```

Allocates and initializes a new Certificate Manager context. This context may be used independent of SSL needs. It may be used to load certificates, verify certificates, and check the revocation status.

Parameters:

- **heap** pointer to a heap hint for memory allocation.

See: wolfSSL_CertManagerFree

Return:

- WOLFSSL_CERT_MANAGER If successful the call will return a valid WOLFSSL_CERT_MANAGER pointer.
- NULL will be returned for an error state.

C.58.4.334 function wolfSSL_CertManagerNew

```
WOLFSSL_CERT_MANAGER * wolfSSL_CertManagerNew(
    void
)
```

Allocates and initializes a new Certificate Manager context. This context may be used independent of SSL needs. It may be used to load certificates, verify certificates, and check the revocation status.

Parameters:

- **none** No parameters.

See: wolfSSL_CertManagerFree

Return:

- WOLFSSL_CERT_MANAGER If successful the call will return a valid WOLFSSL_CERT_MANAGER pointer.
- NULL will be returned for an error state.

Example

```
#import <wolfssl/ssl.h>

WOLFSSL_CERT_MANAGER* cm;
cm = wolfSSL_CertManagerNew();
if (cm == NULL) {
// error creating new cert manager
}
```

C.58.4.335 function wolfSSL_CertManagerFree

```
void wolfSSL_CertManagerFree(
    WOLFSSL_CERT_MANAGER * cm
)
```

Frees all resources associated with the Certificate Manager context. Call this when you no longer need to use the Certificate Manager.

Parameters:

- **cm** a pointer to a WOLFSSL_CERT_MANAGER structure, created using wolfSSL_CertManagerNew().

See: wolfSSL_CertManagerNew

Return: none

Example

```
#include <wolfssl/ssl.h>

WOLFSSL_CERT_MANAGER* cm;
...
wolfSSL_CertManagerFree(cm);
```

C.58.4.336 function wolfSSL_CertManagerLoadCA

```
int wolfSSL_CertManagerLoadCA(
    WOLFSSL_CERT_MANAGER * cm,
    const char * f,
    const char * d
)
```

Specifies the locations for CA certificate loading into the manager context. The PEM certificate CAfile may contain several trusted CA certificates. If CApath is not NULL it specifies a directory containing CA certificates in PEM format.

Parameters:

- **cm** a pointer to a WOLFSSL_CERT_MANAGER structure, created using wolfSSL_CertManagerNew().
- **file** pointer to the name of the file containing CA certificates to load.
- **path** pointer to the name of a directory path containing CA c ertificates to load. The NULL pointer may be used if no certificate directory is desired.

See: wolfSSL_CertManagerVerify

Return:

- SSL_SUCCESS If successful the call will return.
- SSL_BAD_FILETYPE will be returned if the file is the wrong format.
- SSL_BAD_FILE will be returned if the file doesn't exist, can't be read, or is corrupted.
- MEMORY_E will be returned if an out of memory condition occurs.
- ASN_INPUT_E will be returned if Base16 decoding fails on the file.
- BAD_FUNC_ARG is the error that will be returned if a pointer is not provided.
- SSL_FATAL_ERROR - will be returned upon failure.

Example

```
#include <wolfssl/ssl.h>

int ret = 0;
WOLFSSL_CERT_MANAGER* cm;
...
ret = wolfSSL_CertManagerLoadCA(cm, “path/to/cert-file.pem”, 0);
if (ret != SSL_SUCCESS) {
// error loading CA certs into cert manager
}
```

C.58.4.337 function wolfSSL_CertManagerLoadCABuffer

```
int wolfSSL_CertManagerLoadCABuffer(
    WOLFSSL_CERT_MANAGER * cm,
    const unsigned char * buff,
    long sz,
    int format
)
```

Loads the CA Buffer by calling wolfSSL_CTX_load_verify_buffer and returning that result using a temporary cm so as not to lose the information in the cm passed into the function.

Parameters:

- **cm** a pointer to a WOLFSSL_CERT_MANAGER structure, created using wolfSSL_CertManagerNew().
- **in** buffer for cert information.
- **sz** length of the buffer.

- **format** certificate format, either PEM or DER.

See:

- wolfSSL_CTX_load_verify_buffer
- ProcessChainBuffer
- ProcessBuffer
- cm_pick_method

Return:

- SSL_FATAL_ERROR is returned if the WOLFSSL_CERT_MANAGER struct is NULL or if wolfSSL_CTX_new() returns NULL.
- SSL_SUCCESS is returned for a successful execution.

Example

```
WOLFSSL_CERT_MANAGER* cm = (WOLFSSL_CERT_MANAGER*)vp;
…
const unsigned char* in;
long sz;
int format;
…
if(wolfSSL_CertManagerLoadCABuffer(vp, sz, format) != SSL_SUCCESS){
    Error returned. Failure case code block.
}
```

C.58.4.338 function wolfSSL_CertManagerUnloadCAs

```
int wolfSSL_CertManagerUnloadCAs(
    WOLFSSL_CERT_MANAGER * cm
)
```

This function unloads the CA signer list.

Parameters:

- **cm** a pointer to a WOLFSSL_CERT_MANAGER structure, created using wolfSSL_CertManagerNew().

See: UnlockMutex

Return:

- SSL_SUCCESS returned on successful execution of the function.
- BAD_FUNC_ARG returned if the WOLFSSL_CERT_MANAGER is NULL.
- BAD_MUTEX_E returned if there was a mutex error.

Example

```
#include <wolfssl/ssl.h>

WOLFSSL_CTX* ctx = wolfSSL_CTX_new(protocol method);
WOLFSSL_CERT_MANAGER* cm = wolfSSL_CTX_GetCertManager(ctx);
...
if(wolfSSL_CertManagerUnloadCAs(cm) != SSL_SUCCESS){
    Failure case.
}
```

C.58.4.339 function wolfSSL_CertManagerUnloadIntermediateCerts

```
int wolfSSL_CertManagerUnloadIntermediateCerts(
    WOLFSSL_CERT_MANAGER * cm
)
```

This function unloads intermediate certificates add to the CA signer list.

Parameters:

- **cm** a pointer to a WOLFSSL_CERT_MANAGER structure, created using wolfSSL_CertManagerNew().

See: UnlockMutex

Return:

- SSL_SUCCESS returned on successful execution of the function.
- BAD_FUNC_ARG returned if the WOLFSSL_CERT_MANAGER is NULL.
- BAD_MUTEX_E returned if there was a mutex error.

Example

```
#include <wolfssl/ssl.h>

WOLFSSL_CTX* ctx = wolfSSL_CTX_new(protocol method);
WOLFSSL_CERT_MANAGER* cm = wolfSSL_CTX_GetCertManager(ctx);
...
if(wolfSSL_CertManagerUnloadIntermediateCerts(cm) != SSL_SUCCESS){
    Failure case.
}
```

C.58.4.340 function wolfSSL_CertManagerUnload_trust_peers

```
int wolfSSL_CertManagerUnload_trust_peers(
    WOLFSSL_CERT_MANAGER * cm
)
```

The function will free the Trusted Peer linked list and unlocks the trusted peer list.

Parameters:

- **cm** a pointer to a WOLFSSL_CERT_MANAGER structure, created using wolfSSL_CertManagerNew().

See: UnLockMutex

Return:

- SSL_SUCCESS if the function completed normally.
- BAD_FUNC_ARG if the WOLFSSL_CERT_MANAGER is NULL.
- BAD_MUTEX_E mutex error if tpLock, a member of the WOLFSSL_CERT_MANAGER struct, is 0 (nill).

Example

```
#include <wolfssl/ssl.h>

WOLFSSL_CTX* ctx = WOLFSSL_CTX_new(Protocol define);
WOLFSSL_CERT_MANAGER* cm = wolfSSL_CertManagerNew();
...
if(wolfSSL_CertManagerUnload_trust_peers(cm) != SSL_SUCCESS){
    The function did not execute successfully.
}
```

C.58.4.341 function wolfSSL_CertManagerVerify

```
int wolfSSL_CertManagerVerify(
    WOLFSSL_CERT_MANAGER * cm,
    const char * f,
    int format
)
```

Specifies the certificate to verify with the Certificate Manager context. The format can be SSL_FILETYPE_PEM or SSL_FILETYPE_ASN1.

Parameters:

- **cm** a pointer to a WOLFSSL_CERT_MANAGER structure, created using wolfSSL_CertManagerNew().
- **fname** pointer to the name of the file containing the certificates to verify.
- **format** format of the certificate to verify - either SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM.

See:

- wolfSSL_CertManagerLoadCA
- wolfSSL_CertManagerVerifyBuffer

Return:

- SSL_SUCCESS If successful.
- ASN_SIG_CONFIRM_E will be returned if the signature could not be verified.
- ASN_SIG_OID_E will be returned if the signature type is not supported.
- CRL_CERT_REVOKED is an error that is returned if this certificate has been revoked.
- CRL_MISSING is an error that is returned if a current issuer CRL is not available.
- ASN_BEFORE_DATE_E will be returned if the current date is before the before date.
- ASN_AFTER_DATE_E will be returned if the current date is after the after date.
- SSL_BAD_FILETYPE will be returned if the file is the wrong format.
- SSL_BAD_FILE will be returned if the file doesn't exist, can't be read, or is corrupted.
- MEMORY_E will be returned if an out of memory condition occurs.
- ASN_INPUT_E will be returned if Base16 decoding fails on the file.
- BAD_FUNC_ARG is the error that will be returned if a pointer is not provided.

Example

```
int ret = 0;
WOLFSSL_CERT_MANAGER* cm;
...

ret = wolfSSL_CertManagerVerify(cm, “path/to/cert-file.pem”,
SSL_FILETYPE_PEM);
if (ret != SSL_SUCCESS) {
    error verifying certificate
}
```

C.58.4.342 function wolfSSL_CertManagerVerifyBuffer

```
int wolfSSL_CertManagerVerifyBuffer(
    WOLFSSL_CERT_MANAGER * cm,
    const unsigned char * buff,
    long sz,
    int format
)
```

Specifies the certificate buffer to verify with the Certificate Manager context. The format can be SSL_FILETYPE_PEM or SSL_FILETYPE_ASN1.

Parameters:

- **cm** a pointer to a WOLFSSL_CERT_MANAGER structure, created using wolfSSL_CertManagerNew().
- **buff** buffer containing the certificates to verify.
- **sz** size of the buffer, buf.
- **format** format of the certificate to verify, located in buf - either SSL_FILETYPE_ASN1 or SSL_FILETYPE_PEM.

See:

- wolfSSL_CertManagerLoadCA
- wolfSSL_CertManagerVerify

Return:

- SSL_SUCCESS If successful.
- ASN_SIG_CONFIRM_E will be returned if the signature could not be verified.
- ASN_SIG_OID_E will be returned if the signature type is not supported.
- CRL_CERT_REVOKED is an error that is returned if this certificate has been revoked.
- CRL_MISSING is an error that is returned if a current issuer CRL is not available.
- ASN_BEFORE_DATE_E will be returned if the current date is before the before date.
- ASN_AFTER_DATE_E will be returned if the current date is after the after date.
- SSL_BAD_FILETYPE will be returned if the file is the wrong format.
- SSL_BAD_FILE will be returned if the file doesn't exist, can't be read, or is corrupted.
- MEMORY_E will be returned if an out of memory condition occurs.
- ASN_INPUT_E will be returned if Base16 decoding fails on the file.
- BAD_FUNC_ARG is the error that will be returned if a pointer is not provided.

Example

```
#include <wolfssl/ssl.h>

int ret = 0;
int sz = 0;
WOLFSSL_CERT_MANAGER* cm;
byte certBuff[...];
...

ret = wolfSSL_CertManagerVerifyBuffer(cm, certBuff, sz, SSL_FILETYPE_PEM);
if (ret != SSL_SUCCESS) {
    error verifying certificate
}
```

C.58.4.343 function wolfSSL_CertManagerSetVerify

```
void wolfSSL_CertManagerSetVerify(
    WOLFSSL_CERT_MANAGER * cm,
    VerifyCallback verify_callback
)
```

The function sets the verifyCallback function in the Certificate Manager. If present, it will be called for each cert loaded. If there is a verification error, the verify callback can be used to over-ride the error.

Parameters:

- **cm** a pointer to a WOLFSSL_CERT_MANAGER structure, created using wolfSSL_CertManagerNew().
- **verify_callback** a VerifyCallback function pointer to the callback routine

See: wolfSSL_CertManagerVerify

Return: none No return.

Example

```
#include <wolfssl/ssl.h>

int myVerify(int preverify, WOLFSSL_X509_STORE_CTX* store)
{ // do custom verification of certificate }

WOLFSSL_CTX* ctx = WOLFSSL_CTX_new(Protocol define);
WOLFSSL_CERT_MANAGER* cm = wolfSSL_CertManagerNew();
...
wolfSSL_CertManagerSetVerify(cm, myVerify);
```

C.58.4.344 function wolfSSL_CertManagerCheckCRL

```
int wolfSSL_CertManagerCheckCRL(
    WOLFSSL_CERT_MANAGER * cm,
    const unsigned char * der,
    int sz
)
```

Check CRL if the option is enabled and compares the cert to the CRL list.

Parameters:

- **cm** a pointer to a WOLFSSL_CERT_MANAGER struct.
- **der** pointer to a DER formatted certificate.
- **sz** size of the certificate.

See:

- CheckCertCRL
- ParseCertRelative
- wolfSSL_CertManagerSetCRL_CB
- InitDecodedCert

Return:

- SSL_SUCCESS returns if the function returned as expected. If the crlEnabled member of the WOLFSSL_CERT_MANAGER struct is turned on.
- MEMORY_E returns if the allocated memory failed.
- BAD_FUNC_ARG if the WOLFSSL_CERT_MANAGER is NULL.

Example

```
WOLFSSL_CERT_MANAGER* cm;
byte* der;
int sz; // size of der
...
if(wolfSSL_CertManagerCheckCRL(cm, der, sz) != SSL_SUCCESS){
    // Error returned. Deal with failure case.
}
```

C.58.4.345 function wolfSSL_CertManagerEnableCRL

```
int wolfSSL_CertManagerEnableCRL(
    WOLFSSL_CERT_MANAGER * cm,
    int options
)
```

Turns on Certificate Revocation List checking when verifying certificates with the Certificate Manager. By default, CRL checking is off. options include WOLFSSL_CRL_CHECKALL which performs CRL checking on each certificate in the chain versus the Leaf certificate only which is the default.

Parameters:

- **cm** a pointer to a WOLFSSL_CERT_MANAGER structure, created using wolfSSL_CertManagerNew().
- **options** options to use when enabling the Certification Manager, cm.

See: wolfSSL_CertManagerDisableCRL

Return:

- SSL_SUCCESS If successful the call will return.
- NOT_COMPILED_IN will be returned if wolfSSL was not built with CRL enabled.
- MEMORY_E will be returned if an out of memory condition occurs.
- BAD_FUNC_ARG is the error that will be returned if a pointer is not provided.
- SSL_FAILURE will be returned if the CRL context cannot be initialized properly.

Example

```
#include <wolfssl/ssl.h>

int ret = 0;
WOLFSSL_CERT_MANAGER* cm;
...

ret = wolfSSL_CertManagerEnableCRL(cm, 0);
if (ret != SSL_SUCCESS) {
    error enabling cert manager
}

...
```

C.58.4.346 function wolfSSL_CertManagerDisableCRL

```
int wolfSSL_CertManagerDisableCRL(
    WOLFSSL_CERT_MANAGER * cm
)
```

Turns off Certificate Revocation List checking when verifying certificates with the Certificate Manager. By default, CRL checking is off. You can use this function to temporarily or permanently disable CRL checking with this Certificate Manager context that previously had CRL checking enabled.

Parameters:

- **cm** a pointer to a WOLFSSL_CERT_MANAGER structure, created using wolfSSL_CertManagerNew().

See: wolfSSL_CertManagerEnableCRL

Return:

- SSL_SUCCESS If successful the call will return.
- BAD_FUNC_ARG is the error that will be returned if a function pointer is not provided.

Example

```
#include <wolfssl/ssl.h>

int ret = 0;
WOLFSSL_CERT_MANAGER* cm;
...
```

```
ret = wolfSSL_CertManagerDisableCRL(cm);
if (ret != SSL_SUCCESS) {
    error disabling cert manager
}
...
```

C.58.4.347 function wolfSSL_CertManagerLoadCRL

```
int wolfSSL_CertManagerLoadCRL(
    WOLFSSL_CERT_MANAGER * cm,
    const char * path,
    int type,
    int monitor
)
```

Error checks and passes through to LoadCRL() in order to load the cert into the CRL for revocation checking. An updated CRL can be loaded by first calling wolfSSL_CertManagerFreeCRL, then loading the new CRL.

Parameters:

- **cm** a pointer to a WOLFSSL_CERT_MANAGER structure, created using wolfSSL_CertManagerNew().
- **path** a constant char pointer holding the CRL path.
- **type** type of certificate to be loaded.
- **monitor** requests monitoring in LoadCRL().

See:

- wolfSSL_CertManagerEnableCRL
- wolfSSL_LoadCRL
- wolfSSL_CertManagerFreeCRL

Return:

- SSL_SUCCESS if there is no error in wolfSSL_CertManagerLoadCRL and if LoadCRL returns successfully.
- BAD_FUNC_ARG if the WOLFSSL_CERT_MANAGER struct is NULL.
- SSL_FATAL_ERROR if wolfSSL_CertManagerEnableCRL returns anything other than SSL_SUCCESS.
- BAD_PATH_ERROR if the path is NULL.
- MEMORY_E if LoadCRL fails to allocate heap memory.

Example

```
#include <wolfssl/ssl.h>

int wolfSSL_LoadCRL(WOLFSSL* ssl, const char* path, int type,
int monitor);
…
wolfSSL_CertManagerLoadCRL(SSL_CM(ssl), path, type, monitor);
```

C.58.4.348 function wolfSSL_CertManagerLoadCRLBuffer

```
int wolfSSL_CertManagerLoadCRLBuffer(
    WOLFSSL_CERT_MANAGER * cm,
    const unsigned char * buff,
    long sz,
    int type
)
```

The function loads the CRL file by calling BufferLoadCRL.

Parameters:

- **cm** a pointer to a WOLFSSL_CERT_MANAGER structure.
- **buff** a constant byte type and is the buffer.
- **sz** a long int representing the size of the buffer.
- **type** a long integer that holds the certificate type.

See:

- BufferLoadCRL
- wolfSSL_CertManagerEnableCRL

Return:

- SSL_SUCCESS returned if the function completed without errors.
- BAD_FUNC_ARG returned if the WOLFSSL_CERT_MANAGER is NULL.
- SSL_FATAL_ERROR returned if there is an error associated with the WOLFSSL_CERT_MANAGER.

Example

```
#include <wolfssl/ssl.h>

WOLFSSL_CERT_MANAGER* cm;
const unsigned char* buff;
long sz; size of buffer
int type;  cert type
...
int ret = wolfSSL_CertManagerLoadCRLBuffer(cm, buff, sz, type);
if(ret == SSL_SUCCESS){
return ret;
} else {
    Failure case.
}
```

C.58.4.349 function wolfSSL_CertManagerSetCRL_Cb

```
int wolfSSL_CertManagerSetCRL_Cb(
    WOLFSSL_CERT_MANAGER * cm,
    CbMissingCRL cb
)
```

This function sets the CRL Certificate Manager callback. If HAVE_CRL is defined and a matching CRL record is not found then the cbMissingCRL is called (set via wolfSSL_CertManagerSetCRL_Cb). This allows you to externally retrieve the CRL and load it.

Parameters:

- **cm** the WOLFSSL_CERT_MANAGER structure holding the information for the certificate.
- **cb** a function pointer to (*CbMissingCRL) that is set to the cbMissingCRL member of the WOLFSSL_CERT_MANAGER.

See:

- CbMissingCRL
- wolfSSL_SetCRL_Cb

Return:

- SSL_SUCCESS returned upon successful execution of the function and subroutines.
- BAD_FUNC_ARG returned if the WOLFSSL_CERT_MANAGER structure is NULL.

Example

```
#include <wolfssl/ssl.h>

WOLFSSL_CTX* ctx = wolfSSL_CTX_new(protocol method);
WOLFSSL* ssl = wolfSSL_new(ctx);
…
void cb(const char* url){
    Function body.
}
…
CbMissingCRL cb = CbMissingCRL;
…
if(ctx){
    return wolfSSL_CertManagerSetCRL_Cb(SSL_CM(ssl), cb);
}
```

C.58.4.350 function wolfSSL_CertManagerSetCRLUpdate_Cb

```
int wolfSSL_CertManagerSetCRLUpdate_Cb(
    WOLFSSL_CERT_MANAGER * cm,
    CbUpdateCRL cb
)
```

This function sets the CRL Update callback. If HAVE_CRL and HAVE_CRL_UPDATE_CB is defined , and an entry with the same issuer and a lower CRL number exists when a CRL is added, then the CbUpdateCRL is called with the details of the existing entry and the new one replacing it.

Parameters:

- **cm** the WOLFSSL_CERT_MANAGER structure holding the information for the certificate.
- **cb** a function pointer to (*CbUpdateCRL) that is set to the cbUpdateCRL member of the WOLFSSL_CERT_MANAGER. Signature requirement: void (*CbUpdateCRL)(CrlInfo *old, CrlInfo *new);

See: CbUpdateCRL

Return:

- SSL_SUCCESS returned upon successful execution of the function and subroutines.
- BAD_FUNC_ARG returned if the WOLFSSL_CERT_MANAGER structure is NULL.

Example

```
#include <wolfssl/ssl.h>

WOLFSSL_CTX* ctx = wolfSSL_CTX_new(protocol method);
WOLFSSL* ssl = wolfSSL_new(ctx);
…
void cb(CrlInfo *old, CrlInfo *new){
    Function body.
}
…
CbUpdateCRL cb = CbUpdateCRL;
…
if(ctx){
    return wolfSSL_CertManagerSetCRLUpdate_Cb(SSL_CM(ssl), cb);
}
```

C.58.4.351 function wolfSSL_CertManagerGetCRLInfo

```
int wolfSSL_CertManagerGetCRLInfo(
    WOLFSSL_CERT_MANAGER * cm,
    CrlInfo * info,
    const byte * buff,
    long sz,
    int type
)
```

This function yields a structure with parsed CRL information from an encoded CRL buffer.

Parameters:

- **cm** the WOLFSSL_CERT_MANAGER structure..
- **info** pointer to caller managed CrlInfo structure that will receive the CRL information.
- **buff** input buffer containing encoded CRL.
- **sz** the length in bytes of the input CRL data in buff.
- **type** WOLFSSL_FILETYPE_PEM or WOLFSSL_FILETYPE_DER
- **cm** a pointer to a WOLFSSL_CERT_MANAGER structure, created using wolfSSL_CertManagerNew().

See:

- CbUpdateCRL
- wolfSSL_SetCRL_Cb
- wolfSSL_CertManagerLoadCRL

Return:

- SSL_SUCCESS returned upon successful execution of the function and subroutines.
- BAD_FUNC_ARG returned if the WOLFSSL_CERT_MANAGER structure is NULL.
- SSL_SUCCESS returned upon successful execution of the function and subroutines.
- BAD_FUNC_ARG returned if the WOLFSSL_CERT_MANAGER structure is NULL.

Example

```
#include <wolfssl/ssl.h>

CrlInfo info;
WOLFSSL_CERT_MANAGER* cm = NULL;

cm = wolfSSL_CertManagerNew();

// Read crl data from file into buffer

wolfSSL_CertManagerGetCRLInfo(cm, &info, crlData, crlDataLen,
                              WOLFSSL_FILETYPE_PEM);
```

This function frees the CRL stored in the Cert Manager. An application can update the CRL by calling wolfSSL_CertManagerFreeCRL and then loading the new CRL.

Example

```
#include <wolfssl/ssl.h>

const char* crl1     = "./certs/crl/crl.pem";
WOLFSSL_CERT_MANAGER* cm = NULL;

cm = wolfSSL_CertManagerNew();
wolfSSL_CertManagerLoadCRL(cm, crl1, WOLFSSL_FILETYPE_PEM, 0);
```

```
...
wolfSSL_CertManagerFreeCRL(cm);
```

C.58.4.352 function wolfSSL_CertManagerCheckOCSP

```
int wolfSSL_CertManagerCheckOCSP(
    WOLFSSL_CERT_MANAGER * cm,
    const unsigned char * der,
    int sz
)
```

The function enables the WOLFSSL_CERT_MANAGER's member, ocspEnabled to signify that the OCSP check option is enabled.

Parameters:

- **cm** a pointer to a WOLFSSL_CERT_MANAGER structure, created using wolfSSL_CertManagerNew().
- **der** a byte pointer to the certificate.
- **sz** an int type representing the size of the DER cert.

See:

- ParseCertRelative
- CheckCertOCSP

Return:

- SSL_SUCCESS returned on successful execution of the function. The ocspEnabled member of the WOLFSSL_CERT_MANAGER is enabled.
- BAD_FUNC_ARG returned if the WOLFSSL_CERT_MANAGER structure is NULL or if an argument value that is not allowed is passed to a subroutine.
- MEMORY_E returned if there is an error allocating memory within this function or a subroutine.

Example

```
#import <wolfssl/ssl.h>

WOLFSSL* ssl = wolfSSL_new(ctx);
byte* der;
int sz; size of der
...
if(wolfSSL_CertManagerCheckOCSP(cm, der, sz) != SSL_SUCCESS){
 Failure case.
}
```

C.58.4.353 function wolfSSL_CertManagerEnableOCSP

```
int wolfSSL_CertManagerEnableOCSP(
    WOLFSSL_CERT_MANAGER * cm,
    int options
)
```

Turns on OCSP if it's turned off and if compiled with the set option available.

Parameters:

- **cm** a pointer to a WOLFSSL_CERT_MANAGER structure, created using wolfSSL_CertManagerNew().
- **options** used to set values in WOLFSSL_CERT_MANAGER struct.

See: wolfSSL_CertManagerNew

Return:

- SSL_SUCCESS returned if the function call is successful.
- BAD_FUNC_ARG if cm struct is NULL.
- MEMORY_E if WOLFSSL_OCSP struct value is NULL.
- SSL_FAILURE initialization of WOLFSSL_OCSP struct fails to initialize.
- NOT_COMPILED_IN build not compiled with correct feature enabled.

Example

```
#include <wolfssl/ssl.h>

WOLFSSL_CTX* ctx = wolfSSL_CTX_new(protocol method);
WOLFSSL* ssl = wolfSSL_new(ctx);
WOLFSSL_CERT_MANAGER* cm = wolfSSL_CertManagerNew();
int options;
…
if(wolfSSL_CertManagerEnableOCSP(SSL_CM(ssl), options) != SSL_SUCCESS){
    Failure case.
}
```

C.58.4.354 function wolfSSL_CertManagerDisableOCSP

```
int wolfSSL_CertManagerDisableOCSP(
    WOLFSSL_CERT_MANAGER * cm
)
```

Disables OCSP certificate revocation.

Parameters:

- **cm** a pointer to a WOLFSSL_CERT_MANAGER structure.

See: wolfSSL_DisableCRL

Return:

- SSL_SUCCESS wolfSSL_CertMangerDisableCRL successfully disabled the crlEnabled member of the WOLFSSL_CERT_MANAGER structure.
- BAD_FUNC_ARG the WOLFSSL structure was NULL.

Example

```
#include <wolfssl/ssl.h>

WOLFSSL_CTX* ctx = wolfSSL_CTX_new(method);
WOLFSSL* ssl = wolfSSL_new(ctx);
...
if(wolfSSL_CertManagerDisableOCSP(ssl) != SSL_SUCCESS){
    Fail case.
}
```

C.58.4.355 function wolfSSL_CertManagerSetOCSPOverrideURL

```
int wolfSSL_CertManagerSetOCSPOverrideURL(
    WOLFSSL_CERT_MANAGER * cm,
    const char * url
)
```

The function copies the url to the ocspOverrideURL member of the WOLFSSL_CERT_MANAGER structure.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- ocspOverrideURL
- wolfSSL_SetOCSP_OverrideURL

Return:

- SSL_SUCCESS the function was able to execute as expected.
- BAD_FUNC_ARG the WOLFSSL_CERT_MANAGER struct is NULL.
- MEMEORY_E Memory was not able to be allocated for the ocspOverrideURL member of the certificate manager.

Example

```
#include <wolfssl/ssl.h>
WOLFSSL_CERT_MANAGER* cm = wolfSSL_CertManagerNew();
const char* url;
…
int wolfSSL_SetOCSP_OverrideURL(WOLFSSL* ssl, const char* url)
…
if(wolfSSL_CertManagerSetOCSPOverrideURL(SSL_CM(ssl), url) != SSL_SUCCESS){
    Failure case.
}
```

C.58.4.356 function wolfSSL_CertManagerSetOCSP_Cb

```
int wolfSSL_CertManagerSetOCSP_Cb(
    WOLFSSL_CERT_MANAGER * cm,
    CbOCSPIO ioCb,
    CbOCSPRespFree respFreeCb,
    void * ioCbCtx
)
```

The function sets the OCSP callback in the WOLFSSL_CERT_MANAGER.

Parameters:

- **cm** a pointer to a WOLFSSL_CERT_MANAGER structure.
- **ioCb** a function pointer of type CbOCSPIO.
- **respFreeCb** - a function pointer of type CbOCSPRespFree.
- **ioCbCtx** - a void pointer variable to the I/O callback user registered context.

See:

- wolfSSL_CertManagerSetOCSPOverrideURL
- wolfSSL_CertManagerCheckOCSP
- wolfSSL_CertManagerEnableOCSPStapling
- wolfSSL_EnableOCSP
- wolfSSL_DisableOCSP
- wolfSSL_SetOCSP_Cb

Return:

- SSL_SUCCESS returned on successful execution. The arguments are saved in the WOLFSSL_CERT_MANAGER structure.

- BAD_FUNC_ARG returned if the WOLFSSL_CERT_MANAGER is NULL.

Example

```
#include <wolfssl/ssl.h>

wolfSSL_SetOCSP_Cb(WOLFSSL* ssl, CbOCSPIO ioCb,
CbOCSPRespFree respFreeCb, void* ioCbCtx){
…
return wolfSSL_CertManagerSetOCSP_Cb(SSL_CM(ssl), ioCb, respFreeCb, ioCbCtx);
```

C.58.4.357 function wolfSSL_CertManagerEnableOCSPStapling

```
int wolfSSL_CertManagerEnableOCSPStapling(
    WOLFSSL_CERT_MANAGER * cm
)
```

This function turns on OCSP stapling if it is not turned on as well as set the options.

Parameters:

- **cm** a pointer to a WOLFSSL_CERT_MANAGER structure, a member of the WOLFSSL_CTX structure.

See: wolfSSL_CTX_EnableOCSPStapling

Return:

- SSL_SUCCESS returned if there were no errors and the function executed successfully.
- BAD_FUNC_ARG returned if the WOLFSSL_CERT_MANAGER structure is NULL or otherwise if there was a unpermitted argument value passed to a subroutine.
- MEMORY_E returned if there was an issue allocating memory.
- SSL_FAILURE returned if the initialization of the OCSP structure failed.
- NOT_COMPILED_IN returned if wolfSSL was not compiled with HAVE_CERTIFICATE_STATUS_REQUEST option.

Example

```
int wolfSSL_CTX_EnableOCSPStapling(WOLFSSL_CTX* ctx){
…
return wolfSSL_CertManagerEnableOCSPStapling(ctx->cm);
```

C.58.4.358 function wolfSSL_EnableCRL

```
int wolfSSL_EnableCRL(
    WOLFSSL * ssl,
    int options
)
```

Enables CRL certificate revocation.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **options** an integer that is used to determine the setting of crlCheckAll member of the WOLFSSL_CERT_MANAGER structure.

See:

- wolfSSL_CertManagerEnableCRL
- InitCRL

Return:

- SSL_SUCCESS the function and subroutines returned with no errors.
- BAD_FUNC_ARG returned if the WOLFSSL structure is NULL.
- MEMORY_E returned if the allocation of memory failed.
- SSL_FAILURE returned if the InitCRL function does not return successfully.
- NOT_COMPILED_IN HAVE_CRL was not enabled during the compiling.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
…
if (wolfSSL_EnableCRL(ssl, WOLFSSL_CRL_CHECKALL) != SSL_SUCCESS){
    // Failure case. SSL_SUCCESS was not returned by this function or
a subroutine
}
```

C.58.4.359 function wolfSSL_DisableCRL

```
int wolfSSL_DisableCRL(
    WOLFSSL * ssl
)
```

Disables CRL certificate revocation.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_CertManagerDisableCRL
- wolfSSL_CertManagerDisableOCSP

Return:

- SSL_SUCCESS wolfSSL_CertMangerDisableCRL successfully disabled the crlEnabled member of the WOLFSSL_CERT_MANAGER structure.
- BAD_FUNC_ARG the WOLFSSL structure was NULL.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
...
if(wolfSSL_DisableCRL(ssl) != SSL_SUCCESS){
    // Failure case
}
```

C.58.4.360 function wolfSSL_LoadCRL

```
int wolfSSL_LoadCRL(
    WOLFSSL * ssl,
    const char * path,
    int type,
    int monitor
)
```

A wrapper function that ends up calling LoadCRL to load the certificate for revocation checking.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

- **path** a constant character pointer that holds the path to the crl file.
- **type** an integer representing the type of certificate.
- **monitor** an integer variable used to verify the monitor path if requested.

See:

- wolfSSL_CertManagerLoadCRL
- wolfSSL_CertManagerEnableCRL
- LoadCRL

Return:

- WOLFSSL_SUCCESS returned if the function and all of the subroutines executed without error.
- SSL_FATAL_ERROR returned if one of the subroutines does not return successfully.
- BAD_FUNC_ARG if the WOLFSSL_CERT_MANAGER or the WOLFSSL structure are NULL.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
const char* crlPemDir;
…
if(wolfSSL_LoadCRL(ssl, crlPemDir, SSL_FILETYPE_PEM, 0) != SSL_SUCCESS){
    // Failure case. Did not return SSL_SUCCESS.
}
```

C.58.4.361 function wolfSSL_SetCRL_Cb

```
int wolfSSL_SetCRL_Cb(
    WOLFSSL * ssl,
    CbMissingCRL cb
)
```

Sets the CRL callback in the WOLFSSL_CERT_MANAGER structure.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **cb** a function pointer to CbMissingCRL.

See:

- CbMissingCRL
- wolfSSL_CertManagerSetCRL_Cb

Return:

- SSL_SUCCESS returned if the function or subroutine executes without error. The cbMissingCRL member of the WOLFSSL_CERT_MANAGER is set.
- BAD_FUNC_ARG returned if the WOLFSSL or WOLFSSL_CERT_MANAGER structure is NULL.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
WOLFSSL* ssl = wolfSSL_new(ctx);
…
void cb(const char* url) // required signature
{
    // Function body
}
…
int crlCb = wolfSSL_SetCRL_Cb(ssl, cb);
if(crlCb != SSL_SUCCESS){
```

```
    // The callback was not set properly
}
```

C.58.4.362 function wolfSSL_EnableOCSP

```
int wolfSSL_EnableOCSP(
    WOLFSSL * ssl,
    int options
)
```

This function enables OCSP certificate verification. The value of options if formed by or'ing one or more of the following options: WOLFSSL_OCSP_URL_OVERRIDE - use the override URL instead of the URL in certificates. The override URL is specified using the wolfSSL_CTX_SetOCSP_OverrideURL() function. WOLFSSL_OCSP_CHECKALL - Set all OCSP checks on WOLFSSL_OCSP_NO_NONCE - Set nonce option for creating OCSP requests.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **options** an integer type passed to wolfSSL_CertMangerENableOCSP() used for settings check.

See: wolfSSL_CertManagerEnableOCSP

Return:

- SSL_SUCCESS returned if the function and subroutines executes without errors.
- BAD_FUNC_ARG returned if an argument in this function or any subroutine receives an invalid argument value.
- MEMORY_E returned if there was an error allocating memory for a structure or other variable.
- NOT_COMPILED_IN returned if wolfSSL was not compiled with the HAVE_OCSP option.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
int options; // initialize to option constant
…
int ret = wolfSSL_EnableOCSP(ssl, options);
if(ret != SSL_SUCCESS){
    // OCSP is not enabled
}
```

C.58.4.363 function wolfSSL_DisableOCSP

```
int wolfSSL_DisableOCSP(
    WOLFSSL * ssl
)
```

Disables the OCSP certificate revocation option.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See: wolfSSL_CertManagerDisableOCSP

Return:

- SSL_SUCCESS returned if the function and its subroutine return with no errors. The ocspEnabled member of the WOLFSSL_CERT_MANAGER structure was successfully set.
- BAD_FUNC_ARG returned if the WOLFSSL structure is NULL.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
…
if(wolfSSL_DisableOCSP(ssl) != SSL_SUCCESS){
    // Returned with an error. Failure case in this block.
}
```

C.58.4.364 function wolfSSL_SetOCSP_OverrideURL

```
int wolfSSL_SetOCSP_OverrideURL(
    WOLFSSL * ssl,
    const char * url
)
```

This function sets the ocspOverrideURL member in the WOLFSSL_CERT_MANAGER structure.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **url** a constant char pointer to the url that will be stored in the ocspOverrideURL member of the WOLFSSL_CERT_MANAGER structure.

See: wolfSSL_CertManagerSetOCSPOverrideURL

Return:

- SSL_SUCCESS returned on successful execution of the function.
- BAD_FUNC_ARG returned if the WOLFSSL struct is NULL or if a unpermitted argument was passed to a subroutine.
- MEMORY_E returned if there was an error allocating memory in the subroutine.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
char url[URLSZ];
...
if(wolfSSL_SetOCSP_OverrideURL(ssl, url)){
    // The override url is set to the new value
}
```

C.58.4.365 function wolfSSL_SetOCSP_Cb

```
int wolfSSL_SetOCSP_Cb(
    WOLFSSL * ssl,
    CbOCSPIO ioCb,
    CbOCSPRespFree respFreeCb,
    void * ioCbCtx
)
```

This function sets the OCSP callback in the WOLFSSL_CERT_MANAGER structure.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **ioCb** a function pointer to type CbOCSPIO.
- **respFreeCb** a function pointer to type CbOCSPRespFree which is the call to free the response memory.
- **ioCbCtx** a void pointer that will be held in the ocspIOCtx member of the CM.

See:

- wolfSSL_CertManagerSetOCSP_Cb
- CbOCSPIO
- CbOCSPRespFree

Return:

- SSL_SUCCESS returned if the function executes without error. The ocspIOCb, ocspRespFreeCb, and ocspIOCtx members of the CM are set.
- BAD_FUNC_ARG returned if the WOLFSSL or WOLFSSL_CERT_MANAGER structures are NULL.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
…
int OCSPIO_CB(void* , const char*, int , unsigned char* , int,
unsigned char**){  // must have this signature
// Function Body
}
…
void OCSPRespFree_CB(void* , unsigned char* ){ // must have this signature
    // function body
}
…
void* ioCbCtx;
CbOCSPRespFree CB_OCSPRespFree;

if(wolfSSL_SetOCSP_Cb(ssl, OCSPIO_CB( pass args ), CB_OCSPRespFree,
            ioCbCtx) != SSL_SUCCESS){
    // Callback not set
}
```

C.58.4.366 function wolfSSL_CTX_EnableCRL

```
int wolfSSL_CTX_EnableCRL(
    WOLFSSL_CTX * ctx,
    int options
)
```

Enables CRL certificate verification through the CTX.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().
- **options** option flags for enabling CRL.

See:

- wolfSSL_CertManagerEnableCRL
- InitCRL
- wolfSSL_CTX_DisableCRL

Return:

- SSL_SUCCESS returned if this function and it's subroutines execute without errors.
- BAD_FUNC_ARG returned if the CTX struct is NULL or there was otherwise an invalid argument passed in a subroutine.
- MEMORY_E returned if there was an error allocating memory during execution of the function.

- SSL_FAILURE returned if the crl member of the WOLFSSL_CERT_MANAGER fails to initialize correctly.
- BAD_MUTEX_E returned if locking the certificate manager failed.
- NOT_COMPILED_IN wolfSSL was not compiled with the HAVE_CRL option.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
...
if(wolfSSL_CTX_EnableCRL(ssl->ctx, options) != SSL_SUCCESS){
    // The function failed
}
```

C.58.4.367 function wolfSSL_CTX_DisableCRL

```
int wolfSSL_CTX_DisableCRL(
    WOLFSSL_CTX * ctx
)
```

This function disables CRL verification in the CTX structure.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().

See: wolfSSL_CertManagerDisableCRL

Return:

- SSL_SUCCESS returned if the function executes without error. The crlEnabled member of the WOLFSSL_CERT_MANAGER struct is set to 0.
- BAD_FUNC_ARG returned if either the CTX struct or the CM struct has a NULL value.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
...
if(wolfSSL_CTX_DisableCRL(ssl->ctx) != SSL_SUCCESS){
    // Failure case.
}
```

C.58.4.368 function wolfSSL_CTX_LoadCRL

```
int wolfSSL_CTX_LoadCRL(
    WOLFSSL_CTX * ctx,
    const char * path,
    int type,
    int monitor
)
```

This function loads CRL into the WOLFSSL_CTX structure through wolfSSL_CertManagerLoadCRL().

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().
- **path** the path to the certificate.
- **type** an integer variable holding the type of certificate.
- **monitor** an integer variable used to determine if the monitor path is requested.

See:

- wolfSSL_CertManagerLoadCRL
- LoadCRL

Return:

- SSL_SUCCESS - returned if the function and its subroutines execute without error.
- BAD_FUNC_ARG - returned if this function or any subroutines are passed NULL structures.
- BAD_PATH_ERROR - returned if the path variable opens as NULL.
- MEMORY_E - returned if an allocation of memory failed.

Example

```
WOLFSSL_CTX* ctx;
const char* path;
…
return wolfSSL_CTX_LoadCRL(ctx, path, SSL_FILETYPE_PEM, 0);
```

C.58.4.369 function wolfSSL_CTX_SetCRL_Cb

```
int wolfSSL_CTX_SetCRL_Cb(
    WOLFSSL_CTX * ctx,
    CbMissingCRL cb
)
```

This function will set the callback argument to the cbMissingCRL member of the WOLFSSL_CERT_MANAGER structure by calling wolfSSL_CertManagerSetCRL_Cb.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created with wolfSSL_CTX_new().
- **cb** a pointer to a callback function of type CbMissingCRL. Signature requirement: void (*CbMissingCRL)(const char* url);

See:

- wolfSSL_CertManagerSetCRL_Cb
- CbMissingCRL

Return:

- SSL_SUCCESS returned for a successful execution. The WOLFSSL_CERT_MANAGER structure's member cbMssingCRL was successfully set to cb.
- BAD_FUNC_ARG returned if WOLFSSL_CTX or WOLFSSL_CERT_MANAGER are NULL.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
…
void cb(const char* url) // Required signature
{
    // Function body
}
…
if (wolfSSL_CTX_SetCRL_Cb(ctx, cb) != SSL_SUCCESS){
    // Failure case, cb was not set correctly.
}
```

C.58.4.370 function wolfSSL_CTX_EnableOCSP

```
int wolfSSL_CTX_EnableOCSP(
    WOLFSSL_CTX * ctx,
    int options
)
```

This function sets options to configure behavior of OCSP functionality in wolfSSL. The value of options if formed by or'ing one or more of the following options: WOLFSSL_OCSP_URL_OVERRIDE - use the override URL instead of the URL in certificates. The override URL is specified using the wolfSSL_CTX_SetOCSP_OverrideURL() function. WOLFSSL_OCSP_CHECKALL - Set all OCSP checks on WOLFSSL_OCSP_NO_NONCE - Set nonce option for creating OCSP requests.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **options** value used to set the OCSP options.

See:

- wolfSSL_CertManagerEnableOCSP
- wolfSSL_EnableOCSP

Return:

- SSL_SUCCESS is returned upon success.
- SSL_FAILURE is returned upon failure.
- BAD_MUTEX_E returned if locking the certificate manager failed.
- NOT_COMPILED_IN is returned when this function has been called, but OCSP support was not enabled when wolfSSL was compiled.
- BAD_FUNC_ARG will be returned when ctx is NULL.

This function only sets the OCSP options when wolfSSL has been compiled with OCSP support (–enable-ocsp, #define HAVE_OCSP).

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
int options; // initialize to option constant
…
int ret = wolfSSL_CTX_EnableOCSP(ctx, options);
if(ret != SSL_SUCCESS){
    // OCSP is not enabled
}
```

C.58.4.371 function wolfSSL_CTX_DisableOCSP

```
int wolfSSL_CTX_DisableOCSP(
    WOLFSSL_CTX * ctx
)
```

This function disables OCSP certificate revocation checking by affecting the ocspEnabled member of the WOLFSSL_CERT_MANAGER structure.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().

See:

- wolfSSL_DisableOCSP
- wolfSSL_CertManagerDisableOCSP

Return:

- SSL_SUCCESS returned if the function executes without error. The ocspEnabled member of the CM has been disabled.
- BAD_FUNC_ARG returned if the WOLFSSL_CTX structure is NULL.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
...
if(!wolfSSL_CTX_DisableOCSP(ssl->ctx)){
    // OCSP is not disabled
}
```

C.58.4.372 function wolfSSL_CTX_SetOCSP_OverrideURL

```
int wolfSSL_CTX_SetOCSP_OverrideURL(
    WOLFSSL_CTX * ctx,
    const char * url
)
```

This function manually sets the URL for OCSP to use. By default, OCSP will use the URL found in the individual certificate unless the WOLFSSL_OCSP_URL_OVERRIDE option is set using the wolfSSL_CTX_EnableOCSP.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **url** pointer to the OCSP URL for wolfSSL to use.

See: wolfSSL_CTX_OCSP_set_options

Return:

- SSL_SUCCESS is returned upon success.
- SSL_FAILURE is returned upon failure.
- NOT_COMPILED_IN is returned when this function has been called, but OCSP support was not enabled when wolfSSL was compiled.
- BAD_FUNC_ARG will be returned when ctx is NULL.

Example

```
WOLFSSL_CTX* ctx = 0;
...
wolfSSL_CTX_OCSP_set_override_url(ctx, “custom-url-here”);
```

C.58.4.373 function wolfSSL_CTX_SetOCSP_Cb

```
int wolfSSL_CTX_SetOCSP_Cb(
    WOLFSSL_CTX * ctx,
    CbOCSPIO ioCb,
    CbOCSPRespFree respFreeCb,
    void * ioCbCtx
)
```

Sets the callback for the OCSP in the WOLFSSL_CTX structure.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

- **ioCb** a CbOCSPIO type that is a function pointer.
- **respFreeCb** a CbOCSPRespFree type that is a function pointer.
- **ioCbCtx** a void pointer that will be held in the WOLFSSL_CERT_MANAGER.

See:

- wolfSSL_CertManagerSetOCSP_Cb
- CbOCSPIO
- CbOCSPRespFree

Return:

- SSL_SUCCESS returned if the function executed successfully. The ocspIOCb, ocspRespFreeCb, and ocspIOCtx members in the CM were successfully set.
- BAD_FUNC_ARG returned if the WOLFSSL_CTX or WOLFSSL_CERT_MANAGER structure is NULL.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
…
CbOCSPIO ocspIOCb;
CbOCSPRespFree ocspRespFreeCb;
…
void* ioCbCtx;

int isSetOCSP = wolfSSL_CTX_SetOCSP_Cb(ctx, ocspIOCb,
ocspRespFreeCb, ioCbCtx);

if(isSetOCSP != SSL_SUCCESS){
    // The function did not return successfully.
}
```

C.58.4.374 function wolfSSL_CTX_EnableOCSPStapling

```
int wolfSSL_CTX_EnableOCSPStapling(
    WOLFSSL_CTX * ctx
)
```

This function enables OCSP stapling by calling wolfSSL_CertManagerEnableOCSPStapling().

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().

See:

- wolfSSL_CertManagerEnableOCSPStapling
- InitOCSP

Return:

- SSL_SUCCESS returned if there were no errors and the function executed successfully.
- BAD_FUNC_ARG returned if the WOLFSSL_CTX structure is NULL or otherwise if there was a unpermitted argument value passed to a subroutine.
- MEMORY_E returned if there was an issue allocating memory.
- SSL_FAILURE returned if the initialization of the OCSP structure failed.
- BAD_MUTEX_E returned if locking the certificate manager failed.
- NOT_COMPILED_IN returned if wolfSSL was not compiled with HAVE_CERTIFICATE_STATUS_REQUEST option.

Example

```
WOLFSSL* ssl = WOLFSSL_new();
ssl->method.version; // set to desired protocol
...
if(!wolfSSL_CTX_EnableOCSPStapling(ssl->ctx)){
    // OCSP stapling is not enabled
}
```

C.58.4.375 function wolfSSL_KeepArrays

```
void wolfSSL_KeepArrays(
    WOLFSSL * ssl
)
```

Normally, at the end of the SSL handshake, wolfSSL frees temporary arrays. Calling this function before the handshake begins will prevent wolfSSL from freeing temporary arrays. Temporary arrays may be needed for things such as wolfSSL_get_keys() or PSK hints. When the user is done with temporary arrays, either wolfSSL_FreeArrays() may be called to free the resources immediately, or alternatively the resources will be freed when the associated SSL object is freed.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See: wolfSSL_FreeArrays

Return: none No return.

Example

```
WOLFSSL* ssl;
...
wolfSSL_KeepArrays(ssl);
```

C.58.4.376 function wolfSSL_FreeArrays

```
void wolfSSL_FreeArrays(
    WOLFSSL * ssl
)
```

Normally, at the end of the SSL handshake, wolfSSL frees temporary arrays. If wolfSSL_KeepArrays() has been called before the handshake, wolfSSL will not free temporary arrays. This function explicitly frees temporary arrays and should be called when the user is done with temporary arrays and does not want to wait for the SSL object to be freed to free these resources.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See: wolfSSL_KeepArrays

Return: none No return.

Example

```
WOLFSSL* ssl;
...
wolfSSL_FreeArrays(ssl);
```

C.58.4.377 function wolfSSL_UseSNI

```
int wolfSSL_UseSNI(
    WOLFSSL * ssl,
    unsigned char type,
    const void * data,
    unsigned short size
)
```

This function enables the use of Server Name Indication in the SSL object passed in the 'ssl' parameter. It means that the SNI extension will be sent on ClientHello by wolfSSL client and wolfSSL server will respond ClientHello + SNI with either ServerHello + blank SNI or alert fatal in case of SNI mismatch.

Parameters:

- **ssl** pointer to a SSL object, created with wolfSSL_new().
- **type** indicates which type of server name is been passed in data. The known types are: enum { WOLFSSL_SNI_HOST_NAME = 0 };
- **data** pointer to the server name data.
- **size** size of the server name data.

See:

- wolfSSL_new
- wolfSSL_CTX_UseSNI

Return:

- WOLFSSL_SUCCESS upon success.
- BAD_FUNC_ARG is the error that will be returned in one of these cases: ssl is NULL, data is NULL, type is a unknown value. (see below)
- MEMORY_E is the error returned when there is not enough memory.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx = 0;
WOLFSSL* ssl = 0;
ctx = wolfSSL_CTX_new(method);
if (ctx == NULL) {
    // context creation failed
}
ssl = wolfSSL_new(ctx);
if (ssl == NULL) {
    // ssl creation failed
}
ret = wolfSSL_UseSNI(ssl, WOLFSSL_SNI_HOST_NAME, "www.yassl.com",
    strlen("www.yassl.com"));
if (ret != WOLFSSL_SUCCESS) {
    // sni usage failed
}
```

C.58.4.378 function wolfSSL_CTX_UseSNI

```
int wolfSSL_CTX_UseSNI(
    WOLFSSL_CTX * ctx,
    unsigned char type,
    const void * data,
```

```
    unsigned short size
)
```

This function enables the use of Server Name Indication for SSL objects created from the SSL context passed in the 'ctx' parameter. It means that the SNI extension will be sent on ClientHello by wolfSSL clients and wolfSSL servers will respond ClientHello + SNI with either ServerHello + blank SNI or alert fatal in case of SNI mismatch.

Parameters:

- **ctx** pointer to a SSL context, created with wolfSSL_CTX_new().
- **type** indicates which type of server name is been passed in data. The known types are: enum { WOLFSSL_SNI_HOST_NAME = 0 };
- **data** pointer to the server name data.
- **size** size of the server name data.

See:

- wolfSSL_CTX_new
- wolfSSL_UseSNI

Return:

- WOLFSSL_SUCCESS upon success.
- BAD_FUNC_ARG is the error that will be returned in one of these cases: ctx is NULL, data is NULL, type is a unknown value. (see below)
- MEMORY_E is the error returned when there is not enough memory.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx = 0;
ctx = wolfSSL_CTX_new(method);
if (ctx == NULL) {
    // context creation failed
}
ret = wolfSSL_CTX_UseSNI(ctx, WOLFSSL_SNI_HOST_NAME, "www.yassl.com",
    strlen("www.yassl.com"));
if (ret != WOLFSSL_SUCCESS) {
    // sni usage failed
}
```

C.58.4.379 function wolfSSL_SNI_SetOptions

```
void wolfSSL_SNI_SetOptions(
    WOLFSSL * ssl,
    unsigned char type,
    unsigned char options
)
```

This function is called on the server side to configure the behavior of the SSL session using Server Name Indication in the SSL object passed in the 'ssl' parameter. The options are explained below.

Parameters:

- **ssl** pointer to a SSL object, created with wolfSSL_new().
- **type** indicates which type of server name is been passed in data. The known types are: enum { WOLFSSL_SNI_HOST_NAME = 0 };
- **options** a bitwise semaphore with the chosen options. The available options are: enum { WOLFSSL_SNI_CONTINUE_ON_MISMATCH = 0x01, WOLFSSL_SNI_ANSWER_ON_MISMATCH = 0x02 };

Normally the server will abort the handshake by sending a fatal-level unrecognized_name(112) alert if the hostname provided by the client mismatch with the servers.
- **WOLFSSL_SNI_CONTINUE_ON_MISMATCH** With this option set, the server will not send a SNI response instead of aborting the session.
- **WOLFSSL_SNI_ANSWER_ON_MISMATCH** - With this option set, the server will send a SNI response as if the host names match instead of aborting the session.

See:

- wolfSSL_new
- wolfSSL_UseSNI
- wolfSSL_CTX_SNI_SetOptions

Return: none No returns.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx = 0;
WOLFSSL* ssl = 0;
ctx = wolfSSL_CTX_new(method);
if (ctx == NULL) {
    // context creation failed
}
ssl = wolfSSL_new(ctx);
if (ssl == NULL) {
    // ssl creation failed
}
ret = wolfSSL_UseSNI(ssl, 0, "www.yassl.com", strlen("www.yassl.com"));
if (ret != WOLFSSL_SUCCESS) {
    // sni usage failed
}
wolfSSL_SNI_SetOptions(ssl, WOLFSSL_SNI_HOST_NAME,
    WOLFSSL_SNI_CONTINUE_ON_MISMATCH);
```

C.58.4.380 function wolfSSL_CTX_SNI_SetOptions

```
void wolfSSL_CTX_SNI_SetOptions(
    WOLFSSL_CTX * ctx,
    unsigned char type,
    unsigned char options
)
```

This function is called on the server side to configure the behavior of the SSL sessions using Server Name Indication for SSL objects created from the SSL context passed in the 'ctx' parameter. The options are explained below.

Parameters:

- **ctx** pointer to a SSL context, created with wolfSSL_CTX_new().
- **type** indicates which type of server name is been passed in data. The known types are: enum { WOLFSSL_SNI_HOST_NAME = 0 };
- **options** a bitwise semaphore with the chosen options. The available options are: enum { WOLFSSL_SNI_CONTINUE_ON_MISMATCH = 0x01, WOLFSSL_SNI_ANSWER_ON_MISMATCH = 0x02 }; Normally the server will abort the handshake by sending a fatal-level unrecognized_name(112) alert if the hostname provided by the client mismatch with the servers.
- **WOLFSSL_SNI_CONTINUE_ON_MISMATCH** With this option set, the server will not send a SNI response instead of aborting the session.

- **WOLFSSL_SNI_ANSWER_ON_MISMATCH** With this option set, the server will send a SNI response as if the host names match instead of aborting the session.

See:

- wolfSSL_CTX_new
- wolfSSL_CTX_UseSNI
- wolfSSL_SNI_SetOptions

Return: none No returns.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx = 0;
ctx = wolfSSL_CTX_new(method);
if (ctx == NULL) {
   // context creation failed
}
ret = wolfSSL_CTX_UseSNI(ctx, 0, "www.yassl.com", strlen("www.yassl.com"));
if (ret != WOLFSSL_SUCCESS) {
    // sni usage failed
}
wolfSSL_CTX_SNI_SetOptions(ctx, WOLFSSL_SNI_HOST_NAME,
WOLFSSL_SNI_CONTINUE_ON_MISMATCH);
```

C.58.4.381 function wolfSSL_SNI_GetFromBuffer

```
int wolfSSL_SNI_GetFromBuffer(
    const unsigned char * clientHello,
    unsigned int helloSz,
    unsigned char type,
    unsigned char * sni,
    unsigned int * inOutSz
)
```

This function is called on the server side to retrieve the Server Name Indication provided by the client from the Client Hello message sent by the client to start a session. It does not requires context or session setup to retrieve the SNI.

Parameters:

- **buffer** pointer to the data provided by the client (Client Hello).
- **bufferSz** size of the Client Hello message.
- **type** indicates which type of server name is been retrieved from the buffer. The known types are: enum { WOLFSSL_SNI_HOST_NAME = 0 };
- **sni** pointer to where the output is going to be stored.
- **inOutSz** pointer to the output size, this value will be updated to MIN("SNI's length", inOutSz).

See:

- wolfSSL_UseSNI
- wolfSSL_CTX_UseSNI
- wolfSSL_SNI_GetRequest

Return:

- WOLFSSL_SUCCESS upon success.
- BAD_FUNC_ARG is the error that will be returned in one of this cases: buffer is NULL, bufferSz <= 0, sni is NULL, inOutSz is NULL or <= 0

- BUFFER_ERROR is the error returned when there is a malformed Client Hello message.
- INCOMPLETE_DATA is the error returned when there is not enough data to complete the extraction.

Example

```
unsigned char buffer[1024] = {0};
unsigned char result[32]   = {0};
int           length       = 32;
// read Client Hello to buffer...
ret = wolfSSL_SNI_GetFromBuffer(buffer, sizeof(buffer), 0, result, &length));
if (ret != WOLFSSL_SUCCESS) {
    // sni retrieve failed
}
```

C.58.4.382 function wolfSSL_SNI_Status

```
unsigned char wolfSSL_SNI_Status(
    WOLFSSL * ssl,
    unsigned char type
)
```

This function gets the status of an SNI object.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **type** the SNI type.

See:

- TLSX_SNI_Status
- TLSX_SNI_find
- TLSX_Find

Return:

- value This function returns the byte value of the SNI struct's status member if the SNI is not NULL.
- 0 if the SNI object is NULL.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
WOLFSSL* ssl = wolfSSL_new(ctx);
…
#define AssertIntEQ(x, y) AssertInt(x, y, ==, !=)
…
Byte type = WOLFSSL_SNI_HOST_NAME;
char* request = (char*)&type;
AssertIntEQ(WOLFSSL_SNI_NO_MATCH, wolfSSL_SNI_Status(ssl, type));
…
```

C.58.4.383 function wolfSSL_SNI_GetRequest

```
unsigned short wolfSSL_SNI_GetRequest(
    WOLFSSL * ssl,
    unsigned char type,
    void ** data
)
```

This function is called on the server side to retrieve the Server Name Indication provided by the client in a SSL session.

Parameters:

- **ssl** pointer to a SSL object, created with wolfSSL_new().
- **type** indicates which type of server name is been retrieved in data. The known types are: enum { WOLFSSL_SNI_HOST_NAME = 0 };
- **data** pointer to the data provided by the client.

See:

- wolfSSL_UseSNI
- wolfSSL_CTX_UseSNI

Return: size the size of the provided SNI data.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx = 0;
WOLFSSL* ssl = 0;
ctx = wolfSSL_CTX_new(method);
if (ctx == NULL) {
    // context creation failed
}
ssl = wolfSSL_new(ctx);
if (ssl == NULL) {
    // ssl creation failed
}
ret = wolfSSL_UseSNI(ssl, 0, "www.yassl.com", strlen("www.yassl.com"));
if (ret != WOLFSSL_SUCCESS) {
    // sni usage failed
}
if (wolfSSL_accept(ssl) == SSL_SUCCESS) {
    void *data = NULL;
    unsigned short size = wolfSSL_SNI_GetRequest(ssl, 0, &data);
}
```

C.58.4.384 function wolfSSL_UseALPN

```
int wolfSSL_UseALPN(
    WOLFSSL * ssl,
    char * protocol_name_list,
    unsigned int protocol_name_listSz,
    unsigned char options
)
```

Setup ALPN use for a wolfSSL session.

Parameters:

- **ssl** The wolfSSL session to use.
- **protocol_name_list** List of protocol names to use. Comma delimited string is required.
- **protocol_name_listSz** Size of the list of protocol names.
- **options** WOLFSSL_ALPN_CONTINUE_ON_MISMATCH or WOLFSSL_ALPN_FAILED_ON_MISMATCH.

See: TLSX_UseALPN

Return:

- WOLFSSL_SUCCESS: upon success.
- BAD_FUNC_ARG Returned if ssl or protocol_name_list is null or protocol_name_listSz is too large or options contain something not supported.
- MEMORY_ERROR Error allocating memory for protocol list.
- SSL_FAILURE upon failure.

Example

```
wolfSSL_Init();
WOLFSSL_CTX* ctx;
WOLFSSL* ssl;
WOLFSSL_METHOD method = // Some wolfSSL method
ctx = wolfSSL_CTX_new(method);
ssl = wolfSSL_new(ctx);

char alpn_list[] = {};

if (wolfSSL_UseALPN(ssl, alpn_list, sizeof(alpn_list),
    WOLFSSL_APN_FAILED_ON_MISMATCH) != WOLFSSL_SUCCESS)
{
   // Error setting session ticket
}
```

C.58.4.385 function wolfSSL_ALPN_GetProtocol

```
int wolfSSL_ALPN_GetProtocol(
    WOLFSSL * ssl,
    char ** protocol_name,
    unsigned short * size
)
```

This function gets the protocol name set by the server.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **protocol_name** a pointer to a char that represents the protocol name and will be held in the ALPN structure.
- **size** a word16 type that represents the size of the protocol_name.

See:

- TLSX_ALPN_GetRequest
- TLSX_Find

Return:

- SSL_SUCCESS returned on successful execution where no errors were thrown.
- SSL_FATAL_ERROR returned if the extension was not found or if there was no protocol match with peer. There will also be an error thrown if there is more than one protocol name accepted.
- SSL_ALPN_NOT_FOUND returned signifying that no protocol match with peer was found.
- BAD_FUNC_ARG returned if there was a NULL argument passed into the function.

Example

```
WOLFSSL_CTX* ctx = WOLFSSL_CTX_new( protocol method );
WOLFSSL* ssl = WOLFSSL_new(ctx);
...
int err;
char* protocol_name = NULL;
```

```
Word16 protocol_nameSz = 0;
err = wolfSSL_ALPN_GetProtocol(ssl, &protocol_name, &protocol_nameSz);

if(err == SSL_SUCCESS){
    // Sent ALPN protocol
}
```

C.58.4.386 function wolfSSL_ALPN_GetPeerProtocol

```
int wolfSSL_ALPN_GetPeerProtocol(
    WOLFSSL * ssl,
    char ** list,
    unsigned short * listSz
)
```

This function copies the alpn_client_list data from the SSL object to the buffer.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **list** a pointer to the buffer. The data from the SSL object will be copied into it.
- **listSz** the buffer size.

See: wolfSSL_UseALPN

Return:

- SSL_SUCCESS returned if the function executed without error. The alpn_client_list member of the SSL object has been copied to the list parameter.
- BAD_FUNC_ARG returned if the list or listSz parameter is NULL.
- BUFFER_ERROR returned if there will be a problem with the list buffer (either it's NULL or the size is 0).
- MEMORY_ERROR returned if there was a problem dynamically allocating memory.

Example

```
#import <wolfssl/ssl.h>

WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method);
WOLFSSL* ssl = wolfSSL_new(ctx);
…
#ifdef HAVE_ALPN
char* list = NULL;
word16 listSz = 0;
…
err = wolfSSL_ALPN_GetPeerProtocol(ssl, &list, &listSz);

if(err == SSL_SUCCESS){
    List of protocols names sent by client
}
```

C.58.4.387 function wolfSSL_UseMaxFragment

```
int wolfSSL_UseMaxFragment(
    WOLFSSL * ssl,
    unsigned char mfl
)
```

This function is called on the client side to enable the use of Maximum Fragment Length in the SSL object passed in the 'ssl' parameter. It means that the Maximum Fragment Length extension will be sent on ClientHello by wolfSSL clients.

Parameters:

- **ssl** pointer to a SSL object, created with wolfSSL_new().
- **mfl** indicates which is the Maximum Fragment Length requested for the session. The available options are: enum { WOLFSSL_MFL_2_9 = 1, 512 bytes WOLFSSL_MFL_2_10 = 2, 1024 bytes WOLFSSL_MFL_2_11 = 3, 2048 bytes WOLFSSL_MFL_2_12 = 4, 4096 bytes WOLFSSL_MFL_2_13 = 5, 8192 bytes wolfSSL ONLY!!! };

See:

- wolfSSL_new
- wolfSSL_CTX_UseMaxFragment

Return:

- SSL_SUCCESS upon success.
- BAD_FUNC_ARG is the error that will be returned in one of these cases: ssl is NULL, mfl is out of range.
- MEMORY_E is the error returned when there is not enough memory.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx = 0;
WOLFSSL* ssl = 0;
ctx = wolfSSL_CTX_new(method);
if (ctx == NULL) {
    // context creation failed
}
ssl = wolfSSL_new(ctx);
if (ssl == NULL) {
    // ssl creation failed
}
ret = wolfSSL_UseMaxFragment(ssl, WOLFSSL_MFL_2_11);
if (ret != 0) {
    // max fragment usage failed
}
```

C.58.4.388 function wolfSSL_CTX_UseMaxFragment

```
int wolfSSL_CTX_UseMaxFragment(
    WOLFSSL_CTX * ctx,
    unsigned char mfl
)
```

This function is called on the client side to enable the use of Maximum Fragment Length for SSL objects created from the SSL context passed in the 'ctx' parameter. It means that the Maximum Fragment Length extension will be sent on ClientHello by wolfSSL clients.

Parameters:

- **ctx** pointer to a SSL context, created with wolfSSL_CTX_new().
- **mfl** indicates which is the Maximum Fragment Length requested for the session. The available options are: enum { WOLFSSL_MFL_2_9 = 1 512 bytes, WOLFSSL_MFL_2_10 = 2 1024 bytes, WOLFSSL_MFL_2_11 = 3 2048 bytes WOLFSSL_MFL_2_12 = 4 4096 bytes, WOLFSSL_MFL_2_13 = 5 8192 bytes wolfSSL ONLY!!!, WOLFSSL_MFL_2_13 = 6 256 bytes wolfSSL ONLY!!! };

See:

- wolfSSL_CTX_new
- wolfSSL_UseMaxFragment

Return:

- SSL_SUCCESS upon success.
- BAD_FUNC_ARG is the error that will be returned in one of these cases: ctx is NULL, mfl is out of range.
- MEMORY_E is the error returned when there is not enough memory.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx = 0;
ctx = wolfSSL_CTX_new(method);
if (ctx == NULL) {
    // context creation failed
}
ret = wolfSSL_CTX_UseMaxFragment(ctx, WOLFSSL_MFL_2_11);
if (ret != 0) {
    // max fragment usage failed
}
```

C.58.4.389 function wolfSSL_UseTruncatedHMAC

```
int wolfSSL_UseTruncatedHMAC(
    WOLFSSL * ssl
)
```

This function is called on the client side to enable the use of Truncated HMAC in the SSL object passed in the 'ssl' parameter. It means that the Truncated HMAC extension will be sent on ClientHello by wolfSSL clients.

Parameters:

- **ssl** pointer to a SSL object, created with wolfSSL_new()

See:

- wolfSSL_new
- wolfSSL_CTX_UseMaxFragment

Return:

- SSL_SUCCESS upon success.
- BAD_FUNC_ARG is the error that will be returned in one of these cases: ssl is NULL
- MEMORY_E is the error returned when there is not enough memory.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx = 0;
WOLFSSL* ssl = 0;
ctx = wolfSSL_CTX_new(method);
if (ctx == NULL) {
    // context creation failed
}
ssl = wolfSSL_new(ctx);
if (ssl == NULL) {
```

```
    // ssl creation failed
}
ret = wolfSSL_UseTruncatedHMAC(ssl);
if (ret != 0) {
    // truncated HMAC usage failed
}
```

C.58.4.390 function wolfSSL_CTX_UseTruncatedHMAC

```
int wolfSSL_CTX_UseTruncatedHMAC(
    WOLFSSL_CTX * ctx
)
```

This function is called on the client side to enable the use of Truncated HMAC for SSL objects created from the SSL context passed in the 'ctx' parameter. It means that the Truncated HMAC extension will be sent on ClientHello by wolfSSL clients.

Parameters:

- **ctx** pointer to a SSL context, created with wolfSSL_CTX_new().

See:

- wolfSSL_CTX_new
- wolfSSL_UseMaxFragment

Return:

- SSL_SUCCESS upon success.
- BAD_FUNC_ARG is the error that will be returned in one of these cases: ctx is NULL
- MEMORY_E is the error returned when there is not enough memory.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx = 0;
ctx = wolfSSL_CTX_new(method);
if (ctx == NULL) {
    // context creation failed
}
ret = wolfSSL_CTX_UseTruncatedHMAC(ctx);
if (ret != 0) {
    // truncated HMAC usage failed
}
```

C.58.4.391 function wolfSSL_UseOCSPStapling

```
int wolfSSL_UseOCSPStapling(
    WOLFSSL * ssl,
    unsigned char status_type,
    unsigned char options
)
```

Stapling eliminates the need to contact the CA. Stapling lowers the cost of certificate revocation check presented in OCSP.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

- **status_type** a byte type that is passed through to TLSX_UseCertificateStatusRequest() and stored in the CertificateStatusRequest structure.
- **options** a byte type that is passed through to TLSX_UseCertificateStatusRequest() and stored in the CertificateStatusRequest structure.

See:

- TLSX_UseCertificateStatusRequest
- wolfSSL_CTX_UseOCSPStapling

Return:

- SSL_SUCCESS returned if TLSX_UseCertificateStatusRequest executes without error.
- MEMORY_E returned if there is an error with the allocation of memory.
- BAD_FUNC_ARG returned if there is an argument that has a NULL or otherwise unacceptable value passed into the function.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
…
if (wolfSSL_UseOCSPStapling(ssl, WOLFSSL_CSR2_OCSP,
WOLFSSL_CSR2_OCSP_USE_NONCE) != SSL_SUCCESS){
    // Failed case.
}
```

C.58.4.392 function wolfSSL_CTX_UseOCSPStapling

```
int wolfSSL_CTX_UseOCSPStapling(
    WOLFSSL_CTX * ctx,
    unsigned char status_type,
    unsigned char options
)
```

This function requests the certificate status during the handshake.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().
- **status_type** a byte type that is passed through to TLSX_UseCertificateStatusRequest() and stored in the CertificateStatusRequest structure.
- **options** a byte type that is passed through to TLSX_UseCertificateStatusRequest() and stored in the CertificateStatusRequest structure.

See:

- wolfSSL_UseOCSPStaplingV2
- wolfSSL_UseOCSPStapling
- TLSX_UseCertificateStatusRequest

Return:

- SSL_SUCCESS returned if the function and subroutines execute without error.
- BAD_FUNC_ARG returned if the WOLFSSL_CTX structure is NULL or otherwise if a unpermitted value is passed to a subroutine.
- MEMORY_E returned if the function or subroutine failed to properly allocate memory.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
byte statusRequest = 0; // Initialize status request
```

```
…
switch(statusRequest){
    case WOLFSSL_CSR_OCSP:
        if(wolfSSL_CTX_UseOCSPStapling(ssl->ctx, WOLFSSL_CSR_OCSP,
WOLF_CSR_OCSP_USE_NONCE) != SSL_SUCCESS){
// UseCertificateStatusRequest failed
}
// Continue switch cases
```

C.58.4.393 function wolfSSL_UseOCSPStaplingV2

```
int wolfSSL_UseOCSPStaplingV2(
    WOLFSSL * ssl,
    unsigned char status_type,
    unsigned char options
)
```

The function sets the status type and options for OCSP.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **status_type** a byte type that loads the OCSP status type.
- **options** a byte type that holds the OCSP options, set in wolfSSL_SNI_SetOptions() and wolfSSL_CTX_SNI_SetOptions().

See:

- TLSX_UseCertificatStatusRequestV2
- wolfSSL_SNI_SetOptions
- wolfSSL_CTX_SNI_SetOptions

Return:

- SSL_SUCCESS - returned if the function and subroutines executed without error.
- MEMORY_E - returned if there was an allocation of memory error.
- BAD_FUNC_ARG - returned if a NULL or otherwise unaccepted argument was passed to the function or a subroutine.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
...
if (wolfSSL_UseOCSPStaplingV2(ssl, WOLFSSL_CSR2_OCSP_MULTI, 0) != SSL_SUCCESS){
    // Did not execute properly. Failure case code block.
}
```

C.58.4.394 function wolfSSL_CTX_UseOCSPStaplingV2

```
int wolfSSL_CTX_UseOCSPStaplingV2(
    WOLFSSL_CTX * ctx,
    unsigned char status_type,
    unsigned char options
)
```

Creates and initializes the certificate status request for OCSP Stapling.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().

- **status_type** a byte type that is located in the CertificatStatusRequest structure and must be either WOLFSSL_CSR2_OCSP or WOLFSSL_CSR2_OCSP_MULTI.
- **options** a byte type that will be held in CertificateStatusRequestItemV2 struct.

See:

- TLSX_UseCertificateStatusRequestV2
- wc_RNG_GenerateBlock
- TLSX_Push

Return:

- SSL_SUCCESS if the function and subroutines executed without error.
- BAD_FUNC_ARG returned if the WOLFSSL_CTX structure is NULL or if the side variable is not client side.
- MEMORY_E returned if the allocation of memory failed.

Example

```
WOLFSSL_CTX* ctx  = wolfSSL_CTX_new( protocol method );
byte status_type;
byte options;
...
if(wolfSSL_CTX_UseOCSPStaplingV2(ctx, status_type, options); != SSL_SUCCESS){
    // Failure case.
}
```

C.58.4.395 function wolfSSL_UseSupportedCurve

```
int wolfSSL_UseSupportedCurve(
    WOLFSSL * ssl,
    word16 name
)
```

This function is called on the client side to enable the use of Supported Elliptic Curves Extension in the SSL object passed in the 'ssl' parameter. It means that the supported curves enabled will be sent on ClientHello by wolfSSL clients. This function can be called more than one time to enable multiple curves.

Parameters:

- **ssl** pointer to a SSL object, created with wolfSSL_new().
- **name** indicates which curve will be supported for the session. The available options are: enum { WOLFSSL_ECC_SECP160R1 = 0x10, WOLFSSL_ECC_SECP192R1 = 0x13, WOLFSSL_ECC_SECP224R1 = 0x15, WOLFSSL_ECC_SECP256R1 = 0x17, WOLFSSL_ECC_SECP384R1 = 0x18, WOLFSSL_ECC_SECP521R1 = 0x19 };

See:

- wolfSSL_CTX_new
- wolfSSL_CTX_UseSupportedCurve

Return:

- SSL_SUCCESS upon success.
- BAD_FUNC_ARG is the error that will be returned in one of these cases: ssl is NULL, name is a unknown value. (see below)
- MEMORY_E is the error returned when there is not enough memory.
- SSL_FAILURE will be returned when TLS is not compiled in.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx = 0;
WOLFSSL* ssl = 0;
ctx = wolfSSL_CTX_new(method);
if (ctx == NULL) {
    // context creation failed
}
ssl = wolfSSL_new(ctx);
if (ssl == NULL) {
    // ssl creation failed
}
ret = wolfSSL_UseSupportedCurve(ssl, WOLFSSL_ECC_SECP256R1);
if (ret != 0) {
    // Elliptic Curve Extension usage failed
}
```

C.58.4.396 function wolfSSL_CTX_UseSupportedCurve

```
int wolfSSL_CTX_UseSupportedCurve(
    WOLFSSL_CTX * ctx,
    word16 name
)
```

This function is called on the client side to enable the use of Supported Elliptic Curves Extension for SSL objects created from the SSL context passed in the 'ctx' parameter. It means that the supported curves enabled will be sent on ClientHello by wolfSSL clients. This function can be called more than one time to enable multiple curves.

Parameters:

- **ctx** pointer to a SSL context, created with wolfSSL_CTX_new().
- **name** indicates which curve will be supported for the session. The available options are: enum { WOLFSSL_ECC_SECP160R1 = 0x10, WOLFSSL_ECC_SECP192R1 = 0x13, WOLFSSL_ECC_SECP224R1 = 0x15, WOLFSSL_ECC_SECP256R1 = 0x17, WOLFSSL_ECC_SECP384R1 = 0x18, WOLFSSL_ECC_SECP521R1 = 0x19 };

See:

- wolfSSL_CTX_new
- wolfSSL_UseSupportedCurve

Return:

- SSL_SUCCESS upon success.
- BAD_FUNC_ARG is the error that will be returned in one of these cases: ctx is NULL, name is a unknown value. (see below)
- MEMORY_E is the error returned when there is not enough memory.
- SSL_FAILURE will be returned when TLS is not compiled in.

Example

```
int ret = 0;
WOLFSSL_CTX* ctx = 0;
ctx = wolfSSL_CTX_new(method);
if (ctx == NULL) {
    // context creation failed
}
ret = wolfSSL_CTX_UseSupportedCurve(ctx, WOLFSSL_ECC_SECP256R1);
if (ret != 0) {
```

```
    // Elliptic Curve Extension usage failed
}
```

C.58.4.397 function wolfSSL_UseSecureRenegotiation

```
int wolfSSL_UseSecureRenegotiation(
    WOLFSSL * ssl
)
```

This function forces secure renegotiation for the supplied WOLFSSL structure. This is not recommended.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- TLSX_Find
- TLSX_UseSecureRenegotiation

Return:

- SSL_SUCCESS Successfully set secure renegotiation.
- BAD_FUNC_ARG Returns error if ssl is null.
- MEMORY_E Returns error if unable to allocate memory for secure renegotiation.

Example

```
wolfSSL_Init();
WOLFSSL_CTX* ctx;
WOLFSSL* ssl;
WOLFSSL_METHOD method = // Some wolfSSL method
ctx = wolfSSL_CTX_new(method);
ssl = wolfSSL_new(ctx);

if(wolfSSL_UseSecureRenegotiation(ssl) != SSL_SUCCESS)
{
    // Error setting secure renegotiation
}
```

C.58.4.398 function wolfSSL_Rehandshake

```
int wolfSSL_Rehandshake(
    WOLFSSL * ssl
)
```

This function executes a secure renegotiation handshake; this is user forced as wolfSSL discourages this functionality.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_negotiate
- wc_InitSha512
- wc_InitSha384
- wc_InitSha256
- wc_InitSha

- wc_InitMd5

Return:

- SSL_SUCCESS returned if the function executed without error.
- BAD_FUNC_ARG returned if an unacceptable argument was passed in a subroutine.
- SECURE_RENEGOTIATION_E returned if there was an error with renegotiating the handshake.
- SSL_FATAL_ERROR returned if there was an error with the server or client configuration and the renegotiation could not be completed. See wolfSSL_negotiate().
- SSL_FAILURE will be returned when ssl is NULL.

If decrypted application data is waiting to be read, the renegotiation is not continued and wolfSSL_get_error() returns APP_DATA_READY. Read the data with wolfSSL_read(), which also moves the renegotiation forward, or call wolfSSL_Rehandshake() again once it has been read.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
...
if(wolfSSL_Rehandshake(ssl) != SSL_SUCCESS){
    // There was an error and the rehandshake is not successful.
}
```

C.58.4.399 function wolfSSL_UseSessionTicket

```
int wolfSSL_UseSessionTicket(
    WOLFSSL * ssl
)
```

Force provided WOLFSSL structure to use session ticket. The constant HAVE_SESSION_TICKET should be defined and the constant NO_WOLFSSL_CLIENT should not be defined to use this function.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See: TLSX_UseSessionTicket

Return:

- SSL_SUCCESS Successfully set use session ticket.
- BAD_FUNC_ARG Returned if ssl is null.
- MEMORY_E Error allocating memory for setting session ticket.

Example

```
wolfSSL_Init();
WOLFSSL_CTX* ctx;
WOLFSSL* ssl;
WOLFSSL_METHOD method = // Some wolfSSL method
ctx = wolfSSL_CTX_new(method);
ssl = wolfSSL_new(ctx);

if(wolfSSL_UseSessionTicket(ssl) != SSL_SUCCESS)
{
    // Error setting session ticket
}
```

C.58.4.400 function wolfSSL_CTX_UseSessionTicket

```
int wolfSSL_CTX_UseSessionTicket(
    WOLFSSL_CTX * ctx
)
```

This function sets wolfSSL context to use a session ticket.

Parameters:

- **ctx** The WOLFSSL_CTX structure to use.

See: TLSX_UseSessionTicket

Return:

- SSL_SUCCESS Function executed successfully.
- BAD_FUNC_ARG Returned if ctx is null.
- MEMORY_E Error allocating memory in internal function.

Example

```
wolfSSL_Init();
WOLFSSL_CTX* ctx;
WOLFSSL_METHOD method = // Some wolfSSL method ;
ctx = wolfSSL_CTX_new(method);

if(wolfSSL_CTX_UseSessionTicket(ctx) != SSL_SUCCESS)
{
    // Error setting session ticket
}
```

C.58.4.401 function wolfSSL_get_SessionTicket

```
int wolfSSL_get_SessionTicket(
    WOLFSSL * ssl,
    unsigned char * buf,
    word32 * bufSz
)
```

This function copies the ticket member of the Session structure to the buffer. If buf is NULL and bufSz is non-NULL, bufSz will be set to the ticket length.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **buf** a byte pointer representing the memory buffer.
- **bufSz** a word32 pointer representing the buffer size.

See:

- wolfSSL_UseSessionTicket
- wolfSSL_set_SessionTicket

Return:

- SSL_SUCCESS returned if the function executed without error.
- BAD_FUNC_ARG returned if ssl or bufSz is NULL, or if bufSz is non-NULL and buf is NULL
- LENGTH_ONLY_E will be returned when buf is NULL, with the required length returned through bufSz.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
WOLFSSL* ssl = wolfSSL_new(ctx);
byte* buf;
word32 bufSz;  // Initialize with buf size
…
if(wolfSSL_get_SessionTicket(ssl, buf, bufSz) <= 0){
    // Nothing was written to the buffer
} else {
    // the buffer holds the content from ssl->session->ticket
}
```

C.58.4.402 function wolfSSL_set_SessionTicket

```
int wolfSSL_set_SessionTicket(
    WOLFSSL * ssl,
    const unsigned char * buf,
    word32 bufSz
)
```

This function sets the ticket member of the WOLFSSL_SESSION structure within the WOLFSSL struct. The buffer passed into the function is copied to memory.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **buf** a byte pointer that gets loaded into the ticket member of the session structure.
- **bufSz** a word32 type that represents the size of the buffer.

See: wolfSSL_set_SessionTicket_cb

Return:

- SSL_SUCCESS returned on successful execution of the function. The function returned without errors.
- BAD_FUNC_ARG returned if the WOLFSSL structure is NULL. This will also be thrown if the buf argument is NULL but the bufSz argument is not zero.
- MEMORY_ERROR will be returned when the ticket cannot be allocated.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
WOLFSSL* ssl = wolfSSL_new(ctx);
byte* buffer; // File to load
word32 bufSz;
...
if(wolfSSL_KeepArrays(ssl, buffer, bufSz) != SSL_SUCCESS){
    // There was an error loading the buffer to memory.
}
```

C.58.4.403 function wolfSSL_set_SessionTicket_cb

```
int wolfSSL_set_SessionTicket_cb(
    WOLFSSL * ssl,
    CallbackSessionTicket cb,
    void * ctx
)
```

This function sets the session ticket callback. The type CallbackSessionTicket is a function pointer with the signature of: int (*CallbackSessionTicket)(WOLFSSL*, const unsigned char*, int, void*)

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **cb** a function pointer to the type CallbackSessionTicket.
- **ctx** a void pointer to the session_ticket_ctx member of the WOLFSSL structure.

See:

- wolfSSL_get_SessionTicket
- CallbackSessionTicket
- sessionTicketCB

Return:

- SSL_SUCCESS returned if the function executed without error.
- BAD_FUNC_ARG returned if the WOLFSSL structure is NULL.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
…
int sessionTicketCB(WOLFSSL* ssl, const unsigned char* ticket, int ticketSz,
            void* ctx){ … }
wolfSSL_set_SessionTicket_cb(ssl, sessionTicketCB, (void*)"initial session");
```

C.58.4.404 function wolfSSL_send_SessionTicket

```
int wolfSSL_send_SessionTicket(
    WOLFSSL * ssl
)
```

This function sends a session ticket to the client after a TLS v1.3 handhsake has been established.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_get_SessionTicket
- CallbackSessionTicket
- sessionTicketCB

Return:

- WOLFSSL_SUCCESS returned if a new session ticket was sent.
- BAD_FUNC_ARG returned if WOLFSSL structure is NULL, or not using TLS v1.3.
- SIDE_ERROR returned if not a server.
- NOT_READY_ERROR returned if the handshake has not completed.
- WOLFSSL_FATAL_ERROR returned if creating or sending message fails.

Example

```
int ret;
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
…
ret = wolfSSL_send_SessionTicket(ssl);
if (ret != WOLFSSL_SUCCESS) {
    // New session ticket not sent.
}
```

C.58.4.405 function wolfSSL_CTX_set_TicketEncCb

```
int wolfSSL_CTX_set_TicketEncCb(
    WOLFSSL_CTX * ctx,
    SessionTicketEncCb cb
)
```

This function sets the session ticket key encrypt callback function for a server to support session tickets as specified in RFC 5077.

Parameters:

- **ctx** pointer to the WOLFSSL_CTX object, created with wolfSSL_CTX_new().
- **cb** user callback function to encrypt/decrypt session tickets
- **ssl(Callback)** pointer to the WOLFSSL object, created with wolfSSL_new()
- **key_name(Callback)** unique key name for this ticket context, should be randomly generated
- **iv(Callback)** unique IV for this ticket, up to 128 bits, should be randomly generated
- **mac(Callback)** up to 256 bit mac for this ticket
- **enc(Callback)** if this encrypt parameter is true the user should fill in key_name, iv, mac, and encrypt the ticket in-place of length inLen and set the resulting output length in *outLen. Returning WOLFSSL_TICKET_RET_OK tells wolfSSL that the encryption was successful. If this encrypt parameter is false, the user should perform a decrypt of the ticket in-place of length inLen using key_name, iv, and mac. The resulting decrypt length should be set in* outLen. Returning WOLFSSL_TICKET_RET_OK tells wolfSSL to proceed using the decrypted ticket. Returning WOLFSSL_TICKET_RET_CREATE tells wolfSSL to use the decrypted ticket but also to generate a new one to send to the client, helpful if recently rolled keys and don't want to force a full handshake. Returning WOLFSSL_TICKET_RET_REJECT tells wolfSSL to reject this ticket, perform a full handshake, and create a new standard session ID for normal session resumption. Returning WOLFSSL_TICKET_RET_FATAL tells wolfSSL to end the connection attempt with a fatal error.
- **ticket(Callback)** the input/output buffer for the encrypted ticket. See the enc parameter
- **inLen(Callback)** the input length of the ticket parameter
- **outLen(Callback)** the resulting output length of the ticket parameter. When entering the callback outLen will indicate the maximum size available in the ticket buffer.
- **userCtx(Callback)** the user context set with wolfSSL_CTX_set_TicketEncCtx()

See:

- wolfSSL_CTX_set_TicketHint
- wolfSSL_CTX_set_TicketEncCtx

Return:

- SSL_SUCCESS will be returned upon successfully setting the session.
- BAD_FUNC_ARG will be returned on failure. This is caused by passing invalid arguments to the function.

Example

```
See wolfssl/test.h myTicketEncCb() used by the example
server and example echoserver.
```

C.58.4.406 function wolfSSL_CTX_set_TicketHint

```
int wolfSSL_CTX_set_TicketHint(
    WOLFSSL_CTX * ctx,
    int hint
)
```

This function sets the session ticket hint relayed to the client. For server side use.

Parameters:

- **ctx** pointer to the WOLFSSL_CTX object, created with wolfSSL_CTX_new().
- **hint** number of seconds the ticket might be valid for. Hint to client.

See: wolfSSL_CTX_set_TicketEncCb

Return:

- SSL_SUCCESS will be returned upon successfully setting the session.
- BAD_FUNC_ARG will be returned on failure. This is caused by passing invalid arguments to the function.

Example

none

C.58.4.407 function wolfSSL_CTX_set_TicketEncCtx

```
int wolfSSL_CTX_set_TicketEncCtx(
    WOLFSSL_CTX * ctx,
    void * userCtx
)
```

This function sets the session ticket encrypt user context for the callback. For server side use.

Parameters:

- **ctx** pointer to the WOLFSSL_CTX object, created with wolfSSL_CTX_new().
- **userCtx** the user context for the callback

See: wolfSSL_CTX_set_TicketEncCb

Return:

- SSL_SUCCESS will be returned upon successfully setting the session.
- BAD_FUNC_ARG will be returned on failure. This is caused by passing invalid arguments to the function.

Example

none

C.58.4.408 function wolfSSL_CTX_get_TicketEncCtx

```
void * wolfSSL_CTX_get_TicketEncCtx(
    WOLFSSL_CTX * ctx
)
```

This function gets the session ticket encrypt user context for the callback. For server side use.

Parameters:

- **ctx** pointer to the WOLFSSL_CTX object, created with wolfSSL_CTX_new().

See: wolfSSL_CTX_set_TicketEncCtx

Return:

- userCtx will be returned upon successfully getting the session.
- NULL will be returned on failure. This is caused by passing invalid arguments to the function, or when the user context has not been set.

Example

none

C.58.4.409 function wolfSSL_SetHsDoneCb

```
int wolfSSL_SetHsDoneCb(
    WOLFSSL * ssl,
    HandShakeDoneCb cb,
    void * user_ctx
)
```

This function sets the handshake done callback. The hsDoneCb and hsDoneCtx members of the WOLFSSL structure are set in this function.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **cb** a function pointer of type HandShakeDoneCb with the signature of the form: int (*HandShakeDoneCb)(WOLFSSL*, void*);
- **user_ctx** a void pointer to the user registered context.

See: HandShakeDoneCb

Return:

- SSL_SUCCESS returned if the function executed without an error. The hsDoneCb and hsDoneCtx members of the WOLFSSL struct are set.
- BAD_FUNC_ARG returned if the WOLFSSL struct is NULL.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
…
int myHsDoneCb(WOLFSSL* ssl, void* user_ctx){
    // callback function
}
…
wolfSSL_SetHsDoneCb(ssl, myHsDoneCb, NULL);
```

C.58.4.410 function wolfSSL_PrintSessionStats

```
int wolfSSL_PrintSessionStats(
    void
)
```

This function prints the statistics from the session.

Parameters:

- **none** No parameters.

See: wolfSSL_get_session_stats

Return:

- SSL_SUCCESS returned if the function and subroutines return without error. The session stats have been successfully retrieved and printed.
- BAD_FUNC_ARG returned if the subroutine wolfSSL_get_session_stats() was passed an unacceptable argument.
- BAD_MUTEX_E returned if there was a mutex error in the subroutine.

Example

```
// You will need to have a session object to retrieve stats from.
if(wolfSSL_PrintSessionStats(void) != SSL_SUCCESS   ){
    // Did not print session stats
}
```

C.58.4.411 function wolfSSL_get_session_stats

```
int wolfSSL_get_session_stats(
    unsigned int * active,
    unsigned int * total,
    unsigned int * peak,
    unsigned int * maxSessions
)
```

This function gets the statistics for the session.

Parameters:

- **active** a word32 pointer representing the total current sessions.
- **total** a word32 pointer representing the total sessions.
- **peak** a word32 pointer representing the peak sessions.
- **maxSessions** a word32 pointer representing the maximum sessions.

See: wolfSSL_PrintSessionStats

Return:

- SSL_SUCCESS returned if the function and subroutines return without error. The session stats have been successfully retrieved and printed.
- BAD_FUNC_ARG returned if the subroutine wolfSSL_get_session_stats() was passed an unacceptable argument.
- BAD_MUTEX_E returned if there was a mutex error in the subroutine.

Example

```
int wolfSSL_PrintSessionStats(void){
…
ret = wolfSSL_get_session_stats(&totalSessionsNow,
&totalSessionsSeen, &peak, &maxSessions);
…
return ret;
```

C.58.4.412 function wolfSSL_MakeTlsMasterSecret

```
int wolfSSL_MakeTlsMasterSecret(
    unsigned char * ms,
    word32 msLen,
    const unsigned char * pms,
    word32 pmsLen,
    const unsigned char * cr,
    const unsigned char * sr,
    int tls1_2,
    int hash_type
)
```

This function copies the values of cr and sr then passes through to wc_PRF (pseudo random function) and returns that value.

Parameters:

- **ms** the master secret held in the Arrays structure.
- **msLen** the length of the master secret.
- **pms** the pre-master secret held in the Arrays structure.
- **pmsLen** the length of the pre-master secret.
- **cr** the client random.
- **sr** the server random.
- **tls1_2** signifies that the version is at least tls version 1.2.
- **hash_type** signifies the hash type.

See:

- wc_PRF
- MakeTlsMasterSecret

Return:

- 0 on success
- BUFFER_E returned if there will be an error with the size of the buffer.
- MEMORY_E returned if a subroutine failed to allocate dynamic memory.

Example

```
WOLFSSL* ssl;

called in MakeTlsMasterSecret and retrieves the necessary
information as follows:

int MakeTlsMasterSecret(WOLFSSL* ssl){
int ret;
ret = wolfSSL_makeTlsMasterSecret(ssl->arrays->masterSecret, SECRET_LEN,
ssl->arrays->preMasterSecret, ssl->arrays->preMasterSz,
ssl->arrays->clientRandom, ssl->arrays->serverRandom,
IsAtLeastTLSv1_2(ssl), ssl->specs.mac_algorithm);
…
return ret;

}
```

C.58.4.413 function wolfSSL_DeriveTlsKeys

```
int wolfSSL_DeriveTlsKeys(
    unsigned char * key_data,
    word32 keyLen,
    const unsigned char * ms,
    word32 msLen,
    const unsigned char * sr,
    const unsigned char * cr,
    int tls1_2,
    int hash_type
)
```

An external facing wrapper to derive TLS Keys.

Parameters:

- **key_data** a byte pointer that is allocateded in DeriveTlsKeys and passed through to wc_PRF to hold the final hash.
- **keyLen** a word32 type that is derived in DeriveTlsKeys from the WOLFSSL structure's specs member.

- **ms** a constant pointer type holding the master secret held in the arrays structure within the WOLFSSL structure.
- **msLen** a word32 type that holds the length of the master secret in an enumerated define, SECRET_LEN.
- **sr** a constant byte pointer to the serverRandom member of the arrays structure within the WOLFSSL structure.
- **cr** a constant byte pointer to the clientRandom member of the arrays structure within the WOLFSSL structure.
- **tls1_2** an integer type returned from IsAtLeastTLSv1_2().
- **hash_type** an integer type held in the WOLFSSL structure.

See:

- wc_PRF
- DeriveTlsKeys
- IsAtLeastTLSv1_2

Return:

- 0 returned on success.
- BUFFER_E returned if the sum of labLen and seedLen (computes total size) exceeds the maximum size.
- MEMORY_E returned if the allocation of memory failed.

Example

```
int DeriveTlsKeys(WOLFSSL* ssl){
int ret;
…
ret = wolfSSL_DeriveTlsKeys(key_data, length, ssl->arrays->masterSecret,
SECRET_LEN, ssl->arrays->clientRandom,
IsAtLeastTLSv1_2(ssl), ssl->specs.mac_algorithm);
…
}
```

C.58.4.414 function wolfSSL_connect_ex

```
int wolfSSL_connect_ex(
    WOLFSSL * ssl,
    HandShakeCallBack hsCb,
    TimeoutCallBack toCb,
    WOLFSSL_TIMEVAL timeout
)
```

wolfSSL_connect_ex() is an extension that allows a HandShake Callback to be set. This can be useful in embedded systems for debugging support when a debugger isn't available and sniffing is impractical. The HandShake Callback will be called whether or not a handshake error occurred. No dynamic memory is used since the maximum number of SSL packets is known. Packet names can be accessed through packetNames[]. The connect extension also allows a Timeout Callback to be set along with a timeout value. This is useful if the user doesn't want to wait for the TCP stack to timeout. This extension can be called with either, both, or neither callbacks.

Parameters:

- **ssl** pointer to a WOLFSSL structure, created using wolfSSL_new().
- **hsCb** HandShake Callback function pointer.
- **toCb** Timeout Callback function pointer.
- **timeout** timeout value to use with the Timeout Callback.

See: wolfSSL_accept_ex

Return:

- SSL_SUCCESS upon success.
- GETTIME_ERROR will be returned if gettimeofday() encountered an error.
- SETITIMER_ERROR will be returned if setitimer() encountered an error.
- SIGACT_ERROR will be returned if sigaction() encountered an error.
- SSL_FATAL_ERROR will be returned if the underlying SSL_connect() call encountered an error.

Example

none

C.58.4.415 function wolfSSL_accept_ex

```
int wolfSSL_accept_ex(
    WOLFSSL * ssl,
    HandShakeCallBack hsCb,
    TimeoutCallBack toCb,
    WOLFSSL_TIMEVAL timeout
)
```

wolfSSL_accept_ex() is an extension that allows a HandShake Callback to be set. This can be useful in embedded systems for debugging support when a debugger isn't available and sniffing is impractical. The HandShake Callback will be called whether or not a handshake error occurred. No dynamic memory is used since the maximum number of SSL packets is known. Packet names can be accessed through packetNames[]. The connect extension also allows a Timeout Callback to be set along with a timeout value. This is useful if the user doesn't want to wait for the TCP stack to timeout. This extension can be called with either, both, or neither callbacks.

Parameters:

- **ssl** pointer to a WOLFSSL structure, created using wolfSSL_new().
- **hsCb** HandShake Callback function pointer.
- **toCb** Timeout Callback function pointer.
- **timeout** timeout value to use with the Timeout Callback.

See: wolfSSL_connect_ex

Return:

- SSL_SUCCESS upon success.
- GETTIME_ERROR will be returned if gettimeofday() encountered an error.
- SETITIMER_ERROR will be returned if setitimer() encountered an error.
- SIGACT_ERROR will be returned if sigaction() encountered an error.
- SSL_FATAL_ERROR will be returned if the underlying SSL_accept() call encountered an error.

Example

none

C.58.4.416 function wolfSSL_BIO_set_fp

```
long wolfSSL_BIO_set_fp(
    WOLFSSL_BIO * bio,
    XFILE fp,
    int c
)
```

This is used to set the internal file pointer for a BIO.

Parameters:

- **bio** WOLFSSL_BIO structure to set pair.
- **fp** file pointer to set in bio.
- **c** close file behavior flag.

See:

- wolfSSL_BIO_new
- wolfSSL_BIO_s_mem
- wolfSSL_BIO_get_fp
- wolfSSL_BIO_free

Return:

- SSL_SUCCESS On successfully setting file pointer.
- SSL_FAILURE If an error case was encountered.

Example

```
WOLFSSL_BIO* bio;
XFILE fp;
int ret;
bio  = wolfSSL_BIO_new(wolfSSL_BIO_s_file());
ret  = wolfSSL_BIO_set_fp(bio, fp, BIO_CLOSE);
// check ret value
```

C.58.4.417 function wolfSSL_BIO_get_fp

```
long wolfSSL_BIO_get_fp(
    WOLFSSL_BIO * bio,
    XFILE * fp
)
```

This is used to get the internal file pointer for a BIO.

Parameters:

- **bio** WOLFSSL_BIO structure to set pair.
- **fp** file pointer to set in bio.

See:

- wolfSSL_BIO_new
- wolfSSL_BIO_s_mem
- wolfSSL_BIO_set_fp
- wolfSSL_BIO_free

Return:

- SSL_SUCCESS On successfully getting file pointer.
- SSL_FAILURE If an error case was encountered.

Example

```
WOLFSSL_BIO* bio;
XFILE fp;
int ret;
bio  = wolfSSL_BIO_new(wolfSSL_BIO_s_file());
ret  = wolfSSL_BIO_get_fp(bio, &fp);
// check ret value
```

C.58.4.418 function wolfSSL_check_private_key

```
int wolfSSL_check_private_key(
    const WOLFSSL * ssl
)
```

This function checks that the private key is a match with the certificate being used.

Parameters:

- **ssl** WOLFSSL structure to check.

See:

- wolfSSL_new
- wolfSSL_free

Return:

- SSL_SUCCESS On successfully match.
- SSL_FAILURE If an error case was encountered.
- <0 All error cases other than SSL_FAILURE are negative values.

Example

```
WOLFSSL* ssl;
int ret;
// create and set up ssl
ret  = wolfSSL_check_private_key(ssl);
// check ret value
```

C.58.4.419 function wolfSSL_X509_get_ext_by_NID

```
int wolfSSL_X509_get_ext_by_NID(
    const WOLFSSL_X509 * x,
    int nid,
    int lastpos
)
```

This function looks for and returns the extension index matching the passed in NID value.

Parameters:

- **x** certificate to get parse through for extension.
- **nid** extension OID to be found.
- **lastpos** start search from extension after lastpos. Set to -1 initially.

Return:

- = 0 If successful the extension index is returned.
- -1 If extension is not found or error is encountered.

Example

```
const WOLFSSL_X509* x509;
int lastPos = -1;
int idx;

idx = wolfSSL_X509_get_ext_by_NID(x509, NID_basic_constraints, lastPos);
```

C.58.4.420 function wolfSSL_X509_get_ext_d2i

```
void * wolfSSL_X509_get_ext_d2i(
    const WOLFSSL_X509 * x509,
    int nid,
    int * c,
    int * idx
)
```

This function looks for and returns the extension matching the passed in NID value.

Parameters:

- **x509** certificate to get parse through for extension.
- **nid** extension OID to be found.
- **c** if not NULL is set to -2 for multiple extensions found -1 if not found, 0 if found and not critical and 1 if found and critical.
- **idx** if NULL return first extension matched otherwise if not stored in x509 start at idx.

See: wolfSSL_sk_ASN1_OBJECT_free

Return:

- pointer If successful a STACK_OF(WOLFSSL_ASN1_OBJECT) pointer is returned.
- NULL If extension is not found or error is encountered.

Example

```
const WOLFSSL_X509* x509;
int c;
int idx = 0;
STACK_OF(WOLFSSL_ASN1_OBJECT)* sk;

sk = wolfSSL_X509_get_ext_d2i(x509, NID_basic_constraints, &c, &idx);
//check sk for NULL and then use it. sk needs freed after done.
```

C.58.4.421 function wolfSSL_X509_digest

```
int wolfSSL_X509_digest(
    const WOLFSSL_X509 * x509,
    const WOLFSSL_EVP_MD * digest,
    unsigned char * buf,
    unsigned int * len
)
```

This function returns the hash of the DER certificate.

Parameters:

- **x509** certificate to get the hash of.
- **digest** the hash algorithm to use.
- **buf** buffer to hold hash.
- **len** length of buffer.

See: none

Return:

- SSL_SUCCESS On successfully creating a hash.
- SSL_FAILURE Returned on bad input or unsuccessful hash.

Example

```
WOLFSSL_X509* x509;
unsigned char buffer[64];
unsigned int bufferSz;
int ret;

ret = wolfSSL_X509_digest(x509, wolfSSL_EVP_sha256(), buffer, &bufferSz);
//check ret value
```

C.58.4.422 function wolfSSL_use_certificate

```
int wolfSSL_use_certificate(
    WOLFSSL * ssl,
    WOLFSSL_X509 * x509
)
```

his is used to set the certificate for WOLFSSL structure to use during a handshake.

Parameters:

- **ssl** WOLFSSL structure to set certificate in.
- **x509** certificate to use.

See:

- wolfSSL_new
- wolfSSL_free

Return:

- SSL_SUCCESS On successful setting argument.
- SSL_FAILURE If a NULL argument passed in.

Example

```
 WOLFSSL* ssl;
WOLFSSL_X509* x509
int ret;
// create ssl object and x509
ret  = wolfSSL_use_certificate(ssl, x509);
// check ret value
```

C.58.4.423 function wolfSSL_use_certificate_ASN1

```
int wolfSSL_use_certificate_ASN1(
    WOLFSSL * ssl,
    const unsigned char * der,
    int derSz
)
```

This is used to set the certificate for WOLFSSL structure to use during a handshake. A DER formatted buffer is expected.

Parameters:

- **ssl** WOLFSSL structure to set certificate in.
- **der** DER certificate to use.
- **derSz** size of the DER buffer passed in.

See:

- wolfSSL_new

- wolfSSL_free

Return:

- SSL_SUCCESS On successful setting argument.
- SSL_FAILURE If a NULL argument passed in.

Example

```
WOLFSSL* ssl;
unsigned char* der;
int derSz;
int ret;
// create ssl object and set DER variables
ret  = wolfSSL_use_certificate_ASN1(ssl, der, derSz);
// check ret value
```

C.58.4.424 function wolfSSL_use_PrivateKey

```
int wolfSSL_use_PrivateKey(
    WOLFSSL * ssl,
    WOLFSSL_EVP_PKEY * pkey
)
```

This is used to set the private key for the WOLFSSL structure.

Parameters:

- **ssl** WOLFSSL structure to set argument in.
- **pkey** private key to use.

See:

- wolfSSL_new
- wolfSSL_free

Return:

- SSL_SUCCESS On successful setting argument.
- SSL_FAILURE If a NULL ssl passed in. All error cases will be negative values.

Example

```
WOLFSSL* ssl;
WOLFSSL_EVP_PKEY* pkey;
int ret;
// create ssl object and set up private key
ret  = wolfSSL_use_PrivateKey(ssl, pkey);
// check ret value
```

C.58.4.425 function wolfSSL_use_PrivateKey_ASN1

```
int wolfSSL_use_PrivateKey_ASN1(
    int pri,
    WOLFSSL * ssl,
    const unsigned char * der,
    long derSz
)
```

This is used to set the private key for the WOLFSSL structure. A DER formatted key buffer is expected.

Parameters:

- **pri** type of private key.
- **ssl** WOLFSSL structure to set argument in.
- **der** buffer holding DER key.
- **derSz** size of der buffer.

See:

- wolfSSL_new
- wolfSSL_free
- wolfSSL_use_PrivateKey

Return:

- SSL_SUCCESS On successful setting parsing and setting the private key.
- SSL_FAILURE If an NULL ssl passed in. All error cases will be negative values.

Example

```
WOLFSSL* ssl;
unsigned char* pkey;
long pkeySz;
int ret;
// create ssl object and set up private key
ret  = wolfSSL_use_PrivateKey_ASN1(1, ssl, pkey, pkeySz);
// check ret value
```

C.58.4.426 function wolfSSL_use_RSAPrivateKey_ASN1

```
int wolfSSL_use_RSAPrivateKey_ASN1(
    WOLFSSL * ssl,
    unsigned char * der,
    long derSz
)
```

This is used to set the private key for the WOLFSSL structure. A DER formatted RSA key buffer is expected.

Parameters:

- **ssl** WOLFSSL structure to set argument in.
- **der** buffer holding DER key.
- **derSz** size of der buffer.

See:

- wolfSSL_new
- wolfSSL_free
- wolfSSL_use_PrivateKey

Return:

- SSL_SUCCESS On successful setting parsing and setting the private key.
- SSL_FAILURE If an NULL ssl passed in. All error cases will be negative values.

Example

```
WOLFSSL* ssl;
unsigned char* pkey;
long pkeySz;
int ret;
// create ssl object and set up RSA private key
```

```
ret  = wolfSSL_use_RSAPrivateKey_ASN1(ssl, pkey, pkeySz);
// check ret value
```

C.58.4.427 function wolfSSL_DSA_dup_DH

```
WOLFSSL_DH * wolfSSL_DSA_dup_DH(
    const WOLFSSL_DSA * r
)
```

This function duplicates the parameters in dsa to a newly created WOLFSSL_DH structure.

Parameters:

- **dsa** WOLFSSL_DSA structure to duplicate.

See: none

Return:

- WOLFSSL_DH If duplicated returns WOLFSSL_DH structure
- NULL upon failure

Example

```
WOLFSSL_DH* dh;
WOLFSSL_DSA* dsa;
// set up dsa
dh = wolfSSL_DSA_dup_DH(dsa);

// check dh is not null
```

C.58.4.428 function wolfSSL_SESSION_get_master_key

```
int wolfSSL_SESSION_get_master_key(
    const WOLFSSL_SESSION * ses,
    unsigned char * out,
    int outSz
)
```

This is used to get the master key after completing a handshake.

Parameters:

- **ses** WOLFSSL_SESSION structure to get master secret buffer from.
- **out** buffer to hold data.
- **outSz** size of out buffer passed in. (if 0 function will return max buffer size needed)

See:

- wolfSSL_new
- wolfSSL_free

Return:

- 0 On successfully getting data returns a value greater than 0
- 0 If no random data buffer or an error state returns 0
- max If outSz passed in is 0 then the maximum buffer size needed is returned

Example

```
WOLFSSL_SESSION ssl;
unsigned char* buffer;
size_t bufferSz;
size_t ret;
// complete handshake and get session structure
bufferSz  = wolfSSL_SESSION_get_master_secret(ses, NULL, 0);
buffer = malloc(bufferSz);
ret  = wolfSSL_SESSION_get_master_secret(ses, buffer, bufferSz);
// check ret value
```

C.58.4.429 function wolfSSL_SESSION_get_master_key_length

```
int wolfSSL_SESSION_get_master_key_length(
    const WOLFSSL_SESSION * ses
)
```

This is used to get the master secret key length.

Parameters:

- **ses** WOLFSSL_SESSION structure to get master secret buffer from.

See:

- wolfSSL_new
- wolfSSL_free

Return: size Returns master secret key size.

Example

```
WOLFSSL_SESSION ssl;
unsigned char* buffer;
size_t bufferSz;
size_t ret;
// complete handshake and get session structure
bufferSz  = wolfSSL_SESSION_get_master_secret_length(ses);
buffer = malloc(bufferSz);
// check ret value
```

C.58.4.430 function wolfSSL_CTX_set_cert_store

```
void wolfSSL_CTX_set_cert_store(
    WOLFSSL_CTX * ctx,
    WOLFSSL_X509_STORE * str
)
```

This is a setter function for the WOLFSSL_X509_STORE structure in ctx.

Parameters:

- **ctx** pointer to the WOLFSSL_CTX structure for setting cert store pointer.
- **str** pointer to the WOLFSSL_X509_STORE to set in ctx.

See:

- wolfSSL_CTX_new
- wolfSSL_CTX_free

Return: none No return.

Example

```
WOLFSSL_CTX ctx;
WOLFSSL_X509_STORE* st;
// setup ctx and st
st = wolfSSL_CTX_set_cert_store(ctx, st);
//use st
```

C.58.4.431 function wolfSSL_d2i_X509_bio

```
WOLFSSL_X509 * wolfSSL_d2i_X509_bio(
    WOLFSSL_BIO * bio,
    WOLFSSL_X509 ** x509
)
```

This function get the DER buffer from bio and converts it to a WOLFSSL_X509 structure.

Parameters:

- **bio** pointer to the WOLFSSL_BIO structure that has the DER certificate buffer.
- **x509** pointer that get set to new WOLFSSL_X509 structure created.

See: none

Return:

- pointer returns a WOLFSSL_X509 structure pointer on success.
- Null returns NULL on failure

Example

```
WOLFSSL_BIO* bio;
WOLFSSL_X509* x509;
// load DER into bio
x509 = wolfSSL_d2i_X509_bio(bio, NULL);
Or
wolfSSL_d2i_X509_bio(bio, &x509);
// use x509 returned (check for NULL)
```

C.58.4.432 function wolfSSL_CTX_get_cert_store

```
WOLFSSL_X509_STORE * wolfSSL_CTX_get_cert_store(
    WOLFSSL_CTX * ctx
)
```

This is a getter function for the WOLFSSL_X509_STORE structure in ctx.

Parameters:

- **ctx** pointer to the WOLFSSL_CTX structure for getting cert store pointer.

See:

- wolfSSL_CTX_new
- wolfSSL_CTX_free
- wolfSSL_CTX_set_cert_store

Return:

- WOLFSSL_X509_STORE* On successfully getting the pointer.
- NULL Returned if NULL arguments are passed in.

Example

```
WOLFSSL_CTX ctx;
WOLFSSL_X509_STORE* st;
// setup ctx
st = wolfSSL_CTX_get_cert_store(ctx);
//use st
```

C.58.4.433 function wolfSSL_BIO_ctrl_pending

```
size_t wolfSSL_BIO_ctrl_pending(
    WOLFSSL_BIO * b
)
```

Gets the number of pending bytes to read. If BIO type is BIO_BIO then is the number to read from pair. If BIO contains an SSL object then is pending data from SSL object (wolfSSL_pending(ssl)). If is BIO_MEMORY type then returns the size of memory buffer.

Parameters:

- **bio** pointer to the WOLFSSL_BIO structure that has already been created.

See:

- wolfSSL_BIO_make_bio_pair
- wolfSSL_BIO_new

Return: >=0 number of pending bytes.

Example

```
WOLFSSL_BIO* bio;
int pending;
bio = wolfSSL_BIO_new();
…
pending = wolfSSL_BIO_ctrl_pending(bio);
```

C.58.4.434 function wolfSSL_get_server_random

```
size_t wolfSSL_get_server_random(
    const WOLFSSL * ssl,
    unsigned char * out,
    size_t outlen
)
```

This is used to get the random data sent by the server during the handshake.

Parameters:

- **ssl** WOLFSSL structure to get clients random data buffer from.
- **out** buffer to hold random data.
- **outSz** size of out buffer passed in. (if 0 function will return max buffer size needed)

See:

- wolfSSL_new
- wolfSSL_free

Return:

- 0 On successfully getting data returns a value greater than 0
- 0 If no random data buffer or an error state returns 0
- max If outSz passed in is 0 then the maximum buffer size needed is returned

Example

```
WOLFSSL ssl;
unsigned char* buffer;
size_t bufferSz;
size_t ret;
bufferSz  = wolfSSL_get_server_random(ssl, NULL, 0);
buffer = malloc(bufferSz);
ret  = wolfSSL_get_server_random(ssl, buffer, bufferSz);
// check ret value
```

C.58.4.435 function wolfSSL_get_client_random

```
size_t wolfSSL_get_client_random(
    const WOLFSSL * ssl,
    unsigned char * out,
    size_t outSz
)
```

This is used to get the random data sent by the client during the handshake.

Parameters:

- **ssl** WOLFSSL structure to get clients random data buffer from.
- **out** buffer to hold random data.
- **outSz** size of out buffer passed in. (if 0 function will return max buffer size needed)

See:

- wolfSSL_new
- wolfSSL_free

Return:

- 0 On successfully getting data returns a value greater than 0
- 0 If no random data buffer or an error state returns 0
- max If outSz passed in is 0 then the maximum buffer size needed is returned

Example

```
WOLFSSL ssl;
unsigned char* buffer;
size_t bufferSz;
size_t ret;
bufferSz  = wolfSSL_get_client_random(ssl, NULL, 0);
buffer = malloc(bufferSz);
ret  = wolfSSL_get_client_random(ssl, buffer, bufferSz);
// check ret value
```

C.58.4.436 function wolfSSL_CTX_get_default_passwd_cb

```
wc_pem_password_cb * wolfSSL_CTX_get_default_passwd_cb(
    WOLFSSL_CTX * ctx
)
```

This is a getter function for the password callback set in ctx.

Parameters:

- **ctx** WOLFSSL_CTX structure to get call back from.

See:

- wolfSSL_CTX_new
- wolfSSL_CTX_free

Return:

- func On success returns the callback function.
- NULL If ctx is NULL then NULL is returned.

Example

```
WOLFSSL_CTX* ctx;
wc_pem_password_cb cb;
// setup ctx
cb = wolfSSL_CTX_get_default_passwd_cb(ctx);
//use cb
```

C.58.4.437 function wolfSSL_CTX_get_default_passwd_cb_userdata

```
void * wolfSSL_CTX_get_default_passwd_cb_userdata(
    WOLFSSL_CTX * ctx
)
```

This is a getter function for the password callback user data set in ctx.

Parameters:

- **ctx** WOLFSSL_CTX structure to get user data from.

See:

- wolfSSL_CTX_new
- wolfSSL_CTX_free

Return:

- pointer On success returns the user data pointer.
- NULL If ctx is NULL then NULL is returned.

Example

```
WOLFSSL_CTX* ctx;
void* data;
// setup ctx
data = wolfSSL_CTX_get_default_passwd_cb(ctx);
//use data
```

C.58.4.438 function wolfSSL_PEM_read_bio_X509_AUX

```
WOLFSSL_X509 * wolfSSL_PEM_read_bio_X509_AUX(
    WOLFSSL_BIO * bp,
    WOLFSSL_X509 ** x,
    wc_pem_password_cb * cb,
    void * u
)
```

This function behaves the same as wolfSSL_PEM_read_bio_X509. AUX signifies containing extra information such as trusted/rejected use cases and friendly name for human readability.

Parameters:

- **bp** WOLFSSL_BIO structure to get PEM buffer from.

- **x** if setting WOLFSSL_X509 by function side effect.
- **cb** password callback.
- **u** NULL terminated user password.

See: wolfSSL_PEM_read_bio_X509

Return:

- WOLFSSL_X509 on successfully parsing the PEM buffer a WOLFSSL_X509 structure is returned.
- Null if failed to parse PEM buffer.

Example

```
WOLFSSL_BIO* bio;
WOLFSSL_X509* x509;
// setup bio
X509 = wolfSSL_PEM_read_bio_X509_AUX(bio, NULL, NULL, NULL);
//check x509 is not null and then use it
```

C.58.4.439 function wolfSSL_CTX_set_tmp_dh

```
long wolfSSL_CTX_set_tmp_dh(
    WOLFSSL_CTX * ctx,
    WOLFSSL_DH * dh
)
```

Initializes the WOLFSSL_CTX structure's dh member with the Diffie-Hellman parameters.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().
- **dh** a pointer to a WOLFSSL_DH structure.

See: wolfSSL_BN_bn2bin

Return:

- SSL_SUCCESS returned if the function executed successfully.
- BAD_FUNC_ARG returned if the ctx or dh structures are NULL.
- SSL_FATAL_ERROR returned if there was an error setting a structure value.
- MEMORY_E returned if their was a failure to allocate memory.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
WOLFSSL_DH* dh;
…
return wolfSSL_CTX_set_tmp_dh(ctx, dh);
```

C.58.4.440 function wolfSSL_PEM_read_bio_DSAparams

```
WOLFSSL_DSA * wolfSSL_PEM_read_bio_DSAparams(
    WOLFSSL_BIO * bp,
    WOLFSSL_DSA ** x,
    wc_pem_password_cb * cb,
    void * u
)
```

This function get the DSA parameters from a PEM buffer in bio.

Parameters:

- **bio** pointer to the WOLFSSL_BIO structure for getting PEM memory pointer.
- **x** pointer to be set to new WOLFSSL_DSA structure.
- **cb** password callback function.
- **u** null terminated password string.

See: none

Return:

- WOLFSSL_DSA on successfully parsing the PEM buffer a WOLFSSL_DSA structure is created and returned.
- Null if failed to parse PEM buffer.

Example

```
WOLFSSL_BIO* bio;
WOLFSSL_DSA* dsa;
// setup bio
dsa = wolfSSL_PEM_read_bio_DSAparams(bio, NULL, NULL, NULL);

// check dsa is not NULL and then use dsa
```

C.58.4.441 function wolfSSL_ERR_peek_last_error

```
unsigned long wolfSSL_ERR_peek_last_error(
    void
)
```

This function returns the absolute value of the last error from WOLFSSL_ERROR encountered.

Parameters:

- **none** No parameters.

See: wolfSSL_ERR_print_errors_fp

Return: error Returns absolute value of last error.

Example

```
unsigned long err;
...
err = wolfSSL_ERR_peek_last_error();
// inspect err value
```

C.58.4.442 function WOLF_STACK_OF

```
WOLF_STACK_OF(
    WOLFSSL_X509
) const
```

This function gets the peer's certificate chain.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_X509_get_issuer_name
- wolfSSL_X509_get_subject_name
- wolfSSL_X509_get_isCA

Return:

- pointer returns a pointer to the peer's Certificate stack.
- NULL returned if no peer certificate.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
...
wolfSSL_connect(ssl);
STACK_OF(WOLFSSL_X509)* chain = wolfSSL_get_peer_cert_chain(ssl);
ifchain){
    // You have a pointer to the peer certificate chain
}
```

C.58.4.443 function wolfSSL_CTX_clear_options

```
long wolfSSL_CTX_clear_options(
    WOLFSSL_CTX * ctx,
    long opt
)
```

This function resets option bits of WOLFSSL_CTX object.

Parameters:

- **ctx** pointer to the SSL context.

See:

- wolfSSL_CTX_new
- wolfSSL_new
- wolfSSL_free

Return: option new option bits

Example

```
WOLFSSL_CTX* ctx = 0;
...
wolfSSL_CTX_clear_options(ctx, SSL_OP_NO_TLSv1);
```

C.58.4.444 function wolfSSL_set_jobject

```
int wolfSSL_set_jobject(
    WOLFSSL * ssl,
    void * objPtr
)
```

This function sets the jObjectRef member of the WOLFSSL structure.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **objPtr** a void pointer that will be set to jObjectRef.

See: wolfSSL_get_jobject

Return:

- SSL_SUCCESS returned if jObjectRef is properly set to objPtr.
- SSL_FAILURE returned if the function did not properly execute and jObjectRef is not set.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
WOLFSSL* ssl = WOLFSSL_new();
void* objPtr = &obj;
...
if(wolfSSL_set_jobject(ssl, objPtr)){
    // The success case
}
```

C.58.4.445 function wolfSSL_get_jobject

```
void * wolfSSL_get_jobject(
    WOLFSSL * ssl
)
```

This function returns the jObjectRef member of the WOLFSSL structure.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See: wolfSSL_set_jobject

Return:

- value If the WOLFSSL struct is not NULL, the function returns the jObjectRef value.
- NULL returned if the WOLFSSL struct is NULL.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
WOLFSSL* ssl = wolfSSL(ctx);
...
void* jobject = wolfSSL_get_jobject(ssl);

if(jobject != NULL){
    // Success case
}
```

C.58.4.446 function wolfSSL_set_msg_callback

```
int wolfSSL_set_msg_callback(
    WOLFSSL * ssl,
    SSL_Msg_Cb cb
)
```

This function sets a callback in the ssl. The callback is to observe handshake messages. NULL value of cb resets the callback.

Parameters:

- **ssl** WOLFSSL structure to set callback argument.

See: wolfSSL_set_msg_callback_arg

Return:

- SSL_SUCCESS On success.
- SSL_FAILURE If an NULL ssl passed in.

Example

```
static cb(int write_p, int version, int content_type,
const void *buf, size_t len, WOLFSSL *ssl, void *arg)
…
WOLFSSL* ssl;
ret  = wolfSSL_set_msg_callback(ssl, cb);
// check ret
```

C.58.4.447 function wolfSSL_set_msg_callback_arg

```
int wolfSSL_set_msg_callback_arg(
    WOLFSSL * ssl,
    void * arg
)
```

This function sets associated callback context value in the ssl. The value is handed over to the callback argument.

Parameters:

- **ssl** WOLFSSL structure to set callback argument.

See: wolfSSL_set_msg_callback

Return: none No return.

Example

```
static cb(int write_p, int version, int content_type,
const void *buf, size_t len, WOLFSSL *ssl, void *arg)
…
WOLFSSL* ssl;
ret  = wolfSSL_set_msg_callback(ssl, cb);
// check ret
wolfSSL_set_msg_callback(ssl, arg);
```

C.58.4.448 function wolfSSL_X509_get_next_altname

```
char * wolfSSL_X509_get_next_altname(
    WOLFSSL_X509 *
)
```

This function returns the next, if any, altname from the peer certificate.

Parameters:

- **cert** a pointer to the wolfSSL_X509 structure.

See:

- wolfSSL_X509_get_issuer_name
- wolfSSL_X509_get_subject_name
- wolfSSL_X509_get_ext_d2i

Return:

- NULL if there is not a next altname.
- cert->altNamesNext->name from the WOLFSSL_X509 structure that is a string value from the altName list is returned if it exists.

Warning: The returned value is a bare C string with no length. A dNSName, rfc822Name, or uniformResourceIdentifier SAN may legally contain an embedded NUL byte (RFC 6125 Sec. 6.3 treats such a name as an invalid presented identifier, not a malformed certificate, so the certificate still parses),

which silently truncates the returned string. Do not use strlen or strcmp on the result for security comparisons; use wolfSSL_X509_get_ext_d2i and the GENERAL_NAME ASN1_STRING length instead.

Example

```
WOLFSSL_X509 x509 = (WOLFSSL_X509*)XMALLOC(sizeof(WOLFSSL_X509), NULL,
                                                    DYNAMIC_TYPE_X509);
…
int x509NextAltName = wolfSSL_X509_get_next_altname(x509);
if(x509NextAltName == NULL){
        //There isn't another alt name
}
```

C.58.4.449 function wolfSSL_X509_get_notBefore

```
WOLFSSL_ASN1_TIME * wolfSSL_X509_get_notBefore(
    WOLFSSL_X509 *
)
```

The function checks to see if x509 is NULL and if it's not, it returns the notBefore member of the x509 struct.

Parameters:

- **x509** a pointer to the WOLFSSL_X509 struct.

See: wolfSSL_X509_get_notAfter

Return:

- pointer to struct with ASN1_TIME to the notBefore member of the x509 struct.
- NULL the function returns NULL if the x509 structure is NULL.

Example

```
WOLFSSL_X509* x509 = (WOLFSSL_X509)XMALLOC(sizeof(WOLFSSL_X509), NULL,
DYNAMIC_TYPE_X509) ;
…
const WOLFSSL_ASN1_TIME* notAfter = wolfSSL_X509_get_notBefore(x509);
if(notAfter == NULL){
        //The x509 object was NULL
}
```

C.58.4.450 function wolfSSL_connect

```
int wolfSSL_connect(
    WOLFSSL * ssl
)
```

This function is called on the client side and initiates an SSL/TLS handshake with a server. When this function is called, the underlying communication channel has already been set up. wolfSSL_connect() works with both blocking and non_blocking I/O. When the underlying I/O is non_blocking, wolfSSL_connect() will return when the underlying I/O could not satisfy the needs of wolfSSL_connect to continue the handshake. In this case, a call to wolfSSL_get_error() will yield either SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE. The calling process must then repeat the call to wolfSSL_connect() when the underlying I/O is ready and wolfSSL will pick up where it left off. When using a non_blocking socket, nothing needs to be done, but select() can be used to check for the required condition. If the underlying I/O is blocking, wolfSSL_connect() will only return once the handshake has been finished or an error occurred. wolfSSL takes a different approach to certificate verification than OpenSSL does. The default policy for the client is to verify the server, this means

that if you don't load CAs to verify the server you'll get a connect error, unable to verify (_155). It you want to mimic OpenSSL behavior of having SSL_connect succeed even if verifying the server fails and reducing security you can do this by calling: SSL_CTX_set_verify(ctx, SSL_VERIFY_NONE, 0); before calling SSL_new(); Though it's not recommended.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_get_error
- wolfSSL_accept

Return:

- SSL_SUCCESS If successful.
- SSL_FATAL_ERROR will be returned if an error occurred. To get a more detailed error code, call wolfSSL_get_error().
- BAD_FUNC_ARG will be returned when ssl is NULL.

If decrypted application data is waiting to be read, for example data received during a secure renegotiation, the handshake is not continued and wolfSSL_get_error() returns APP_DATA_READY. Read the data with wolfSSL_read() and then call wolfSSL_connect() again.

Example

```
int ret = 0;
int err = 0;
WOLFSSL* ssl;
char buffer[80];
...
ret = wolfSSL_connect(ssl);
if (ret != SSL_SUCCESS) {
err = wolfSSL_get_error(ssl, ret);
printf("error = %d, %s\n", err, wolfSSL_ERR_error_string(err, buffer));
}
```

C.58.4.451 function wolfSSL_send_hrr_cookie

```
int wolfSSL_send_hrr_cookie(
    WOLFSSL * ssl,
    const unsigned char * secret,
    unsigned int secretSz
)
```

This function is called on the server side to indicate that a HelloRetryRequest message must contain a Cookie and, in case of using protocol DTLS v1.3, that the handshake will always include a cookie exchange. Please note that when using protocol DTLS v1.3, the cookie exchange is enabled by default. The Cookie holds a hash of the current transcript so that another server process can handle the ClientHello in reply. The secret is used when generating the integrity check on the Cookie data. This replaces or regenerates the HRR secret, then delegates to wolfSSL_enable_cookie(). Changing cookie mode after handshake processing starts is unsupported; rotating a secret while cookies are already enabled remains supported. DTLS 1.2_only callers should use wolfSSL_enable_cookie() and wolfSSL_DTLS_SetCookieSecret().

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

- **secret** a pointer to a buffer holding the secret. Passing NULL indicates to generate a new random secret.
- **secretSz** Size of the secret in bytes. Passing 0 indicates to use the default size: the digest size of the hash the cookie MAC uses, WC_SHA256_DIGEST_SIZE, or when SHA-256 is not available WC_SHA384_DIGEST_SIZE, WC_SHA512_DIGEST_SIZE or WC_SM3_DIGEST_SIZE, in that order.

See:

- wolfSSL_new
- wolfSSL_disable_hrr_cookie

Return:

- BAD_FUNC_ARG if ssl is NULL or not using TLS v1.3.
- SIDE_ERROR if called with a client.
- BAD_STATE_E if the DTLS handshake already committed to stateful processing, as for wolfSSL_enable_cookie(), or if a secret must be generated (secret is NULL, or a DTLS 1.3 server is missing its DTLS 1.2 secret) and the session's RNG has been released. The installed secret is left unchanged.
- WOLFSSL_SUCCESS if successful.
- MEMORY_ERROR if allocating dynamic memory for storing secret failed.
- Another -ve value on internal error. Every failure is all or nothing: the secret in use and the cookie policy are left exactly as they were found, so the object stays usable.

Example

```
int ret;
WOLFSSL* ssl;
char secret[32];
...
ret = wolfSSL__send_hrr_cookie(ssl, secret, sizeof(secret));
if (ret != WOLFSSL_SUCCESS) {
    // failed to set use of Cookie and secret
}
```

C.58.4.452 function wolfSSL_set_hrr_cookie_secret_secondary

```
int wolfSSL_set_hrr_cookie_secret_secondary(
    WOLFSSL * ssl,
    const unsigned char * secret,
    unsigned int secretSz
)
```

This function sets a secondary HelloRetryRequest cookie secret on a DTLS 1.3 server. It is used only when verifying a received cookie, and only if the primary secret (set with wolfSSL_send_hrr_cookie()) fails to verify it. This lets an application rotate the cookie secret on a stateless DTLS 1.3 server without rejecting clients whose cookie was issued under the previous secret: install the new secret as the primary and the previous secret here for an overlap window. The secondary secret is never used to issue cookies. This API is DTLS only; TLS 1.3 over a reliable transport does not verify cookies statelessly across the HelloRetryRequest exchange.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **secret** a pointer to a buffer holding the secondary secret. Passing NULL (or a secretSz of 0) clears any previously set secondary secret.
- **secretSz** Size of the secret in bytes.

See:

- wolfSSL_send_hrr_cookie
- wolfSSL_disable_hrr_cookie

Return:

- BAD_FUNC_ARG if ssl is NULL, not using TLS v1.3, or not using DTLS.
- SIDE_ERROR if called with a client.
- WOLFSSL_SUCCESS if successful.
- MEMORY_ERROR if allocating dynamic memory for storing secret failed. The secondary secret already in use, if any, is kept.

Example

```
int ret;
WOLFSSL* ssl;
char newSecret[32];
char oldSecret[32];
...
// rotate: new secret becomes primary, previous secret stays valid
wolfSSL_send_hrr_cookie(ssl, newSecret, sizeof(newSecret));
ret = wolfSSL_set_hrr_cookie_secret_secondary(ssl, oldSecret,
    sizeof(oldSecret));
if (ret != WOLFSSL_SUCCESS) {
    // failed to set the secondary cookie secret
}
```

C.58.4.453 function wolfSSL_disable_hrr_cookie

```
int wolfSSL_disable_hrr_cookie(
    WOLFSSL * ssl
)
```

This function is called on the server side to indicate that a HelloRetryRequest message must NOT contain a Cookie and that, if using protocol DTLS v1.3, a cookie exchange will not be included in the handshake. Please note that not doing a cookie exchange when using protocol DTLS v1.3 can make the server susceptible to DoS/Amplification attacks. This delegates to wolfSSL_disable_cookie(): on a DTLS object it also disables the DTLS 1.2 HelloVerifyRequest exchange, and it fails with BAD_STATE_E once the handshake has committed to stateful processing.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_disable_cookie
- wolfSSL_send_hrr_cookie

Return:

- WOLFSSL_SUCCESS if successful
- BAD_FUNC_ARG if ssl is NULL or not using TLS v1.3
- SIDE_ERROR if invoked on a client
- BAD_STATE_E if the DTLS handshake already committed to stateful processing

C.58.4.454 function wolfSSL_CTX_no_ticket_TLSv13

```
int wolfSSL_CTX_no_ticket_TLSv13(
    WOLFSSL_CTX * ctx
)
```

This function is called on the server to stop it from sending a resumption session ticket once the handshake is complete.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created with wolfSSL_CTX_new().

See: wolfSSL_no_ticket_TLSv13

Return:

- BAD_FUNC_ARG if ctx is NULL or not using TLS v1.3.
- SIDE_ERROR if called with a client.
- 0 if successful.

Example

```
int ret;
WOLFSSL_CTX* ctx;
...
ret = wolfSSL_CTX_no_ticket_TLSv13(ctx);
if (ret != 0) {
    // failed to set no ticket
}
```

C.58.4.455 function wolfSSL_no_ticket_TLSv13

```
int wolfSSL_no_ticket_TLSv13(
    WOLFSSL * ssl
)
```

This function is called on the server to stop it from sending a resumption session ticket once the handshake is complete.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See: wolfSSL_CTX_no_ticket_TLSv13

Return:

- BAD_FUNC_ARG if ssl is NULL or not using TLS v1.3.
- SIDE_ERROR if called with a client.
- 0 if successful.

Example

```
int ret;
WOLFSSL* ssl;
...
ret = wolfSSL_no_ticket_TLSv13(ssl);
if (ret != 0) {
    // failed to set no ticket
}
```

C.58.4.456 function wolfSSL_CTX_no_dhe_psk

```
int wolfSSL_CTX_no_dhe_psk(
    WOLFSSL_CTX * ctx
)
```

This function is called on a TLS v1.3 wolfSSL context to disallow Diffie-Hellman (DH) style key exchanges when handshakes are using pre-shared keys for authentication.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created with wolfSSL_CTX_new().

See: wolfSSL_no_dhe_psk

Return:

- BAD_FUNC_ARG if ctx is NULL or not using TLS v1.3.
- 0 if successful.

Example

```
int ret;
WOLFSSL_CTX* ctx;
...
ret = wolfSSL_CTX_no_dhe_psk(ctx);
if (ret != 0) {
    // failed to set no DHE for PSK handshakes
}
```

C.58.4.457 function wolfSSL_no_dhe_psk

```
int wolfSSL_no_dhe_psk(
    WOLFSSL * ssl
)
```

This function is called on a TLS v1.3 client or server wolfSSL to disallow Diffie-Hellman (DH) style key exchanges when handshakes are using pre-shared keys for authentication.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See: wolfSSL_CTX_no_dhe_psk

Return:

- BAD_FUNC_ARG if ssl is NULL or not using TLS v1.3.
- 0 if successful.

Example

```
int ret;
WOLFSSL* ssl;
...
ret = wolfSSL_no_dhe_psk(ssl);
if (ret != 0) {
    // failed to set no DHE for PSK handshakes
}
```

C.58.4.458 function wolfSSL_CTX_require_psk

```
int wolfSSL_CTX_require_psk(
    WOLFSSL_CTX * ctx
)
```

This function is called on a TLS v1.3 / DTLS v1.3 context to require that an external Pre-Shared Key is negotiated for the handshake to succeed. When set, a handshake that completes without negotiating

an external PSK is aborted with PSK_MISSING_ERROR instead of falling back to a certificate handshake, so the PSK acts as an additional security factor. The requirement keys off the external-PSK callback (it has no effect unless one is registered) and session-ticket resumption is exempt. To preserve forward secrecy a mandatory external PSK must also use an (EC)DHE key exchange; a pure psk_ke handshake is rejected with PSK_KEY_ERROR. This applies to TLS 1.3 and DTLS 1.3 only; in (D)TLS 1.2 the use of a PSK is determined by the negotiated cipher suite, so a mandatory PSK is instead configured by restricting the cipher suite list to (preferably (EC)DHE-)PSK suites.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().

See: wolfSSL_require_psk

Return:

- BAD_FUNC_ARG if ctx is NULL or not at least TLS v1.3.
- 0 if successful.

Note: In builds compiled without external-PSK and without session-ticket support (NO_PSK defined and HAVE_SESSION_TICKET undefined) the requirement cannot be enforced; the function still returns 0 but has no effect.

Warning: Because the requirement can only be enforced for (D)TLS 1.3, this function also disables version downgrade on the context so it cannot silently fall back to (D)TLS 1.2 and complete a handshake without a PSK. A peer that does not support (D)TLS 1.3 will therefore fail to connect.

Example

```
int ret;
WOLFSSL_CTX* ctx;
...
ret = wolfSSL_CTX_require_psk(ctx);
if (ret != 0) {
    // failed to make a PSK mandatory
}
```

C.58.4.459 function wolfSSL_require_psk

```
int wolfSSL_require_psk(
    WOLFSSL * ssl
)
```

This function is called on a TLS v1.3 / DTLS v1.3 wolfSSL object to require that an external Pre-Shared Key is negotiated for the handshake to succeed. See wolfSSL_CTX_require_psk() for the full behaviour.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See: wolfSSL_CTX_require_psk

Return:

- BAD_FUNC_ARG if ssl is NULL or not at least TLS v1.3.
- 0 if successful.

Example

```
int ret;
WOLFSSL* ssl;
...
ret = wolfSSL_require_psk(ssl);
```

```
if (ret != 0) {
    // failed to make a PSK mandatory
}
```

C.58.4.460 function wolfSSL_update_keys

```
int wolfSSL_update_keys(
    WOLFSSL * ssl
)
```

This function is called on a TLS v1.3 client or server wolfSSL to force the rollover of keys. A KeyUpdate message is sent to the peer and new keys are calculated for encryption. The peer will send back a KeyUpdate message and the new decryption keys will then be calculated. This function can only be called after a handshake has been completed.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See: wolfSSL_write

Return:

- BAD_FUNC_ARG if ssl is NULL or not using TLS v1.3.
- WANT_WRITE if the writing is not ready.
- BAD_STATE_E if the connection has already performed the maximum number of key updates. RFC 9846, Section 4.7.3 caps a TLS 1.3 sender at 2^48-1 key updates; beyond that the connection must be closed rather than rekeyed. Note that a KeyUpdate arriving from the peer with request_update set is ignored once this cap is reached, rather than failing the connection, so only an application-initiated update reports this error.
- WOLFSSL_SUCCESS if successful.

Example

```
int ret;
WOLFSSL* ssl;
...
ret = wolfSSL_update_keys(ssl);
if (ret == WANT_WRITE) {
    // need to call again when I/O ready
}
else if (ret != WOLFSSL_SUCCESS) {
    // failed to send key update
}
```

C.58.4.461 function wolfSSL_key_update_response

```
int wolfSSL_key_update_response(
    WOLFSSL * ssl,
    int * required
)
```

This function is called on a TLS v1.3 client or server wolfSSL to determine whether a rollover of keys is in progress. When wolfSSL_update_keys() is called, a KeyUpdate message is sent and the encryption key is updated. The decryption key is updated when the response is received.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

- **required** 0 when no key update response is required. 1 when a key update response from the peer is still outstanding.

See: wolfSSL_update_keys

Return:

- 0 on successful.
- BAD_FUNC_ARG if ssl is NULL or not using TLS v1.3.

Example

```
int ret;
WOLFSSL* ssl;
int required;
...
ret = wolfSSL_key_update_response(ssl, &required);
if (ret != 0) {
    // bad parameters
}
if (required) {
    // encrypt Key updated, awaiting response to change decrypt key
}
```

C.58.4.462 function wolfSSL_CTX_allow_post_handshake_auth

```
int wolfSSL_CTX_allow_post_handshake_auth(
    WOLFSSL_CTX * ctx
)
```

This function is called on a TLS v1.3 client wolfSSL context to allow a client certificate to be sent post handshake upon request from server. This is useful when connecting to a web server that has some pages that require client authentication and others that don't.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created with wolfSSL_CTX_new().

See:

- wolfSSL_allow_post_handshake_auth
- wolfSSL_request_certificate

Return:

- BAD_FUNC_ARG if ctx is NULL or not using TLS v1.3.
- SIDE_ERROR if called with a server.
- 0 if successful.

Example

```
int ret;
WOLFSSL_CTX* ctx;
...
ret = wolfSSL_allow_post_handshake_auth(ctx);
if (ret != 0) {
    // failed to allow post handshake authentication
}
```

C.58.4.463 function wolfSSL_allow_post_handshake_auth

```
int wolfSSL_allow_post_handshake_auth(
    WOLFSSL * ssl
)
```

This function is called on a TLS v1.3 client wolfSSL to allow a client certificate to be sent post handshake upon request from server. A Post-Handshake Client Authentication extension is sent in the ClientHello. This is useful when connecting to a web server that has some pages that require client authentication and others that don't.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_CTX_allow_post_handshake_auth
- wolfSSL_request_certificate

Return:

- BAD_FUNC_ARG if ssl is NULL or not using TLS v1.3.
- SIDE_ERROR if called with a server.
- BAD_STATE_E if called after the handshake has started.
- 0 if successful.

This function must be called before wolfSSL_connect() on the WOLFSSL object.

Example

```
int ret;
WOLFSSL* ssl;
...
ret = wolfSSL_allow_post_handshake_auth(ssl);
if (ret != 0) {
    // failed to allow post handshake authentication
}
```

C.58.4.464 function wolfSSL_request_certificate

```
int wolfSSL_request_certificate(
    WOLFSSL * ssl
)
```

This function requests a client certificate from the TLS v1.3 client. This is useful when a web server is serving some pages that require client authentication and others that don't. A maximum of 256 requests can be sent on a connection.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_allow_post_handshake_auth
- wolfSSL_write

Return:

- BAD_FUNC_ARG if ssl is NULL or not using TLS v1.3.
- WANT_WRITE if the writing is not ready.
- SIDE_ERROR if called with a client.

- NOT_READY_ERROR if called when the handshake is not finished.
- POST_HAND_AUTH_ERROR if posthandshake authentication is disallowed.
- MEMORY_E if dynamic memory allocation fails.
- WOLFSSL_SUCCESS if successful.

Example

```
int ret;
WOLFSSL* ssl;
...
ret = wolfSSL_request_certificate(ssl);
if (ret == WANT_WRITE) {
    // need to call again when I/O ready
}
else if (ret != WOLFSSL_SUCCESS) {
    // failed to request a client certificate
}
```

C.58.4.465 function wolfSSL_CTX_set1_sigalgs_list

```
int wolfSSL_CTX_set1_sigalgs_list(
    WOLFSSL_CTX * ctx,
    const char * list
)
```

This function sets the list of signature algorithms to allow on a wolfSSL context in order of preference. The list is a null-terminated text string and a colon-delimited list, where each element is of the form "+" (for example "RSA-PSS+SHA256:ECDSA+SHA384"). The Edwards-curve algorithms "ED25519" and "ED448" are written without a digest suffix, since the hash is implied by the algorithm. The previous list stored in the context is replaced.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created with wolfSSL_CTX_new().
- **list** a colon-delimited list of "+" elements (or "ED25519" / "ED448" without a digest).

See:

- wolfSSL_set1_sigalgs_list
- wolfSSL_CTX_set1_groups_list

Return:

- WOLFSSL_SUCCESS if successful.
- WOLFSSL_FAILURE if a pointer parameter is NULL, allocation of the suites structure fails, or any token in the list is not recognized or not supported by the current build.

Recognized public-key tokens and digest tokens, together with the build options that must be enabled for each token to be accepted, are listed in the tables below.

Public-key tokens:

Token	Required build option
RSA	!NO_RSA
RSA-PSS / PSS	!NO_RSA and WC_RSA_PSS
ECDSA	HAVE_ECC
ED25519	HAVE_ED25519 (no digest suffix)
ED448	HAVE_ED448 (no digest suffix)
DSA	!NO_DSA

Token	Required build option
SM2	WOLFSSL_SM2 and WOLFSSL_SM3 (digest is SM3)

Digest tokens:

Token	Required build option
SHA256	!NO_SHA256
SHA384	WOLFSSL_SHA384
SHA512	WOLFSSL_SHA512
SHA224	WOLFSSL_SHA224
SM3	WOLFSSL_SM3
SHA1	!NO_SHA, plus !NO_OLD_TLS or WOLFSSL_ALLOW_TLS_SHA1

Notes for TLS 1.3: per RFC 8446, RSA PKCS#1 v1.5, DSA, SHA-1, and SHA-224 cannot be used as handshake signatures and will be filtered out at negotiation time even if listed. Specifying "RSA-PSS+SHAxxx" causes both the rsa_pss_rsae_shaxxx and rsa_pss_pss_shaxxx schemes to be added. Brainpool ECDSA signature schemes (RFC 8734) cannot be selected through this string interface; they are negotiated automatically when HAVE_ECC_BRAINPOOL is enabled.

Example

```
int ret;
WOLFSSL_CTX* ctx;
const char* list = "RSA-PSS+SHA256:ECDSA+SHA384:ED25519";
...
ret = wolfSSL_CTX_set1_sigalgs_list(ctx, list);
if (ret != WOLFSSL_SUCCESS) {
    // failed to set signature algorithm list
}
```

C.58.4.466 function wolfSSL_set1_sigalgs_list

```
int wolfSSL_set1_sigalgs_list(
    WOLFSSL * ssl,
    const char * list
)
```

This function sets the list of signature algorithms to allow on a wolfSSL session in order of preference. The list format and the set of recognized public-key and digest tokens are identical to those documented for wolfSSL_CTX_set1_sigalgs_list(); refer to that function for the full token tables and TLS 1.3 caveats. The previous list stored in the session is replaced.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **list** a colon-delimited list of "+" elements (or "ED25519" / "ED448" without a digest).

See:

- wolfSSL_CTX_set1_sigalgs_list
- wolfSSL_set1_groups_list

Return:

- WOLFSSL_SUCCESS if successful.

- WOLFSSL_FAILURE if a pointer parameter is NULL, allocation of the suites structure fails, or any token in the list is not recognized or not supported by the current build.

Example

```
int ret;
WOLFSSL* ssl;
const char* list = "RSA-PSS+SHA256:ECDSA+SHA384:ED25519";
...
ret = wolfSSL_set1_sigalgs_list(ssl, list);
if (ret != WOLFSSL_SUCCESS) {
    // failed to set signature algorithm list
}
```

C.58.4.467 function wolfSSL_CTX_set1_groups_list

```
int wolfSSL_CTX_set1_groups_list(
    WOLFSSL_CTX * ctx,
    const char * list
)
```

This function sets the list of key-exchange groups (named elliptic curves and KEMs) to allow on a wolfSSL context in order of preference. The list is a null-terminated, colon-delimited text string of group names, for example "P-384:P-256:X25519". Call this function to set the key-exchange parameters used with TLS v1.3 connections (the function is compiled in only when HAVE_ECC, WOLFSSL_TLS13, and HAVE_SUPPORTED_CURVES are defined).

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created with wolfSSL_CTX_new().
- **list** a string that is a colon-delimited list of key-exchange group names.

See:

- wolfSSL_set1_groups_list
- wolfSSL_CTX_set_groups
- wolfSSL_set_groups
- wolfSSL_UseKeyShare
- wolfSSL_preferred_group

Return:

- WOLFSSL_FAILURE if pointer parameters are NULL, there are more than WOLFSSL_MAX_GROUP_COUNT groups, a group name is not recognized or not using TLS v1.3.
- WOLFSSL_SUCCESS if successful.

Recognized group names and the build options each one requires are listed below. Names are matched case-sensitively against the table.

NIST / SEC curves (require HAVE_ECC):

Name	Curve / Group
P-160	secp160r1
P-160-2	secp160r2
P-192	secp192r1 (prime192v1)
P-224	secp224r1
P-256	secp256r1 (prime256v1) — also accepted as "prime256v1" / "secp256r1"
P-384	secp384r1 — also accepted as "secp384r1"

Name	Curve / Group
P-521	secp521r1 — also accepted as “secp521r1”
K-160	secp160k1
K-192	secp192k1
K-224	secp224k1
K-256	secp256k1

Brainpool curves (require HAVE_ECC plus WOLFSSL_CUSTOM_CURVES and HAVE_ECC_BRAINPOOL — typically enabled by –enable-ecccustcurves=all):

Name	Curve
B-256	brainpoolP256r1
B-384	brainpoolP384r1
B-512	brainpoolP512r1

Edwards / Montgomery curves:

Name	Required build option
X25519	HAVE_CURVE25519
X448	HAVE_CURVE448

SM2 (requires WOLFSSL_SM2):

Name	Group
SM2	sm2p256v1
sm2p256v1	sm2p256v1 (alias)

ML-KEM (post-quantum) groups (require WOLFSSL_HAVE_MLKEM and !WOLFSSL_NO_ML_KEM):

Name
ML_KEM_512
ML_KEM_768
ML_KEM_1024

ML-KEM hybrid groups additionally require HAVE_ECC together with either WOLFSSL_WC_MLKEM, and WOLFSSL_PQC_HYBRIDS (or WOLFSSL_EXTRA_PQC_HYBRIDS for the “extra” set):

Name	Hybrid flag set
SecP256r1MLKEM768	WOLFSSL_PQC_HYBRIDS
SecP384r1MLKEM1024	WOLFSSL_PQC_HYBRIDS
X25519MLKEM768	WOLFSSL_PQC_HYBRIDS
SecP256r1MLKEM512	WOLFSSL_EXTRA_PQC_HYBRIDS
SecP384r1MLKEM768	WOLFSSL_EXTRA_PQC_HYBRIDS
SecP521r1MLKEM1024	WOLFSSL_EXTRA_PQC_HYBRIDS

COPYRIGHT ©2024 wolfSSL Inc.

Name	Hybrid flag set
X25519MLKEM512	WOLFSSL_EXTRA_PQC_HYBRIDS
X448MLKEM768	WOLFSSL_EXTRA_PQC_HYBRIDS

Legacy Kyber groups (require WOLFSSL_MLKEM_KYBER; hybrids additionally require HAVE_ECC together with WOLFSSL_WC_MLKEM):

Name
KYBER_LEVEL1
KYBER_LEVEL3
KYBER_LEVEL5
P256_KYBER_LEVEL1
P256_KYBER_LEVEL3
P384_KYBER_LEVEL3
P521_KYBER_LEVEL5
X25519_KYBER_LEVEL1
X25519_KYBER_LEVEL3
X448_KYBER_LEVEL3

In addition to the names above, when HAVE_FIPS and HAVE_SELFTEST are not defined, any curve name registered with wolfCrypt (looked up via wc_ecc_get_curve_idx_from_name(), e.g. “brainpoolP256r1”) is also accepted.

The order of the names in the list is preserved and used as the local preference order for KeyShare selection in TLS 1.3.

Example

```
int ret;
WOLFSSL_CTX* ctx;
const char* list = "P-384:P-256";
...
ret = wolfSSL_CTX_set1_groups_list(ctx, list);
if (ret != WOLFSSL_SUCCESS) {
    // failed to set group list
}
```

C.58.4.468 function wolfSSL_set1_groups_list

```
int wolfSSL_set1_groups_list(
    WOLFSSL * ssl,
    const char * list
)
```

This function sets the list of key-exchange groups (named elliptic curves and KEMs) to allow on a wolfSSL session in order of preference. The list format and the set of recognized group names are identical to those documented for wolfSSL_CTX_set1_groups_list(); refer to that function for the full token tables and required build options.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **list** a string that is a colon separated list of key exchange groups.

See:

- wolfSSL_CTX_set1_groups_list
- wolfSSL_CTX_set_groups
- wolfSSL_set_groups
- wolfSSL_UseKeyShare
- wolfSSL_preferred_group

Return:

- WOLFSSL_FAILURE if pointer parameters are NULL, there are more than WOLFSSL_MAX_GROUP_COUNT groups, a group name is not recognized or not using TLS v1.3.
- WOLFSSL_SUCCESS if successful.

Example

```
int ret;
WOLFSSL* ssl;
const char* list = "P-384:P-256";
...
ret = wolfSSL_CTX_set1_groups_list(ssl, list);
if (ret != WOLFSSL_SUCCESS) {
    // failed to set group list
}
```

C.58.4.469 function wolfSSL_preferred_group

```
int wolfSSL_preferred_group(
    WOLFSSL * ssl
)
```

This function returns the key exchange group the client prefers to use in the TLS v1.3 handshake. Call this function to after a handshake is complete to determine which group the server prefers so that this information can be used in future connections to pre-generate a key pair for key exchange.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_UseKeyShare
- wolfSSL_CTX_set_groups
- wolfSSL_set_groups
- wolfSSL_CTX_set1_groups_list
- wolfSSL_set1_groups_list

Return:

- BAD_FUNC_ARG if ssl is NULL or not using TLS v1.3.
- SIDE_ERROR if called with a server.
- NOT_READY_ERROR if called before handshake is complete.
- Group identifier if successful.

Example

```
int ret;
int group;
WOLFSSL* ssl;
...
ret = wolfSSL_CTX_set1_groups_list(ssl)
```

```
if (ret < 0) {
    // failed to get group
}
group = ret;
```

C.58.4.470 function wolfSSL_CTX_set_groups

```
int wolfSSL_CTX_set_groups(
    WOLFSSL_CTX * ctx,
    int * groups,
    int count
)
```

This function sets the list of key-exchange groups (named elliptic curves and KEMs) to allow on a wolfSSL context in order of preference. The list is an array of named-group identifiers (see the table below) and `count` is the number of identifiers in the array. Use this function to set the key-exchange parameters used by TLS v1.3 connections; the order of the array becomes the local KeyShare preference order.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created with wolfSSL_CTX_new().
- **groups** a list of key-exchange groups by identifier.
- **count** the number of identifiers in `groups` (must not exceed WOLFSSL_MAX_GROUP_COUNT).

See:

- wolfSSL_set_groups
- wolfSSL_UseKeyShare
- wolfSSL_CTX_set1_groups_list
- wolfSSL_set1_groups_list
- wolfSSL_preferred_group

Return:

- BAD_FUNC_ARG if a pointer parameter is NULL, `count` exceeds WOLFSSL_MAX_GROUP_COUNT, or the underlying method is not a TLS method.
- WOLFSSL_SUCCESS if successful.

Recognized identifiers and the build options each one requires are listed below. The identifiers are defined in the anonymous enum in <wolfssl/ssl.h>.

NIST / SEC curves (require HAVE_ECC):

Identifier	Curve / Group
WOLFSSL_ECC_SECP160K1	secp160k1
WOLFSSL_ECC_SECP160R1	secp160r1
WOLFSSL_ECC_SECP160R2	secp160r2
WOLFSSL_ECC_SECP192K1	secp192k1
WOLFSSL_ECC_SECP192R1	secp192r1 (prime192v1)
WOLFSSL_ECC_SECP224K1	secp224k1
WOLFSSL_ECC_SECP224R1	secp224r1
WOLFSSL_ECC_SECP256K1	secp256k1
WOLFSSL_ECC_SECP256R1	secp256r1 (prime256v1)
WOLFSSL_ECC_SECP384R1	secp384r1
WOLFSSL_ECC_SECP521R1	secp521r1

Brainpool curves (require HAVE_ECC plus WOLFSSL_CUSTOM_CURVES and HAVE_ECC_BRAINPOOL — typically enabled by –enable-ecccustcurves=all):

Identifier	Curve	Notes
WOLFSSL_ECC_BRAINPOOLP256R1	brainpoolP256r1	TLS 1.2 group ID 26
WOLFSSL_ECC_BRAINPOOLP384R1	brainpoolP384r1	TLS 1.2 group ID 27
WOLFSSL_ECC_BRAINPOOLP512R1	brainpoolP512r1	TLS 1.2 group ID 28
WOLFSSL_ECC_BRAINPOOLP256R1TLS13	brainpoolP256r1	RFC 8734 TLS 1.3 ID
WOLFSSL_ECC_BRAINPOOLP384R1TLS13	brainpoolP384r1	RFC 8734 TLS 1.3 ID
WOLFSSL_ECC_BRAINPOOLP512R1TLS13	brainpoolP512r1	RFC 8734 TLS 1.3 ID

Edwards / Montgomery curves:

Identifier	Required build option
WOLFSSL_ECC_X25519	HAVE_CURVE25519
WOLFSSL_ECC_X448	HAVE_CURVE448

SM2 (requires WOLFSSL_SM2):

Identifier	Group
WOLFSSL_ECC_SM2P256V1	sm2p256v1

Finite-field DH (RFC 7919) groups (require HAVE_FFDHE and the matching HAVE_FFDHE_NNNN macro for each size):

Identifier	Group
WOLFSSL_FFDHE_2048	ffdhe2048
WOLFSSL_FFDHE_3072	ffdhe3072
WOLFSSL_FFDHE_4096	ffdhe4096
WOLFSSL_FFDHE_6144	ffdhe6144
WOLFSSL_FFDHE_8192	ffdhe8192

ML-KEM (post-quantum) groups (require HAVE_PQC, WOLFSSL_HAVE_MLKEM and !WOLFSSL_NO_ML_KEM):

Identifier
WOLFSSL_ML_KEM_512
WOLFSSL_ML_KEM_768
WOLFSSL_ML_KEM_1024

ML-KEM hybrid groups additionally require HAVE_ECC together with either WOLFSSL_WC_MLKEM, and WOLFSSL_PQC_HYBRIDS (or WOLFSSL_EXTRA_PQC_HYBRIDS for the “extra” set):

Identifier	Hybrid flag set
WOLFSSL_SECP256R1MLKEM768	WOLFSSL_PQC_HYBRIDS

Identifier	Hybrid flag set
WOLFSSL_X25519MLKEM768	WOLFSSL_PQC_HYBRIDS
WOLFSSL_SECP384R1MLKEM1024	WOLFSSL_PQC_HYBRIDS
WOLFSSL_SECP256R1MLKEM512	WOLFSSL_EXTRA_PQC_HYBRIDS
WOLFSSL_SECP384R1MLKEM768	WOLFSSL_EXTRA_PQC_HYBRIDS
WOLFSSL_SECP521R1MLKEM1024	WOLFSSL_EXTRA_PQC_HYBRIDS
WOLFSSL_X25519MLKEM512	WOLFSSL_EXTRA_PQC_HYBRIDS
WOLFSSL_X448MLKEM768	WOLFSSL_EXTRA_PQC_HYBRIDS

Legacy Kyber groups (require HAVE_PQC and WOLFSSL_MLKEM_KYBER; hybrids additionally require HAVE_ECC together with WOLFSSL_WC_MLKEM):

Identifier
WOLFSSL_KYBER_LEVEL1
WOLFSSL_KYBER_LEVEL3
WOLFSSL_KYBER_LEVEL5
WOLFSSL_P256_KYBER_LEVEL1
WOLFSSL_P256_KYBER_LEVEL3
WOLFSSL_P384_KYBER_LEVEL3
WOLFSSL_P521_KYBER_LEVEL5
WOLFSSL_X25519_KYBER_LEVEL1
WOLFSSL_X25519_KYBER_LEVEL3
WOLFSSL_X448_KYBER_LEVEL3

Example

```
int ret;
WOLFSSL_CTX* ctx;
int groups[] = { WOLFSSL_ECC_X25519, WOLFSSL_ECC_SECP256R1 };
int count = sizeof(groups) / sizeof(groups[0]);
...
ret = wolfSSL_CTX_set_groups(ctx, groups, count);
if (ret != WOLFSSL_SUCCESS) {
    // failed to set group list
}
```

C.58.4.471 function wolfSSL_set_groups

```
int wolfSSL_set_groups(
    WOLFSSL * ssl,
    int * groups,
    int count
)
```

This function sets the list of key-exchange groups (named elliptic curves and KEMs) to allow on a wolfSSL session in order of preference. The array format and the set of recognized identifiers are identical to those documented for wolfSSL_CTX_set_groups(); refer to that function for the full identifier table and required build options.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **groups** a list of key-exchange groups by identifier.

- **count** the number of identifiers in groups (must not exceed WOLFSSL_MAX_GROUP_COUNT).

See:

- wolfSSL_CTX_set_groups
- wolfSSL_UseKeyShare
- wolfSSL_CTX_set1_groups_list
- wolfSSL_set1_groups_list
- wolfSSL_preferred_group

Return:

- BAD_FUNC_ARG if a pointer parameter is NULL, count exceeds WOLFSSL_MAX_GROUP_COUNT, any of the identifiers are unrecognized, or the underlying method is not a TLS method.
- WOLFSSL_SUCCESS if successful.

Example

```
int ret;
WOLFSSL* ssl;
int groups[] = { WOLFSSL_ECC_X25519, WOLFSSL_ECC_SECP256R1 };
int count = sizeof(groups) / sizeof(groups[0]);
...
ret = wolfSSL_set_groups(ssl, groups, count);
if (ret != WOLFSSL_SUCCESS) {
    // failed to set group list
}
```

C.58.4.472 function wolfSSL_connect_TLSv13

```
int wolfSSL_connect_TLSv13(
    WOLFSSL * ssl
)
```

This function is called on the client side and initiates a TLS v1.3 handshake with a server. When this function is called, the underlying communication channel has already been set up. wolfSSL_connect() works with both blocking and non_blocking I/O. When the underlying I/O is non_blocking, wolfSSL_connect() will return when the underlying I/O could not satisfy the needs of wolfSSL_connect to continue the handshake. In this case, a call to wolfSSL_get_error() will yield either SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE. The calling process must then repeat the call to wolfSSL_connect() when the underlying I/O is ready and wolfSSL will pick up where it left off. When using a non_blocking socket, nothing needs to be done, but select() can be used to check for the required condition. If the underlying I/O is blocking, wolfSSL_connect() will only return once the handshake has been finished or an error occurred. wolfSSL takes a different approach to certificate verification than OpenSSL does. The default policy for the client is to verify the server, this means that if you don't load CAs to verify the server you'll get a connect error, unable to verify (_155). It you want to mimic OpenSSL behavior of having SSL_connect succeed even if verifying the server fails and reducing security you can do this by calling: SSL_CTX_set_verify(ctx, SSL_VERIFY_NONE, 0); before calling SSL_new(); Though it's not recommended.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_get_error
- wolfSSL_connect
- wolfSSL_accept_TLSv13
- wolfSSL_accept

Return:

- SSL_SUCCESS upon success.
- SSL_FATAL_ERROR will be returned if an error occurred. To get a more detailed error code, call wolfSSL_get_error().

If decrypted application data is waiting to be read, the handshake is not continued and wolfSSL_get_error() returns APP_DATA_READY. Read the data with wolfSSL_read() and then call wolfSSL_connect_TLSv13() again.

Example

```
int ret = 0;
int err = 0;
WOLFSSL* ssl;
char buffer[80];
...

ret = wolfSSL_connect_TLSv13(ssl);
if (ret != SSL_SUCCESS) {
    err = wolfSSL_get_error(ssl, ret);
    printf("error = %d, %s\n", err, wolfSSL_ERR_error_string(err, buffer));
}
```

C.58.4.473 function wolfSSL_accept_TLSv13

```
wolfSSL_accept_TLSv13(
    WOLFSSL * ssl
)
```

This function is called on the server side and waits for a SSL/TLS client to initiate the SSL/TLS handshake. When this function is called, the underlying communication channel has already been set up. wolfSSL_accept() works with both blocking and non_blocking I/O. When the underlying I/O is non_blocking, wolfSSL_accept() will return when the underlying I/O could not satisfy the needs of wolfSSL_accept to continue the handshake. In this case, a call to wolfSSL_get_error() will yield either SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE. The calling process must then repeat the call to wolfSSL_accept when data is available to read and wolfSSL will pick up where it left off. When using a non_blocking socket, nothing needs to be done, but select() can be used to check for the required condition. If the underlying I/O is blocking, wolfSSL_accept() will only return once the handshake has been finished or an error occurred. Call this function when expecting a TLS v1.3 connection though older version ClientHello messages are supported.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_get_error
- wolfSSL_connect_TLSv13
- wolfSSL_connect
- wolfSSL_accept_TLSv13
- wolfSSL_accept

Return:

- SSL_SUCCESS upon success.
- SSL_FATAL_ERROR will be returned if an error occurred. To get a more detailed error code, call wolfSSL_get_error().

Example

```
int ret = 0;
int err = 0;
WOLFSSL* ssl;
char buffer[80];
...

ret = wolfSSL_accept_TLSv13(ssl);
if (ret != SSL_SUCCESS) {
    err = wolfSSL_get_error(ssl, ret);
    printf("error = %d, %s\n", err, wolfSSL_ERR_error_string(err, buffer));
}
```

C.58.4.474 function wolfSSL_CTX_set_max_early_data

```
int wolfSSL_CTX_set_max_early_data(
    WOLFSSL_CTX * ctx,
    unsigned int sz
)
```

This function sets the maximum amount of early data that a TLS v1.3 client or server is willing to exchange using the wolfSSL context. Call this function to limit the amount of early data to process to mitigate replay attacks. Early data is protected by keys derived from those of the connection that the session ticket was sent and therefore will be the same every time a session ticket is used in resumption. The value is included in the session ticket for resumption. A server value of zero indicates no early data is to be sent by client using session tickets. A client value of zero indicates that the client will not send any early data. The default value is zero: per RFC 8446 Appendix E.5, TLS implementations "MUST NOT enable 0-RTT (either sending or accepting) unless specifically requested by the application." Servers must call this function (or the per-SSL equivalent) with a non-zero value to opt in. It is recommended that the number of early data bytes be kept as low as practically possible in the application.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created with wolfSSL_CTX_new().
- **sz** the amount of early data to accept in bytes.

See:

- wolfSSL_set_max_early_data
- wolfSSL_write_early_data
- wolfSSL_read_early_data

Return:

- BAD_FUNC_ARG if ctx is NULL or not using TLS v1.3.
- 0 if successful.

Example

```
int ret;
WOLFSSL_CTX* ctx;
...
ret = wolfSSL_CTX_set_max_early_data(ctx, 128);
if (ret != WOLFSSL_SUCCESS) {
    // failed to set group list
}
```

C.58.4.475 function wolfSSL_set_max_early_data

```
int wolfSSL_set_max_early_data(
    WOLFSSL * ssl,
    unsigned int sz
)
```

This function sets the maximum amount of early data that a TLS v1.3 client or server is willing to exchange. Call this function to limit the amount of early data to process to mitigate replay attacks. Early data is protected by keys derived from those of the connection that the session ticket was sent and therefore will be the same every time a session ticket is used in resumption. The value is included in the session ticket for resumption. A server value of zero indicates no early data is to be sent by client using session tickets. A client value of zero indicates that the client will not send any early data. It is recommended that the number of early data bytes be kept as low as practically possible in the application.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **sz** the amount of early data to accept from client in bytes.

See:

- wolfSSL_CTX_set_max_early_data
- wolfSSL_write_early_data
- wolfSSL_read_early_data

Return:

- BAD_FUNC_ARG if ssl is NULL or not using TLS v1.3.
- 0 if successful.

Example

```
int ret;
WOLFSSL* ssl;
...
ret = wolfSSL_set_max_early_data(ssl, 128);
if (ret != WOLFSSL_SUCCESS) {
    // failed to set group list
}
```

C.58.4.476 function wolfSSL_write_early_data

```
int wolfSSL_write_early_data(
    WOLFSSL * ssl,
    const void * data,
    int sz,
    int * outSz
)
```

This function writes early data to the server on resumption. Call this function before wolfSSL_connect() or wolfSSL_connect_TLSv13(). This function is only used with clients.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **data** the buffer holding the early data to write to server.
- **sz** the amount of early data to write in bytes.
- **outSz** the amount of early data written in bytes.

See:

- wolfSSL_read_early_data
- wolfSSL_connect
- wolfSSL_connect_TLSv13

Return:

- BAD_FUNC_ARG if a pointer parameter is NULL, sz is less than 0 or not using TLSv1.3.
- SIDE_ERROR if called with a server.
- BAD_STATE_E if invoked without a valid session or without a valid PSK cb
- WOLFSSL_FATAL_ERROR if the connection is not made, or if the AEAD key usage limit would be exceeded by this write, in which case wolfSSL_get_error() reports TOO_MUCH_EARLY_DATA. A KeyUpdate cannot be performed while sending early data (RFC 9846, Section 5.5), so no further early data can be sent on this connection. The write is all-or-nothing as usual: a value less than sz is never returned. Note that a failed call may still have put records on the wire before the limit was reached, so treat the connection as unusable for early data rather than resuming the send from an offset.
- the amount of early data written in bytes if successful.

Example

```
int ret = 0;
int err = 0;
WOLFSSL* ssl;
byte earlyData[] = { early data };
int outSz;
char buffer[80];
...

ret = wolfSSL_write_early_data(ssl, earlyData, sizeof(earlyData), &outSz);
if (ret < 0) {
    err = wolfSSL_get_error(ssl, ret);
    printf("error = %d, %s\n", err, wolfSSL_ERR_error_string(err, buffer));
    goto err_label;
}
if (outSz < sizeof(earlyData)) {
    // not all early data was sent
}
ret = wolfSSL_connect_TLSv13(ssl);
if (ret != SSL_SUCCESS) {
    err = wolfSSL_get_error(ssl, ret);
    printf("error = %d, %s\n", err, wolfSSL_ERR_error_string(err, buffer));
}
```

C.58.4.477 function wolfSSL_read_early_data

```
int wolfSSL_read_early_data(
    WOLFSSL * ssl,
    void * data,
    int sz,
    int * outSz
)
```

This function reads any early data from a client on resumption. Call this function instead of wolfSSL_accept() or wolfSSL_accept_TLSv13() to accept a client and read any early data in the handshake. The function should be invoked until wolfSSL_is_init_finished() returns true. Early data may be sent

by the client in multiple messages. If there is no early data then the handshake will be processed as normal. This function is only used with servers.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **data** a buffer to hold the early data read from client.
- **sz** size of the buffer in bytes.
- **outSz** number of bytes of early data read.

See:

- wolfSSL_write_early_data
- wolfSSL_accept
- wolfSSL_accept_TLSv13

Return:

- BAD_FUNC_ARG if a pointer parameter is NULL, sz is less than 0 or not using TLSv1.3.
- SIDE_ERROR if called with a client.
- WOLFSSL_FATAL_ERROR if accepting a connection fails.
- Number of early data bytes read (may be zero).

Example

```
int ret = 0;
int err = 0;
WOLFSSL* ssl;
byte earlyData[128];
int outSz;
char buffer[80];
...

do {
    ret = wolfSSL_read_early_data(ssl, earlyData, sizeof(earlyData), &outSz);
    if (ret < 0) {
        err = wolfSSL_get_error(ssl, ret);
        printf("error = %d, %s\n", err, wolfSSL_ERR_error_string(err, buffer));
    }
    if (outSz > 0) {
        // early data available
    }
} while (!wolfSSL_is_init_finished(ssl));
```

C.58.4.478 function wolfSSL_CTX_no_early_data_fresh_start_check

```
int wolfSSL_CTX_no_early_data_fresh_start_check(
    WOLFSSL_CTX * ctx
)
```

This function is called on the server to disable the RFC 8446 Section 8.2 fresh start protection. By default a freshly created context rejects early data, but not resumption, for session tickets minted before the context was created, since the anti-replay state for those tickets may not have survived a server restart. Only call this function when the anti-replay state (session cache or external cache) reliably survives server restarts.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created with wolfSSL_CTX_new().

See:

- wolfSSL_CTX_set_max_early_data
- wolfSSL_read_early_data

Return:

- BAD_FUNC_ARG if ctx is NULL or not using TLS v1.3.
- SIDE_ERROR if called with a client.
- 0 if successful.

The check compares the ticket timestamp against the context creation time, both taken from TimeNowInMilliseconds(). That clock is only required to be millisecond accurate, not correlated to the epoch, so on ports where it counts from boot (Windows QPC, Zephyr, FreeRTOS, Micrium, Microchip) it restarts near zero and the check does not fire for tickets minted before a reboot. Such deployments must rely on ticket key rotation instead.

Example

```
int ret;
WOLFSSL_CTX* ctx;
...
ret = wolfSSL_CTX_no_early_data_fresh_start_check(ctx);
if (ret != 0) {
    // failed to disable the fresh start check
}
```

C.58.4.479 function wolfSSL_inject

```
int wolfSSL_inject(
    WOLFSSL * ssl,
    const void * data,
    int sz
)
```

This function is called to inject data into the WOLFSSL object. This is useful when data needs to be read from a single place and demultiplexed into multiple connections. The caller should then call wolfSSL_read() to extract the plaintext data from the WOLFSSL object.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **data** data to inject into the ssl object.
- **sz** number of bytes of data to inject.

See: wolfSSL_read

Return:

- BAD_FUNC_ARG if any pointer parameter is NULL or sz <= 0
- BUFFER_ERROR if the input buffer lengths are inconsistent
- APP_DATA_READY if the input buffer must be grown while there is application data left to read
- MEMORY_E if allocation fails
- WOLFSSL_SUCCESS on success

Example

```
byte buf[2000]
sz = recv(fd, buf, sizeof(buf), 0);
if (sz <= 0)
    // error
```

```
if (wolfSSL_inject(ssl, buf, sz) != WOLFSSL_SUCCESS)
    // error
sz = wolfSSL_read(ssl, buf, sizeof(buf);
```

C.58.4.480 function wolfSSL_CTX_set_psk_client_tls13_callback

```
void wolfSSL_CTX_set_psk_client_tls13_callback(
    WOLFSSL_CTX * ctx,
    wc_psk_client_tls13_callback cb
)
```

This function sets the Pre-Shared Key (PSK) client side callback for TLS v1.3 connections. The callback is used to find a PSK identity and return its key and the name of the cipher to use for the handshake. The function sets the client_psk_tls13_cb member of the WOLFSSL_CTX structure.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created with wolfSSL_CTX_new().
- **cb** a Pre-Shared Key (PSK) callback for a TLS 1.3 client.

See:

- wolfSSL_set_psk_client_tls13_callback
- wolfSSL_CTX_set_psk_server_tls13_callback
- wolfSSL_set_psk_server_tls13_callback

Example

```
WOLFSSL_CTX* ctx;
...
wolfSSL_CTX_set_psk_client_tls13_callback(ctx, my_psk_client_tls13_cb);
```

C.58.4.481 function wolfSSL_set_psk_client_tls13_callback

```
void wolfSSL_set_psk_client_tls13_callback(
    WOLFSSL * ssl,
    wc_psk_client_tls13_callback cb
)
```

This function sets the Pre-Shared Key (PSK) client side callback for TLS v1.3 connections. The callback is used to find a PSK identity and return its key and the name of the cipher to use for the handshake. The function sets the client_psk_tls13_cb member of the options field in WOLFSSL structure.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **cb** a Pre-Shared Key (PSK) callback for a TLS 1.3 client.

See:

- wolfSSL_CTX_set_psk_client_tls13_callback
- wolfSSL_CTX_set_psk_server_tls13_callback
- wolfSSL_set_psk_server_tls13_callback

Example

```
WOLFSSL* ssl;
...
wolfSSL_set_psk_client_tls13_callback(ssl, my_psk_client_tls13_cb);
```

C.58.4.482 function wolfSSL_CTX_set_psk_server_tls13_callback

```
void wolfSSL_CTX_set_psk_server_tls13_callback(
    WOLFSSL_CTX * ctx,
    wc_psk_server_tls13_callback cb
)
```

This function sets the Pre-Shared Key (PSK) server side callback for TLS v1.3 connections. The callback is used to find a PSK identity and return its key and the name of the cipher to use for the handshake. The function sets the server_psk_tls13_cb member of the WOLFSSL_CTX structure.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created with wolfSSL_CTX_new().
- **cb** a Pre-Shared Key (PSK) callback for a TLS 1.3 server.

See:

- wolfSSL_CTX_set_psk_client_tls13_callback
- wolfSSL_set_psk_client_tls13_callback
- wolfSSL_set_psk_server_tls13_callback

Example

```
WOLFSSL_CTX* ctx;
...
wolfSSL_CTX_set_psk_server_tls13_callback(ctx, my_psk_client_tls13_cb);
```

C.58.4.483 function wolfSSL_set_psk_server_tls13_callback

```
void wolfSSL_set_psk_server_tls13_callback(
    WOLFSSL * ssl,
    wc_psk_server_tls13_callback cb
)
```

This function sets the Pre-Shared Key (PSK) server side callback for TLS v1.3 connections. The callback is used to find a PSK identity and return its key and the name of the cipher to use for the handshake. The function sets the server_psk_tls13_cb member of the options field in WOLFSSL structure.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **cb** a Pre-Shared Key (PSK) callback for a TLS 1.3 server.

See:

- wolfSSL_CTX_set_psk_client_tls13_callback
- wolfSSL_set_psk_client_tls13_callback
- wolfSSL_CTX_set_psk_server_tls13_callback

Example

```
WOLFSSL* ssl;
...
wolfSSL_set_psk_server_tls13_callback(ssl, my_psk_server_tls13_cb);
```

C.58.4.484 function wolfSSL_CTX_set_cert_with_extern_psk

```
int wolfSSL_CTX_set_cert_with_extern_psk(
    WOLFSSL_CTX * ctx,
    int state
)
```

Enable or disable TLS 1.3 certificate authentication with external PSK (RFC 9973) on a context.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created with wolfSSL_CTX_new().
- **state** 0 to disable, non-zero to enable.

See:

- wolfSSL_set_cert_with_extern_psk
- wolfSSL_CTX_set_psk_client_tls13_callback
- wolfSSL_CTX_set_psk_server_tls13_callback

Return:

- WOLFSSL_SUCCESS on success.
- WOLFSSL_FAILURE when `ctx` is NULL.

When enabled, wolfSSL advertises and accepts the `tls_cert_with_extern_psk` extension for TLS 1.3 handshakes using external PSKs. Any non-zero `state` value enables the feature and zero disables it.

Availability:

- Built with `--enable-tls13 --enable-psk --enable-cert-with-extern-psk`
- Or with `WOLFSSL_TLS13` and `WOLFSSL_CERT_WITH_EXTERN_PSK` defined

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new(wolfTLSv1_3_client_method());
if (wolfSSL_CTX_set_cert_with_extern_psk(ctx, 1) != WOLFSSL_SUCCESS) {
    /* handle error */
}
```

C.58.4.485 function wolfSSL_set_cert_with_extern_psk

```
int wolfSSL_set_cert_with_extern_psk(
    WOLFSSL * ssl,
    int state
)
```

Enable or disable TLS 1.3 certificate authentication with external PSK (RFC 9973) on a connection.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **state** 0 to disable, non-zero to enable.

See:

- wolfSSL_CTX_set_cert_with_extern_psk
- wolfSSL_set_psk_client_tls13_callback
- wolfSSL_set_psk_server_tls13_callback

Return:

- WOLFSSL_SUCCESS on success.
- WOLFSSL_FAILURE when `ssl` is NULL.

This call applies to a single WOLFSSL object. Any non-zero `state` value enables the feature and zero disables it.

Availability:

- Built with `--enable-tls13 --enable-psk --enable-cert-with-extern-psk`

- Or with WOLFSSL_TLS13 and WOLFSSL_CERT_WITH_EXTERN_PSK defined

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
if (wolfSSL_set_cert_with_extern_psk(ssl, 1) != WOLFSSL_SUCCESS) {
    /* handle error */
}
```

C.58.4.486 function wolfSSL_UseKeyShare

```
int wolfSSL_UseKeyShare(
    WOLFSSL * ssl,
    word16 group
)
```

This function creates a key share entry from the group including generating a key pair. The KeyShare extension contains all the generated public keys for key exchange. If this function is called, then only the groups specified will be included. Call this function when a preferred group has been previously established for the server.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **group** a key exchange group identifier.

See:

- wolfSSL_preferred_group
- wolfSSL_CTX_set1_groups_list
- wolfSSL_set1_groups_list
- wolfSSL_CTX_set_groups
- wolfSSL_set_groups
- wolfSSL_NoKeyShares

Return:

- BAD_FUNC_ARG if ssl is NULL.
- MEMORY_E when dynamic memory allocation fails.
- WOLFSSL_SUCCESS if successful.

Example

```
int ret;
WOLFSSL* ssl;
...
ret = wolfSSL_UseKeyShare(ssl, WOLFSSL_ECC_X25519);
if (ret != WOLFSSL_SUCCESS) {
    // failed to set key share
}
```

C.58.4.487 function wolfSSL_NoKeyShares

```
int wolfSSL_NoKeyShares(
    WOLFSSL * ssl
)
```

This function is called to ensure no key shares are sent in the ClientHello. This will force the server to respond with a HelloRetryRequest if a key exchange is required in the handshake. Call this function when the expected key exchange group is not known and to avoid the generation of keys unnecessarily.

Note that an extra round-trip will be required to complete the handshake when a key exchange is required.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See: wolfSSL_UseKeyShare

Return:

- BAD_FUNC_ARG if ssl is NULL.
- SIDE_ERROR if called with a server.
- WOLFSSL_SUCCESS if successful.

Example

```
int ret;
WOLFSSL* ssl;
...
ret = wolfSSL_NoKeyShares(ssl);
if (ret != WOLFSSL_SUCCESS) {
    // failed to set no key shares
}
```

C.58.4.488 function wolfTLSv1_3_server_method_ex

```
WOLFSSL_METHOD * wolfTLSv1_3_server_method_ex(
    void * heap
)
```

This function is used to indicate that the application is a server and will only support the TLS 1.3 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().

Parameters:

- **heap** a pointer to a buffer that the static memory allocator will use during dynamic memory allocation.

See:

- wolfSSLv3_server_method
- wolfTLSv1_server_method
- wolfTLSv1_1_server_method
- wolfTLSv1_2_server_method
- wolfTLSv1_3_server_method
- wolfDTLSv1_server_method
- wolfSSLv23_server_method
- wolfSSL_CTX_new

Return:

- If successful, the call will return a pointer to the newly created WOLFSSL_METHOD structure.
- FAIL If memory allocation fails when calling XMALLOC, the failure value of the underlying malloc() implementation will be returned (typically NULL with errno will be set to ENOMEM).

Example

```
#include <wolfssl/ssl.h>

WOLFSSL_METHOD* method;
```

```
WOLFSSL_CTX* ctx;

method = wolfTLSv1_3_server_method_ex(NULL);
if (method == NULL) {
    // unable to get method
}

ctx = wolfSSL_CTX_new(method);
...
```

C.58.4.489 function wolfTLSv1_3_client_method_ex

```
WOLFSSL_METHOD * wolfTLSv1_3_client_method_ex(
    void * heap
)
```

This function is used to indicate that the application is a client and will only support the TLS 1.3 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().

Parameters:

- **heap** a pointer to a buffer that the static memory allocator will use during dynamic memory allocation.

See:

- wolfSSLv3_client_method
- wolfTLSv1_client_method
- wolfTLSv1_1_client_method
- wolfTLSv1_2_client_method
- wolfTLSv1_3_client_method
- wolfDTLSv1_client_method
- wolfSSLv23_client_method
- wolfSSL_CTX_new

Return:

- If successful, the call will return a pointer to the newly created WOLFSSL_METHOD structure.
- FAIL If memory allocation fails when calling XMALLOC, the failure value of the underlying malloc() implementation will be returned (typically NULL with errno will be set to ENOMEM).

Example

```
#include <wolfssl/ssl.h>

WOLFSSL_METHOD* method;
WOLFSSL_CTX* ctx;

method = wolfTLSv1_3_client_method_ex(NULL);
if (method == NULL) {
    // unable to get method
}

ctx = wolfSSL_CTX_new(method);
...
```

C.58.4.490 function wolfTLSv1_3_server_method

```
WOLFSSL_METHOD * wolfTLSv1_3_server_method(
    void
)
```

This function is used to indicate that the application is a server and will only support the TLS 1.3 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().

See:

- wolfSSLv3_server_method
- wolfTLSv1_server_method
- wolfTLSv1_1_server_method
- wolfTLSv1_2_server_method
- wolfTLSv1_3_server_method_ex
- wolfDTLSv1_server_method
- wolfSSLv23_server_method
- wolfSSL_CTX_new

Return:

- If successful, the call will return a pointer to the newly created WOLFSSL_METHOD structure.
- FAIL If memory allocation fails when calling XMALLOC, the failure value of the underlying malloc() implementation will be returned (typically NULL with errno will be set to ENOMEM).

Example

```
#include <wolfssl/ssl.h>

WOLFSSL_METHOD* method;
WOLFSSL_CTX* ctx;

method = wolfTLSv1_3_server_method();
if (method == NULL) {
    // unable to get method
}

ctx = wolfSSL_CTX_new(method);
...
```

C.58.4.491 function wolfTLSv1_3_client_method

```
WOLFSSL_METHOD * wolfTLSv1_3_client_method(
    void
)
```

This function is used to indicate that the application is a client and will only support the TLS 1.3 protocol. This function allocates memory for and initializes a new wolfSSL_METHOD structure to be used when creating the SSL/TLS context with wolfSSL_CTX_new().

See:

- wolfSSLv3_client_method
- wolfTLSv1_client_method
- wolfTLSv1_1_client_method
- wolfTLSv1_2_client_method
- wolfTLSv1_3_client_method_ex
- wolfDTLSv1_client_method

- wolfSSLv23_client_method
- wolfSSL_CTX_new

Return:

- If successful, the call will return a pointer to the newly created WOLFSSL_METHOD structure.
- FAIL If memory allocation fails when calling XMALLOC, the failure value of the underlying malloc() implementation will be returned (typically NULL with errno will be set to ENOMEM).

Example

```
#include <wolfssl/ssl.h>

WOLFSSL_METHOD* method;
WOLFSSL_CTX* ctx;

method = wolfTLSv1_3_client_method();
if (method == NULL) {
    // unable to get method
}

ctx = wolfSSL_CTX_new(method);
...
```

C.58.4.492 function wolfTLSv1_3_method_ex

```
WOLFSSL_METHOD * wolfTLSv1_3_method_ex(
    void * heap
)
```

This function returns a WOLFSSL_METHOD similar to wolfTLSv1_3_client_method except that it is not determined which side yet (server/client).

Parameters:

- **heap** a pointer to a buffer that the static memory allocator will use during dynamic memory allocation.

See:

- wolfSSL_new
- wolfSSL_free

Return:

- WOLFSSL_METHOD On successful creations returns a WOLFSSL_METHOD pointer
- NULL Null if memory allocation error or failure to create method

Example

```
WOLFSSL* ctx;
ctx  = wolfSSL_CTX_new(wolfTLSv1_3_method_ex(NULL));
// check ret value
```

C.58.4.493 function wolfTLSv1_3_method

```
WOLFSSL_METHOD * wolfTLSv1_3_method(
    void
)
```

This function returns a WOLFSSL_METHOD similar to wolfTLSv1_3_client_method except that it is not determined which side yet (server/client).

See:

- wolfSSL_new
- wolfSSL_free

Return:

- WOLFSSL_METHOD On successful creations returns a WOLFSSL_METHOD pointer
- NULL Null if memory allocation error or failure to create method

Example

```
WOLFSSL* ctx;
ctx  = wolfSSL_CTX_new(wolfTLSv1_3_method());
// check ret value
```

C.58.4.494 function wolfSSL_CTX_set_ephemeral_key

```
int wolfSSL_CTX_set_ephemeral_key(
    WOLFSSL_CTX * ctx,
    int keyAlgo,
    const char * key,
    unsigned int keySz,
    int format
)
```

This function sets a fixed / static ephemeral key for testing only.

Parameters:

- **ctx** A WOLFSSL_CTX context pointer
- **keyAlgo** enum wc_PkType like WC_PK_TYPE_DH and WC_PK_TYPE_ECDH
- **key** key file path (if keySz == 0) or actual key buffer (PEM or ASN.1)
- **keySz** key size (should be 0 for “key” arg is file path)
- **format** WOLFSSL_FILETYPE_ASN1 or WOLFSSL_FILETYPE_PEM

See: wolfSSL_CTX_get_ephemeral_key

Return: 0 Key loaded successfully

C.58.4.495 function wolfSSL_set_ephemeral_key

```
int wolfSSL_set_ephemeral_key(
    WOLFSSL * ssl,
    int keyAlgo,
    const char * key,
    unsigned int keySz,
    int format
)
```

This function sets a fixed / static ephemeral key for testing only.

Parameters:

- **ssl** A WOLFSSL object pointer
- **keyAlgo** enum wc_PkType like WC_PK_TYPE_DH and WC_PK_TYPE_ECDH
- **key** key file path (if keySz == 0) or actual key buffer (PEM or ASN.1)
- **keySz** key size (should be 0 for “key” arg is file path)

- **format** WOLFSSL_FILETYPE_ASN1 or WOLFSSL_FILETYPE_PEM

See: wolfSSL_get_ephemeral_key

Return: 0 Key loaded successfully

C.58.4.496 function wolfSSL_CTX_get_ephemeral_key

```
int wolfSSL_CTX_get_ephemeral_key(
    WOLFSSL_CTX * ctx,
    int keyAlgo,
    const unsigned char ** key,
    unsigned int * keySz
)
```

This function returns pointer to loaded key as ASN.1/DER.

Parameters:

- **ctx** A WOLFSSL_CTX context pointer
- **keyAlgo** enum wc_PkType like WC_PK_TYPE_DH and WC_PK_TYPE_ECDH
- **key** key buffer pointer
- **keySz** key size pointer

See: wolfSSL_CTX_set_ephemeral_key

Return: 0 Key returned successfully

C.58.4.497 function wolfSSL_get_ephemeral_key

```
int wolfSSL_get_ephemeral_key(
    WOLFSSL * ssl,
    int keyAlgo,
    const unsigned char ** key,
    unsigned int * keySz
)
```

This function returns pointer to loaded key as ASN.1/DER.

Parameters:

- **ssl** A WOLFSSL object pointer
- **keyAlgo** enum wc_PkType like WC_PK_TYPE_DH and WC_PK_TYPE_ECDH
- **key** key buffer pointer
- **keySz** key size pointer

See: wolfSSL_set_ephemeral_key

Return: 0 Key returned successfully

C.58.4.498 function wolfSSL_RSA_sign_generic_padding

```
int wolfSSL_RSA_sign_generic_padding(
    int hashAlg,
    const unsigned char * hash,
    unsigned int hLen,
    unsigned char * sigRet,
    unsigned int * sigLen,
    WOLFSSL_RSA * rsa,
    int flag,
```

```
    int padding
)
```

Sign a message with the chosen message digest, padding, and RSA key.

Parameters:

- **type** Hash NID
- **m** Message to sign. Most likely this will be the digest of the message to sign
- **mLen** Length of message to sign
- **sigRet** Output buffer
- **sigLen** On Input: length of sigRet buffer On Output: length of data written to sigRet
- **rsa** RSA key used to sign the input
- **flag** 1: Output the signature 0: Output the value that the unpadded signature should be compared to. Note: for RSA_PKCS1_PSS_PADDING the wc_RsaPSS_CheckPadding_ex function should be used to check the output of a *Verify* function.
- **padding** Padding to use. Only RSA_PKCS1_PSS_PADDING and RSA_PKCS1_PADDING are currently supported for signing.

Return: WOLFSSL_SUCCESS on success and c on error

C.58.4.499 function wolfSSL_dtls13_has_pending_msg

```
int wolfSSL_dtls13_has_pending_msg(
    WOLFSSL * ssl
)
```

checks if DTLSv1.3 stack has some messages sent but not yet acknowledged by the other peer

Parameters:

- **ssl** A WOLFSSL object pointer

Return: 1 if there are pending messages, 0 otherwise

C.58.4.500 function wolfSSL_SESSION_get_max_early_data

```
unsigned int wolfSSL_SESSION_get_max_early_data(
    const WOLFSSL_SESSION * s
)
```

Get the maximum size of Early Data from a session.

Parameters:

- **s** the WOLFSSL_SESSION instance.

See:

- wolfSSL_set_max_early_data
- wolfSSL_write_early_data
- wolfSSL_read_early_data

Return: the value of max_early_data that was configured in the WOLFSSL* the session was derived from.

C.58.4.501 function wolfSSL_CRYPTO_get_ex_new_index

```
int wolfSSL_CRYPTO_get_ex_new_index(
    int class_index,
    long argl,
```

```
    void * argp,
    WOLFSSL_CRYPTO_EX_new * new_func,
    WOLFSSL_CRYPTO_EX_dup * dup_func,
    WOLFSSL_CRYPTO_EX_free * free_func
)
```

Get a new index for external data. This entry applies also for the following API:

Parameters:

- **class_index** Identifier for the object class the external data index applies to. Ignored by wolfSSL.
- **argl** Optional long argument passed through for compatibility. Ignored by wolfSSL.
- **argp** Optional pointer argument passed through for compatibility. Ignored by wolfSSL.
- **new_func** Pointer to an external data constructor callback. Ignored by wolfSSL.
- **dup_func** Pointer to an external data duplicate callback. Ignored by wolfSSL.
- **free_func** Pointer to an external data destructor callback. Ignored by wolfSSL.

Return: The new index value to be used with the external data API for this object class.

- wolfSSL_CTX_get_ex_new_index
- wolfSSL_get_ex_new_index
- wolfSSL_SESSION_get_ex_new_index
- wolfSSL_X509_get_ex_new_index

C.58.4.502 function wolfSSL_CTX_set_client_cert_type

```
int wolfSSL_CTX_set_client_cert_type(
    WOLFSSL_CTX * ctx,
    const char * buf,
    int len
)
```

In case this function is called in a client side, set certificate types that can be sent to its peer. In case called in a server side, set certificate types that can be acceptable from its peer. Put cert types in the buffer with prioritised order. To reset the settings to default, pass NULL for the buffer or pass zero for len. By default, certificate type is only X509. In case both side intend to send or accept “Raw public key” cert, WOLFSSL_CERT_TYPE_RPK should be included in the buffer to set.

Parameters:

- **ctx** WOLFSSL_CTX object pointer
- **buf** A buffer where certificate types are stored
- **len** buf size in bytes (same as number of certificate types included) *Example*

```
int ret;
WOLFSSL_CTX* ctx;
char buf[] = {WOLFSSL_CERT_TYPE_RPK, WOLFSSL_CERT_TYPE_X509};
int len = sizeof(buf)/sizeof(char);
...

ret = wolfSSL_CTX_set_client_cert_type(ctx, buf, len);
```

See:

- wolfSSL_set_client_cert_type
- wolfSSL_CTX_set_server_cert_type
- wolfSSL_set_server_cert_type
- wolfSSL_get_negotiated_client_cert_type
- wolfSSL_get_negotiated_server_cert_type

Return:

- WOLFSSL_SUCCESS if cert types set successfully
- BAD_FUNC_ARG if NULL was passed for ctx, illegal value was specified as cert type, buf size exceed MAX_CLIENT_CERT_TYPE_CNT was specified or a duplicate value is found in buf.

C.58.4.503 function wolfSSL_CTX_set_server_cert_type

```
int wolfSSL_CTX_set_server_cert_type(
    WOLFSSL_CTX * ctx,
    const char * buf,
    int len
)
```

In case this function is called in a server side, set certificate types that can be sent to its peer. In case called in a client side, set certificate types that can be acceptable from its peer. Put cert types in the buffer with prioritised order. To reset the settings to default, pass NULL for the buffer or pass zero for len. By default, certificate type is only X509. In case both side intend to send or accept "Raw public key" cert, WOLFSSL_CERT_TYPE_RPK should be included in the buffer to set.

Parameters:

- **ctx** WOLFSSL_CTX object pointer
- **buf** A buffer where certificate types are stored
- **len** buf size in bytes (same as number of certificate types included) *Example*

```
int ret;
WOLFSSL_CTX* ctx;
char buf[] = {WOLFSSL_CERT_TYPE_RPK, WOLFSSL_CERT_TYPE_X509};
int len = sizeof(buf)/sizeof(char);
...

ret = wolfSSL_CTX_set_server_cert_type(ctx, buf, len);
```

See:

- wolfSSL_set_client_cert_type
- wolfSSL_CTX_set_client_cert_type
- wolfSSL_set_server_cert_type
- wolfSSL_get_negotiated_client_cert_type
- wolfSSL_get_negotiated_server_cert_type

Return:

- WOLFSSL_SUCCESS if cert types set successfully
- BAD_FUNC_ARG if NULL was passed for ctx, illegal value was specified as cert type, buf size exceed MAX_SERVER_CERT_TYPE_CNT was specified or a duplicate value is found in buf.

C.58.4.504 function wolfSSL_set_client_cert_type

```
int wolfSSL_set_client_cert_type(
    WOLFSSL * ssl,
    const char * buf,
    int len
)
```

In case this function is called in a client side, set certificate types that can be sent to its peer. In case called in a server side, set certificate types that can be acceptable from its peer. Put cert types in the buffer with prioritised order. To reset the settings to default, pass NULL for the buffer or pass zero for

len. By default, certificate type is only X509. In case both side intend to send or accept “Raw public key” cert, WOLFSSL_CERT_TYPE_RPK should be included in the buffer to set.

Parameters:

- **ssl** WOLFSSL object pointer
- **buf** A buffer where certificate types are stored
- **len** buf size in bytes (same as number of certificate types included) *Example*

```
int ret;
WOLFSSL* ssl;
char buf[] = {WOLFSSL_CERT_TYPE_RPK, WOLFSSL_CERT_TYPE_X509};
int len = sizeof(buf)/sizeof(char);
...

ret = wolfSSL_set_client_cert_type(ssl, buf, len);
```

See:

- wolfSSL_CTX_set_client_cert_type
- wolfSSL_CTX_set_server_cert_type
- wolfSSL_set_server_cert_type
- wolfSSL_get_negotiated_client_cert_type
- wolfSSL_get_negotiated_server_cert_type

Return:

- WOLFSSL_SUCCESS if cert types set successfully
- BAD_FUNC_ARG if NULL was passed for ctx, illegal value was specified as cert type, buf size exceed MAX_CLIENT_CERT_TYPE_CNT was specified or a duplicate value is found in buf.

C.58.4.505 function wolfSSL_set_server_cert_type

```
int wolfSSL_set_server_cert_type(
    WOLFSSL * ssl,
    const char * buf,
    int len
)
```

In case this function is called in a server side, set certificate types that can be sent to its peer. In case called in a client side, set certificate types that can be acceptable from its peer. Put cert types in the buffer with prioritised order. To reset the settings to default, pass NULL for the buffer or pass zero for len. By default, certificate type is only X509. In case both side intend to send or accept “Raw public key” cert, WOLFSSL_CERT_TYPE_RPK should be included in the buffer to set.

Parameters:

- **ctx** WOLFSSL_CTX object pointer
- **buf** A buffer where certificate types are stored
- **len** buf size in bytes (same as number of certificate types included) *Example*

```
int ret;
WOLFSSL* ssl;
char buf[] = {WOLFSSL_CERT_TYPE_RPK, WOLFSSL_CERT_TYPE_X509};
int len = sizeof(buf)/sizeof(char);
...

ret = wolfSSL_set_server_cert_type(ssl, buf, len);
```

See:

- wolfSSL_set_client_cert_type
- wolfSSL_CTX_set_server_cert_type
- wolfSSL_set_server_cert_type
- wolfSSL_get_negotiated_client_cert_type
- wolfSSL_get_negotiated_server_cert_type

Return:

- WOLFSSL_SUCCESS if cert types set successfully
- BAD_FUNC_ARG if NULL was passed for ctx, illegal value was specified as cert type, buf size exceed MAX_SERVER_CERT_TYPE_CNT was specified or a duplicate value is found in buf.

C.58.4.506 function wolfSSL_CTX_clear_group_messages

```
int wolfSSL_CTX_clear_group_messages(
    WOLFSSL_CTX * ctx
)
```

Disables handshake message grouping for the given WOLFSSL_CTX context.

Parameters:

- **ctx** Pointer to the WOLFSSL_CTX structure.

See:

- wolfSSL_CTX_set_group_messages
- wolfSSL_set_group_messages
- wolfSSL_clear_group_messages

Return:

- WOLFSSL_SUCCESS on success.
- BAD_FUNC_ARG if ctx is NULL.

This function turns off handshake message grouping for all SSL objects created from the specified context.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new(wolfTLSv1_2_client_method());
wolfSSL_CTX_clear_group_messages(ctx);
```

C.58.4.507 function wolfSSL_clear_group_messages

```
int wolfSSL_clear_group_messages(
    WOLFSSL * ssl
)
```

Disables handshake message grouping for the given WOLFSSL object.

Parameters:

- **ssl** Pointer to the WOLFSSL structure.

See:

- wolfSSL_set_group_messages
- wolfSSL_CTX_set_group_messages
- wolfSSL_CTX_clear_group_messages

Return:

- WOLFSSL_SUCCESS on success.

- BAD_FUNC_ARG if ssl is NULL.

This function turns off handshake message grouping for the specified SSL object.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
wolfSSL_clear_group_messages(ssl);
```

C.58.4.508 function wolfSSL_get_negotiated_client_cert_type

```
int wolfSSL_get_negotiated_client_cert_type(
    WOLFSSL * ssl,
    int * tp
)
```

This function returns the result of the client certificate type negotiation done in ClientHello and ServerHello. WOLFSSL_SUCCESS is returned as a return value if no negotiation occurs and WOLFSSL_CERT_TYPE_UNKNOWN is returned as the certificate type.

Parameters:

- **ssl** WOLFSSL object pointer
- **tp** A buffer where a certificate type is to be returned. One of three certificate types will be returned: WOLFSSL_CERT_TYPE_RPK, WOLFSSL_CERT_TYPE_X509 or WOLFSSL_CERT_TYPE_UNKNOWN.

See:

- wolfSSL_set_client_cert_type
- wolfSSL_CTX_set_client_cert_type
- wolfSSL_set_server_cert_type
- wolfSSL_CTX_set_server_cert_type
- wolfSSL_get_negotiated_server_cert_type

Return:

- WOLFSSL_SUCCESS if a negotiated certificate type could be got
- BAD_FUNC_ARG if NULL was passed for ctx or tp

Example

```
int ret;
WOLFSSL* ssl;
int tp;
...

ret = wolfSSL_get_negotiated_client_cert_type(ssl, &tp);
```

C.58.4.509 function wolfSSL_get_negotiated_server_cert_type

```
int wolfSSL_get_negotiated_server_cert_type(
    WOLFSSL * ssl,
    int * tp
)
```

This function returns the result of the server certificate type negotiation done in ClientHello and ServerHello. WOLFSSL_SUCCESS is returned as a return value if no negotiation occurs and WOLFSSL_CERT_TYPE_UNKNOWN is returned as the certificate type.

Parameters:

- **ssl** WOLFSSL object pointer

- **tp** A buffer where a certificate type is to be returned. One of three certificate types will be returned: WOLFSSL_CERT_TYPE_RPK, WOLFSSL_CERT_TYPE_X509 or WOLFSSL_CERT_TYPE_UNKNOWN. *Example*

```
int ret;
WOLFSSL* ssl;
int tp;
...

ret = wolfSSL_get_negotiated_server_cert_type(ssl, &tp);
```

See:

- wolfSSL_set_client_cert_type
- wolfSSL_CTX_set_client_cert_type
- wolfSSL_set_server_cert_type
- wolfSSL_CTX_set_server_cert_type
- wolfSSL_get_negotiated_client_cert_type

Return:

- WOLFSSL_SUCCESS if a negotiated certificate type could be got
- BAD_FUNC_ARG if NULL was passed for ctx or tp

C.58.4.510 function wolfSSL_CTX_set_expected_rpk

```
int wolfSSL_CTX_set_expected_rpk(
    WOLFSSL_CTX * ctx,
    const unsigned char * spki,
    unsigned int spkiSz
)
```

Pin a DER-encoded SubjectPublicKeyInfo that the peer is expected to present as a Raw Public Key (RFC 7250), establishing out-of-band trust on the WOLFSSL_CTX object. An unauthenticated RPK peer is otherwise rejected: when the peer is being authenticated (any verify mode other than WOLFSSL_VERIFY_NONE) the handshake fails closed unless the presented key matches a pin (or a verify callback accepts it). May be called more than once to pin several keys, up to WOLFSSL_MAX_RPK_PINS. The key is stored as its SHA-256 digest, so this API requires SHA-256. Pins are append-only - there is no per-entry remove, but wolfSSL_CTX_clear_expected_rpk() empties the table so it can be repopulated.

Parameters:

- **ctx** WOLFSSL_CTX object pointer
- **spki** DER-encoded SubjectPublicKeyInfo the peer is expected to present
- **spkiSz** length of spki in bytes *Example*

```
int ret;
WOLFSSL_CTX* ctx;
const unsigned char* spki;
unsigned int spkiSz;
...

ret = wolfSSL_CTX_set_expected_rpk(ctx, spki, spkiSz);
```

See:

- wolfSSL_set_expected_rpk
- wolfSSL_CTX_clear_expected_rpk
- wolfSSL_set_client_cert_type
- wolfSSL_set_server_cert_type

Return:

- WOLFSSL_SUCCESS on success
- BAD_FUNC_ARG if ctx or spki is NULL, or spkiSz is 0
- BUFFER_E if the pin table is already full (WOLFSSL_MAX_RPK_PINS)
- other negative error code on a hashing failure

C.58.4.511 function wolfSSL_set_expected_rpk

```
int wolfSSL_set_expected_rpk(
    WOLFSSL * ssl,
    const unsigned char * spki,
    unsigned int spkiSz
)
```

Pin a DER-encoded SubjectPublicKeyInfo that the peer is expected to present as a Raw Public Key (RFC 7250), establishing out-of-band trust on the WOLFSSL object. An unauthenticated RPK peer is otherwise rejected: when the peer is being authenticated (any verify mode other than WOLFSSL_VERIFY_NONE) the handshake fails closed unless the presented key matches a pin (or a verify callback accepts it). May be called more than once to pin several keys, up to WOLFSSL_MAX_RPK_PINS. The key is stored as its SHA-256 digest, so this API requires SHA-256. Pins are append-only - there is no per-entry remove, but wolfSSL_clear_expected_rpk() empties the table so it can be repopulated.

Parameters:

- **ssl** WOLFSSL object pointer
- **spki** DER-encoded SubjectPublicKeyInfo the peer is expected to present
- **spkiSz** length of spki in bytes *Example*

```
int ret;
WOLFSSL* ssl;
const unsigned char* spki;
unsigned int spkiSz;
...

ret = wolfSSL_set_expected_rpk(ssl, spki, spkiSz);
```

See:

- wolfSSL_CTX_set_expected_rpk
- wolfSSL_clear_expected_rpk
- wolfSSL_set_client_cert_type
- wolfSSL_set_server_cert_type

Return:

- WOLFSSL_SUCCESS on success
- BAD_FUNC_ARG if ssl or spki is NULL, or spkiSz is 0
- BUFFER_E if the pin table is already full (WOLFSSL_MAX_RPK_PINS)
- other negative error code on a hashing failure

C.58.4.512 function wolfSSL_CTX_clear_expected_rpk

```
int wolfSSL_CTX_clear_expected_rpk(
    WOLFSSL_CTX * ctx
)
```

Remove all pinned expected peer Raw Public Keys (RFC 7250) from the WOLFSSL_CTX object, emptying the table so it can be repopulated - for example across a peer key rotation, since the pinning APIs are

otherwise append-only. Like other WOLFSSL_CTX setters this is not locked, so reconfigure the pins on a shared CTX while no handshakes are in flight (a WOLFSSL created with wolfSSL_new() copies the pin table by value at creation time).

Parameters:

- **ctx** WOLFSSL_CTX object pointer *Example*

```
WOLFSSL_CTX* ctx;
...

wolfSSL_CTX_clear_expected_rpk(ctx);
```

See:

- wolfSSL_CTX_set_expected_rpk
- wolfSSL_clear_expected_rpk

Return:

- WOLFSSL_SUCCESS on success
- BAD_FUNC_ARG if ctx is NULL

C.58.4.513 function wolfSSL_clear_expected_rpk

```
int wolfSSL_clear_expected_rpk(
    WOLFSSL * ssl
)
```

Remove all pinned expected peer Raw Public Keys (RFC 7250) from the WOLFSSL object, emptying the table so it can be repopulated - for example across a peer key rotation, since the pinning APIs are otherwise append-only.

Parameters:

- **ssl** WOLFSSL object pointer *Example*

```
WOLFSSL* ssl;
...

wolfSSL_clear_expected_rpk(ssl);
```

See:

- wolfSSL_set_expected_rpk
- wolfSSL_CTX_clear_expected_rpk

Return:

- WOLFSSL_SUCCESS on success
- BAD_FUNC_ARG if ssl is NULL

C.58.4.514 function wolfSSL_dtls_cid_use

```
int wolfSSL_dtls_cid_use(
    WOLFSSL * ssl
)
```

Enable use of ConnectionID extensions for the SSL object. See RFC 9146 and RFC 9147.

Parameters:

- **ssl** A WOLFSSL object pointer

See:

- wolfSSL_dtls_cid_is_enabled
- wolfSSL_dtls_cid_set
- wolfSSL_dtls_cid_get_rx_size
- wolfSSL_dtls_cid_get_rx
- wolfSSL_dtls_cid_get_tx_size
- wolfSSL_dtls_cid_get_tx

Return: WOLFSSL_SUCCESS on success, error code otherwise

C.58.4.515 function wolfSSL_dtls_cid_is_enabled

```
int wolfSSL_dtls_cid_is_enabled(
    WOLFSSL * ssl
)
```

If invoked after the handshake is complete it checks if ConnectionID was successfully negotiated for the SSL object. See RFC 9146 and RFC 9147.

Parameters:

- **ssl** A WOLFSSL object pointer

See:

- wolfSSL_dtls_cid_use
- wolfSSL_dtls_cid_set
- wolfSSL_dtls_cid_get_rx_size
- wolfSSL_dtls_cid_get_rx
- wolfSSL_dtls_cid_get_tx_size
- wolfSSL_dtls_cid_get_tx

Return: 1 if ConnectionID was correctly negotiated, 0 otherwise

C.58.4.516 function wolfSSL_dtls_cid_set

```
int wolfSSL_dtls_cid_set(
    WOLFSSL * ssl,
    unsigned char * cid,
    unsigned int size
)
```

Set the ConnectionID used by the other peer to send records in this connection. See RFC 9146 and RFC 9147. The ConnectionID must be at maximum DTLS_CID_MAX_SIZE, that is an tunable compile time define, and it can't never be bigger than 255 bytes.

Parameters:

- **ssl** A WOLFSSL object pointern
- **cid** the ConnectionID to be used
- **size** of the ConnectionID provided

See:

- wolfSSL_dtls_cid_use
- wolfSSL_dtls_cid_is_enabled
- wolfSSL_dtls_cid_get_rx_size
- wolfSSL_dtls_cid_get_rx
- wolfSSL_dtls_cid_get_tx_size
- wolfSSL_dtls_cid_get_tx

Return: WOLFSSL_SUCCESS if ConnectionID was correctly set, error code otherwise

C.58.4.517 function wolfSSL_dtls_cid_get_rx_size

```
int wolfSSL_dtls_cid_get_rx_size(
    WOLFSSL * ssl,
    unsigned int * size
)
```

Get the size of the ConnectionID used by the other peer to send records in this connection. See RFC 9146 and RFC 9147. The size is stored in the parameter size.

Parameters:

- **ssl** A WOLFSSL object pointern
- **size** a pointer to an unsigned int where the size will be stored

See:

- wolfSSL_dtls_cid_use
- wolfSSL_dtls_cid_is_enabled
- wolfSSL_dtls_cid_set
- wolfSSL_dtls_cid_get_rx
- wolfSSL_dtls_cid_get_tx_size
- wolfSSL_dtls_cid_get_tx

Return: WOLFSSL_SUCCESS if ConnectionID was correctly negotiated, error code otherwise

C.58.4.518 function wolfSSL_dtls_cid_get_rx

```
int wolfSSL_dtls_cid_get_rx(
    WOLFSSL * ssl,
    unsigned char * buffer,
    unsigned int bufferSz
)
```

Copy the ConnectionID used by the other peer to send records in this connection into the buffer pointed by the parameter buffer. See RFC 9146 and RFC.

1. The available space in the buffer need to be provided in bufferSz. WOLFSSL_SUCCESS if ConnectionID was correctly copied, error code otherwise

sslA WOLFSSL object pointern

bufferA buffer where the ConnectionID will be copied

bufferSzavailable space in buffer

wolfSSL_dtls_cid_get0_rx

wolfSSL_dtls_cid_use

wolfSSL_dtls_cid_is_enabled

wolfSSL_dtls_cid_set

wolfSSL_dtls_cid_get_rx_size

wolfSSL_dtls_cid_get_tx_size

wolfSSL_dtls_cid_get_tx

C.58.4.519 function wolfSSL_dtls_cid_get0_rx

```
int wolfSSL_dtls_cid_get0_rx(
    WOLFSSL * ssl,
    unsigned char ** cid
)
```

Get the ConnectionID used by the other peer. See RFC 9146 and RFC 9147.

Parameters:

- **ssl** A WOLFSSL object pointern
- **cid** Pointer that will be set to the internal memory that holds the CID

See:

- wolfSSL_dtls_cid_get_rx
- wolfSSL_dtls_cid_use
- wolfSSL_dtls_cid_is_enabled
- wolfSSL_dtls_cid_set
- wolfSSL_dtls_cid_get_rx_size
- wolfSSL_dtls_cid_get_tx_size
- wolfSSL_dtls_cid_get_tx

Return: WOLFSSL_SUCCESS if ConnectionID was correctly set in cid.

C.58.4.520 function wolfSSL_dtls_cid_get_tx_size

```
int wolfSSL_dtls_cid_get_tx_size(
    WOLFSSL * ssl,
    unsigned int * size
)
```

Get the size of the ConnectionID used to send records in this connection. See RFC 9146 and RFC 9147. The size is stored in the parameter size. The send ConnectionID is chosen by the peer. On DTLS 1.3 it may be up to 255 bytes and is not bounded by wolfSSL_dtls_cid_max_size(); on DTLS 1.2 it never exceeds wolfSSL_dtls_cid_max_size().

Parameters:

- **ssl** A WOLFSSL object pointern
- **size** a pointer to an unsigned int where the size will be stored

See:

- wolfSSL_dtls_cid_use
- wolfSSL_dtls_cid_is_enabled
- wolfSSL_dtls_cid_set
- wolfSSL_dtls_cid_get_rx_size
- wolfSSL_dtls_cid_get_rx
- wolfSSL_dtls_cid_get_tx

Return: WOLFSSL_SUCCESS if ConnectionID size was correctly stored, error code otherwise

C.58.4.521 function wolfSSL_dtls_cid_get_tx

```
int wolfSSL_dtls_cid_get_tx(
    WOLFSSL * ssl,
    unsigned char * buffer,
    unsigned int bufferSz
)
```

Copy the ConnectionID used when sending records in this connection into the buffer pointer by the parameter buffer. See RFC 9146 and RFC 9147. The available size need to be provided in bufferSz. The send ConnectionID is chosen by the peer. On DTLS 1.3 it may be up to 255 bytes and is not bounded by wolfSSL_dtls_cid_max_size(), so size the buffer from wolfSSL_dtls_cid_get_tx_size() (or use 255 bytes) rather than from wolfSSL_dtls_cid_max_size(), otherwise this returns LENGTH_ERROR.

Parameters:

- **ssl** A WOLFSSL object pointern
- **buffer** A buffer where the ConnectionID will be copied
- **bufferSz** available space in buffer

See:

- wolfSSL_dtls_cid_get0_tx
- wolfSSL_dtls_cid_use
- wolfSSL_dtls_cid_is_enabled
- wolfSSL_dtls_cid_set
- wolfSSL_dtls_cid_get_rx_size
- wolfSSL_dtls_cid_get_rx
- wolfSSL_dtls_cid_get_tx_size

Return: WOLFSSL_SUCCESS if ConnectionID was correctly copied, error code otherwise

C.58.4.522 function wolfSSL_dtls_cid_get0_tx

```
int wolfSSL_dtls_cid_get0_tx(
    WOLFSSL * ssl,
    unsigned char ** cid
)
```

Get the ConnectionID used when sending records in this connection. See RFC 9146 and RFC 9147. The send ConnectionID is chosen by the peer. On DTLS 1.3 it may be up to 255 bytes and is not bounded by wolfSSL_dtls_cid_max_size(); use wolfSSL_dtls_cid_get_tx_size() to learn its length.

Parameters:

- **ssl** A WOLFSSL object pointern
- **cid** Pointer that will be set to the internal memory that holds the CID

See:

- wolfSSL_dtls_cid_get_tx
- wolfSSL_dtls_cid_use
- wolfSSL_dtls_cid_is_enabled
- wolfSSL_dtls_cid_set
- wolfSSL_dtls_cid_get_rx_size
- wolfSSL_dtls_cid_get_rx
- wolfSSL_dtls_cid_get_tx_size

Return: WOLFSSL_SUCCESS if ConnectionID was correctly retrieved, error code otherwise

C.58.4.523 function wolfSSL_dtls_cid_max_size

```
int wolfSSL_dtls_cid_max_size(
    void
)
```

Get the maximum size of the ConnectionID that this build can receive, that is the largest size accepted by wolfSSL_dtls_cid_set(). This is the compile time define DTLS_CID_MAX_SIZE and it can never be

bigger than 255 bytes. It does not bound the ConnectionID used to send records, which is chosen by the peer and, on DTLS 1.3, may be up to 255 bytes.

See:

- wolfSSL_dtls_cid_set
- wolfSSL_dtls_cid_get_rx_size
- wolfSSL_dtls_cid_get_tx_size

Return: the maximum receive ConnectionID size in bytes

C.58.4.524 function wolfSSL_dtls_cid_parse

```
const unsigned char * wolfSSL_dtls_cid_parse(
    const unsigned char * msg,
    unsigned int msgSz,
    unsigned int cidSz
)
```

Extract the ConnectionID from a record datagram/message. See RFC 9146 and RFC 9147.

Parameters:

- **msg** buffer holding the datagram read from the network
- **msgSz** size of msg in bytes
- **cid** pointer to the start of the CID inside the msg buffer
- **cidSz** the expected size of the CID. The record layer does not have a CID size field so we have to know beforehand the size of the CID. It is recommended to use a constant CID for all connections.

See:

- wolfSSL_dtls_cid_get_tx
- wolfSSL_dtls_cid_use
- wolfSSL_dtls_cid_is_enabled
- wolfSSL_dtls_cid_set
- wolfSSL_dtls_cid_get_rx_size
- wolfSSL_dtls_cid_get_rx
- wolfSSL_dtls_cid_get_tx_size

C.58.4.525 function wolfSSL_CTX_set_client_CA_list

```
void wolfSSL_CTX_set_client_CA_list(
    WOLFSSL_CTX * ctx,
    WOLF_STACK_OF(WOLFSSL_X509_NAME) * names
)
```

On the server, this sets a list of CA names to be sent to clients in certificate requests as a hint for which CA's are supported by the server.

Parameters:

- **ctx** Pointer to the wolfSSL context
- **names** List of names to be set

See:

- wolfSSL_set_client_CA_list
- wolfSSL_CTX_get_client_CA_list
- wolfSSL_get_client_CA_list
- wolfSSL_CTX_set0_CA_list
- wolfSSL_set0_CA_list

- wolfSSL_CTX_get0_CA_list
- wolfSSL_get0_CA_list
- wolfSSL_get0_peer_CA_list

On the client, this function has no effect.

C.58.4.526 function wolfSSL_CTX_get_client_CA_list

```
WOLFSSL_STACK * wolfSSL_CTX_get_client_CA_list(
    const WOLFSSL_CTX * ctx
)
```

This retrieves the list previously set via wolfSSL_CTX_set_client_CA_list, or NULL if no list has been set.

Parameters:

- **ctx** Pointer to the wolfSSL context

See:

- wolfSSL_set_client_CA_list
- wolfSSL_CTX_set_client_CA_list
- wolfSSL_get_client_CA_list
- wolfSSL_CTX_set0_CA_list
- wolfSSL_set0_CA_list
- wolfSSL_CTX_get0_CA_list
- wolfSSL_get0_CA_list
- wolfSSL_get0_peer_CA_list

Return: A stack of WOLFSSL_X509_NAMEs containing the CA names

C.58.4.527 function wolfSSL_set_client_CA_list

```
void wolfSSL_set_client_CA_list(
    WOLFSSL * ssl,
    WOLF_STACK_OF(WOLFSSL_X509_NAME) * names
)
```

Same as wolfSSL_CTX_set_client_CA_list, but specific to a session. If a CA list is set on both the context and the session, the list on the session is used.

Parameters:

- **ssl** Pointer to the WOLFSSL object
- **names** List of names to be set.

See:

- wolfSSL_CTX_set_client_CA_list
- wolfSSL_CTX_get_client_CA_list
- wolfSSL_get_client_CA_list
- wolfSSL_CTX_set0_CA_list
- wolfSSL_set0_CA_list
- wolfSSL_CTX_get0_CA_list
- wolfSSL_get0_CA_list
- wolfSSL_get0_peer_CA_list

C.58.4.528 function wolfSSL_get_client_CA_list

```
WOLFSSL_STACK * wolfSSL_get_client_CA_list(
    const WOLFSSL * ssl
)
```

On the server, this retrieves the list previously set via wolfSSL_set_client_CA_list. If none was set, returns the list previously set via wolfSSL_CTX_set_client_CA_list. If no list at all was set, returns NULL.

Parameters:

- **ssl** Pointer to the WOLFSSL object

See:

- wolfSSL_CTX_set_cert_cb
- wolfSSL_CTX_set_client_CA_list
- wolfSSL_CTX_get_client_CA_list
- wolfSSL_get_client_CA_list
- wolfSSL_CTX_set0_CA_list
- wolfSSL_set0_CA_list
- wolfSSL_CTX_get0_CA_list
- wolfSSL_get0_CA_list
- wolfSSL_get0_peer_CA_list

Return: A stack of WOLFSSL_X509_NAMEs containing the CA names

On the client, this retrieves the list that was received from the server, or NULL if none was received. wolfSSL_CTX_set_cert_cb can be used to register a callback to dynamically load certificates when a certificate request is received from the server.

C.58.4.529 function wolfSSL_CTX_set0_CA_list

```
void wolfSSL_CTX_set0_CA_list(
    WOLFSSL_CTX * ctx,
    WOLF_STACK_OF(WOLFSSL_X509_NAME) * names
)
```

This function sets a list of CA names to be sent to the peer as a hint for which CA's are supported for its authentication.

Parameters:

- **ctx** Pointer to the wolfSSL context
- **names** List of names to be set

See:

- wolfSSL_CTX_set_client_CA_list
- wolfSSL_set_client_CA_list
- wolfSSL_CTX_get_client_CA_list
- wolfSSL_get_client_CA_list
- wolfSSL_set0_CA_list
- wolfSSL_CTX_get0_CA_list
- wolfSSL_get0_CA_list
- wolfSSL_get0_peer_CA_list

In TLS >= 1.3, this is supported in both directions between the client and the server. On the server, the CA names will be sent as part of a CertificateRequest, making this function an equivalent of *_set_client_CA_list; on the client, these are sent as part of ClientHello.

In TLS < 1.3, sending CA names from the client to the server is not supported, therefore this function is equivalent to wolfSSL_CTX_set_client_CA_list.

Note that the lists set via *_set_client_CA_list and *_set0_CA_list are separate internally, i.e. calling *_get_client_CA_list will not retrieve a list set via *_set0_CA_list and vice versa. If both are set, the server will ignore *_set0_CA_list when sending CA names to the client.

C.58.4.530 function wolfSSL_CTX_get0_CA_list

```
WOLFSSL_STACK * wolfSSL_CTX_get0_CA_list(
    const WOLFSSL_CTX * ctx
)
```

This retrieves the list previously set via wolfSSL_CTX_set0_CA_list, or NULL if no list has been set.

Parameters:

- **ctx** Pointer to the wolfSSL context

See:

- wolfSSL_CTX_set_client_CA_list
- wolfSSL_set_client_CA_list
- wolfSSL_CTX_get_client_CA_list
- wolfSSL_get_client_CA_list
- wolfSSL_CTX_set0_CA_list
- wolfSSL_set0_CA_list
- wolfSSL_get0_CA_list
- wolfSSL_get0_peer_CA_list

Return: A stack of WOLFSSL_X509_NAMEs containing the CA names

C.58.4.531 function wolfSSL_set0_CA_list

```
void wolfSSL_set0_CA_list(
    WOLFSSL * ssl,
    WOLF_STACK_OF(WOLFSSL_X509_NAME) * names
)
```

Same as wolfSSL_CTX_set0_CA_list, but specific to a session. If a CA list is set on both the context and the session, the list on the session is used.

Parameters:

- **ssl** Pointer to the WOLFSSL object
- **names** List of names to be set.

See:

- wolfSSL_CTX_set_client_CA_list
- wolfSSL_set_client_CA_list
- wolfSSL_CTX_get_client_CA_list
- wolfSSL_get_client_CA_list
- wolfSSL_CTX_set0_CA_list
- wolfSSL_CTX_get0_CA_list
- wolfSSL_get0_CA_list
- wolfSSL_get0_peer_CA_list

C.58.4.532 function wolfSSL_get0_CA_list

```
WOLFSSL_STACK * wolfSSL_get0_CA_list(
    const WOLFSSL * ssl
)
```

This retrieves the list previously set via wolfSSL_set0_CA_list. If none was set, returns the list previously set via wolfSSL_CTX_set0_CA_list. If no list at all was set, returns NULL.

Parameters:

- **ssl** Pointer to the WOLFSSL object

See:

- wolfSSL_CTX_set_client_CA_list
- wolfSSL_set_client_CA_list
- wolfSSL_CTX_get_client_CA_list
- wolfSSL_get_client_CA_list
- wolfSSL_CTX_set0_CA_list
- wolfSSL_set0_CA_list
- wolfSSL_CTX_get0_CA_list
- wolfSSL_get0_peer_CA_list

Return: A stack of WOLFSSL_X509_NAMEs containing the CA names

C.58.4.533 function wolfSSL_get0_peer_CA_list

```
WOLFSSL_STACK * wolfSSL_get0_peer_CA_list(
    const WOLFSSL * ssl
)
```

This returns the CA list received from the peer.

Parameters:

- **ssl** Pointer to the WOLFSSL object

See:

- wolfSSL_CTX_set_cert_cb
- wolfSSL_CTX_set_client_CA_list
- wolfSSL_set_client_CA_list
- wolfSSL_CTX_get_client_CA_list
- wolfSSL_get_client_CA_list
- wolfSSL_CTX_set0_CA_list
- wolfSSL_set0_CA_list
- wolfSSL_CTX_get0_CA_list
- wolfSSL_get0_CA_list

Return: A stack of WOLFSSL_X509_NAMEs containing the CA names

On the client, this is the list sent by the server in a CertificateRequest, and this function is equivalent to wolfSSL_get_client_CA_list.

On the server, this is the list sent by the client in the ClientHello message in TLS >= 1.3; in TLS < 1.3, the function always returns NULL on the server side.

wolfSSL_CTX_set_cert_cb can be used to register a callback to dynamically load certificates when a CA list is received from the peer.

C.58.4.534 function wolfSSL_get_client_suites_sigalgs

```
int wolfSSL_get_client_suites_sigalgs(
    const WOLFSSL * ssl,
    const byte ** suites,
    word16 * suiteSz,
    const byte ** hashSigAlgo,
    word16 * hashSigAlgoSz
)
```

This function returns the raw list of ciphersuites and signature algorithms offered by the client. The lists are only stored and returned inside a callback setup with wolfSSL_CTX_set_cert_cb(). This is useful to be able to dynamically load certificates and keys based on the available ciphersuites and signature algorithms.

Parameters:

- **ssl** The WOLFSSL object to extract the lists from.
- **suites** Raw and unfiltered list of client ciphersuites. May be NULL if no suites are available.
- **suiteSz** Size of suites in bytes.
- **hashSigAlgo** Raw and unfiltered list of client signature algorithms. May be NULL if not provided.
- **hashSigAlgoSz** Size of hashSigAlgo in bytes.

See:

- wolfSSL_get_ciphersuite_info
- wolfSSL_get_sigalg_info

Return:

- WOLFSSL_SUCCESS when suites available
- WOLFSSL_FAILURE when suites not available

Example

```
int certCB(WOLFSSL* ssl, void* arg)
{
    const byte* suites = NULL;
    word16 suiteSz = 0;
    const byte* hashSigAlgo = NULL;
    word16 hashSigAlgoSz = 0;

    wolfSSL_get_client_suites_sigalgs(ssl, &suites, &suiteSz, &hashSigAlgo,
            &hashSigAlgoSz);

    // Choose certificate to load based on ciphersuites and sigalgs
}

WOLFSSL* ctx;
ctx  = wolfSSL_CTX_new(wolfTLSv1_3_method_ex(NULL));
wolfSSL_CTX_set_cert_cb(ctx, certCB, NULL);
```

C.58.4.535 function wolfSSL_get_ciphersuite_info

```
WOLFSSL_CIPHERSUITE_INFO wolfSSL_get_ciphersuite_info(
    byte first,
    byte second
)
```

This returns information about the ciphersuite directly from the raw ciphersuite bytes.

Parameters:

- **first** First byte of the ciphersuite
- **second** Second byte of the ciphersuite

See:

- wolfSSL_get_client_suites_sigalgs
- wolfSSL_get_sigalg_info

Return: WOLFSSL_CIPHERSUITE_INFO A struct containing information about the type of authentication used in the ciphersuite.

Example

```
WOLFSSL_CIPHERSUITE_INFO info =
        wolfSSL_get_ciphersuite_info(suites[0], suites[1]);
if (info.rsaAuth)
    haveRSA = 1;
else if (info.eccAuth)
    haveECC = 1;
```

C.58.4.536 function wolfSSL_get_sigalg_info

```
int wolfSSL_get_sigalg_info(
    byte first,
    byte second,
    int * hashAlgo,
    int * sigAlgo
)
```

This returns information about the hash and signature algorithm directly from the raw ciphersuite bytes.

Parameters:

- **first** First byte of the hash and signature algorithm
- **second** Second byte of the hash and signature algorithm
- **hashAlgo** The enum wc_HashType of the MAC algorithm
- **sigAlgo** The enum Key_Sum of the authentication algorithm

See:

- wolfSSL_get_client_suites_sigalgs
- wolfSSL_get_ciphersuite_info

Return:

- 0 when info was correctly set
- BAD_FUNC_ARG when either input parameters are NULL or the bytes are not a recognized sigalg suite

Example

```
enum wc_HashType hashAlgo;
enum Key_Sum sigAlgo;

wolfSSL_get_sigalg_info(hashSigAlgo[idx+0], hashSigAlgo[idx+1],
        &hashAlgo, &sigAlgo);
```

```
if (sigAlgo == RSAk || sigAlgo == RSAPSSk)
    haveRSA = 1;
else if (sigAlgo == ECDSAk)
    haveECC = 1;
```

C.58.4.537 function wolfSSL_CTX_set_default_passwd_cb

```
void wolfSSL_CTX_set_default_passwd_cb(
    WOLFSSL_CTX * ctx,
    wc_pem_password_cb * cb
)
```

This function will set the password callback in the provided CTX. This callback is used when loading an encrypted cert or key which requires a password.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created with wolfSSL_CTX_new().
- **cb** a function pointer to (*wc_pem_password_cb) that is set to the passwd_cb member of the WOLFSSL_CTX.

See: wolfSSL_CTX_set_default_passwd_cb_userdata

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
int PasswordCallBack(char* passwd, int sz, int rw, void* userdata) {

}
…
wolfSSL_CTX_set_default_passwd_cb(ctx, PasswordCallBack);
```

C.58.4.538 function wolfSSL_CTX_set_default_passwd_cb_userdata

```
void wolfSSL_CTX_set_default_passwd_cb_userdata(
    WOLFSSL_CTX * ctx,
    void * userdata
)
```

This function will set the userdata argument to the passwd_userdata member of the WOLFSSL_CTX structure. This member is passed into the CTX's password callback when called.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created with wolfSSL_CTX_new().
- **userdata** a pointer to userdata which is passed into the password callback.

See: wolfSSL_CTX_set_default_passwd_cb

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
int data;
…
wolfSSL_CTX_set_default_passwd_cb_userdata(ctx, (void*)&data);
```

C.58.4.539 function wolfSSL_get_scr_check_enabled

```
int wolfSSL_get_scr_check_enabled(
    const WOLFSSL * ssl
)
```

Gets the state of the secure renegotiation (SCR) check requirement.

Parameters:

- **ssl** Pointer to the WOLFSSL structure, created with wolfSSL_new().

See: wolfSSL_set_scr_check_enabled

Return:

- 1 if the SCR check is enabled.
- 0 if the SCR check is disabled.
- BAD_FUNC_ARG if ssl is NULL.

This function returns whether the client requires the server to acknowledge the secure renegotiation extension and enable secure renegotiation when sending it from the client. When enabled, the client will generate a fatal handshake_failure alert if the server does not acknowledge the extension in the ServerHello message, as required by RFC 9325.

Example

```
WOLFSSL* ssl;
int enabled;

ssl = wolfSSL_new(ctx);
enabled = wolfSSL_get_scr_check_enabled(ssl);
if (enabled) {
    // SCR check is enabled
}
```

C.58.4.540 function wolfSSL_set_scr_check_enabled

```
int wolfSSL_set_scr_check_enabled(
    WOLFSSL * ssl,
    byte enabled
)
```

Sets the state of the secure renegotiation (SCR) check requirement.

Parameters:

- **ssl** Pointer to the WOLFSSL structure, created with wolfSSL_new().
- **enabled** Non-zero to enable the SCR check, zero to disable it.

See: wolfSSL_get_scr_check_enabled

Return:

- WOLFSSL_SUCCESS on success.
- BAD_FUNC_ARG if ssl is NULL.

This function enables or disables the requirement for the server to acknowledge the secure renegotiation extension and enable secure renegotiation when sending it from the client. When enabled, the client will generate a fatal handshake_failure alert if the server does not acknowledge the extension in the ServerHello message, as required by RFC 9325.

Example

```
WOLFSSL* ssl;
int ret;

ssl = wolfSSL_new(ctx);
ret = wolfSSL_set_scr_check_enabled(ssl, 1);
if (ret != WOLFSSL_SUCCESS) {
    // Error setting SCR check
}
```

C.58.4.541 function wolfSSL_CTX_DisableExtendedMasterSecret

```
int wolfSSL_CTX_DisableExtendedMasterSecret(
    WOLFSSL_CTX * ctx
)
```

Disables the TLS Extended Master Secret extension (RFC 7627) on the context: a client stops advertising it and a server ignores the peer's request, so a standard master secret is negotiated. A server also declines resumption of sessions or tickets that used EMS and does a full handshake instead. TLS 1.2 and earlier only. Requires HAVE_EXTENDED_MASTER.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().

See:

- wolfSSL_DisableExtendedMasterSecret
- wolfSSL_CTX_EnableExtendedMasterSecret
- wolfSSL_CTX_RequireExtendedMasterSecret

Return:

- WOLFSSL_SUCCESS on success.
- BAD_FUNC_ARG if ctx is NULL.

Example

```
wolfSSL_CTX_DisableExtendedMasterSecret(ctx);
```

C.58.4.542 function wolfSSL_DisableExtendedMasterSecret

```
int wolfSSL_DisableExtendedMasterSecret(
    WOLFSSL * ssl
)
```

Disables the TLS Extended Master Secret extension (RFC 7627) on the SSL object: a client stops advertising it and a server ignores the peer's request, so a standard master secret is negotiated. A server also declines resumption of sessions or tickets that used EMS and does a full handshake instead. Call before the handshake starts, or after wolfSSL_clear. TLS 1.2 and earlier only. Requires HAVE_EXTENDED_MASTER.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_CTX_DisableExtendedMasterSecret
- wolfSSL_EnableExtendedMasterSecret
- wolfSSL_RequireExtendedMasterSecret

Return:

- WOLFSSL_SUCCESS on success.
- BAD_FUNC_ARG if ssl is NULL.
- BAD_STATE_E if the handshake has started.

Example

```
wolfSSL_DisableExtendedMasterSecret(ssl);
```

C.58.4.543 function wolfSSL_CTX_EnableExtendedMasterSecret

```
int wolfSSL_CTX_EnableExtendedMasterSecret(
    WOLFSSL_CTX * ctx
)
```

Re-enables the TLS Extended Master Secret extension (RFC 7627) on the context (the default): EMS is used when the peer supports it but is not mandatory. Undoes a previous disable or require. Requires HAVE_EXTENDED_MASTER.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().

See:

- wolfSSL_EnableExtendedMasterSecret
- wolfSSL_CTX_DisableExtendedMasterSecret
- wolfSSL_CTX_RequireExtendedMasterSecret

Return:

- WOLFSSL_SUCCESS on success.
- BAD_FUNC_ARG if ctx is NULL.

Example

```
wolfSSL_CTX_EnableExtendedMasterSecret(ctx);
```

C.58.4.544 function wolfSSL_EnableExtendedMasterSecret

```
int wolfSSL_EnableExtendedMasterSecret(
    WOLFSSL * ssl
)
```

Re-enables the TLS Extended Master Secret extension (RFC 7627) on the SSL object (the default): EMS is used when the peer supports it but is not mandatory. Undoes a previous disable or require. Call before the handshake starts, or after wolfSSL_clear. Requires HAVE_EXTENDED_MASTER.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_CTX_EnableExtendedMasterSecret
- wolfSSL_DisableExtendedMasterSecret
- wolfSSL_RequireExtendedMasterSecret

Return:

- WOLFSSL_SUCCESS on success.
- BAD_FUNC_ARG if ssl is NULL.
- BAD_STATE_E if the handshake has started.

Example

```
wolfSSL_EnableExtendedMasterSecret(ssl);
```

C.58.4.545 function wolfSSL_CTX_RequireExtendedMasterSecret

```
int wolfSSL_CTX_RequireExtendedMasterSecret(
    WOLFSSL_CTX * ctx
)
```

Makes the TLS Extended Master Secret extension (RFC 7627) mandatory on the context: if it is not negotiated, the connection is aborted with EXT_MASTER_SECRET_NEEDED_E. A client advertises the extension even after a previous disable. TLS 1.2 and earlier only. Requires HAVE_EXTENDED_MASTER.

Parameters:

- **ctx** a pointer to a WOLFSSL_CTX structure, created using wolfSSL_CTX_new().

See:

- wolfSSL_RequireExtendedMasterSecret
- wolfSSL_CTX_EnableExtendedMasterSecret
- wolfSSL_CTX_DisableExtendedMasterSecret

Return:

- WOLFSSL_SUCCESS on success.
- BAD_FUNC_ARG if ctx is NULL.

Example

```
wolfSSL_CTX_RequireExtendedMasterSecret(ctx);
```

C.58.4.546 function wolfSSL_RequireExtendedMasterSecret

```
int wolfSSL_RequireExtendedMasterSecret(
    WOLFSSL * ssl
)
```

Makes the TLS Extended Master Secret extension (RFC 7627) mandatory on the SSL object: if it is not negotiated, including on resumption, the connection is aborted with EXT_MASTER_SECRET_NEEDED_E. A client advertises the extension even after a previous disable. Call before the handshake starts, or after wolfSSL_clear. TLS 1.2 and earlier only. Requires HAVE_EXTENDED_MASTER.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_CTX_RequireExtendedMasterSecret
- wolfSSL_EnableExtendedMasterSecret
- wolfSSL_DisableExtendedMasterSecret

Return:

- WOLFSSL_SUCCESS on success.
- BAD_FUNC_ARG if ssl is NULL.
- BAD_STATE_E if the handshake has started.

Example

```
wolfSSL_RequireExtendedMasterSecret(ssl);
```

C.58.4.547 function wolfSSL_UseCertificateAuthority

```
int wolfSSL_UseCertificateAuthority(
    WOLFSSL * ssl,
    const unsigned char * dn,
    unsigned int dnSz
)
```

Adds a CA distinguished name to the list of certificate authorities announced via the TLS 1.3 certificate_authorities extension (RFC 8446 section 4.2.4) on the given SSL session. The DN must be the inner content of a DER-encoded X.509 Name (the bytes after the SEQUENCE tag and length), as returned by wc_GetDecodedCertSubjectRaw(). The library copies the bytes and prepends the SEQUENCE header on the wire automatically.

Parameters:

- **ssl** pointer to a WOLFSSL object, created with wolfSSL_new().
- **dn** pointer to the DER-encoded subject Name content.
- **dnSz** size in bytes of the DN content.

See:

- wolfSSL_CTX_UseCertificateAuthority
- wolfSSL_ClearCertificateAuthorities
- wolfSSL_GetPeerCertificateAuthorityCount
- wolfSSL_GetPeerCertificateAuthority
- wc_GetDecodedCertSubjectRaw

Return:

- 0 on success.
- BAD_FUNC_ARG if ssl or dn is NULL, dnSz is 0, or dnSz exceeds the maximum content size.
- MEMORY_ERROR if memory allocation fails.

Multiple DNs may be added; each call appends to the list. Use wolfSSL_ClearCertificateAuthorities() to reset the list.

Requires WOLFSSL_TLS13 and !NO_CERTS and !WOLFSSL_NO_CA_NAMES.

Example

```
DecodedCert decoded;
const byte* subject = NULL;
int subjectSz = 0;

wc_InitDecodedCert(&decoded, certDer, certDerSz, NULL);
wc_ParseCert(&decoded, CERT_TYPE, NO_VERIFY, NULL);
wc_GetDecodedCertSubjectRaw(&decoded, &subject, &subjectSz);

ret = wolfSSL_UseCertificateAuthority(ssl, subject,
        (unsigned int)subjectSz);
if (ret != 0) {
    // error adding CA DN
}
wc_FreeDecodedCert(&decoded);
```

C.58.4.548 function wolfSSL_CTX_UseCertificateAuthority

```
int wolfSSL_CTX_UseCertificateAuthority(
    WOLFSSL_CTX * ctx,
```

```
    const unsigned char * dn,
    unsigned int dnSz
)
```

Adds a CA distinguished name to the list of certificate authorities announced via the TLS 1.3 certificate_authorities extension (RFC 8446 section 4.2.4) on all SSL sessions created from this context. The DN format and requirements are identical to wolfSSL_UseCertificateAuthority().

Parameters:

- **ctx** pointer to a WOLFSSL_CTX object, created with wolfSSL_CTX_new().
- **dn** pointer to the DER-encoded subject Name content.
- **dnSz** size in bytes of the DN content.

See:

- wolfSSL_UseCertificateAuthority
- wolfSSL_CTX_ClearCertificateAuthorities
- wc_GetDecodedCertSubjectRaw

Return:

- 0 on success.
- BAD_FUNC_ARG if ctx or dn is NULL, dnSz is 0, or dnSz exceeds the maximum content size.
- MEMORY_ERROR if memory allocation fails.

Per-session lists set via wolfSSL_UseCertificateAuthority() take precedence; if the SSL object has its own list, the CTX list is not sent.

Requires WOLFSSL_TLS13 and !NO_CERTS and !WOLFSSL_NO_CA_NAMES.

Example

```
ret = wolfSSL_CTX_UseCertificateAuthority(ctx, subject,
        (unsigned int)subjectSz);
if (ret != 0) {
    // error adding CA DN
}
```

C.58.4.549 function wolfSSL_ClearCertificateAuthorities

```
void wolfSSL_ClearCertificateAuthorities(
    WOLFSSL * ssl
)
```

Frees and removes all CA distinguished names previously added to the SSL session via wolfSSL_UseCertificateAuthority(). After this call the session_level native CA list is empty; the CTX_level list (if any) is not affected.

Parameters:

- **ssl** pointer to a WOLFSSL object, created with wolfSSL_new().

See:

- wolfSSL_UseCertificateAuthority
- wolfSSL_CTX_ClearCertificateAuthorities

Return: none No return value.

Requires WOLFSSL_TLS13 and !NO_CERTS and !WOLFSSL_NO_CA_NAMES.

Example

```
wolfSSL_UseCertificateAuthority(ssl, dn1, dn1Sz);
wolfSSL_UseCertificateAuthority(ssl, dn2, dn2Sz);
// Clear all session-level CA DNs:
wolfSSL_ClearCertificateAuthorities(ssl);
```

C.58.4.550 function wolfSSL_CTX_ClearCertificateAuthorities

```
void wolfSSL_CTX_ClearCertificateAuthorities(
    WOLFSSL_CTX * ctx
)
```

Frees and removes all CA distinguished names previously added to the context via wolfSSL_CTX_UseCertificateAuthorit
After this call the CTX-level native CA list is empty.

Parameters:

- **ctx** pointer to a WOLFSSL_CTX object, created with wolfSSL_CTX_new().

See:

- wolfSSL_CTX_UseCertificateAuthority
- wolfSSL_ClearCertificateAuthorities

Return: none No return value.

Requires WOLFSSL_TLS13 and !NO_CERTS and !WOLFSSL_NO_CA_NAMES.

Example

```
wolfSSL_CTX_UseCertificateAuthority(ctx, dn, dnSz);
// Clear all CTX-level CA DNs:
wolfSSL_CTX_ClearCertificateAuthorities(ctx);
```

C.58.4.551 function wolfSSL_GetPeerCertificateAuthorityCount

```
int wolfSSL_GetPeerCertificateAuthorityCount(
    const WOLFSSL * ssl
)
```

Returns the number of CA distinguished names received from the peer in the TLS 1.3 certificate_authorities extension. This is typically called inside a cert_cb (WOLFSSL_CERT_SETUP_CB) on the server side to inspect which CAs the client trusts.

Parameters:

- **ssl** pointer to a WOLFSSL object, created with wolfSSL_new().

See:

- wolfSSL_GetPeerCertificateAuthority
- wolfSSL_UseCertificateAuthority

Return: >= 0 The number of peer CA DNs. Returns 0 if ssl is NULL or no certificate_authorities extension was received.

Requires WOLFSSL_TLS13 and !NO_CERTS and !WOLFSSL_NO_CA_NAMES.

Example

```
int count = wolfSSL_GetPeerCertificateAuthorityCount(ssl);
for (int i = 0; i < count; i++) {
    int sz = wolfSSL_GetPeerCertificateAuthority(ssl, i, NULL, 0);
```

```
    // sz is the DN size in bytes
}
```

C.58.4.552 function wolfSSL_GetPeerCertificateAuthority

```
int wolfSSL_GetPeerCertificateAuthority(
    const WOLFSSL * ssl,
    int idx,
    unsigned char * outDn,
    unsigned int outDnSz
)
```

Copies the idx-th CA distinguished name received from the peer in the TLS 1.3 certificate_authorities extension into the caller's buffer. The DN is the inner content of the DER-encoded Name (without the SEQUENCE header), matching the format accepted by wolfSSL_UseCertificateAuthority().

Parameters:

- **ssl** pointer to a WOLFSSL object, created with wolfSSL_new().
- **idx** zero-based index of the peer CA DN to retrieve. Must be less than the count returned by wolfSSL_GetPeerCertificateAuthorityCount().
- **outDn** output buffer to receive the DN bytes, or NULL to query size.
- **outDnSz** size of the output buffer in bytes.

See:

- wolfSSL_GetPeerCertificateAuthorityCount
- wolfSSL_UseCertificateAuthority
- wc_GetDecodedCertSubjectRaw

Return:

- 0 The number of bytes written to outDn, or the DN size if outDn is NULL.
- BAD_FUNC_ARG if ssl is NULL or idx is out of range.
- BUFFER_E if outDnSz is smaller than the DN.

If outDn is NULL, returns the size of the DN in bytes (allowing the caller to allocate the right amount of memory). If outDn is non-NULL and outDnSz is large enough, copies the DN bytes and returns the number of bytes written. If outDnSz is too small, returns BUFFER_E.

Requires WOLFSSL_TLS13 and !NO_CERTS and !WOLFSSL_NO_CA_NAMES.

Example

```
int count = wolfSSL_GetPeerCertificateAuthorityCount(ssl);
for (int i = 0; i < count; i++) {
    int sz = wolfSSL_GetPeerCertificateAuthority(ssl, i, NULL, 0);
    if (sz > 0) {
        unsigned char* dn = malloc(sz);
        wolfSSL_GetPeerCertificateAuthority(ssl, i, dn,
                (unsigned int)sz);
        // use dn[0..sz-1]
        free(dn);
    }
}
```

C.59.1 Functions

	Name
word32	**CheckRunTimeFastMath**(void)This function checks the runtime fastmath settings for the maximum size of an integer. It is important when a user is using a wolfCrypt library independently, as the FP_SIZE must match for each library in order for math to work correctly. This check is defined as CheckFastMathSettings(), which simply compares CheckRunTimeFastMath and FP_SIZE, returning 0 if there is a mismatch, or 1 if they match.

C.59.2 Functions Documentation

C.59.2.1 function CheckRunTimeFastMath

```
word32 CheckRunTimeFastMath(
    void
)
```

This function checks the runtime fastmath settings for the maximum size of an integer. It is important when a user is using a wolfCrypt library independently, as the FP_SIZE must match for each library in order for math to work correctly. This check is defined as CheckFastMathSettings(), which simply compares CheckRunTimeFastMath and FP_SIZE, returning 0 if there is a mismatch, or 1 if they match.

Parameters:

- **none** No parameters.

See: CheckRunTimeSettings

Return: FP_SIZE Returns FP_SIZE, corresponding to the max size available for the math library.

Example

```
if (CheckFastMathSettings() != 1) {
return err_sys("Build vs. runtime fastmath FP_MAX_BITS mismatch\n");
}
// This is converted by the preprocessor to:
// if ( (CheckRunTimeFastMath() == FP_SIZE) != 1) {
// and confirms that the fast math settings match
// the compile time settings
```

C.59.3 Source code

```
word32 CheckRunTimeFastMath(void);
```

int	**wolfSSL_CondEnd**(COND_TYPE * cond)Ends condition variable.

C.60.2 Functions Documentation

C.60.2.1 function XMALLOC

```
void * XMALLOC(
    size_t n,
    void * heap,
    int type
)
```

This is not actually a function, but rather a preprocessor macro, which allows the user to substitute in their own malloc, realloc, and free functions in place of the standard C memory functions. To use external memory functions, define XMALLOC_USER. This will cause the memory functions to be replaced by external functions of the form: extern void *XMALLOC(size_t n, void* heap, int type); extern void _XREALLOC(void *p, size_t n, void_ heap, int type); extern void XFREE(void* p, void *heap, int type); To use the basic C memory functions in place of wolfSSL_Malloc, wolfSSL_Realloc, wolfSSL_Free, define NO_WOLFSSL_MEMORY. This will replace the memory functions with: #define XMALLOC(s, h, t) ((void)h, (void)t, malloc((s))) #define XFREE(p, h, t) {void* xp = (p); if((xp)) free((xp));} #define XREALLOC(p, n, h, t) realloc((p), (n)) If none of these options are selected, the system will default to use the wolfSSL memory functions. A user can set custom memory functions through callback hooks, (see wolfSSL_Malloc, wolfSSL_Realloc, wolfSSL_Free). This option will replace the memory functions with: #define XMALLOC(s, h, t) ((void)h, (void)t, wolfSSL_Malloc((s))) #define XFREE(p, h, t) {void* xp = (p); if((xp)) wolfSSL_Free((xp));} #define XREALLOC(p, n, h, t) wolfSSL_Realloc((p), (n))

Parameters:

- **s** size of memory to allocate
- **h** (used by custom XMALLOC function) pointer to the heap to use
- **t** memory allocation types for user hints. See enum in types.h

See:

- wolfSSL_Malloc
- wolfSSL_Realloc
- wolfSSL_Free
- wolfSSL_SetAllocators

Return:

- pointer Return a pointer to allocated memory on success
- NULL on failure

Example

```
int* tenInts = XMALLOC(sizeof(int)*10, NULL, DYNAMIC_TYPE_TMP_BUFFER);
if (tenInts == NULL) {
    // error allocating space
    return MEMORY_E;
}
```

C.60.2.2 function XREALLOC

```
void * XREALLOC(
    void * p,
    size_t n,
    void * heap,
    int type
)
```

This is not actually a function, but rather a preprocessor macro, which allows the user to substitute in their own malloc, realloc, and free functions in place of the standard C memory functions. To use external memory functions, define XMALLOC_USER. This will cause the memory functions to be replaced by external functions of the form: extern void *XMALLOC(size_t n, void* heap, int type); extern void _XREALLOC(void *p, size_t n, void_ heap, int type); extern void XFREE(void* p, void *heap, int type); To use the basic C memory functions in place of wolfSSL_Malloc, wolfSSL_Realloc, wolfSSL_Free, define NO_WOLFSSL_MEMORY. This will replace the memory functions with: #define XMALLOC(s, h, t) ((void)h, (void)t, malloc((s))) #define XFREE(p, h, t) {void* xp = (p); if((xp)) free((xp));} #define XREALLOC(p, n, h, t) realloc((p), (n)) If none of these options are selected, the system will default to use the wolfSSL memory functions. A user can set custom memory functions through callback hooks, (see wolfSSL_Malloc, wolfSSL_Realloc, wolfSSL_Free).

This option will replace the memory functions with: #define XMALLOC(s, h, t) ((void)h, (void)t, wolfSSL_Malloc((s))) #define XFREE(p, h, t) {void* xp = (p); if((xp)) wolfSSL_Free((xp));} #define XREALLOC(p, n, h, t) wolfSSL_Realloc((p), (n))

Parameters:

- **p** pointer to the address to reallocate
- **n** size of memory to allocate
- **h** (used by custom XREALLOC function) pointer to the heap to use
- **t** memory allocation types for user hints. See enum in types.h

See:

- wolfSSL_Malloc
- wolfSSL_Realloc
- wolfSSL_Free
- wolfSSL_SetAllocators

Return:

- Return a pointer to allocated memory on success
- NULL on failure

Example

```
int* tenInts = (int*)XMALLOC(sizeof(int)*10, NULL, DYNAMIC_TYPE_TMP_BUFFER);
int* twentyInts = (int*)XREALLOC(tenInts, sizeof(int)*20, NULL,
    DYNAMIC_TYPE_TMP_BUFFER);
```

C.60.2.3 function XFREE

```
void XFREE(
    void * p,
    void * heap,
    int type
)
```

This is not actually a function, but rather a preprocessor macro, which allows the user to substitute in their own malloc, realloc, and free functions in place of the standard C memory functions. To use external memory functions, define XMALLOC_USER. This will cause the memory functions to be replaced by external functions of the form: extern void *XMALLOC(size_t n, void* heap, int type); extern void _XREALLOC(void *p, size_t n, void_ heap, int type); extern void XFREE(void* p, void *heap, int type); To use the basic C memory functions in place of wolfSSL_Malloc, wolfSSL_Realloc, wolfSSL_Free, define NO_WOLFSSL_MEMORY. This will replace the memory functions with: #define XMALLOC(s, h, t) ((void)h, (void)t, malloc((s))) #define XFREE(p, h, t) {void* xp = (p); if((xp)) free((xp));} #define XREALLOC(p, n, h, t) realloc((p), (n)) If none of these options are selected, the system will default to use the wolfSSL memory functions. A user can set custom memory functions through callback hooks, (see wolfSSL_Malloc, wolfSSL_Realloc, wolfSSL_Free). This option will replace the memory functions with: #define XMALLOC(s, h, t) ((void)h, (void)t, wolfSSL_Malloc((s))) #define XFREE(p, h, t) {void* xp = (p); if((xp)) wolfSSL_Free((xp));} #define XREALLOC(p, n, h, t) wolfSSL_Realloc((p), (n))

Parameters:

- **p** pointer to the address to free
- **h** (used by custom XFREE function) pointer to the heap to use
- **t** memory allocation types for user hints. See enum in types.h

See:

- wolfSSL_Malloc
- wolfSSL_Realloc

- wolfSSL_Free
- wolfSSL_SetAllocators

Return: none No returns.

Example

```
int* tenInts = XMALLOC(sizeof(int) * 10, NULL, DYNAMIC_TYPE_TMP_BUFFER);
if (tenInts == NULL) {
    // error allocating space
    return MEMORY_E;
}
```

C.60.2.4 function CheckRunTimeSettings

```
word32 CheckRunTimeSettings(
    void
)
```

This function checks the compile time class settings. It is important when a user is using a wolfCrypt library independently, as the settings must match between libraries for math to work correctly. This check is defined as CheckCtcSettings(), which simply compares CheckRunTimeSettings and CTC_SETTINGS, returning 0 if there is a mismatch, or 1 if they match.

Parameters:

- **none** No Parameters.

See: CheckRunTimeFastMath

Return: settings Returns the runtime CTC_SETTINGS (Compile Time Settings)

Example

```
if (CheckCtcSettings() != 1) {
    return err_sys("Build vs. runtime math mismatch\n");
}
// This is converted by the preprocessor to:
// if ( (CheckCtcSettings() == CTC_SETTINGS) != 1) {
// and will compare whether the compile time class settings
// match the current settings
```

C.60.2.5 function wc_strtok

```
char * wc_strtok(
    char * str,
    const char * delim,
    char ** nextp
)
```

Thread-safe string tokenization.

Parameters:

- **str** String to tokenize (NULL for continuation)
- **delim** Delimiter characters
- **nextp** Pointer to save position

See: wc_strsep

Return: Pointer to next token or NULL

Example

```
char str[] = "one,two,three";
char* saveptr;
char* token = wc_strtok(str, ",", &saveptr);
```

C.60.2.6 function wc_strsep

```
char * wc_strsep(
    char ** stringp,
    const char * delim
)
```

Separates string by delimiter.

Parameters:

- **stringp** Pointer to string pointer
- **delim** Delimiter characters

See: wc_strtok

Return: Pointer to token or NULL

Example

```
char str[] = "one,two,three";
char* ptr = str;
char* token = wc_strsep(&ptr, ",");
```

C.60.2.7 function wc_strlcpy

```
size_t wc_strlcpy(
    char * dst,
    const char * src,
    size_t dstSize
)
```

Safely copies string with size limit.

Parameters:

- **dst** Destination buffer
- **src** Source string
- **dstSize** Destination buffer size

See: wc_strlcat

Return: Length of source string

Example

```
char dst[10];
size_t len = wc_strlcpy(dst, "hello", sizeof(dst));
```

C.60.2.8 function wc_UnpackOctets

```
int wc_UnpackOctets(
    byte * out,
    word32 outSz,
    const byte * in,
    word32 inSz,
```

```
    word32 octetSz
)
```

Expands a packed octet stream into the one-octet-per-byte-cell form every wolfCrypt byte* API expects. Declared only when WOLFSSL_WIDE_BYTE is set (CHAR_BIT != 8); elsewhere the two layouts coincide and no conversion is needed.

Parameters:

- **out** Destination, one octet per cell
- **outSz** Size of out in byte cells
- **in** Packed source, WC_OCTETS_PER_BYTE octets per cell, low octet first, and must not overlap out
- **inSz** Size of in in byte cells; must be at least WC_PACKED_CELLS(octetSz)
- **octetSz** Number of octets to expand

See: wc_PackOctets

Return:

- 0 on success
- BAD_FUNC_ARG when out or in is NULL
- BUFFER_E when out is smaller than octetSz, or in smaller than WC_PACKED_CELLS(octetSz)

Example

```
byte sig[WC_MLDSA_65_SIG_SIZE];
int ret = wc_UnpackOctets(sig, (word32)sizeof(sig), sigPacked,
                          (word32)sizeof(sigPacked),
                          WC_MLDSA_65_SIG_SIZE);
```

C.60.2.9 function wc_PackOctets

```
int wc_PackOctets(
    byte * out,
    word32 outSz,
    const byte * in,
    word32 inSz,
    word32 octetSz
)
```

Packs a one-octet-per-byte-cell buffer into an octet stream, for storing to flash or handing to a byte-oriented peripheral. Inverse of wc_UnpackOctets(); requires WOLFSSL_WIDE_BYTE.

Parameters:

- **out** Destination for the packed stream
- **outSz** Size of out in byte cells
- **in** Source, one octet per cell, and must not overlap out
- **inSz** Size of in in byte cells; must be at least octetSz
- **octetSz** Number of octets to pack

See: wc_UnpackOctets

Return:

- 0 on success
- BAD_FUNC_ARG when out or in is NULL
- BUFFER_E when out is smaller than WC_PACKED_CELLS(octetSz), or in smaller than octetSz

Example

```
byte packed[WC_PACKED_CELLS(sizeof(sig))];
int ret = wc_PackOctets(packed, (word32)sizeof(packed), sig,
                        (word32)sizeof(sig), (word32)sizeof(sig));
```

C.60.2.10 function wc_strlcat

```
size_t wc_strlcat(
    char * dst,
    const char * src,
    size_t dstSize
)
```

Safely concatenates strings with size limit.

Parameters:

- **dst** Destination buffer
- **src** Source string
- **dstSize** Destination buffer size

See: wc_strlcpy

Return: Total length attempted

Example

```
char dst[20] = "hello";
size_t len = wc_strlcat(dst, " world", sizeof(dst));
```

C.60.2.11 function wc_strcasecmp

```
int wc_strcasecmp(
    const char * s1,
    const char * s2
)
```

Case-insensitive string comparison.

Parameters:

- **s1** First string
- **s2** Second string

See: wc_strncasecmp

Return: 0 if equal, non-zero otherwise

Example

```
if (wc_strcasecmp("Hello", "hello") == 0) {
    // strings are equal
}
```

C.60.2.12 function wc_strncasecmp

```
int wc_strncasecmp(
    const char * s1,
    const char * s2,
    size_t n
)
```

Case-insensitive string comparison with length limit.

Parameters:

- **s1** First string
- **s2** Second string
- **n** Maximum characters to compare

See: wc_strcasecmp

Return: 0 if equal, non-zero otherwise

Example

```
if (wc_strncasecmp("Hello", "hello", 5) == 0) {
    // strings are equal
}
```

C.60.2.13 function wolfSSL_NewThread

```
int wolfSSL_NewThread(
    THREAD_TYPE * thread,
    THREAD_CB cb,
    void * arg
)
```

Creates a new thread.

Parameters:

- **thread** Thread handle pointer
- **cb** Thread callback function
- **arg** Argument to pass to callback

See: wolfSSL_JoinThread

Return:

- 0 on success
- negative on error

Example

```
THREAD_TYPE thread;
int ret = wolfSSL_NewThread(&thread, myCallback, NULL);
```

C.60.2.14 function wolfSSL_NewThreadNoJoin

```
int wolfSSL_NewThreadNoJoin(
    THREAD_CB_NOJOIN cb,
    void * arg
)
```

Creates a detached thread.

Parameters:

- **cb** Thread callback function
- **arg** Argument to pass to callback

See: wolfSSL_NewThread

Return:

- 0 on success
- negative on error

Example

```
int ret = wolfSSL_NewThreadNoJoin(myCallback, NULL);
```

C.60.2.15 function wolfSSL_JoinThread

```
int wolfSSL_JoinThread(
    THREAD_TYPE thread
)
```

Waits for thread to complete.

Parameters:

- **thread** Thread handle

See: wolfSSL_NewThread

Return:

- 0 on success
- negative on error

Example

```
THREAD_TYPE thread;
wolfSSL_NewThread(&thread, myCallback, NULL);
int ret = wolfSSL_JoinThread(thread);
```

C.60.2.16 function wolfSSL_CondInit

```
int wolfSSL_CondInit(
    COND_TYPE * cond
)
```

Initializes condition variable.

Parameters:

- **cond** Condition variable pointer

See: wolfSSL_CondFree

Return:

- 0 on success
- negative on error

Example

```
COND_TYPE cond;
int ret = wolfSSL_CondInit(&cond);
```

C.60.2.17 function wolfSSL_CondFree

```
int wolfSSL_CondFree(
    COND_TYPE * cond
)
```

Frees condition variable.

Parameters:

- **cond** Condition variable pointer

See: wolfSSL_CondInit

Return:

- 0 on success
- negative on error

Example

```
COND_TYPE cond;
wolfSSL_CondInit(&cond);
int ret = wolfSSL_CondFree(&cond);
```

C.60.2.18 function wolfSSL_CondSignal

```
int wolfSSL_CondSignal(
    COND_TYPE * cond
)
```

Signals condition variable.

Parameters:

- **cond** Condition variable pointer

See: wolfSSL_CondWait

Return:

- 0 on success
- negative on error

Example

```
COND_TYPE cond;
int ret = wolfSSL_CondSignal(&cond);
```

C.60.2.19 function wolfSSL_CondWait

```
int wolfSSL_CondWait(
    COND_TYPE * cond
)
```

Waits on condition variable.

Parameters:

- **cond** Condition variable pointer

See: wolfSSL_CondSignal

Return:

- 0 on success
- negative on error

Example

```
COND_TYPE cond;
int ret = wolfSSL_CondWait(&cond);
```

C.60.2.20 function wolfSSL_CondStart

```
int wolfSSL_CondStart(
    COND_TYPE * cond
)
```

Starts condition variable.

Parameters:

- **cond** Condition variable pointer

See: wolfSSL_CondEnd

Return:

- 0 on success
- negative on error

Example

```
COND_TYPE cond;
int ret = wolfSSL_CondStart(&cond);
```

C.60.2.21 function wolfSSL_CondEnd

```
int wolfSSL_CondEnd(
    COND_TYPE * cond
)
```

Ends condition variable.

Parameters:

- **cond** Condition variable pointer

See: wolfSSL_CondStart

Return:

- 0 on success
- negative on error

Example

```
COND_TYPE cond;
wolfSSL_CondStart(&cond);
int ret = wolfSSL_CondEnd(&cond);
```

C.60.3 Source code

```
void* XMALLOC(size_t n, void* heap, int type);

void* XREALLOC(void *p, size_t n, void* heap, int type);

void XFREE(void *p, void* heap, int type);

word32 CheckRunTimeSettings(void);

int wolfSSL_CondStart(COND_TYPE* cond);

int wolfSSL_CondEnd(COND_TYPE* cond);
```

C.61 wc_encrypt.h

C.61.1 Functions

	Name
int	**wc_AesCbcDecryptWithKey**(byte * out, const byte * in, word32 inSz, const byte * key, word32 keySz, const byte * iv)Decrypts a cipher from the input buffer in, and places the resulting plain text in the output buffer out using cipher block chaining with AES. This function does not require an AES structure to be initialized. Instead, it takes in a key and an iv (initialization vector) and uses these to initialize an AES object and then decrypt the cipher text.

	Name
int	**wc_Des_CbcDecryptWithKey**(byte * out, const byte * in, word32 sz, const byte * key, const byte * iv)This function decrypts the input ciphertext, in, and stores the resulting plaintext in the output buffer, out. It uses DES encryption with cipher block chaining (CBC) mode. This function is a substitute for wc_Des_CbcDecrypt, allowing the user to decrypt a message without directly instantiating a Des structure.
int	**wc_Des_CbcEncryptWithKey**(byte * out, const byte * in, word32 sz, const byte * key, const byte * iv)This function encrypts the input plaintext, in, and stores the resulting ciphertext in the output buffer, out. It uses DES encryption with cipher block chaining (CBC) mode. This function is a substitute for wc_Des_CbcEncrypt, allowing the user to encrypt a message without directly instantiating a Des structure.
int	**wc_Des3_CbcEncryptWithKey**(byte * out, const byte * in, word32 sz, const byte * key, const byte * iv)This function encrypts the input plaintext, in, and stores the resulting ciphertext in the output buffer, out. It uses Triple DES (3DES) encryption with cipher block chaining (CBC) mode. This function is a substitute for wc_Des3_CbcEncrypt, allowing the user to encrypt a message without directly instantiating a Des3 structure.
int	**wc_Des3_CbcDecryptWithKey**(byte * out, const byte * in, word32 sz, const byte * key, const byte * iv)This function decrypts the input ciphertext, in, and stores the resulting plaintext in the output buffer, out. It uses Triple Des (3DES) encryption with cipher block chaining (CBC) mode. This function is a substitute for wc_Des3_CbcDecrypt, allowing the user to decrypt a message without directly instantiating a Des3 structure.
int	**wc_AesCbcEncryptWithKey**(byte * out, const byte * in, word32 inSz, const byte * key, word32 keySz, const byte * iv)This function encrypts a plaintext message and stores the result in the output buffer. It uses AES encryption with cipher block chaining (CBC) mode. This function does not require an AES structure to be initialized. Instead, it takes in a key and an iv and uses these to encrypt the message.

	Name
int	**wc_BufferKeyDecrypt**(struct EncryptedInfo * info, byte * der, word32 derSz, const byte * password, int passwordSz, int hashType)This function decrypts an encrypted key buffer using the provided password. It supports encryption algorithms DES, 3DES, and AES. The encryption information is provided in the EncryptedInfo structure.
int	**wc_BufferKeyEncrypt**(struct EncryptedInfo * info, byte * der, word32 derSz, const byte * password, int passwordSz, int hashType)This function encrypts a key buffer using the provided password. It supports encryption algorithms DES, 3DES, and AES. The encryption information is provided in the EncryptedInfo structure.

C.61.2 Functions Documentation

C.61.2.1 function wc_AesCbcDecryptWithKey

```
int wc_AesCbcDecryptWithKey(
    byte * out,
    const byte * in,
    word32 inSz,
    const byte * key,
    word32 keySz,
    const byte * iv
)
```

Decrypts a cipher from the input buffer in, and places the resulting plain text in the output buffer out using cipher block chaining with AES. This function does not require an AES structure to be initialized. Instead, it takes in a key and an iv (initialization vector) and uses these to initialize an AES object and then decrypt the cipher text.

Parameters:

- **out** pointer to the output buffer in which to store the plain text of the decrypted message
- **in** pointer to the input buffer containing cipher text to be decrypted
- **inSz** size of input message
- **key** 16, 24, or 32 byte secret key for decryption
- **keySz** size of key used for decryption

See:

- wc_AesSetKey
- wc_AesSetIV
- wc_AesCbcEncrypt
- wc_AesCbcDecrypt

Return:

- 0 On successfully decrypting message
- BAD_ALIGN_E Returned on block align error
- BAD_FUNC_ARG Returned if key length is invalid or AES object is null during AesSetIV

- MEMORY_E Returned if WOLFSSL_SMALL_STACK is enabled and XMALLOC fails to instantiate an AES object.

Example

```
int ret = 0;
byte key[] = { some 16, 24, or 32 byte key };
byte iv[]  = { some 16 byte iv };
byte cipher[AES_BLOCK_SIZE * n]; //n being a positive integer making
cipher some multiple of 16 bytes
// fill cipher with cipher text
byte plain [AES_BLOCK_SIZE * n];
if ((ret = wc_AesCbcDecryptWithKey(plain, cipher, AES_BLOCK_SIZE, key,
AES_BLOCK_SIZE, iv)) != 0 ) {
// Decrypt Error
}
```

C.61.2.2 function wc_Des_CbcDecryptWithKey

```
int wc_Des_CbcDecryptWithKey(
    byte * out,
    const byte * in,
    word32 sz,
    const byte * key,
    const byte * iv
)
```

This function decrypts the input ciphertext, in, and stores the resulting plaintext in the output buffer, out. It uses DES encryption with cipher block chaining (CBC) mode. This function is a substitute for wc_Des_CbcDecrypt, allowing the user to decrypt a message without directly instantiating a Des structure.

Parameters:

- **out** pointer to the buffer in which to store the decrypted plaintext
- **in** pointer to the input buffer containing the encrypted ciphertext
- **sz** length of the ciphertext to decrypt
- **key** pointer to the buffer containing the 8 byte key to use for decryption
- **iv** pointer to the buffer containing the 8 byte iv to use for decryption. If no iv is provided, the iv defaults to 0

See: wc_Des_CbcDecrypt

Return:

- 0 Returned upon successfully decrypting the given ciphertext
- MEMORY_E Returned if there is an error allocating space for a Des structure

3

Example

```
int ret;
byte key[] = { // initialize with 8 byte key };
byte iv[]  = { // initialize with 8 byte iv };

byte cipher[]  = { // initialize with ciphertext };
byte decoded[sizeof(cipher)];

if ( wc_Des_CbcDecryptWithKey(decoded, cipher, sizeof(cipher), key,
```

```
iv) != 0) {
    // error decrypting message
}
```

C.61.2.3 function wc_Des_CbcEncryptWithKey

```
int wc_Des_CbcEncryptWithKey(
    byte * out,
    const byte * in,
    word32 sz,
    const byte * key,
    const byte * iv
)
```

This function encrypts the input plaintext, in, and stores the resulting ciphertext in the output buffer, out. It uses DES encryption with cipher block chaining (CBC) mode. This function is a substitute for wc_Des_CbcEncrypt, allowing the user to encrypt a message without directly instantiating a Des structure.

Parameters:

- **out** Final encrypted data
- **in** Data to be encrypted, must be padded to Des block size.
- **sz** Size of input buffer.
- **key** Pointer to the key to use for encryption.
- **iv** Initialization vector

See:

- wc_Des_CbcDecryptWithKey
- wc_Des_CbcEncrypt

Return:

- 0 Returned after successfully encrypting data.
- MEMORY_E Returned if there's an error allocating memory for a Des structure.
- <0 Returned on any error during encryption.

3

Example

```
byte key[] = { // initialize with 8 byte key };
byte iv[]  = { // initialize with 8 byte iv };
byte in[] = { // Initialize with plaintext };
byte out[sizeof(in)];
if ( wc_Des_CbcEncryptWithKey(&out, in, sizeof(in), key, iv) != 0)
{
    // error encrypting message
}
```

C.61.2.4 function wc_Des3_CbcEncryptWithKey

```
int wc_Des3_CbcEncryptWithKey(
    byte * out,
    const byte * in,
    word32 sz,
    const byte * key,
```

```
    const byte * iv
)
```

This function encrypts the input plaintext, in, and stores the resulting ciphertext in the output buffer, out. It uses Triple DES (3DES) encryption with cipher block chaining (CBC) mode. This function is a substitute for wc_Des3_CbcEncrypt, allowing the user to encrypt a message without directly instantiating a Des3 structure.

Parameters:

- **out** Final encrypted data
- **in** Data to be encrypted, must be padded to Des block size.
- **sz** Size of input buffer.
- **key** Pointer to the key to use for encryption.
- **iv** Initialization vector

See:

- wc_Des3_CbcDecryptWithKey
- wc_Des_CbcEncryptWithKey
- wc_Des_CbcDecryptWithKey

Return:

- 0 Returned after successfully encrypting data.
- MEMORY_E Returned if there's an error allocating memory for a Des structure.
- <0 Returned on any error during encryption.

3

Example

```
byte key[] = { // initialize with 8 byte key };
byte iv[]  = { // initialize with 8 byte iv };

byte in[] = { // Initialize with plaintext };
byte out[sizeof(in)];

if ( wc_Des3_CbcEncryptWithKey(&out, in, sizeof(in), key, iv) != 0)
{
    // error encrypting message
}
```

C.61.2.5 function wc_Des3_CbcDecryptWithKey

```
int wc_Des3_CbcDecryptWithKey(
    byte * out,
    const byte * in,
    word32 sz,
    const byte * key,
    const byte * iv
)
```

This function decrypts the input ciphertext, in, and stores the resulting plaintext in the output buffer, out. It uses Triple Des (3DES) encryption with cipher block chaining (CBC) mode. This function is a substitute for wc_Des3_CbcDecrypt, allowing the user to decrypt a message without directly instantiating a Des3 structure.

Parameters:

- **out** pointer to the buffer in which to store the decrypted plaintext

- **in** pointer to the input buffer containing the encrypted ciphertext
- **sz** length of the ciphertext to decrypt
- **key** pointer to the buffer containing the 24 byte key to use for decryption
- **iv** pointer to the buffer containing the 8 byte iv to use for decryption. If no iv is provided, the iv defaults to 0

See: wc_Des3_CbcDecrypt

Return:

- 0 Returned upon successfully decrypting the given ciphertext
- MEMORY_E Returned if there is an error allocating space for a Des structure

3

Example

```
int ret;
byte key[] = { // initialize with 24 byte key };
byte iv[]  = { // initialize with 8 byte iv };

byte cipher[]  = { // initialize with ciphertext };
byte decoded[sizeof(cipher)];

if ( wc_Des3_CbcDecryptWithKey(decoded, cipher, sizeof(cipher),
key, iv) != 0) {
    // error decrypting message
}
```

C.61.2.6 function wc_AesCbcEncryptWithKey

```
int wc_AesCbcEncryptWithKey(
    byte * out,
    const byte * in,
    word32 inSz,
    const byte * key,
    word32 keySz,
    const byte * iv
)
```

This function encrypts a plaintext message and stores the result in the output buffer. It uses AES encryption with cipher block chaining (CBC) mode. This function does not require an AES structure to be initialized. Instead, it takes in a key and an iv and uses these to encrypt the message.

Parameters:

- **out** pointer to the output buffer in which to store the ciphertext of the encrypted message
- **in** pointer to the input buffer containing plaintext to encrypt
- **inSz** size of input message
- **key** 16, 24, or 32 byte secret key for encryption
- **keySz** size of key used for encryption
- **iv** pointer to the 16 byte initialization vector to use

See:

- wc_AesCbcDecryptWithKey
- wc_AesSetKey
- wc_AesCbcEncrypt

Return:

- 0 On successfully encrypting the message
- BAD_ALIGN_E Returned on block align error
- BAD_FUNC_ARG Returned if key length is invalid
- MEMORY_E Returned if WOLFSSL_SMALL_STACK is enabled and XMALLOC fails to instantiate an AES object

Example

```
byte key[]; // 16, 24, or 32 byte key
byte iv[]; // 16 byte iv
byte plain[]; // plaintext to encrypt
byte cipher[sizeof(plain)];

int ret = wc_AesCbcEncryptWithKey(cipher, plain, sizeof(plain),
                                  key, sizeof(key), iv);
if (ret != 0) {
    // encryption error
}
```

C.61.2.7 function wc_BufferKeyDecrypt

```
int wc_BufferKeyDecrypt(
    struct EncryptedInfo * info,
    byte * der,
    word32 derSz,
    const byte * password,
    int passwordSz,
    int hashType
)
```

This function decrypts an encrypted key buffer using the provided password. It supports encryption algorithms DES, 3DES, and AES. The encryption information is provided in the EncryptedInfo structure.

Parameters:

- **info** pointer to EncryptedInfo structure containing encryption algorithm and parameters
- **der** pointer to the encrypted key buffer
- **derSz** size of the encrypted key buffer
- **password** pointer to the password buffer
- **passwordSz** size of the password
- **hashType** hash algorithm to use for key derivation

See: wc_BufferKeyEncrypt

Return:

- 0 on success
- BAD_FUNC_ARG if der is NULL
- BAD_FUNC_ARG if password is NULL
- BAD_FUNC_ARG if info is NULL
- BAD_FUNC_ARG if info->keySz is 0
- BAD_FUNC_ARG if info->keySz > WC_MAX_SYM_KEY_SIZE
- ALGO_ID_E if info->cipherType is not one of the cipher types this function handles
- BUFFER_E if IV buffer is too small
- NOT_COMPILED_IN if info->cipherType is a cipher type this function handles, but support for it was disabled in this build
- Negative value on error

Example

```
EncryptedInfo info;
byte encryptedKey[32]; // encrypted key data, decrypted in place
byte password[] = "mypassword";

XMEMSET(&info, 0, sizeof(info));
info.cipherType = WC_CIPHER_AES_CBC;
info.keySz = 16;       // size of the key derived from the password

// info.iv holds the IV as hex characters, the way it appears in a PEM
// DEK-Info header.  It is Base16-decoded in place, and must decode to
// at least PKCS5_SALT_SZ bytes.  The decoded bytes are used both as the
// key derivation salt and as the cipher IV.
XMEMCPY(info.iv, "0123456789ABCDEF0123456789ABCDEF", 32);
info.ivSz = 32;        // length of the hex string, not the decoded IV

int ret = wc_BufferKeyDecrypt(&info, encryptedKey,
                              sizeof(encryptedKey), password,
                              sizeof(password)-1, WC_SHA256);
if (ret != 0) {
    // decryption error
}
```

C.61.2.8 function wc_BufferKeyEncrypt

```
int wc_BufferKeyEncrypt(
    struct EncryptedInfo * info,
    byte * der,
    word32 derSz,
    const byte * password,
    int passwordSz,
    int hashType
)
```

This function encrypts a key buffer using the provided password. It supports encryption algorithms DES, 3DES, and AES. The encryption information is provided in the EncryptedInfo structure.

Parameters:

- **info** pointer to EncryptedInfo structure containing encryption algorithm and parameters
- **der** pointer to the key buffer to encrypt
- **derSz** size of the key buffer
- **password** pointer to the password buffer
- **passwordSz** size of the password
- **hashType** hash algorithm to use for key derivation

See: wc_BufferKeyDecrypt

Return:

- 0 on success
- BAD_FUNC_ARG if der is NULL
- BAD_FUNC_ARG if password is NULL
- BAD_FUNC_ARG if info is NULL
- BAD_FUNC_ARG if info->keySz is 0
- BAD_FUNC_ARG if info->keySz > WC_MAX_SYM_KEY_SIZE
- BAD_FUNC_ARG if info->ivSz < PKCS5_SALT_SZ
- ALGO_ID_E if info->cipherType is not one of the cipher types this function handles

- NOT_COMPILED_IN if info->cipherType is a cipher type this function handles, but support for it was disabled in this build
- Negative value on error

Example

```
EncryptedInfo info;
byte key[32]; // key data to encrypt, encrypted in place
byte password[] = "mypassword";

XMEMSET(&info, 0, sizeof(info));
info.cipherType = WC_CIPHER_AES_CBC;
info.keySz = 16;   // size of the key derived from the password
info.ivSz  = 16;   // must be at least PKCS5_SALT_SZ

// Unlike wc_BufferKeyDecrypt, info.iv holds raw bytes here.  Fill it
// with info.ivSz random bytes; the first PKCS5_SALT_SZ of them are used
// as the key derivation salt, and the buffer is also used as the
// cipher IV.
WC_RNG rng;
wc_InitRng(&rng);
wc_RNG_GenerateBlock(&rng, info.iv, info.ivSz);

int ret = wc_BufferKeyEncrypt(&info, key, sizeof(key), password,
                              sizeof(password)-1, WC_SHA256);
if (ret != 0) {
    // encryption error
}
wc_FreeRng(&rng);
```

C.61.3 Source code

```
int  wc_AesCbcDecryptWithKey(byte* out, const byte* in, word32 inSz,
                                        const byte* key, word32 keySz,
                                        const byte* iv);

int  wc_Des_CbcDecryptWithKey(byte* out,
                                         const byte* in, word32 sz,
                                         const byte* key, const byte* iv);

int  wc_Des_CbcEncryptWithKey(byte* out,
                                         const byte* in, word32 sz,
                                         const byte* key, const byte* iv);

int  wc_Des3_CbcEncryptWithKey(byte* out,
                                          const byte* in, word32 sz,
                                          const byte* key, const byte* iv);

int  wc_Des3_CbcDecryptWithKey(byte* out,
                                          const byte* in, word32 sz,
                                          const byte* key, const byte* iv);

int wc_AesCbcEncryptWithKey(byte* out, const byte* in, word32 inSz,
                            const byte* key, word32 keySz,
```

```
                            const byte* iv);

int wc_BufferKeyDecrypt(struct EncryptedInfo* info, byte* der,
                        word32 derSz, const byte* password,
                        int passwordSz, int hashType);

int wc_BufferKeyEncrypt(struct EncryptedInfo* info, byte* der,
                        word32 derSz, const byte* password,
                        int passwordSz, int hashType);
```

C.62 wc_lms.h

C.62.1 Functions

	Name
int	**wc_LmsKey_Init**(LmsKey * key, void * heap, int devId)Initializes an LmsKey object. Must be called before any other LMS/HSS operation. Use wc_LmsKey_Free() to release resources when done.
int	**wc_LmsKey_InitId**(LmsKey * key, const unsigned char * id, int len, void * heap, int devId)Initializes an LmsKey with a device_side key identifier. Equivalent to wc_LmsKey_Init() but also stashes a binary id that a crypto callback can use to look up the underlying key material on the device. Only available when wolfSSL is built with WOLF_PRIVATE_KEY_ID.
int	**wc_LmsKey_InitLabel**(LmsKey * key, const char * label, void * heap, int devId)Initializes an LmsKey with a device_side key label. Equivalent to wc_LmsKey_Init() but also stashes a label string that a crypto callback can use to look up the underlying key material on the device. Only available when wolfSSL is built with WOLF_PRIVATE_KEY_ID.
int	**wc_LmsKey_SetLmsParm**(LmsKey * key, enum wc_LmsParm lmsParm)Selects a predefined LMS/HSS parameter set by name. The enum wc_LmsParm encodes the tree depth (levels), per-tree height, Winternitz parameter and hash family in a single value. See the wc_LmsParm definition for the list of names available in a given build.
int	**wc_LmsKey_SetParameters**(LmsKey * key, int levels, int height, int winternitz)Sets the LMS/HSS parameters individually. The default SHA_256/256 hash is used. For finer control over the hash family use wc_LmsKey_SetParameters_ex().

	Name
int	**wc_LmsKey_SetParameters_ex**(LmsKey * key, int levels, int height, int winternitz, int hash)Sets the LMS/HSS parameters individually with an explicit hash family selector.
int	**wc_LmsKey_GetParameters**(const LmsKey * key, int * levels, int * height, int * winternitz)Retrieves the LMS/HSS parameters previously set on this key.
int	**wc_LmsKey_GetParameters_ex**(const LmsKey * key, int * levels, int * height, int * winternitz, int * hash)Retrieves the LMS/HSS parameters and hash family selector from this key.
int	**wc_LmsKey_SetWriteCb**(LmsKey * key, wc_lms_write_private_key_cb write_cb)Registers the callback that wolfSSL invokes to persist updated private key state. Because LMS/HSS is stateful, the application MUST persist the private key after each successful sign before the signature is released to a peer; otherwise a crash or restart can lead to one-time key reuse and break the scheme.
int	**wc_LmsKey_SetReadCb**(LmsKey * key, wc_lms_read_private_key_cb read_cb)Registers the callback that wolfSSL invokes to load persisted private key state. Used by wc_LmsKey_Reload() to bring a saved key back into memory for further signing.
int	**wc_LmsKey_SetContext**(LmsKey * key, void * context)Sets the opaque context pointer passed to both the read and write private-key callbacks. Typically used to carry a file handle, database connection, or other persistence-layer state.
int	**wc_LmsKey_MakeKey**(LmsKey * key, WC_RNG * rng)Generates a fresh LMS/HSS key pair. Parameters must already be set (via wc_LmsKey_SetLmsParm() or wc_LmsKey_SetParameters()) and read/write callbacks must be registered. The newly generated private key is persisted via the write callback before the function returns; on success the key transitions to state WC_LMS_STATE_OK.
int	**wc_LmsKey_Reload**(LmsKey * key)Reloads a previously generated LMS/HSS private key from persistent storage using the registered read callback, restoring the key to a state where it can sign further messages. On success the key is in state WC_LMS_STATE_OK.
int	**wc_LmsKey_GetPrivLen**(const LmsKey * key, word32 * len)Returns the size in bytes of the encoded private key for the parameter set selected on this key.

	Name
int	**wc_LmsKey_GetPubLen**(const LmsKey * key, word32 * len)Returns the size in bytes of the LMS/HSS public key for the parameter set selected on this key.
int	**wc_LmsKey_GetSigLen**(const LmsKey * key, word32 * len)Returns the LMS/HSS signature size in bytes for the parameter set selected on this key.
int	**wc_LmsKey_Sign**(LmsKey * key, byte * sig, word32 * sigSz, const byte * msg, int msgSz)Signs msg with the LMS/HSS private key in key. On entry sigSz is the size of the sig buffer; on success it is updated to the bytes written.
int	**wc_LmsKey_SigsLeft**(LmsKey * key)Reports whether this key can create another signature. It does not return a count. A key whose one-time keys are used up returns 0 and should be retired.
void	**wc_LmsKey_Free**(LmsKey * key)Releases resources held by an LmsKey. Safe to call with a NULL pointer. After this call the key is in state WC_LMS_STATE_FREED and must be re-initialized before reuse.
int	**wc_LmsKey_ExportPub**(LmsKey * keyDst, const LmsKey * keySrc)Copies the public part of keySrc into keyDst. The destination key inherits the same parameters and may be used for verification; it does not carry the private key state and cannot sign. Useful for handing a verifier the minimal data it needs.
int	**wc_LmsKey_ExportPub_ex**(LmsKey * keyDst, const LmsKey * keySrc, void * heap, int devId)Like wc_LmsKey_ExportPub() but the destination key is initialized fresh with the supplied heap and devId.
int	**wc_LmsKey_ExportPubRaw**(const LmsKey * key, byte * out, word32 * outLen)Exports the LMS/HSS public key as a raw byte string. On entry *outLen is the size of out; on success it is updated to the bytes written.
int	**wc_LmsKey_ImportPubRaw**(LmsKey * key, const byte * in, word32 inLen)Imports a raw LMS/HSS public key into key. The key must be in state WC_LMS_STATE_INITED. Parameter information is recovered from the encoded header, after which the key transitions to state WC_LMS_STATE_VERIFYONLY.

	Name
int	**wc_LmsKey_Verify**(LmsKey * key, const byte * sig, word32 sigSz, const byte * msg, int msgSz)Verifies an LMS/HSS signature against msg using the public key held in key. The function returns 0 only when the signature is valid; any other value indicates the signature was rejected.
const char *	**wc_LmsKey_ParmToStr**(enum wc_LmsParm lmsParm)Returns a static, NUL-terminated string describing an LMS parameter set. Useful for logging and diagnostics.
int	**wc_LmsKey_GetKid**(LmsKey * key, const byte ** kid, word32 * kidSz)Returns a pointer to the 16_byte LMS Key Identifier (I) embedded in the private key, together with its length. The returned pointer aliases internal key memory and is valid only until the key is freed.
const byte *	**wc_LmsKey_GetKidFromPrivRaw**(const byte * priv, word32 privSz)Returns a pointer to the LMS Key Identifier (I) within a raw encoded private key buffer, without requiring an LmsKey object. Used to look up the matching state record in persistent storage during reload.

C.62.2 Functions Documentation

C.62.2.1 function wc_LmsKey_Init

```
int wc_LmsKey_Init(
    LmsKey * key,
    void * heap,
    int devId
)
```

Initializes an LmsKey object. Must be called before any other LMS/HSS operation. Use wc_LmsKey_Free() to release resources when done.

Parameters:

- **key** Pointer to the LmsKey to initialize.
- **heap** Heap hint for dynamic memory allocation. May be NULL.
- **devId** Device identifier for hardware crypto callbacks. Use INVALID_DEVID for software-only.

See:

- wc_LmsKey_Free
- wc_LmsKey_SetLmsParm
- wc_LmsKey_SetParameters
- wc_LmsKey_MakeKey

Return:

- 0 on success.
- BAD_FUNC_ARG if key is NULL.

LMS (Leighton-Micali Signatures) and the HSS multi-tree composition (RFC 8554, NIST SP 800-208) are STATEFUL hash-based signature schemes: each call to wc_LmsKey_Sign() consumes a one_time component of the private key, and reusing a one_time key breaks the security of the scheme. Applications MUST persist the private key state between sign calls; see wc_LmsKey_SetWriteCb() and wc_LmsKey_SetReadCb().

After init the key is in state WC_LMS_STATE_INITED. The parameters must be set with wc_LmsKey_SetLmsParm() or wc_LmsKey_SetParameters() before generating or reloading a key.

Example

```
LmsKey key;
int ret;

ret = wc_LmsKey_Init(&key, NULL, INVALID_DEVID);
if (ret != 0) {
    // error initializing key
}
wc_LmsKey_SetLmsParm(&key, WC_LMS_PARM_L2_H10_W8);
// ... use key ...
wc_LmsKey_Free(&key);
```

C.62.2.2 function wc_LmsKey_InitId

```
int wc_LmsKey_InitId(
    LmsKey * key,
    const unsigned char * id,
    int len,
    void * heap,
    int devId
)
```

Initializes an LmsKey with a device-side key identifier. Equivalent to wc_LmsKey_Init() but also stashes a binary id that a crypto callback can use to look up the underlying key material on the device. Only available when wolfSSL is built with WOLF_PRIVATE_KEY_ID.

Parameters:

- **key** Pointer to the LmsKey to initialize.
- **id** Pointer to the device-side key identifier bytes. May be NULL when len is 0.
- **len** Number of bytes in id; must be in [0, LMS_MAX_ID_LEN].
- **heap** Heap hint for dynamic memory allocation.
- **devId** Device identifier for the crypto callback.

See:

- wc_LmsKey_Init
- wc_LmsKey_InitLabel
- wc_LmsKey_Free

Return:

- 0 on success.
- BAD_FUNC_ARG if key is NULL, or id is NULL while len > 0.
- BUFFER_E if len is negative or greater than LMS_MAX_ID_LEN.

The id is copied into the key object; the caller may free its buffer immediately after this call returns.

C.62.2.3 function wc_LmsKey_InitLabel

```
int wc_LmsKey_InitLabel(
    LmsKey * key,
    const char * label,
    void * heap,
    int devId
)
```

Initializes an LmsKey with a device-side key label. Equivalent to wc_LmsKey_Init() but also stashes a label string that a crypto callback can use to look up the underlying key material on the device. Only available when wolfSSL is built with WOLF_PRIVATE_KEY_ID.

Parameters:

- **key** Pointer to the LmsKey to initialize.
- **label** NUL-terminated device-side key label.
- **heap** Heap hint for dynamic memory allocation.
- **devId** Device identifier for the crypto callback.

See:

- wc_LmsKey_Init
- wc_LmsKey_InitId

Return:

- 0 on success.
- BAD_FUNC_ARG if key or label is NULL.
- BUFFER_E if label is empty or longer than LMS_MAX_LABEL_LEN.

C.62.2.4 function wc_LmsKey_SetLmsParm

```
int wc_LmsKey_SetLmsParm(
    LmsKey * key,
    enum wc_LmsParm lmsParm
)
```

Selects a predefined LMS/HSS parameter set by name. The enum wc_LmsParm encodes the tree depth (levels), per-tree height, Winternitz parameter and hash family in a single value. See the wc_LmsParm definition for the list of names available in a given build.

Parameters:

- **key** Pointer to an LmsKey in state WC_LMS_STATE_INITED.
- **lmsParm** A wc_LmsParm constant (e.g. WC_LMS_PARM_L2_H10_W8).

See:

- wc_LmsKey_SetParameters
- wc_LmsKey_GetParameters
- wc_LmsKey_ParmToStr

Return:

- 0 on success.
- BAD_FUNC_ARG if key is NULL, or if lmsParm is not recognized or names a parameter set that was not compiled in.
- BAD_STATE_E if key is not in state WC_LMS_STATE_INITED.

Example

```
LmsKey key;

wc_LmsKey_Init(&key, NULL, INVALID_DEVID);
wc_LmsKey_SetLmsParm(&key, WC_LMS_PARM_L2_H10_W8);
```

C.62.2.5 function wc_LmsKey_SetParameters

```
int wc_LmsKey_SetParameters(
    LmsKey * key,
    int levels,
    int height,
    int winternitz
)
```

Sets the LMS/HSS parameters individually. The default SHA-256/256 hash is used. For finer control over the hash family use wc_LmsKey_SetParameters_ex().

Parameters:

- **key** Pointer to an LmsKey in state WC_LMS_STATE_INITED.
- **levels** Number of Merkle-tree levels in the HSS chain.
- **height** Height of each individual Merkle tree.
- **winternitz** Winternitz parameter (1, 2, 4 or 8).

See:

- wc_LmsKey_SetParameters_ex
- wc_LmsKey_SetLmsParm
- wc_LmsKey_GetParameters

Return:

- 0 on success.
- BAD_FUNC_ARG if key is NULL, or if the requested parameter combination is not supported in this build.
- BAD_STATE_E if key is not in state WC_LMS_STATE_INITED.

The combination of parameters must match one of the allowed sets in RFC 8554:

- levels: 1..8
- height: 5, 10, 15, 20 (and 25 in some builds)
- winternitz: 1, 2, 4, or 8

The maximum number of signatures available from a key is 2^(levels * height).

C.62.2.6 function wc_LmsKey_SetParameters_ex

```
int wc_LmsKey_SetParameters_ex(
    LmsKey * key,
    int levels,
    int height,
    int winternitz,
    int hash
)
```

Sets the LMS/HSS parameters individually with an explicit hash family selector.

Parameters:

- **key** Pointer to an LmsKey in state WC_LMS_STATE_INITED.
- **levels** Number of Merkle-tree levels.

- **height** Height of each tree.
- **winternitz** Winternitz parameter (1, 2, 4 or 8).
- **hash** Hash family selector identifying SHA-256/256, SHA-256/192, SHAKE256/256 or SHAKE256/192, as supported by the build.

See:

- wc_LmsKey_SetParameters
- wc_LmsKey_GetParameters_ex

Return:

- 0 on success.
- BAD_FUNC_ARG if key is NULL, or if the requested parameter combination is not supported in this build.
- BAD_STATE_E if key is not in state WC_LMS_STATE_INITED.

C.62.2.7 function wc_LmsKey_GetParameters

```
int wc_LmsKey_GetParameters(
    const LmsKey * key,
    int * levels,
    int * height,
    int * winternitz
)
```

Retrieves the LMS/HSS parameters previously set on this key.

Parameters:

- **key** Pointer to an LmsKey with parameters set.
- **levels** Receives the number of tree levels.
- **height** Receives the per-tree height.
- **winternitz** Receives the Winternitz parameter.

See:

- wc_LmsKey_SetParameters
- wc_LmsKey_GetParameters_ex

Return:

- 0 on success.
- BAD_FUNC_ARG if any pointer is NULL or no parameters are set.

C.62.2.8 function wc_LmsKey_GetParameters_ex

```
int wc_LmsKey_GetParameters_ex(
    const LmsKey * key,
    int * levels,
    int * height,
    int * winternitz,
    int * hash
)
```

Retrieves the LMS/HSS parameters and hash family selector from this key.

Parameters:

- **key** Pointer to an LmsKey with parameters set.
- **levels** Receives the number of tree levels.

- **height** Receives the per-tree height.
- **winternitz** Receives the Winternitz parameter.
- **hash** Receives the hash family selector.

See: wc_LmsKey_SetParameters_ex

Return:

- 0 on success.
- BAD_FUNC_ARG if any pointer is NULL or no parameters are set.

C.62.2.9 function wc_LmsKey_SetWriteCb

```
int wc_LmsKey_SetWriteCb(
    LmsKey * key,
    wc_lms_write_private_key_cb write_cb
)
```

Registers the callback that wolfSSL invokes to persist updated private key state. Because LMS/HSS is stateful, the application MUST persist the private key after each successful sign before the signature is released to a peer; otherwise a crash or restart can lead to one-time key reuse and break the scheme.

Parameters:

- **key** Pointer to an LmsKey.
- **write_cb** Callback invoked to persist the private key.

See:

- wc_LmsKey_SetReadCb
- wc_LmsKey_SetContext
- wc_LmsKey_Sign

Return:

- 0 on success.
- BAD_FUNC_ARG if key or write_cb is NULL.

The callback receives the encoded private key bytes and returns one of the wc_LmsRc codes. WC_LMS_RC_SAVED_TO_NV_MEMORY signals a durable write; other return codes are treated as failures.

C.62.2.10 function wc_LmsKey_SetReadCb

```
int wc_LmsKey_SetReadCb(
    LmsKey * key,
    wc_lms_read_private_key_cb read_cb
)
```

Registers the callback that wolfSSL invokes to load persisted private key state. Used by wc_LmsKey_Reload() to bring a saved key back into memory for further signing.

Parameters:

- **key** Pointer to an LmsKey.
- **read_cb** Callback invoked to load the private key.

See:

- wc_LmsKey_SetWriteCb
- wc_LmsKey_SetContext
- wc_LmsKey_Reload

Return:

- 0 on success.
- BAD_FUNC_ARG if key or read_cb is NULL.

C.62.2.11 function wc_LmsKey_SetContext

```
int wc_LmsKey_SetContext(
    LmsKey * key,
    void * context
)
```

Sets the opaque context pointer passed to both the read and write private-key callbacks. Typically used to carry a file handle, database connection, or other persistence-layer state.

Parameters:

- **key** Pointer to an LmsKey.
- **context** Application-defined pointer; may be NULL.

See:

- wc_LmsKey_SetReadCb
- wc_LmsKey_SetWriteCb

Return:

- 0 on success.
- BAD_FUNC_ARG if key is NULL.

C.62.2.12 function wc_LmsKey_MakeKey

```
int wc_LmsKey_MakeKey(
    LmsKey * key,
    WC_RNG * rng
)
```

Generates a fresh LMS/HSS key pair. Parameters must already be set (via wc_LmsKey_SetLmsParm() or wc_LmsKey_SetParameters()) and read/write callbacks must be registered. The newly generated private key is persisted via the write callback before the function returns; on success the key transitions to state WC_LMS_STATE_OK.

Parameters:

- **key** Pointer to an LmsKey in state WC_LMS_STATE_PARMSET with callbacks set.
- **rng** Pointer to an initialized WC_RNG.

See:

- wc_LmsKey_Sign
- wc_LmsKey_Reload

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL.
- MEMORY_E on allocation failure.

Key generation runtime grows quickly with the first tree's height: a 3-level h=5 tree is much faster than a 1-level h=15 tree even though both yield the same total signature count.

Example

```
LmsKey key;
WC_RNG rng;

wc_LmsKey_Init(&key, NULL, INVALID_DEVID);
wc_LmsKey_SetLmsParm(&key, WC_LMS_PARM_L2_H10_W8);
wc_LmsKey_SetWriteCb(&key, my_write_cb);
wc_LmsKey_SetReadCb(&key, my_read_cb);
wc_LmsKey_SetContext(&key, &my_storage);
wc_InitRng(&rng);

if (wc_LmsKey_MakeKey(&key, &rng) != 0) {
    // error generating key
}
```

C.62.2.13 function wc_LmsKey_Reload

```
int wc_LmsKey_Reload(
    LmsKey * key
)
```

Reloads a previously generated LMS/HSS private key from persistent storage using the registered read callback, restoring the key to a state where it can sign further messages. On success the key is in state WC_LMS_STATE_OK.

Parameters:

- **key** Pointer to an LmsKey with parameters and read callback set.

See:

- wc_LmsKey_MakeKey
- wc_LmsKey_SetReadCb

Return:

- 0 on success, including the device-backed no-op.
- BAD_FUNC_ARG if any required pointer is NULL.
- WC_LMS_RC_* mapped error if the read callback fails.
- IO_FAILED_E if the private key could not be read.
- NO_VALID_DEVID with WOLF_CRYPTO_CB_ONLY_LMS when the key is not device-backed.

The same parameters set at key-generation time must be reapplied to the LmsKey before calling Reload (the persisted blob is just the private key bytes; the parameter set is metadata the application owns).

With WOLF_CRYPTO_CB, a key on a devId with no read callback is taken to be device-backed and Reload is a no-op. With a read callback the software reload runs as usual.

WOLF_CRYPTO_CB_ONLY_LMS removes the software reload, so the read callback is never called and only the device-backed no-op succeeds.

A reloaded key holds no public key: neither arm populates it. Call wc_LmsKey_ImportPubRaw() on a separate key to verify, or keep the public key exported at generation time.

C.62.2.14 function wc_LmsKey_GetPrivLen

```
int wc_LmsKey_GetPrivLen(
    const LmsKey * key,
    word32 * len
)
```

Returns the size in bytes of the encoded private key for the parameter set selected on this key.

Parameters:

- **key** Pointer to an LmsKey with parameters set.
- **len** Receives the private key size in bytes.

See:

- wc_LmsKey_GetPubLen
- wc_LmsKey_GetSigLen

Return:

- 0 on success.
- BAD_FUNC_ARG if key or len is NULL.

C.62.2.15 function wc_LmsKey_GetPubLen

```
int wc_LmsKey_GetPubLen(
    const LmsKey * key,
    word32 * len
)
```

Returns the size in bytes of the LMS/HSS public key for the parameter set selected on this key.

Parameters:

- **key** Pointer to an LmsKey with parameters set.
- **len** Receives the public key size in bytes.

See:

- wc_LmsKey_ExportPubRaw
- wc_LmsKey_GetPrivLen

Return:

- 0 on success.
- BAD_FUNC_ARG if key or len is NULL.

C.62.2.16 function wc_LmsKey_GetSigLen

```
int wc_LmsKey_GetSigLen(
    const LmsKey * key,
    word32 * len
)
```

Returns the LMS/HSS signature size in bytes for the parameter set selected on this key.

Parameters:

- **key** Pointer to an LmsKey with parameters set.
- **len** Receives the signature size in bytes.

See: wc_LmsKey_Sign

Return:

- 0 on success.
- BAD_FUNC_ARG if key or len is NULL.

C.62.2.17 function wc_LmsKey_Sign

```
int wc_LmsKey_Sign(
    LmsKey * key,
    byte * sig,
    word32 * sigSz,
    const byte * msg,
    int msgSz
)
```

Signs msg with the LMS/HSS private key in key. On entry sigSz is the size of the sig buffer; on success it is updated to the bytes written.

Parameters:

- **key** Pointer to an LmsKey in state WC_LMS_STATE_OK.
- **sig** Buffer that receives the signature.
- **sigSz** In: size of sig. Out: bytes written.
- **msg** Message to sign.
- **msgSz** Length of msg in bytes.

See:

- wc_LmsKey_Verify
- wc_LmsKey_SigsLeft
- wc_LmsKey_SetWriteCb

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL.
- BUFFER_E if *sigSz is smaller than the signature size.
- -1 (or similar) if all one-time keys have been used.

Each successful sign call consumes a one-time component of the private key. The updated key state is persisted via the registered write callback BEFORE the new signature is returned to the caller. If the write callback fails the sign call fails and the signature is not released. When the supply of one-time keys is exhausted the key transitions to state WC_LMS_STATE_NOSIGS and further sign attempts return SIG_OTHER_E (or similar) – query wc_LmsKey_SigsLeft() to detect this condition in advance.

C.62.2.18 function wc_LmsKey_SigsLeft

```
int wc_LmsKey_SigsLeft(
    LmsKey * key
)
```

Reports whether this key can create another signature. It does not return a count. A key whose one-time keys are used up returns 0 and should be retired.

Parameters:

- **key** Pointer to an LmsKey in state WC_LMS_STATE_OK.

See: wc_LmsKey_Sign

Return:

- 1 if at least one signature remains.
- 0 if the one-time keys are exhausted, if key is NULL, has no parameters set or is verify-only, or if a crypto callback device returns an error.

C.62.2.19 function wc_LmsKey_Free

```
void wc_LmsKey_Free(
    LmsKey * key
)
```

Releases resources held by an LmsKey. Safe to call with a NULL pointer. After this call the key is in state WC_LMS_STATE_FREED and must be re-initialized before reuse.

Parameters:

- **key** Pointer to the LmsKey to free.

See: wc_LmsKey_Init

C.62.2.20 function wc_LmsKey_ExportPub

```
int wc_LmsKey_ExportPub(
    LmsKey * keyDst,
    const LmsKey * keySrc
)
```

Copies the public part of keySrc into keyDst. The destination key inherits the same parameters and may be used for verification; it does not carry the private key state and cannot sign. Useful for handing a verifier the minimal data it needs.

Parameters:

- **keyDst** Pointer to an initialized destination LmsKey.
- **keySrc** Pointer to an LmsKey with the public key.

See:

- wc_LmsKey_ExportPub_ex
- wc_LmsKey_ExportPubRaw

Return:

- 0 on success.
- BAD_FUNC_ARG if keyDst or keySrc is NULL.
- BAD_STATE_E if keySrc holds no public key.

C.62.2.21 function wc_LmsKey_ExportPub_ex

```
int wc_LmsKey_ExportPub_ex(
    LmsKey * keyDst,
    const LmsKey * keySrc,
    void * heap,
    int devId
)
```

Like wc_LmsKey_ExportPub() but the destination key is initialized fresh with the supplied heap and devId.

Parameters:

- **keyDst** Pointer to an LmsKey to populate.
- **keySrc** Pointer to an LmsKey with the public key.
- **heap** Heap hint for keyDst.
- **devId** Device identifier for keyDst.

See: wc_LmsKey_ExportPub

Return:

- 0 on success.
- BAD_FUNC_ARG if keyDst or keySrc is NULL.
- BAD_STATE_E if keySrc holds no public key.

C.62.2.22 function wc_LmsKey_ExportPubRaw

```
int wc_LmsKey_ExportPubRaw(
    const LmsKey * key,
    byte * out,
    word32 * outLen
)
```

Exports the LMS/HSS public key as a raw byte string. On entry *outLen is the size of out; on success it is updated to the bytes written.

Parameters:

- **key** Pointer to an LmsKey.
- **out** Buffer that receives the public key.
- **outLen** In: size of out. Out: bytes written.

See:

- wc_LmsKey_ImportPubRaw
- wc_LmsKey_GetPubLen

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL.
- BAD_STATE_E if key holds no public key.
- BUFFER_E if *outLen is smaller than the public key size.

C.62.2.23 function wc_LmsKey_ImportPubRaw

```
int wc_LmsKey_ImportPubRaw(
    LmsKey * key,
    const byte * in,
    word32 inLen
)
```

Imports a raw LMS/HSS public key into key. The key must be in state WC_LMS_STATE_INITED. Parameter information is recovered from the encoded header, after which the key transitions to state WC_LMS_STATE_VERIFYONLY.

Parameters:

- **key** Pointer to an LmsKey in WC_LMS_STATE_INITED.
- **in** Raw public key bytes.
- **inLen** Length of in in bytes.

See:

- wc_LmsKey_ExportPubRaw
- wc_LmsKey_Verify

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL.
- BUFFER_E if inLen is too small.

C.62.2.24 function wc_LmsKey_Verify

```
int wc_LmsKey_Verify(
    LmsKey * key,
    const byte * sig,
    word32 sigSz,
    const byte * msg,
    int msgSz
)
```

Verifies an LMS/HSS signature against msg using the public key held in key. The function returns 0 only when the signature is valid; any other value indicates the signature was rejected.

Parameters:

- **key** Pointer to an LmsKey with the public key set.
- **sig** Signature bytes to verify.
- **sigSz** Length of sig in bytes.
- **msg** Message that was signed.
- **msgSz** Length of msg in bytes.

See:

- wc_LmsKey_Sign
- wc_LmsKey_ImportPubRaw

Return:

- 0 on a valid signature.
- BAD_FUNC_ARG if any required pointer is NULL.
- BAD_STATE_E if key holds no public key.
- SIG_VERIFY_E (or similar) if the signature is invalid or malformed.

C.62.2.25 function wc_LmsKey_ParmToStr

```
const char * wc_LmsKey_ParmToStr(
    enum wc_LmsParm lmsParm
)
```

Returns a static, NUL-terminated string describing an LMS parameter set. Useful for logging and diagnostics.

Parameters:

- **lmsParm** A wc_LmsParm constant.

See: wc_LmsKey_SetLmsParm

Return:

- Pointer to a static string on success.
- NULL if lmsParm is not recognized.

C.62.2.26 function wc_LmsKey_GetKid

```
int wc_LmsKey_GetKid(
    LmsKey * key,
    const byte ** kid,
    word32 * kidSz
)
```

Returns a pointer to the 16-byte LMS Key Identifier (I) embedded in the private key, together with its length. The returned pointer aliases internal key memory and is valid only until the key is freed.

Parameters:

- **key** Pointer to an LmsKey with a private key.
- **kid** Receives a pointer to the I bytes.
- **kidSz** Receives the length (16 / WC_LMS_I_LEN).

See: wc_LmsKey_GetKidFromPrivRaw

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL.
- BAD_STATE_E if the private key is not in memory, such as when a device keeps it.

C.62.2.27 function wc_LmsKey_GetKidFromPrivRaw

```
const byte * wc_LmsKey_GetKidFromPrivRaw(
    const byte * priv,
    word32 privSz
)
```

Returns a pointer to the LMS Key Identifier (I) within a raw encoded private key buffer, without requiring an LmsKey object. Used to look up the matching state record in persistent storage during reload.

Parameters:

- **priv** Encoded private key bytes.
- **privSz** Length of priv in bytes.

See: wc_LmsKey_GetKid

Return:

- Pointer to the I bytes within priv on success.
- NULL if priv is NULL or privSz is too small to contain a valid header.

C.62.3 Source code

C.63 wc_mldsa.h

C.63.1 Functions

	Name
int	**wc_MlDsaKey_Init**(wc_MlDsaKey * key, void * heap, int devId)Initializes a wc_MlDsaKey object. Must be called before any other ML_DSA operation. Use wc_MlDsaKey_Free() to release resources when done.
wc_MlDsaKey *	**wc_MlDsaKey_New**(void * heap, int devId)Allocates and initializes a new wc_MlDsaKey on the heap. The returned pointer must be released with wc_MlDsaKey_Delete(). Only available when wolfSSL is built without WC_NO_CONSTRUCTORS.
int	**wc_MlDsaKey_Delete**(wc_MlDsaKey * key, wc_MlDsaKey ** key_p)Frees and zeros a heap_allocated wc_MlDsaKey previously returned by wc_MlDsaKey_New(). On success the caller's pointer variable is set to NULL via key_p when key_p is not NULL. Only available when wolfSSL is built without WC_NO_CONSTRUCTORS.
int	**wc_MlDsaKey_InitId**(wc_MlDsaKey * key, const unsigned char * id, int len, void * heap, int devId)Initializes a wc_MlDsaKey with a device_side key identifier. Equivalent to wc_MlDsaKey_Init() but also stashes a binary id that a crypto callback can use to look up the underlying key material on the device. Only available when wolfSSL is built with WOLF_PRIVATE_KEY_ID.
int	**wc_MlDsaKey_InitLabel**(wc_MlDsaKey * key, const char * label, void * heap, int devId)Initializes a wc_MlDsaKey with a device_side key label. Equivalent to wc_MlDsaKey_Init() but also stashes a label string that a crypto callback can use to look up the underlying key material on the device. Only available when wolfSSL is built with WOLF_PRIVATE_KEY_ID.
int	**wc_MlDsaKey_SetParams**(wc_MlDsaKey * key, byte level)Selects the ML_DSA parameter set for this key. Must be called after wc_MlDsaKey_Init() and before key generation, signing or verifying.
int	**wc_MlDsaKey_GetParams**(wc_MlDsaKey * key, byte * level)Retrieves the ML-DSA parameter set currently selected on this key.

	Name
void	**wc_MlDsaKey_Free**(wc_MlDsaKey * key)Releases resources held by a wc_MlDsaKey. After this call the object must be re_initialized with wc_MlDsaKey_Init() before it can be used again. Safe to call with a NULL pointer.
int	**wc_MlDsaKey_MakeKey**(wc_MlDsaKey * key, WC_RNG * rng)Generates a new ML_DSA key pair using the provided RNG. The parameter set must already be set with wc_MlDsaKey_SetParams(). Both the public and private key components are populated on success.
int	**wc_MlDsaKey_MakeKeyFromSeed**(wc_MlDsaKey * key, const byte * seed)Deterministically generates an ML-DSA key pair from a 32-byte seed. Useful for known-answer tests and for applications that derive the seed from another secret. The seed buffer must contain exactly 32 bytes.
int	**wc_MlDsaKey_MakePublicKey**(wc_MlDsaKey * key)Derives public key for a wc_MlDsaKey with private key set. If the public key is already set, it is only checked against the private key's tr (H(pk)); use wc_MlDsaKey_CheckKey() for a full key pair check. The private key is still required: a public-only key returns BAD_FUNC_ARG. Available when WC_MLDSA_HAVE_MAKE_PUBLIC_KEY is defined: that is, when WOLFSSL_MLDSA_ASSIGN_KEY, WOLFSSL_MLDSA_NO_MAKE_KEY and WOLFSSL_MLDSA_VERIFY_ONLY are not defined.
int	**wc_MlDsaKey_SignCtx**(wc_MlDsaKey * key, const byte * ctx, byte ctxLen, byte * sig, word32 * sigLen, const byte * msg, word32 msgLen, WC_RNG * rng)Signs a message with ML-DSA using the FIPS 204 randomized-with-context signing API. Pass ctx=NULL and ctxLen=0 for an empty context.
int	**wc_MlDsaKey_SignCtxHash**(wc_MlDsaKey * key, const byte * ctx, byte ctxLen, byte * sig, word32 * sigLen, const byte * hash, word32 hashLen, int hashAlg, WC_RNG * rng)HashML-DSA signing variant: signs a pre-hashed message. The caller supplies the hash bytes and identifies the hash algorithm. This is the "pre-hash" mode of FIPS 204.

	Name
int	**wc_MlDsaKey_Sign**(wc_MlDsaKey * key, byte * sig, word32 * sigLen, const byte * msg, word32 msgLen, WC_RNG * rng)Legacy ML_DSA signing API without a context parameter. Only available when wolfSSL is built with WOLFSSL_MLDSA_NO_CTX. New code should call wc_MlDsaKey_SignCtx() with ctx=NULL and ctxLen=0 for a FIPS 204 compliant empty-context signature.
int	**wc_MlDsaKey_SignCtxWithSeed**(wc_MlDsaKey * key, const byte * ctx, byte ctxLen, byte * sig, word32 * sigLen, const byte * msg, word32 msgLen, const byte * seed)Deterministic signing variant of wc_MlDsaKey_SignCtx(). The 32-byte seed replaces the randomness an RNG would supply, so the same key/ctx/msg/seed always produces the same signature.
int	**wc_MlDsaKey_SignCtxHashWithSeed**(wc_MlDsaKey * key, const byte * ctx, byte ctxLen, byte * sig, word32 * sigLen, const byte * hash, word32 hashLen, int hashAlg, const byte * seed)Deterministic HashML_DSA signing: like wc_MlDsaKey_SignCtxHash() but uses the supplied 32-byte seed in place of an RNG.
int	**wc_MlDsaKey_SignMuWithSeed**(wc_MlDsaKey * key, byte * sig, word32 * sigLen, const byte * mu, word32 muLen, const byte * seed)Signs a pre_computed mu value (the externally derived SHAKE256 hash of (tr
int	**wc_MlDsaKey_SignWithSeed**(wc_MlDsaKey * key, byte * sig, word32 * sigLen, const byte * msg, word32 msgLen, const byte * seed)Legacy seed_based signing API without a context parameter. Only available when wolfSSL is built with WOLFSSL_MLDSA_NO_CTX. New code should use wc_MlDsaKey_SignCtxWithSeed().
int	**wc_MlDsaKey_VerifyCtx**(wc_MlDsaKey * key, const byte * sig, word32 sigLen, const byte * ctx, byte ctxLen, const byte * msg, word32 msgLen, int * res)Verifies an ML_DSA signature produced by wc_MlDsaKey_SignCtx() or one of its variants. On entry res is set to 0; on success it is set to 1 when the signature is valid and left at 0 otherwise. The function's return value reports whether verification could be carried out at all; a bad signature is NOT a function-level error.

	Name
int	**wc_MlDsaKey_VerifyCtxHash**(wc_MlDsaKey * key, const byte * sig, word32 sigLen, const byte * ctx, byte ctxLen, const byte * hash, word32 hashLen, int hashAlg, int * res)Verifies a HashML_DSA signature where the message digest was supplied directly. See wc_MlDsaKey_VerifyCtx() for the semantics of res.
int	**wc_MlDsaKey_VerifyMu**(wc_MlDsaKey * key, const byte * sig, word32 sigLen, const byte * mu, word32 muLen, int * res)Verifies a signature over a pre_computed 64_byte mu value (see wc_MlDsaKey_SignMuWithSeed()). See wc_MlDsaKey_VerifyCtx() for the semantics of res.
int	**wc_MlDsaKey_SetPrecompA**(wc_MlDsaKey * key, const sword32 * a, word32 aLen, const byte * rho, word32 rhoLen)Attaches a matrix A that was expanded off target, so verification can skip the SHAKE128 rejection sampling that otherwise dominates it. A is a function of the public seed rho alone, so wherever the verification key is fixed at build time - secure boot being the usual case - A can be computed once on a host and stored in flash. Available only when WOLFSSL_MLDSA_VERIFY_PRECOMP_A is defined, and honoured by both the default and the small-memory verifiers.
int	**wc_MlDsaKey_Verify**(wc_MlDsaKey * key, const byte * sig, word32 sigLen, const byte * msg, word32 msgLen, int * res)Legacy ML_DSA verify API without a context parameter. Only available when wolfSSL is built with WOLFSSL_MLDSA_NO_CTX. New code should use wc_MlDsaKey_VerifyCtx() with ctx=NULL and ctxLen=0.
int	**wc_MlDsaKey_Size**(wc_MlDsaKey * key)Returns the size in bytes of the encoded private key for the parameter set selected on this key. Equivalent to wc_MlDsaKey_PrivSize() and provided for API compatibility.
int	**wc_MlDsaKey_PrivSize**(wc_MlDsaKey * key)Returns the size in bytes of the encoded private key for the parameter set selected on this key.
int	**wc_MlDsaKey_PubSize**(wc_MlDsaKey * key)Returns the size in bytes of the encoded public key for the parameter set selected on this key.

	Name
int	**wc_MlDsaKey_SigSize**(wc_MlDsaKey * key)Returns the size in bytes of the signature produced by this key's parameter set.
int	**wc_MlDsaKey_GetPrivLen**(wc_MlDsaKey * key, int * len)Writes the encoded private key size into *len. Equivalent information to wc_MlDsaKey_PrivSize() but uses an out-parameter style.
int	**wc_MlDsaKey_GetPubLen**(wc_MlDsaKey * key, int * len)Writes the encoded public key size into *len. Equivalent information to wc_MlDsaKey_PubSize() but uses an out-parameter style.
int	**wc_MlDsaKey_GetSigLen**(wc_MlDsaKey * key, int * len)Writes the signature size into *len. Equivalent information to wc_MlDsaKey_SigSize() but uses an out-parameter style.
int	**wc_MlDsaKey_CheckKey**(wc_MlDsaKey * key)Self-checks an ML-DSA key by recomputing the public key from the private and comparing against the stored public. Only available when wolfSSL is built with WOLFSSL_MLDSA_CHECK_KEY.
int	**wc_MlDsaKey_ImportPubRaw**(wc_MlDsaKey * key, const byte * in, word32 inLen)Imports a raw ML_DSA public key. The parameter set must already be selected on the key. inLen must match the size returned by wc_MlDsaKey_PubSize() for the selected parameter set.
int	**wc_MlDsaKey_ImportPrivRaw**(wc_MlDsaKey * key, const byte * priv, word32 privSz)Imports a raw ML_DSA private key. The parameter set must already be selected. privSz must match the size returned by wc_MlDsaKey_PrivSize().
int	**wc_MlDsaKey_ImportKey**(wc_MlDsaKey * key, const byte * priv, word32 privSz, const byte * pub, word32 pubSz)Imports a raw ML_DSA key pair (private and public parts together). The parameter set must already be selected.
int	**wc_MlDsaKey_ExportPubRaw**(wc_MlDsaKey * key, byte * out, word32 * outLen)Exports the raw ML-DSA public key. On entry *outLen is the size of out; on success it is updated to the bytes written.
int	**wc_MlDsaKey_ExportPrivRaw**(wc_MlDsaKey * key, byte * out, word32 * outLen)Exports the raw ML-DSA private key. On entry *outLen is the size of out; on success it is updated to the bytes written.

	Name
int	**wc_MlDsaKey_ExportKey**(wc_MlDsaKey * key, byte * priv, word32 * privSz, byte * pub, word32 * pubSz)Exports both raw public and private ML-DSA key components in one call.
int	**wc_MlDsaKey_PrivateKeyDecode**(wc_MlDsaKey * key, const byte * input, word32 inSz, word32 * inOutIdx)Parses an ML_DSA private key from a DER/ASN.1 encoded buffer (PKCS#8 OneAsymmetricKey). The parameter set is inferred from the algorithm identifier in the encoding, so it does NOT need to be set beforehand. On success *inOutIdx is advanced past the consumed bytes.
int	**wc_MlDsaKey_PublicKeyDecode**(wc_MlDsaKey * key, const byte * input, word32 inSz, word32 * inOutIdx)Parses an ML_DSA public key from a DER/ASN.1 encoded buffer (SubjectPublicKeyInfo). The parameter set is inferred from the algorithm identifier. On success *inOutIdx is advanced past the consumed bytes.
int	**wc_MlDsaKey_PublicKeyToDer**(wc_MlDsaKey * key, byte * output, word32 inLen, int withAlg)Encodes an ML_DSA public key to DER. When withAlg is non_zero the output is a full SubjectPublicKeyInfo (with AlgorithmIdentifier); when zero the output is the raw public key bytes.
int	**wc_MlDsaKey_KeyToDer**(wc_MlDsaKey * key, byte * output, word32 inLen)Encodes an ML_DSA key pair (public + private) to DER as a PKCS#8 OneAsymmetricKey structure. Pass NULL as output to query the required buffer size.
int	**wc_MlDsaKey_PrivateKeyToDer**(wc_MlDsaKey * key, byte * output, word32 inLen)Encodes the ML_DSA private key to DER. Per FIPS 204 the private key encoding includes the public component, so this function is currently an alias of wc_MlDsaKey_KeyToDer() kept for API parity with other algorithms.

C.63.2 Functions Documentation

C.63.2.1 function wc_MlDsaKey_Init

```
int wc_MlDsaKey_Init(
    wc_MlDsaKey * key,
    void * heap,
    int devId
)
```

Initializes a wc_MlDsaKey object. Must be called before any other ML-DSA operation. Use

wc_MlDsaKey_Free() to release resources when done.

Parameters:

- **key** Pointer to the wc_MlDsaKey to initialize.
- **heap** Heap hint for dynamic memory allocation. May be NULL.
- **devId** Device identifier for hardware crypto callbacks. Use INVALID_DEVID for software-only.

See:

- wc_MlDsaKey_Free
- wc_MlDsaKey_SetParams
- wc_MlDsaKey_MakeKey

Return:

- 0 on success.
- BAD_FUNC_ARG if key is NULL.
- Other negative value if initializing the key's SHAKE-256 object fails.

ML-DSA (FIPS 204) is a quantum-resistant digital signature algorithm. Three parameter sets are defined and selected via wc_MlDsaKey_SetParams() after init:

- WC_ML_DSA_44 (NIST security level 2),
- WC_ML_DSA_65 (level 3),
- WC_ML_DSA_87 (level 5).

Example

```
wc_MlDsaKey key;
int ret;

ret = wc_MlDsaKey_Init(&key, NULL, INVALID_DEVID);
if (ret != 0) {
    // error initializing key
}
ret = wc_MlDsaKey_SetParams(&key, WC_ML_DSA_65);
// ... use key ...
wc_MlDsaKey_Free(&key);
```

C.63.2.2 function wc_MlDsaKey_New

```
wc_MlDsaKey * wc_MlDsaKey_New(
    void * heap,
    int devId
)
```

Allocates and initializes a new wc_MlDsaKey on the heap. The returned pointer must be released with wc_MlDsaKey_Delete(). Only available when wolfSSL is built without WC_NO_CONSTRUCTORS.

Parameters:

- **heap** Heap hint for dynamic memory allocation. May be NULL.
- **devId** Device identifier for hardware crypto callbacks. Use INVALID_DEVID for software-only.

See:

- wc_MlDsaKey_Delete
- wc_MlDsaKey_Init

Return:

- Pointer to a freshly allocated wc_MlDsaKey on success.

- NULL on allocation failure.

Example

```
wc_MlDsaKey* key = wc_MlDsaKey_New(NULL, INVALID_DEVID);
if (key == NULL) {
    // allocation failed
}
// ... use key ...
wc_MlDsaKey_Delete(key, &key);
```

C.63.2.3 function wc_MlDsaKey_Delete

```
int wc_MlDsaKey_Delete(
    wc_MlDsaKey * key,
    wc_MlDsaKey ** key_p
)
```

Frees and zeros a heap-allocated wc_MlDsaKey previously returned by wc_MlDsaKey_New(). On success the caller's pointer variable is set to NULL via key_p when key_p is not NULL. Only available when wolfSSL is built without WC_NO_CONSTRUCTORS.

Parameters:

- **key** The wc_MlDsaKey to free.
- **key_p** Optional address of the caller's pointer variable; when not NULL, it is set to NULL on success.

See: wc_MlDsaKey_New

Return:

- 0 on success.
- BAD_FUNC_ARG if key is NULL.

C.63.2.4 function wc_MlDsaKey_InitId

```
int wc_MlDsaKey_InitId(
    wc_MlDsaKey * key,
    const unsigned char * id,
    int len,
    void * heap,
    int devId
)
```

Initializes a wc_MlDsaKey with a device-side key identifier. Equivalent to wc_MlDsaKey_Init() but also stashes a binary id that a crypto callback can use to look up the underlying key material on the device. Only available when wolfSSL is built with WOLF_PRIVATE_KEY_ID.

Parameters:

- **key** Pointer to the wc_MlDsaKey to initialize.
- **id** Pointer to the device-side key identifier bytes. May be NULL when len is 0.
- **len** Number of bytes in id; must be in [0, MLDSA_MAX_ID_LEN].
- **heap** Heap hint for dynamic memory allocation. May be NULL.
- **devId** Device identifier for the crypto callback. Should be a registered cb devId, not INVALID_DEVID.

See:

- wc_MlDsaKey_Init

- wc_MlDsaKey_InitLabel
- wc_MlDsaKey_Free

Return:

- 0 on success.
- BAD_FUNC_ARG if key is NULL, or if id is NULL and len is positive.
- BUFFER_E if len is negative or exceeds MLDSA_MAX_ID_LEN.

The id is copied into the key object; the caller may free its buffer immediately after this call returns.

The key is given the highest parameter set compiled in (WC_ML_DSA_87 unless it was disabled at build time), as the parameter set of the key held on the device is not known here. Call wc_MlDsaKey_SetParams() to select a different one.

C.63.2.5 function wc_MlDsaKey_InitLabel

```
int wc_MlDsaKey_InitLabel(
    wc_MlDsaKey * key,
    const char * label,
    void * heap,
    int devId
)
```

Initializes a wc_MlDsaKey with a device-side key label. Equivalent to wc_MlDsaKey_Init() but also stashes a label string that a crypto callback can use to look up the underlying key material on the device. Only available when wolfSSL is built with WOLF_PRIVATE_KEY_ID.

Parameters:

- **key** Pointer to the wc_MlDsaKey to initialize.
- **label** NUL-terminated device-side key label string.
- **heap** Heap hint for dynamic memory allocation. May be NULL.
- **devId** Device identifier for the crypto callback.

See:

- wc_MlDsaKey_Init
- wc_MlDsaKey_InitId
- wc_MlDsaKey_Free

Return:

- 0 on success.
- BAD_FUNC_ARG if key or label is NULL.
- BUFFER_E if label is empty or longer than MLDSA_MAX_LABEL_LEN.

The label length is taken via XSTRLEN, so embedded NUL bytes terminate the label.

The parameter set is chosen as in wc_MlDsaKey_InitId().

C.63.2.6 function wc_MlDsaKey_SetParams

```
int wc_MlDsaKey_SetParams(
    wc_MlDsaKey * key,
    byte level
)
```

Selects the ML-DSA parameter set for this key. Must be called after wc_MlDsaKey_Init() and before key generation, signing or verifying.

Parameters:

- **key** Pointer to an initialized wc_MlDsaKey.
- **level** Parameter set: WC_ML_DSA_44, WC_ML_DSA_65 or WC_ML_DSA_87.

See:

- wc_MlDsaKey_GetParams
- wc_MlDsaKey_Init

Return:

- 0 on success.
- BAD_FUNC_ARG if key is NULL or level is not a recognized parameter set.
- NOT_COMPILED_IN if level names a parameter set that was disabled at build time.

C.63.2.7 function wc_MlDsaKey_GetParams

```
int wc_MlDsaKey_GetParams(
    wc_MlDsaKey * key,
    byte * level
)
```

Retrieves the ML-DSA parameter set currently selected on this key.

Parameters:

- **key** Pointer to an initialized wc_MlDsaKey.
- **level** Receives WC_ML_DSA_44, WC_ML_DSA_65 or WC_ML_DSA_87.

See: wc_MlDsaKey_SetParams

Return:

- 0 on success.
- BAD_FUNC_ARG if key or level is NULL.

C.63.2.8 function wc_MlDsaKey_Free

```
void wc_MlDsaKey_Free(
    wc_MlDsaKey * key
)
```

Releases resources held by a wc_MlDsaKey. After this call the object must be re-initialized with wc_MlDsaKey_Init() before it can be used again. Safe to call with a NULL pointer.

Parameters:

- **key** Pointer to the wc_MlDsaKey to free.

See: wc_MlDsaKey_Init

C.63.2.9 function wc_MlDsaKey_MakeKey

```
int wc_MlDsaKey_MakeKey(
    wc_MlDsaKey * key,
    WC_RNG * rng
)
```

Generates a new ML-DSA key pair using the provided RNG. The parameter set must already be set with wc_MlDsaKey_SetParams(). Both the public and private key components are populated on success.

Parameters:

- **key** Pointer to a wc_MlDsaKey with parameters set.

- **rng** Pointer to an initialized WC_RNG.

See:

- wc_MlDsaKey_MakeKeyFromSeed
- wc_MlDsaKey_SetParams

Return:

- 0 on success.
- BAD_FUNC_ARG if key or rng is NULL.
- MEMORY_E on allocation failure.

Example

```
wc_MlDsaKey key;
WC_RNG rng;

wc_MlDsaKey_Init(&key, NULL, INVALID_DEVID);
wc_MlDsaKey_SetParams(&key, WC_ML_DSA_65);
wc_InitRng(&rng);

if (wc_MlDsaKey_MakeKey(&key, &rng) != 0) {
    // error generating key pair
}
```

C.63.2.10 function wc_MlDsaKey_MakeKeyFromSeed

```
int wc_MlDsaKey_MakeKeyFromSeed(
    wc_MlDsaKey * key,
    const byte * seed
)
```

Deterministically generates an ML-DSA key pair from a 32-byte seed. Useful for known-answer tests and for applications that derive the seed from another secret. The seed buffer must contain exactly 32 bytes.

Parameters:

- **key** Pointer to a wc_MlDsaKey with parameters set.
- **seed** Pointer to a 32-byte seed buffer.

See: wc_MlDsaKey_MakeKey

Return:

- 0 on success.
- BAD_FUNC_ARG if key or seed is NULL.

C.63.2.11 function wc_MlDsaKey_MakePublicKey

```
int wc_MlDsaKey_MakePublicKey(
    wc_MlDsaKey * key
)
```

Derives public key for a wc_MlDsaKey with private key set. If the public key is already set, it is only checked against the private key's tr (H(pk)); use wc_MlDsaKey_CheckKey() for a full key pair check. The private key is still required: a public-only key returns BAD_FUNC_ARG. Available when WC_MLDSA_HAVE_MAKE_PUBLIC_KEY is defined: that is, when WOLFSSL_MLDSA_ASSIGN_KEY, WOLFSSL_MLDSA_NO_MAKE_KEY and WOLFSSL_MLDSA_VERIFY_ONLY are not defined.

Parameters:

- **key** Pointer to wc_MlDsaKey.

See:

- wc_MlDsaKey_ImportPrivRaw
- wc_MlDsaKey_MakeKey
- wc_MlDsaKey_CheckKey

Return:

- 0 on success or already set.
- BAD_FUNC_ARG if invalid args or the private key is not set.
- MEMORY_E on allocation failure.
- PUBLIC_KEY_E if the public key does not match the private key's tr or, when derived, its t0.
- NO_VALID_DEVID with WOLF_CRYPTO_CB_ONLY_MLDSA.
- Other negative on error.

Derivation is always done in software from the local private key bytes, including for a key initialized with a devId: a key whose private key was imported with wc_MlDsaKey_ImportPrivRaw() (or generated in software) derives normally. A key that only references a private key held on a device (wc_MlDsaKey_InitId() / wc_MlDsaKey_InitLabel()) has no local private bytes, so it returns BAD_FUNC_ARG. On PUBLIC_KEY_E an already set public key is left in place; set the matching public key, or re-initialize the key, before deriving.

C.63.2.12 function wc_MlDsaKey_SignCtx

```
int wc_MlDsaKey_SignCtx(
    wc_MlDsaKey * key,
    const byte * ctx,
    byte ctxLen,
    byte * sig,
    word32 * sigLen,
    const byte * msg,
    word32 msgLen,
    WC_RNG * rng
)
```

Signs a message with ML-DSA using the FIPS 204 randomized-with-context signing API. Pass ctx=NULL and ctxLen=0 for an empty context.

Parameters:

- **key** Pointer to a wc_MlDsaKey with the private key.
- **ctx** Optional context string (may be NULL when ctxLen=0).
- **ctxLen** Length of ctx in bytes; must be 0 when ctx is NULL, and no greater than 255.
- **sig** Buffer that receives the signature.
- **sigLen** In: size of sig. Out: bytes written.
- **msg** Message to sign.
- **msgLen** Length of msg in bytes.
- **rng** Pointer to an initialized WC_RNG.

See:

- wc_MlDsaKey_VerifyCtx
- wc_MlDsaKey_SignCtxWithSeed
- wc_MlDsaKey_SignCtxHash

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL, ctxLen is invalid or the key has no private key set.
- BUFFER_E if the sig buffer is too small.

On entry *sigLen is the size of the sig buffer; on success it is updated to the number of bytes written. Use wc_MlDsaKey_SigSize() or wc_MlDsaKey_GetSigLen() to determine the required buffer size.

C.63.2.13 function wc_MlDsaKey_SignCtxHash

```
int wc_MlDsaKey_SignCtxHash(
    wc_MlDsaKey * key,
    const byte * ctx,
    byte ctxLen,
    byte * sig,
    word32 * sigLen,
    const byte * hash,
    word32 hashLen,
    int hashAlg,
    WC_RNG * rng
)
```

HashML-DSA signing variant: signs a pre-hashed message. The caller supplies the hash bytes and identifies the hash algorithm. This is the “pre-hash” mode of FIPS 204.

Parameters:

- **key** Pointer to a wc_MlDsaKey with the private key.
- **ctx** Optional context string (NULL when ctxLen=0).
- **ctxLen** Length of ctx in bytes; no greater than 255.
- **sig** Buffer that receives the signature.
- **sigLen** In: size of sig. Out: bytes written.
- **hash** The message digest to sign.
- **hashLen** Length of hash in bytes.
- **hashAlg** Hash algorithm identifier (e.g. WC_HASH_TYPE_SHA256).
- **rng** Pointer to an initialized WC_RNG.

See:

- wc_MlDsaKey_SignCtx
- wc_MlDsaKey_VerifyCtxHash

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL, ctxLen is invalid, hashAlg is not supported or is weaker than the parameter set (FIPS 204 sec 5.4), or the key has no private key set.
- BUFFER_E if the sig buffer is too small.

Note: WOLFSSL_MLDSA_ALLOW_WEAK_PREHASH accepts a supported hash weaker than the parameter set instead of returning BAD_FUNC_ARG. An unsupported hash is still refused. Not FIPS 204 section 5.4 compliant.

C.63.2.14 function wc_MlDsaKey_Sign

```
int wc_MlDsaKey_Sign(
    wc_MlDsaKey * key,
    byte * sig,
    word32 * sigLen,
```

```
    const byte * msg,
    word32 msgLen,
    WC_RNG * rng
)
```

Legacy ML-DSA signing API without a context parameter. Only available when wolfSSL is built with WOLFSSL_MLDSA_NO_CTX. New code should call wc_MlDsaKey_SignCtx() with ctx=NULL and ctxLen=0 for a FIPS 204 compliant empty-context signature.

Parameters:

- **key** Pointer to a wc_MlDsaKey with the private key.
- **sig** Buffer that receives the signature.
- **sigLen** In: size of sig. Out: bytes written.
- **msg** Message to sign.
- **msgLen** Length of msg in bytes.
- **rng** Pointer to an initialized WC_RNG.

See:

- wc_MlDsaKey_SignCtx
- wc_MlDsaKey_Verify

Return: See wc_MlDsaKey_SignCtx().

C.63.2.15 function wc_MlDsaKey_SignCtxWithSeed

```
int wc_MlDsaKey_SignCtxWithSeed(
    wc_MlDsaKey * key,
    const byte * ctx,
    byte ctxLen,
    byte * sig,
    word32 * sigLen,
    const byte * msg,
    word32 msgLen,
    const byte * seed
)
```

Deterministic signing variant of wc_MlDsaKey_SignCtx(). The 32-byte seed replaces the randomness an RNG would supply, so the same key/ctx/msg/seed always produces the same signature.

Parameters:

- **key** Pointer to a wc_MlDsaKey with the private key.
- **ctx** Optional context string (NULL when ctxLen=0).
- **ctxLen** Length of ctx; no greater than 255.
- **sig** Buffer that receives the signature.
- **sigLen** In: size of sig. Out: bytes written.
- **msg** Message to sign.
- **msgLen** Length of msg in bytes.
- **seed** 32-byte seed bytes.

See:

- wc_MlDsaKey_SignCtx
- wc_MlDsaKey_SignCtxHashWithSeed

Return: See wc_MlDsaKey_SignCtx().

C.63.2.16 function wc_MlDsaKey_SignCtxHashWithSeed

```
int wc_MlDsaKey_SignCtxHashWithSeed(
    wc_MlDsaKey * key,
    const byte * ctx,
    byte ctxLen,
    byte * sig,
    word32 * sigLen,
    const byte * hash,
    word32 hashLen,
    int hashAlg,
    const byte * seed
)
```

Deterministic HashML-DSA signing: like wc_MlDsaKey_SignCtxHash() but uses the supplied 32-byte seed in place of an RNG.

Parameters:

- **key** Pointer to a wc_MlDsaKey with the private key.
- **ctx** Optional context string (NULL when ctxLen=0).
- **ctxLen** Length of ctx; no greater than 255.
- **sig** Buffer that receives the signature.
- **sigLen** In: size of sig. Out: bytes written.
- **hash** The message digest to sign.
- **hashLen** Length of hash in bytes.
- **hashAlg** Hash algorithm identifier.
- **seed** 32-byte seed bytes.

See: wc_MlDsaKey_SignCtxHash

Return: See wc_MlDsaKey_SignCtxHash().

C.63.2.17 function wc_MlDsaKey_SignMuWithSeed

```
int wc_MlDsaKey_SignMuWithSeed(
    wc_MlDsaKey * key,
    byte * sig,
    word32 * sigLen,
    const byte * mu,
    word32 muLen,
    const byte * seed
)
```

Signs a pre-computed mu value (the externally derived SHAKE256 hash of (tr || ctx || msg) per FIPS 204) using a deterministic 32-byte seed. Used by protocols that need to split the message-hashing step from the signing step.

Parameters:

- **key** Pointer to a wc_MlDsaKey with the private key.
- **sig** Buffer that receives the signature.
- **sigLen** In: size of sig. Out: bytes written.
- **mu** The 64-byte mu value (SHAKE256 output).
- **muLen** Length of mu; must be 64.
- **seed** 32-byte seed bytes.

See: wc_MlDsaKey_VerifyMu

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL, muLen is not 64 or the key has no private key set.
- BUFFER_E if the sig buffer is too small.

C.63.2.18 function wc_MlDsaKey_SignWithSeed

```
int wc_MlDsaKey_SignWithSeed(
    wc_MlDsaKey * key,
    byte * sig,
    word32 * sigLen,
    const byte * msg,
    word32 msgLen,
    const byte * seed
)
```

Legacy seed-based signing API without a context parameter. Only available when wolfSSL is built with WOLFSSL_MLDSA_NO_CTX. New code should use wc_MlDsaKey_SignCtxWithSeed().

Parameters:

- **key** Pointer to a wc_MlDsaKey with the private key.
- **sig** Buffer that receives the signature.
- **sigLen** In: size of sig. Out: bytes written.
- **msg** Message to sign.
- **msgLen** Length of msg in bytes.
- **seed** 32-byte seed bytes.

See: wc_MlDsaKey_SignCtxWithSeed

Return: See wc_MlDsaKey_SignCtxWithSeed().

C.63.2.19 function wc_MlDsaKey_VerifyCtx

```
int wc_MlDsaKey_VerifyCtx(
    wc_MlDsaKey * key,
    const byte * sig,
    word32 sigLen,
    const byte * ctx,
    byte ctxLen,
    const byte * msg,
    word32 msgLen,
    int * res
)
```

Verifies an ML-DSA signature produced by wc_MlDsaKey_SignCtx() or one of its variants. On entry res is set to 0; on success it is set to 1 when the signature is valid and left at 0 otherwise. The function's return value reports whether verification could be carried out at all; a bad signature is NOT a function-level error.

Parameters:

- **key** Pointer to a wc_MlDsaKey with the public key.
- **sig** Signature bytes to verify.
- **sigLen** Length of sig in bytes.
- **ctx** Optional context string (NULL when ctxLen=0).
- **ctxLen** Length of ctx; no greater than 255.
- **msg** Message that was signed.

- **msgLen** Length of msg in bytes.
- **res** Set to 1 on a valid signature, 0 otherwise.

See:

- wc_MlDsaKey_SignCtx
- wc_MlDsaKey_VerifyCtxHash
- wc_MlDsaKey_VerifyMu

Return:

- 0 if verification completed (check res for the result).
- BAD_FUNC_ARG if any required pointer is NULL or ctxLen is invalid.

C.63.2.20 function wc_MlDsaKey_VerifyCtxHash

```
int wc_MlDsaKey_VerifyCtxHash(
    wc_MlDsaKey * key,
    const byte * sig,
    word32 sigLen,
    const byte * ctx,
    byte ctxLen,
    const byte * hash,
    word32 hashLen,
    int hashAlg,
    int * res
)
```

Verifies a HashML-DSA signature where the message digest was supplied directly. See wc_MlDsaKey_VerifyCtx() for the semantics of res.

Parameters:

- **key** Pointer to a wc_MlDsaKey with the public key.
- **sig** Signature bytes to verify.
- **sigLen** Length of sig in bytes.
- **ctx** Optional context string (NULL when ctxLen=0).
- **ctxLen** Length of ctx; no greater than 255.
- **hash** The message digest that was signed.
- **hashLen** Length of hash in bytes.
- **hashAlg** Hash algorithm identifier.
- **res** Set to 1 on a valid signature, 0 otherwise.

See:

- wc_MlDsaKey_SignCtxHash
- wc_MlDsaKey_VerifyCtx

Return:

- 0 if verification completed (check res for the result).
- BAD_FUNC_ARG if any required pointer is NULL, ctxLen is invalid, or hashAlg is unsupported or weaker than the parameter set (FIPS 204 sec 5.4).

Note: WOLFSSL_MLDSA_ALLOW_WEAK_PREHASH verifies such a signature rather than refusing it. An unsupported hash is still refused.

C.63.2.21 function wc_MlDsaKey_VerifyMu

```
int wc_MlDsaKey_VerifyMu(
    wc_MlDsaKey * key,
    const byte * sig,
    word32 sigLen,
    const byte * mu,
    word32 muLen,
    int * res
)
```

Verifies a signature over a pre-computed 64-byte mu value (see wc_MlDsaKey_SignMuWithSeed()). See wc_MlDsaKey_VerifyCtx() for the semantics of res.

Parameters:

- **key** Pointer to a wc_MlDsaKey with the public key.
- **sig** Signature bytes to verify.
- **sigLen** Length of sig in bytes.
- **mu** The 64-byte mu value.
- **muLen** Length of mu; must be 64.
- **res** Set to 1 on a valid signature, 0 otherwise.

See: wc_MlDsaKey_SignMuWithSeed

Return:

- 0 if verification completed (check res for the result).
- BAD_FUNC_ARG if any required pointer is NULL or muLen is not 64.

C.63.2.22 function wc_MlDsaKey_SetPrecompA

```
int wc_MlDsaKey_SetPrecompA(
    wc_MlDsaKey * key,
    const sword32 * a,
    word32 aLen,
    const byte * rho,
    word32 rhoLen
)
```

Attaches a matrix A that was expanded off target, so verification can skip the SHAKE128 rejection sampling that otherwise dominates it. A is a function of the public seed rho alone, so wherever the verification key is fixed at build time - secure boot being the usual case - A can be computed once on a host and stored in flash. Available only when WOLFSSL_MLDSA_VERIFY_PRECOMP_A is defined, and honoured by both the default and the small-memory verifiers.

Parameters:

- **key** Pointer to a wc_MlDsaKey holding the public key.
- **a** Expanded matrix A, k * l * MLDSA_N elements, caller owned.
- **aLen** Number of sword32 elements in a.
- **rho** Public seed the matrix was expanded from.
- **rhoLen** Length of rho; must be MLDSA_PUB_SEED_SZ.

See:

- wc_MlDsaKey_VerifyMu
- wc_MlDsaKey_ImportPubRaw

Return:

- 0 on success.

- BAD_FUNC_ARG if a pointer is NULL, rhoLen is not MLDSA_PUB_SEED_SZ, aLen is not k * l * MLDSA_N, or no public key has been imported yet.
- PUBLIC_KEY_E if rho does not match the imported public key.

Note: A is derived from the public key and must be integrity-protected exactly as the public key is. An attacker able to substitute it can influence verification. In a secure-boot design the key already lives in protected flash, so store the two together.

The matrix is borrowed, never copied and never freed: it must stay valid and unchanged for as long as the key uses it. It holds k * l * MLDSA_N sword32 elements (not bytes) in row-major (r, s) order and in the NTT domain, exactly as ExpandA produces them.

Import the public key first: the matrix is bound to it by comparing rho. The binding is re-checked on every verify, so replacing the key or the parameters afterwards simply discards the matrix and falls back to expanding A rather than using a stale one.

Example

```
wc_MlDsaKey key;
int res = 0;

wc_MlDsaKey_Init(&key, NULL, INVALID_DEVID);
wc_MlDsaKey_SetParams(&key, WC_ML_DSA_87);
wc_MlDsaKey_ImportPubRaw(&key, pub, pubLen);
if (wc_MlDsaKey_SetPrecompA(&key, matrixA, matrixALen, pub,
        MLDSA_PUB_SEED_SZ) != 0) {
    // handle error
}
wc_MlDsaKey_VerifyMu(&key, sig, sigLen, mu, muLen, &res);
```

C.63.2.23 function wc_MlDsaKey_Verify

```
int wc_MlDsaKey_Verify(
    wc_MlDsaKey * key,
    const byte * sig,
    word32 sigLen,
    const byte * msg,
    word32 msgLen,
    int * res
)
```

Legacy ML-DSA verify API without a context parameter. Only available when wolfSSL is built with WOLFSSL_MLDSA_NO_CTX. New code should use wc_MlDsaKey_VerifyCtx() with ctx=NULL and ctxLen=0.

Parameters:

- **key** Pointer to a wc_MlDsaKey with the public key.
- **sig** Signature bytes to verify.
- **sigLen** Length of sig in bytes.
- **msg** Message that was signed.
- **msgLen** Length of msg in bytes.
- **res** Set to 1 on a valid signature, 0 otherwise.

See:

- wc_MlDsaKey_VerifyCtx
- wc_MlDsaKey_Sign

Return: See wc_MlDsaKey_VerifyCtx().

C.63.2.24 function wc_MlDsaKey_Size

```
int wc_MlDsaKey_Size(
    wc_MlDsaKey * key
)
```

Returns the size in bytes of the encoded private key for the parameter set selected on this key. Equivalent to wc_MlDsaKey_PrivSize() and provided for API compatibility.

Parameters:

- **key** Pointer to a wc_MlDsaKey with parameters set.

See:

- wc_MlDsaKey_PrivSize
- wc_MlDsaKey_PubSize
- wc_MlDsaKey_SigSize

Return:

- Encoded private key size in bytes on success (positive value).
- BAD_FUNC_ARG if key is NULL or no parameter set is selected.

C.63.2.25 function wc_MlDsaKey_PrivSize

```
int wc_MlDsaKey_PrivSize(
    wc_MlDsaKey * key
)
```

Returns the size in bytes of the encoded private key for the parameter set selected on this key.

Parameters:

- **key** Pointer to a wc_MlDsaKey with parameters set.

See:

- wc_MlDsaKey_PubSize
- wc_MlDsaKey_GetPrivLen

Return:

- Encoded private key size on success (positive value).
- BAD_FUNC_ARG if key is NULL or no parameter set is selected.

C.63.2.26 function wc_MlDsaKey_PubSize

```
int wc_MlDsaKey_PubSize(
    wc_MlDsaKey * key
)
```

Returns the size in bytes of the encoded public key for the parameter set selected on this key.

Parameters:

- **key** Pointer to a wc_MlDsaKey with parameters set.

See:

- wc_MlDsaKey_PrivSize
- wc_MlDsaKey_GetPubLen

Return:

- Encoded public key size on success (positive value).
- BAD_FUNC_ARG if key is NULL or no parameter set is selected.

C.63.2.27 function wc_MlDsaKey_SigSize

```
int wc_MlDsaKey_SigSize(
    wc_MlDsaKey * key
)
```

Returns the size in bytes of the signature produced by this key's parameter set.

Parameters:

- **key** Pointer to a wc_MlDsaKey with parameters set.

See:

- wc_MlDsaKey_GetSigLen
- wc_MlDsaKey_SignCtx

Return:

- Signature size on success (positive value).
- BAD_FUNC_ARG if key is NULL or no parameter set is selected.

C.63.2.28 function wc_MlDsaKey_GetPrivLen

```
int wc_MlDsaKey_GetPrivLen(
    wc_MlDsaKey * key,
    int * len
)
```

Writes the encoded private key size into *len. Equivalent information to wc_MlDsaKey_PrivSize() but uses an out-parameter style.

Parameters:

- **key** Pointer to a wc_MlDsaKey with parameters set.
- **len** Receives the private key size in bytes.

See: wc_MlDsaKey_PrivSize

Return:

- 0 on success.
- BAD_FUNC_ARG if key or len is NULL, or no parameter set is selected.

C.63.2.29 function wc_MlDsaKey_GetPubLen

```
int wc_MlDsaKey_GetPubLen(
    wc_MlDsaKey * key,
    int * len
)
```

Writes the encoded public key size into *len. Equivalent information to wc_MlDsaKey_PubSize() but uses an out-parameter style.

Parameters:

- **key** Pointer to a wc_MlDsaKey with parameters set.
- **len** Receives the public key size in bytes.

See: wc_MlDsaKey_PubSize

Return:

- 0 on success.
- BAD_FUNC_ARG if key or len is NULL, or no parameter set is selected.

C.63.2.30 function wc_MlDsaKey_GetSigLen

```
int wc_MlDsaKey_GetSigLen(
    wc_MlDsaKey * key,
    int * len
)
```

Writes the signature size into *len. Equivalent information to wc_MlDsaKey_SigSize() but uses an out-parameter style.

Parameters:

- **key** Pointer to a wc_MlDsaKey with parameters set.
- **len** Receives the signature size in bytes.

See: wc_MlDsaKey_SigSize

Return:

- 0 on success.
- BAD_FUNC_ARG if key or len is NULL, or no parameter set is selected.

C.63.2.31 function wc_MlDsaKey_CheckKey

```
int wc_MlDsaKey_CheckKey(
    wc_MlDsaKey * key
)
```

Self-checks an ML-DSA key by recomputing the public key from the private and comparing against the stored public. Only available when wolfSSL is built with WOLFSSL_MLDSA_CHECK_KEY.

Parameters:

- **key** Pointer to a wc_MlDsaKey with both public and private parts populated.

Return:

- 0 if the key is consistent.
- BAD_FUNC_ARG if key is NULL.
- PUBLIC_KEY_E if the recomputed public does not match.

C.63.2.32 function wc_MlDsaKey_ImportPubRaw

```
int wc_MlDsaKey_ImportPubRaw(
    wc_MlDsaKey * key,
    const byte * in,
    word32 inLen
)
```

Imports a raw ML-DSA public key. The parameter set must already be selected on the key. inLen must match the size returned by wc_MlDsaKey_PubSize() for the selected parameter set.

Parameters:

- **key** Pointer to a wc_MlDsaKey with parameters set.

- **in** Raw public key bytes.
- **inLen** Length of in in bytes.

See:

- wc_MlDsaKey_ExportPubRaw
- wc_MlDsaKey_ImportPrivRaw

Return:

- 0 on success.
- BAD_FUNC_ARG if key or in is NULL.
- BUFFER_E if inLen does not match the expected public key size.

C.63.2.33 function wc_MlDsaKey_ImportPrivRaw

```
int wc_MlDsaKey_ImportPrivRaw(
    wc_MlDsaKey * key,
    const byte * priv,
    word32 privSz
)
```

Imports a raw ML-DSA private key. The parameter set must already be selected. privSz must match the size returned by wc_MlDsaKey_PrivSize().

Parameters:

- **key** Pointer to a wc_MlDsaKey with parameters set.
- **priv** Raw private key bytes.
- **privSz** Length of priv in bytes.

See:

- wc_MlDsaKey_ExportPrivRaw
- wc_MlDsaKey_ImportKey

Return:

- 0 on success.
- BAD_FUNC_ARG if key or priv is NULL.
- BUFFER_E if privSz does not match the expected private key size.

C.63.2.34 function wc_MlDsaKey_ImportKey

```
int wc_MlDsaKey_ImportKey(
    wc_MlDsaKey * key,
    const byte * priv,
    word32 privSz,
    const byte * pub,
    word32 pubSz
)
```

Imports a raw ML-DSA key pair (private and public parts together). The parameter set must already be selected.

Parameters:

- **key** Pointer to a wc_MlDsaKey with parameters set.
- **priv** Raw private key bytes.
- **privSz** Length of priv.
- **pub** Raw public key bytes.

- **pubSz** Length of pub.

See: wc_MlDsaKey_ExportKey

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL.
- BUFFER_E if privSz or pubSz does not match the expected sizes.

C.63.2.35 function wc_MlDsaKey_ExportPubRaw

```
int wc_MlDsaKey_ExportPubRaw(
    wc_MlDsaKey * key,
    byte * out,
    word32 * outLen
)
```

Exports the raw ML-DSA public key. On entry *outLen is the size of out; on success it is updated to the bytes written.

Parameters:

- **key** Pointer to a wc_MlDsaKey with a public key.
- **out** Buffer that receives the public key.
- **outLen** In: size of out. Out: bytes written.

See: wc_MlDsaKey_ImportPubRaw

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL.
- BUFFER_E if *outLen is smaller than the public key size.

C.63.2.36 function wc_MlDsaKey_ExportPrivRaw

```
int wc_MlDsaKey_ExportPrivRaw(
    wc_MlDsaKey * key,
    byte * out,
    word32 * outLen
)
```

Exports the raw ML-DSA private key. On entry *outLen is the size of out; on success it is updated to the bytes written.

Parameters:

- **key** Pointer to a wc_MlDsaKey with a private key.
- **out** Buffer that receives the private key.
- **outLen** In: size of out. Out: bytes written.

See: wc_MlDsaKey_ImportPrivRaw

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL.
- BUFFER_E if *outLen is smaller than the private key size.

C.63.2.37 function wc_MlDsaKey_ExportKey

```
int wc_MlDsaKey_ExportKey(
    wc_MlDsaKey * key,
    byte * priv,
    word32 * privSz,
    byte * pub,
    word32 * pubSz
)
```

Exports both raw public and private ML-DSA key components in one call.

Parameters:

- **key** Pointer to a wc_MlDsaKey with both key parts.
- **priv** Buffer that receives the private key.
- **privSz** In: size of priv. Out: bytes written.
- **pub** Buffer that receives the public key.
- **pubSz** In: size of pub. Out: bytes written.

See: wc_MlDsaKey_ImportKey

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL.
- BUFFER_E if either buffer is too small.

C.63.2.38 function wc_MlDsaKey_PrivateKeyDecode

```
int wc_MlDsaKey_PrivateKeyDecode(
    wc_MlDsaKey * key,
    const byte * input,
    word32 inSz,
    word32 * inOutIdx
)
```

Parses an ML-DSA private key from a DER/ASN.1 encoded buffer (PKCS#8 OneAsymmetricKey). The parameter set is inferred from the algorithm identifier in the encoding, so it does NOT need to be set beforehand. On success *inOutIdx is advanced past the consumed bytes.

Parameters:

- **key** Pointer to an initialized wc_MlDsaKey.
- **input** DER-encoded private key bytes.
- **inSz** Length of input in bytes.
- **inOutIdx** In: offset into input where decoding starts. Out: offset past the consumed bytes.

See:

- wc_MlDsaKey_PrivateKeyToDer
- wc_MlDsaKey_PublicKeyDecode

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL.
- ASN_PARSE_E on malformed encoding.

Only available when WOLFSSL_MLDSA_NO_ASN1 is not defined.

C.63.2.39 function wc_MlDsaKey_PublicKeyDecode

```
int wc_MlDsaKey_PublicKeyDecode(
    wc_MlDsaKey * key,
    const byte * input,
    word32 inSz,
    word32 * inOutIdx
)
```

Parses an ML-DSA public key from a DER/ASN.1 encoded buffer (SubjectPublicKeyInfo). The parameter set is inferred from the algorithm identifier. On success *inOutIdx is advanced past the consumed bytes.

Parameters:

- **key** Pointer to an initialized wc_MlDsaKey.
- **input** DER-encoded SPKI bytes.
- **inSz** Length of input in bytes.
- **inOutIdx** In: offset into input where decoding starts. Out: offset past the consumed bytes.

See: wc_MlDsaKey_PublicKeyToDer

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL.
- ASN_PARSE_E on malformed encoding.

C.63.2.40 function wc_MlDsaKey_PublicKeyToDer

```
int wc_MlDsaKey_PublicKeyToDer(
    wc_MlDsaKey * key,
    byte * output,
    word32 inLen,
    int withAlg
)
```

Encodes an ML-DSA public key to DER. When withAlg is non-zero the output is a full SubjectPublicKeyInfo (with AlgorithmIdentifier); when zero the output is the raw public key bytes.

Parameters:

- **key** Pointer to a wc_MlDsaKey with a public key.
- **output** Buffer that receives the DER encoding, or NULL to query size.
- **inLen** Size of output (ignored when output is NULL).
- **withAlg** Non-zero to emit SubjectPublicKeyInfo, zero for the raw public key only.

See:

- wc_MlDsaKey_PublicKeyDecode
- wc_MlDsaKey_KeyToDer

Return:

- Size of the encoded DER in bytes on success.
- BAD_FUNC_ARG if key is NULL or no parameter set is selected.
- BUFFER_E if output is non-NULL and inLen is smaller than the required size.

Pass NULL as output to query the required buffer size.

C.63.2.41 function wc_MlDsaKey_KeyToDer

```
int wc_MlDsaKey_KeyToDer(
    wc_MlDsaKey * key,
    byte * output,
    word32 inLen
)
```

Encodes an ML-DSA key pair (public + private) to DER as a PKCS#8 OneAsymmetricKey structure. Pass NULL as output to query the required buffer size.

Parameters:

- **key** Pointer to a wc_MlDsaKey with the private key.
- **output** Buffer that receives the DER encoding, or NULL to query size.
- **inLen** Size of output (ignored when output is NULL).

See:

- wc_MlDsaKey_PrivateKeyDecode
- wc_MlDsaKey_PrivateKeyToDer
- wc_MlDsaKey_PublicKeyToDer

Return:

- Size of the encoded DER in bytes on success.
- BAD_FUNC_ARG if key is NULL or no parameter set is selected.
- MISSING_KEY if the private key has not been set.
- BUFFER_E if output is non-NULL and inLen is too small.

C.63.2.42 function wc_MlDsaKey_PrivateKeyToDer

```
int wc_MlDsaKey_PrivateKeyToDer(
    wc_MlDsaKey * key,
    byte * output,
    word32 inLen
)
```

Encodes the ML-DSA private key to DER. Per FIPS 204 the private key encoding includes the public component, so this function is currently an alias of wc_MlDsaKey_KeyToDer() kept for API parity with other algorithms.

Parameters:

- **key** Pointer to a wc_MlDsaKey with the private key.
- **output** Buffer that receives the DER encoding, or NULL to query size.
- **inLen** Size of output (ignored when output is NULL).

See:

- wc_MlDsaKey_KeyToDer
- wc_MlDsaKey_PrivateKeyDecode

Return:

- Size of the encoded DER in bytes on success.
- Inherited error codes from wc_MlDsaKey_KeyToDer().

C.63.3 Source code

```
int wc_MlDsaKey_Init(wc_MlDsaKey* key, void* heap, int devId);
```

```
wc_MlDsaKey* wc_MlDsaKey_New(void* heap, int devId);

int wc_MlDsaKey_PublicKeyToDer(wc_MlDsaKey* key, byte* output,
    word32 inLen, int withAlg);

int wc_MlDsaKey_KeyToDer(wc_MlDsaKey* key, byte* output, word32 inLen);

int wc_MlDsaKey_PrivateKeyToDer(wc_MlDsaKey* key, byte* output,
    word32 inLen);
```

C.64 wc_mlkem.h

C.64.1 Functions

	Name
MlKemKey *	**wc_MlKemKey_New**(int type, void * heap, int devId)Allocates and initializes a new MlKemKey on the heap. The returned pointer must be released with wc_MlKemKey_Delete().
int	**wc_MlKemKey_Delete**(MlKemKey * key, MlKemKey ** key_p)Frees and zeros a heap_allocated MlKemKey previously returned by wc_MlKemKey_New(). On success the caller's pointer variable is set to NULL via key_p when key_p is not NULL.
int	**wc_MlKemKey_Init**(MlKemKey * key, int type, void * heap, int devId)Initializes an MlKemKey object in place. The type parameter selects the ML-KEM variant and must be one of WC_ML_KEM_512, WC_ML_KEM_768 or WC_ML_KEM_1024.
int	**wc_MlKemKey_Free**(MlKemKey * key)Releases resources held by an MlKemKey. After this call the object must be re_initialized with wc_MlKemKey_Init() before it can be used again. Safe to call with a NULL pointer.
int	**wc_MlKemKey_Init_Id**(MlKemKey * key, int type, const unsigned char * id, int len, void * heap, int devId)Initializes an MlKemKey with a device_side key identifier. Equivalent to wc_MlKemKey_Init() but also stashes a binary id that a crypto callback can use to look up the underlying key material on the device. Only available when wolfSSL is built with WOLF_PRIVATE_KEY_ID.
int	**wc_MlKemKey_Init_Label**(MlKemKey * key, int type, const char * label, void * heap, int devId)Initializes an MlKemKey with a device_side key label. Equivalent to wc_MlKemKey_Init() but also stashes a label string that a crypto callback can use to look up the underlying key material on the device. Only available when wolfSSL is built with WOLF_PRIVATE_KEY_ID.
int	**wc_MlKemKey_MakeKey**(MlKemKey * key, WC_RNG * rng)Generates a new ML-KEM key pair using the provided RNG. Both the public and private components are populated on success.

	Name
int	**wc_MlKemKey_MakeKeyWithRandom**(MlKemKey * key, const unsigned char * rand, int len)Deterministic key generation: produces an ML-KEM key pair from the supplied 64 bytes of randomness instead of an RNG. Useful for known-answer tests and for applications that derive key randomness from another secret.
int	**wc_MlKemKey_CipherTextSize**(MlKemKey * key, word32 * len)Returns the ciphertext size in bytes for the variant selected on this key.
int	**wc_MlKemKey_SharedSecretSize**(MlKemKey * key, word32 * len)Returns the shared_secret size in bytes for ML_KEM. The value is the same (32 bytes) across all parameter sets but is queried programmatically for symmetry with wc_MlKemKey_CipherTextSize().
int	**wc_MlKemKey_Encapsulate**(MlKemKey * key, unsigned char * ct, unsigned char * ss, WC_RNG * rng)Encapsulates a fresh shared secret against the public key held in key. Produces a ciphertext that the holder of the corresponding private key can pass to wc_MlKemKey_Decapsulate() to recover the same shared secret.
int	**wc_MlKemKey_EncapsulateWithRandom**(MlKemKey * key, unsigned char * ct, unsigned char * ss, const unsigned char * rand, int len)Deterministic variant of wc_MlKemKey_Encapsulate(). Uses the supplied 32 bytes of randomness instead of consuming output from an RNG.
int	**wc_MlKemKey_Decapsulate**(MlKemKey * key, unsigned char * ss, const unsigned char * ct, word32 len)Decapsulates a ciphertext using the private key held in key and recovers the shared secret produced by wc_MlKemKey_Encapsulate(). ML_KEM decapsulation is constant time and includes an implicit_rejection check on malformed ciphertexts (an attacker cannot learn the validity of ct from the runtime).
int	**wc_MlKemKey_DecodePrivateKey**(MlKemKey * key, const unsigned char * in, word32 len)Decodes a raw ML_KEM private key into key. The variant must already be selected on the key (typically via wc_MlKemKey_Init() or wc_MlKemKey_New()) and len must match the private key size for that variant.

	Name
int	**wc_MlKemKey_DecodePublicKey**(MlKemKey * key, const unsigned char * in, word32 len)Decodes a raw ML-KEM public key into key. The variant must already be selected on the key and len must match the public key size for that variant.
int	**wc_MlKemKey_PrivateKeySize**(MlKemKey * key, word32 * len)Returns the encoded private key size in bytes for the variant selected on this key.
int	**wc_MlKemKey_PublicKeySize**(MlKemKey * key, word32 * len)Returns the encoded public key size in bytes for the variant selected on this key.
int	**wc_MlKemKey_EncodePrivateKey**(MlKemKey * key, unsigned char * out, word32 len)Encodes the ML_KEM private key into out. The out buffer length must be exactly wc_MlKemKey_PrivateKeySize() bytes.
int	**wc_MlKemKey_EncodePublicKey**(MlKemKey * key, unsigned char * out, word32 len)Encodes the ML_KEM public key into out. The out buffer length must be exactly wc_MlKemKey_PublicKeySize() bytes.
int	**wc_MlKemKey_PublicKeyToDer**(MlKemKey * key, byte * output, word32 len, int withAlg)Encodes the ML-KEM public key as a DER SubjectPublicKeyInfo. Pass NULL for output to obtain the required length.
int	**wc_MlKemKey_PrivateKeyToDer**(MlKemKey * key, byte * output, word32 len)Encodes the ML-KEM private key as a DER PKCS#8 OneAsymmetricKey, carrying the expanded decapsulation key. Pass NULL for output to obtain the required length.
int	**wc_MlKemKey_PublicKeyDecode**(MlKemKey * key, const byte * input, word32 inSz, word32 * inOutIdx)Decodes a DER SubjectPublicKeyInfo into an ML-KEM public key. Takes wrapped DER, where wc_MlKemKey_DecodePublicKey takes the raw encoded key. A key initialized for a parameter set holds the DER to that same one. A key initialized with WC_ML_KEM_TYPE_UNSET takes the parameter set from the algorithm OID in the DER instead.

	Name
int	**wc_MlKemKey_PrivateKeyDecode**(MlKemKey * key, const byte * input, word32 inSz, word32 * inOutIdx)Decodes a DER PKCS#8 OneAsymmetricKey into an ML_KEM private key. Takes wrapped DER, where wc_MlKemKey_DecodePrivateKey takes the raw encoded key. All three RFC 9935 Section 6 CHOICE forms are accepted: the 64_byte seed under an implicit [0], the expanded decapsulation key as an OCTET STRING, and the SEQUENCE carrying both. A seed is expanded with ML_KEM.KeyGen_internal(d,z). For the “both” form the expanded key is regenerated from the seed and the two are compared, so a key whose halves disagree is rejected as malformed, as RFC 9935 Section 8 requires. A key initialized for a parameter set holds the DER to that same parameter set; a key initialized with WC_ML_KEM_TYPE_UNSET takes it from the algorithm OID in the DER instead.

C.64.2 Functions Documentation

C.64.2.1 function wc_MlKemKey_New

```
MlKemKey * wc_MlKemKey_New(
    int type,
    void * heap,
    int devId
)
```

Allocates and initializes a new MlKemKey on the heap. The returned pointer must be released with wc_MlKemKey_Delete().

Parameters:

- **type** ML-KEM variant: WC_ML_KEM_512, WC_ML_KEM_768 or WC_ML_KEM_1024.
- **heap** Heap hint for dynamic memory allocation. May be NULL.
- **devId** Device identifier for hardware crypto callbacks. Use INVALID_DEVID for software-only.

See:

- wc_MlKemKey_Delete
- wc_MlKemKey_Init

Return:

- Pointer to a freshly allocated MlKemKey on success.
- NULL on allocation failure or if type is invalid.

ML-KEM (FIPS 203) is a quantum-resistant key encapsulation mechanism. The type parameter selects the variant: WC_ML_KEM_512 (NIST security level 1), WC_ML_KEM_768 (level 3) or WC_ML_KEM_1024 (level 5).

Example

```
MlKemKey* key = wc_MlKemKey_New(WC_ML_KEM_768, NULL,
    INVALID_DEVID);
if (key == NULL) {
    // allocation failed
}
// ... use key ...
wc_MlKemKey_Delete(key, &key);
```

C.64.2.2 function wc_MlKemKey_Delete

```
int wc_MlKemKey_Delete(
    MlKemKey * key,
    MlKemKey ** key_p
)
```

Frees and zeros a heap-allocated MlKemKey previously returned by wc_MlKemKey_New(). On success the caller's pointer variable is set to NULL via key_p when key_p is not NULL.

Parameters:

- **key** The MlKemKey to free.
- **key_p** Optional address of the caller's pointer variable; when not NULL, it is set to NULL on success.

See: wc_MlKemKey_New

Return:

- 0 on success.
- BAD_FUNC_ARG if key is NULL.

C.64.2.3 function wc_MlKemKey_Init

```
int wc_MlKemKey_Init(
    MlKemKey * key,
    int type,
    void * heap,
    int devId
)
```

Initializes an MlKemKey object in place. The type parameter selects the ML-KEM variant and must be one of WC_ML_KEM_512, WC_ML_KEM_768 or WC_ML_KEM_1024.

Parameters:

- **key** Pointer to the MlKemKey to initialize.
- **type** ML-KEM variant: WC_ML_KEM_512, WC_ML_KEM_768 or WC_ML_KEM_1024. Pass WC_ML_KEM_TYPE_UNSET to set the object up without a parameter set, leaving wc_MlKemKey_PublicKeyDecode or wc_MlKemKey_PrivateKeyDecode to take it from the algorithm OID in the DER. Every other operation needs a parameter set and fails with BAD_FUNC_ARG until a decode has named one.
- **heap** Heap hint for dynamic memory allocation. May be NULL.
- **devId** Device identifier for hardware crypto callbacks.

See:

- wc_MlKemKey_Free
- wc_MlKemKey_MakeKey

Return:

- 0 on success.

- BAD_FUNC_ARG if key is NULL or type is invalid.
- NOT_COMPILED_IN if type names a variant that was disabled at build time.

Example

```
MlKemKey key;
int ret;

ret = wc_MlKemKey_Init(&key, WC_ML_KEM_768, NULL, INVALID_DEVID);
if (ret != 0) {
    // error initializing key
}
// ... use key ...
wc_MlKemKey_Free(&key);
```

C.64.2.4 function wc_MlKemKey_Free

```
int wc_MlKemKey_Free(
    MlKemKey * key
)
```

Releases resources held by an MlKemKey. After this call the object must be re-initialized with wc_MlKemKey_Init() before it can be used again. Safe to call with a NULL pointer.

Parameters:

- **key** Pointer to the MlKemKey to free.

See: wc_MlKemKey_Init

Return: 0 on success, including when key is NULL.

C.64.2.5 function wc_MlKemKey_Init_Id

```
int wc_MlKemKey_Init_Id(
    MlKemKey * key,
    int type,
    const unsigned char * id,
    int len,
    void * heap,
    int devId
)
```

Initializes an MlKemKey with a device-side key identifier. Equivalent to wc_MlKemKey_Init() but also stashes a binary id that a crypto callback can use to look up the underlying key material on the device. Only available when wolfSSL is built with WOLF_PRIVATE_KEY_ID.

Parameters:

- **key** Pointer to the MlKemKey to initialize.
- **type** ML-KEM variant identifier.
- **id** Pointer to the device-side key identifier bytes. May be NULL when len is 0.
- **len** Number of bytes in id. Must be in the range [0, MLKEM_MAX_ID_LEN].
- **heap** Heap hint for dynamic memory allocation.
- **devId** Device identifier for the crypto callback.

See:

- wc_MlKemKey_Init
- wc_MlKemKey_Init_Label

- wc_MlKemKey_Free

Return:

- 0 on success.
- BAD_FUNC_ARG if key is NULL, if id is NULL while len is non-zero, or if type is invalid.
- BUFFER_E if len is negative or exceeds MLKEM_MAX_ID_LEN.

The id is copied into the key object; the caller may free its buffer immediately after this call returns.

C.64.2.6 function wc_MlKemKey_Init_Label

```
int wc_MlKemKey_Init_Label(
    MlKemKey * key,
    int type,
    const char * label,
    void * heap,
    int devId
)
```

Initializes an MlKemKey with a device-side key label. Equivalent to wc_MlKemKey_Init() but also stashes a label string that a crypto callback can use to look up the underlying key material on the device. Only available when wolfSSL is built with WOLF_PRIVATE_KEY_ID.

Parameters:

- **key** Pointer to the MlKemKey to initialize.
- **type** ML-KEM variant identifier.
- **label** NUL-terminated device-side key label.
- **heap** Heap hint for dynamic memory allocation.
- **devId** Device identifier for the crypto callback.

See:

- wc_MlKemKey_Init
- wc_MlKemKey_Init_Id
- wc_MlKemKey_Free

Return:

- 0 on success.
- BAD_FUNC_ARG if key or label is NULL or type is invalid.

C.64.2.7 function wc_MlKemKey_MakeKey

```
int wc_MlKemKey_MakeKey(
    MlKemKey * key,
    WC_RNG * rng
)
```

Generates a new ML-KEM key pair using the provided RNG. Both the public and private components are populated on success.

Parameters:

- **key** Pointer to an initialized MlKemKey.
- **rng** Pointer to an initialized WC_RNG.

See:

- wc_MlKemKey_MakeKeyWithRandom
- wc_MlKemKey_Encapsulate

- wc_MlKemKey_Decapsulate

Return:

- 0 on success.
- BAD_FUNC_ARG if key or rng is NULL.
- MEMORY_E on allocation failure.

Example

```
MlKemKey key;
WC_RNG rng;

wc_MlKemKey_Init(&key, WC_ML_KEM_768, NULL, INVALID_DEVID);
wc_InitRng(&rng);

if (wc_MlKemKey_MakeKey(&key, &rng) != 0) {
    // error generating key pair
}
```

C.64.2.8 function wc_MlKemKey_MakeKeyWithRandom

```
int wc_MlKemKey_MakeKeyWithRandom(
    MlKemKey * key,
    const unsigned char * rand,
    int len
)
```

Deterministic key generation: produces an ML-KEM key pair from the supplied 64 bytes of randomness instead of an RNG. Useful for known-answer tests and for applications that derive key randomness from another secret.

Parameters:

- **key** Pointer to an initialized MlKemKey.
- **rand** Pointer to a buffer of randomness.
- **len** Length of rand in bytes; must be 64.

See: wc_MlKemKey_MakeKey

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL or len is not 64.

C.64.2.9 function wc_MlKemKey_CipherTextSize

```
int wc_MlKemKey_CipherTextSize(
    MlKemKey * key,
    word32 * len
)
```

Returns the ciphertext size in bytes for the variant selected on this key.

Parameters:

- **key** Pointer to an initialized MlKemKey.
- **len** Receives the ciphertext size in bytes.

See:

- wc_MlKemKey_SharedSecretSize

- wc_MlKemKey_Encapsulate

Return:

- 0 on success.
- BAD_FUNC_ARG if key or len is NULL.

C.64.2.10 function wc_MlKemKey_SharedSecretSize

```
int wc_MlKemKey_SharedSecretSize(
    MlKemKey * key,
    word32 * len
)
```

Returns the shared-secret size in bytes for ML-KEM. The value is the same (32 bytes) across all parameter sets but is queried programmatically for symmetry with wc_MlKemKey_CipherTextSize().

Parameters:

- **key** Pointer to an initialized MlKemKey.
- **len** Receives the shared-secret size in bytes.

See: wc_MlKemKey_CipherTextSize

Return:

- 0 on success.
- BAD_FUNC_ARG if key or len is NULL.

C.64.2.11 function wc_MlKemKey_Encapsulate

```
int wc_MlKemKey_Encapsulate(
    MlKemKey * key,
    unsigned char * ct,
    unsigned char * ss,
    WC_RNG * rng
)
```

Encapsulates a fresh shared secret against the public key held in key. Produces a ciphertext that the holder of the corresponding private key can pass to wc_MlKemKey_Decapsulate() to recover the same shared secret.

Parameters:

- **key** Pointer to an MlKemKey containing a public key.
- **ct** Buffer that receives the ciphertext.
- **ss** Buffer that receives the 32-byte shared secret.
- **rng** Pointer to an initialized WC_RNG.

See:

- wc_MlKemKey_EncapsulateWithRandom
- wc_MlKemKey_Decapsulate

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL.
- BAD_STATE_E if the public key has not been set.
- NOT_COMPILED_IN if wolfSSL was built with WC_NO_RNG.
- MEMORY_E on allocation failure inside the encapsulation routine.

The ct buffer must be at least wc_MlKemKey_CipherTextSize() bytes and ss must be at least wc_MlKemKey_SharedSecretSize() bytes.

Example

```
MlKemKey key;
unsigned char ct[WC_ML_KEM_768_CIPHER_TEXT_SIZE];
unsigned char ss[WC_ML_KEM_SS_SZ];

// ... key holds the recipient's public key ...
if (wc_MlKemKey_Encapsulate(&key, ct, ss, &rng) != 0) {
    // error during encapsulation
}
// Send ct to the holder of the matching private key.
```

C.64.2.12 function wc_MlKemKey_EncapsulateWithRandom

```
int wc_MlKemKey_EncapsulateWithRandom(
    MlKemKey * key,
    unsigned char * ct,
    unsigned char * ss,
    const unsigned char * rand,
    int len
)
```

Deterministic variant of wc_MlKemKey_Encapsulate(). Uses the supplied 32 bytes of randomness instead of consuming output from an RNG.

Parameters:

- **key** Pointer to an MlKemKey containing a public key.
- **ct** Buffer that receives the ciphertext.
- **ss** Buffer that receives the 32-byte shared secret.
- **rand** Buffer of randomness.
- **len** Length of rand in bytes; must be 32.

See: wc_MlKemKey_Encapsulate

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL or len is not 32.

C.64.2.13 function wc_MlKemKey_Decapsulate

```
int wc_MlKemKey_Decapsulate(
    MlKemKey * key,
    unsigned char * ss,
    const unsigned char * ct,
    word32 len
)
```

Decapsulates a ciphertext using the private key held in key and recovers the shared secret produced by wc_MlKemKey_Encapsulate(). ML_KEM decapsulation is constant time and includes an implicit_rejection check on malformed ciphertexts (an attacker cannot learn the validity of ct from the runtime).

Parameters:

- **key** Pointer to an MlKemKey with the private key.

- **ss** Buffer that receives the 32-byte shared secret.
- **ct** The ciphertext to decapsulate.
- **len** Length of ct in bytes.

See:

- wc_MlKemKey_Encapsulate
- wc_MlKemKey_CipherTextSize

Return:

- 0 on success (a shared secret was written to ss).
- BAD_FUNC_ARG if any required pointer is NULL.
- BAD_STATE_E if the private key has not been set.
- BUFFER_E if len does not match the expected ciphertext size for the configured ML-KEM variant.
- NOT_COMPILED_IN if the key's ML-KEM variant was disabled at build time.
- MEMORY_E on allocation failure.

The ss buffer must be at least wc_MlKemKey_SharedSecretSize() bytes and ct must be exactly wc_MlKemKey_CipherTextSize() bytes.

C.64.2.14 function wc_MlKemKey_DecodePrivateKey

```
int wc_MlKemKey_DecodePrivateKey(
    MlKemKey * key,
    const unsigned char * in,
    word32 len
)
```

Decodes a raw ML-KEM private key into key. The variant must already be selected on the key (typically via wc_MlKemKey_Init() or wc_MlKemKey_New()) and len must match the private key size for that variant.

Parameters:

- **key** Pointer to an initialized MlKemKey.
- **in** Raw private key bytes.
- **len** Length of in in bytes.

See:

- wc_MlKemKey_EncodePrivateKey
- wc_MlKemKey_PrivateKeySize

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL or len does not match the expected size.

C.64.2.15 function wc_MlKemKey_DecodePublicKey

```
int wc_MlKemKey_DecodePublicKey(
    MlKemKey * key,
    const unsigned char * in,
    word32 len
)
```

Decodes a raw ML-KEM public key into key. The variant must already be selected on the key and len must match the public key size for that variant.

Parameters:

- **key** Pointer to an initialized MlKemKey.
- **in** Raw public key bytes.
- **len** Length of in in bytes.

See:

- wc_MlKemKey_EncodePublicKey
- wc_MlKemKey_PublicKeySize

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL or len does not match the expected size.

C.64.2.16 function wc_MlKemKey_PrivateKeySize

```
int wc_MlKemKey_PrivateKeySize(
    MlKemKey * key,
    word32 * len
)
```

Returns the encoded private key size in bytes for the variant selected on this key.

Parameters:

- **key** Pointer to an initialized MlKemKey.
- **len** Receives the private key size in bytes.

See: wc_MlKemKey_PublicKeySize

Return:

- 0 on success.
- BAD_FUNC_ARG if key or len is NULL.

C.64.2.17 function wc_MlKemKey_PublicKeySize

```
int wc_MlKemKey_PublicKeySize(
    MlKemKey * key,
    word32 * len
)
```

Returns the encoded public key size in bytes for the variant selected on this key.

Parameters:

- **key** Pointer to an initialized MlKemKey.
- **len** Receives the public key size in bytes.

See: wc_MlKemKey_PrivateKeySize

Return:

- 0 on success.
- BAD_FUNC_ARG if key or len is NULL.

C.64.2.18 function wc_MlKemKey_EncodePrivateKey

```
int wc_MlKemKey_EncodePrivateKey(
    MlKemKey * key,
    unsigned char * out,
```

```
    word32 len
)
```

Encodes the ML-KEM private key into out. The out buffer length must be exactly wc_MlKemKey_PrivateKeySize() bytes.

Parameters:

- **key** Pointer to an MlKemKey with a private key.
- **out** Buffer that receives the encoded private key.
- **len** Length of out in bytes.

See:

- wc_MlKemKey_DecodePrivateKey
- wc_MlKemKey_PrivateKeySize

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL.
- BAD_STATE_E if the private and public keys are not both set on the key object.
- BUFFER_E if len does not exactly equal the encoded private key size for the configured ML-KEM variant.
- NOT_COMPILED_IN if the key's ML-KEM variant was disabled at build time.

C.64.2.19 function wc_MlKemKey_EncodePublicKey

```
int wc_MlKemKey_EncodePublicKey(
    MlKemKey * key,
    unsigned char * out,
    word32 len
)
```

Encodes the ML-KEM public key into out. The out buffer length must be exactly wc_MlKemKey_PublicKeySize() bytes.

Parameters:

- **key** Pointer to an MlKemKey with a public key.
- **out** Buffer that receives the encoded public key.
- **len** Length of out in bytes.

See:

- wc_MlKemKey_DecodePublicKey
- wc_MlKemKey_PublicKeySize

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL.
- BAD_STATE_E if the public key has not been set.
- BUFFER_E if len does not exactly equal the encoded public key size for the configured ML-KEM variant.
- NOT_COMPILED_IN if the key's ML-KEM variant was disabled at build time.

C.64.2.20 function wc_MlKemKey_PublicKeyToDer

```
int wc_MlKemKey_PublicKeyToDer(
    MlKemKey * key,
```

```
    byte * output,
    word32 len,
    int withAlg
)
```

Encodes the ML-KEM public key as a DER SubjectPublicKeyInfo. Pass NULL for output to obtain the required length.

Parameters:

- **key** Pointer to an MlKemKey with a public key.
- **output** Buffer that receives the DER, or NULL for a length.
- **len** Length of output in bytes.
- **withAlg** Include the SubjectPublicKeyInfo wrapper when 1, or emit only the raw public key bytes when 0.

See:

- wc_MlKemKey_PublicKeyDecode
- wc_MlKemKey_PrivateKeyToDer

Return:

- Length of the encoding in bytes on success.
- BAD_FUNC_ARG if key is NULL or its type has no standardised OID.
- MEMORY_E if dynamic memory allocation fails.

C.64.2.21 function wc_MlKemKey_PrivateKeyToDer

```
int wc_MlKemKey_PrivateKeyToDer(
    MlKemKey * key,
    byte * output,
    word32 len
)
```

Encodes the ML-KEM private key as a DER PKCS#8 OneAsymmetricKey, carrying the expanded decapsulation key. Pass NULL for output to obtain the required length.

Parameters:

- **key** Pointer to an MlKemKey with a private key.
- **output** Buffer that receives the DER, or NULL for a length.
- **len** Length of output in bytes.

See:

- wc_MlKemKey_PrivateKeyDecode
- wc_MlKemKey_PublicKeyToDer

Return:

- Length of the encoding in bytes on success.
- BAD_FUNC_ARG if key is NULL or its type has no standardised OID.
- MEMORY_E if dynamic memory allocation fails.

C.64.2.22 function wc_MlKemKey_PublicKeyDecode

```
int wc_MlKemKey_PublicKeyDecode(
    MlKemKey * key,
    const byte * input,
    word32 inSz,
```

```
    word32 * inOutIdx
)
```

Decodes a DER SubjectPublicKeyInfo into an ML-KEM public key. Takes wrapped DER, where wc_MlKemKey_DecodePublicKey takes the raw encoded key. A key initialized for a parameter set holds the DER to that same one. A key initialized with WC_ML_KEM_TYPE_UNSET takes the parameter set from the algorithm OID in the DER instead.

Parameters:

- **key** Pointer to an initialized MlKemKey.
- **input** Buffer holding the DER.
- **inSz** Length of input in bytes.
- **inOutIdx** On in, index into input; on out, index after.

See:

- wc_MlKemKey_PublicKeyToDer
- wc_MlKemKey_Init

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL.
- ASN_PARSE_E if the DER is invalid or names another parameter set.
- NOT_COMPILED_IN if the DER names a parameter set this build lacks.

C.64.2.23 function wc_MlKemKey_PrivateKeyDecode

```
int wc_MlKemKey_PrivateKeyDecode(
    MlKemKey * key,
    const byte * input,
    word32 inSz,
    word32 * inOutIdx
)
```

Decodes a DER PKCS#8 OneAsymmetricKey into an ML-KEM private key. Takes wrapped DER, where wc_MlKemKey_DecodePrivateKey takes the raw encoded key. All three RFC 9935 Section 6 CHOICE forms are accepted: the 64-byte seed under an implicit [0], the expanded decapsulation key as an OCTET STRING, and the SEQUENCE carrying both. A seed is expanded with ML-KEM.KeyGen_internal(d,z). For the “both” form the expanded key is regenerated from the seed and the two are compared, so a key whose halves disagree is rejected as malformed, as RFC 9935 Section 8 requires. A key initialized for a parameter set holds the DER to that same parameter set; a key initialized with WC_ML_KEM_TYPE_UNSET takes it from the algorithm OID in the DER instead.

Parameters:

- **key** Pointer to an initialized MlKemKey.
- **input** Buffer holding the DER.
- **inSz** Length of input in bytes.
- **inOutIdx** On in, index into input; on out, index after.

See: wc_MlKemKey_PrivateKeyToDer

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL.
- MEMORY_E if dynamic memory allocation fails.
- ASN_PARSE_E if the DER is invalid, names another parameter set, carries a seed of the wrong length, or pairs a seed with an expanded key that does not match it.

- NOT_COMPILED_IN if the key carries a seed and the build defines WOLFSSL_MLKEM_NO_MAKE_KEY or WOLF_CRYPTO_CB_ONLY_MLKEM.

A build defining WOLFSSL_MLKEM_NO_MAKE_KEY or WOLF_CRYPTO_CB_ONLY_MLKEM cannot expand a seed, and so cannot perform the Section 8 comparison either. Such a build rejects every key that carries a seed, the "both" form included, rather than accepting its expanded half unchecked.

C.65.2 Functions Documentation

C.65.2.1 function wolfCrypt_Init

```
int wolfCrypt_Init(
    void
)
```

Used to initialize resources used by wolfCrypt.

Parameters:

- **none** No parameters.

See: wolfCrypt_Cleanup

Return:

- 0 upon success.
- <0 upon failure of init resources.

Example

```
...
if (wolfCrypt_Init() != 0) {
    WOLFSSL_MSG("Error with wolfCrypt_Init call");
}
```

C.65.2.2 function wolfCrypt_Cleanup

```
int wolfCrypt_Cleanup(
    void
)
```

Used to clean up resources used by wolfCrypt.

Parameters:

- **none** No parameters.

See: wolfCrypt_Init

Return:

- 0 upon success.
- <0 upon failure of cleaning up resources.

Example

```
...
if (wolfCrypt_Cleanup() != 0) {
    WOLFSSL_MSG("Error with wolfCrypt_Cleanup call");
}
```

C.65.2.3 function wolfSSL_Atomic_Int_Init

```
void wolfSSL_Atomic_Int_Init(
    wolfSSL_Atomic_Int * c,
    int i
)
```

Initializes atomic integer.

Parameters:

- **c** Atomic integer pointer
- **i** Initial value

See: wolfSSL_Atomic_Int_FetchAdd

Return: none No returns

Example

```
wolfSSL_Atomic_Int counter;
wolfSSL_Atomic_Int_Init(&counter, 0);
```

C.65.2.4 function wolfSSL_Atomic_Uint_Init

```
void wolfSSL_Atomic_Uint_Init(
    wolfSSL_Atomic_Uint * c,
    unsigned int i
)
```

Initializes atomic unsigned integer.

Parameters:

- **c** Atomic unsigned integer pointer
- **i** Initial value

See: wolfSSL_Atomic_Uint_FetchAdd

Return: none No returns

Example

```
wolfSSL_Atomic_Uint counter;
wolfSSL_Atomic_Uint_Init(&counter, 0);
```

C.65.2.5 function wolfSSL_Atomic_Int_FetchAdd

```
int wolfSSL_Atomic_Int_FetchAdd(
    wolfSSL_Atomic_Int * c,
    int i
)
```

Atomically adds to integer and returns old value.

Parameters:

- **c** Atomic integer pointer
- **i** Value to add

See: wolfSSL_Atomic_Int_AddFetch

Return: Old value before addition

Example

```
wolfSSL_Atomic_Int counter;
int old = wolfSSL_Atomic_Int_FetchAdd(&counter, 1);
```

C.65.2.6 function wolfSSL_Atomic_Int_FetchSub

```
int wolfSSL_Atomic_Int_FetchSub(
    wolfSSL_Atomic_Int * c,
    int i
)
```

Atomically subtracts from integer and returns old value.

Parameters:

- **c** Atomic integer pointer
- **i** Value to subtract

See: wolfSSL_Atomic_Int_SubFetch

Return: Old value before subtraction

Example

```
wolfSSL_Atomic_Int counter;
int old = wolfSSL_Atomic_Int_FetchSub(&counter, 1);
```

C.65.2.7 function wolfSSL_Atomic_Int_AddFetch

```
int wolfSSL_Atomic_Int_AddFetch(
    wolfSSL_Atomic_Int * c,
    int i
)
```

Atomically adds to integer and returns new value.

Parameters:

- **c** Atomic integer pointer
- **i** Value to add

See: wolfSSL_Atomic_Int_FetchAdd

Return: New value after addition

Example

```
wolfSSL_Atomic_Int counter;
int new_val = wolfSSL_Atomic_Int_AddFetch(&counter, 1);
```

C.65.2.8 function wolfSSL_Atomic_Int_SubFetch

```
int wolfSSL_Atomic_Int_SubFetch(
    wolfSSL_Atomic_Int * c,
    int i
)
```

Atomically subtracts from integer and returns new value.

Parameters:

- **c** Atomic integer pointer
- **i** Value to subtract

See: wolfSSL_Atomic_Int_FetchSub

Return: New value after subtraction

Example

```
wolfSSL_Atomic_Int counter;
int new_val = wolfSSL_Atomic_Int_SubFetch(&counter, 1);
```

C.65.2.9 function wolfSSL_Atomic_Int_CompareExchange

```
int wolfSSL_Atomic_Int_CompareExchange(
    wolfSSL_Atomic_Int * c,
    int * expected_i,
    int new_i
)
```

Atomically compares and exchanges integer.

Parameters:

- **c** Atomic integer pointer
- **expected_i** Pointer to expected value
- **new_i** New value to set

See: wolfSSL_Atomic_Int_FetchAdd

Return: 1 if exchange occurred, 0 otherwise

Example

```
wolfSSL_Atomic_Int counter;
int expected = 0;
int ret = wolfSSL_Atomic_Int_CompareExchange(&counter, &expected, 1);
```

C.65.2.10 function wolfSSL_Atomic_Uint_FetchAdd

```
unsigned int wolfSSL_Atomic_Uint_FetchAdd(
    wolfSSL_Atomic_Uint * c,
    unsigned int i
)
```

Atomically adds to unsigned integer and returns old value.

Parameters:

- **c** Atomic unsigned integer pointer
- **i** Value to add

See: wolfSSL_Atomic_Uint_AddFetch

Return: Old value before addition

Example

```
wolfSSL_Atomic_Uint counter;
unsigned int old = wolfSSL_Atomic_Uint_FetchAdd(&counter, 1);
```

C.65.2.11 function wolfSSL_Atomic_Uint_FetchSub

```
unsigned int wolfSSL_Atomic_Uint_FetchSub(
    wolfSSL_Atomic_Uint * c,
    unsigned int i
)
```

Atomically subtracts from unsigned integer, returns old value.

Parameters:

- **c** Atomic unsigned integer pointer
- **i** Value to subtract

See: wolfSSL_Atomic_Uint_SubFetch

Return: Old value before subtraction

Example

```
wolfSSL_Atomic_Uint counter;
unsigned int old = wolfSSL_Atomic_Uint_FetchSub(&counter, 1);
```

C.65.2.12 function wolfSSL_Atomic_Uint_AddFetch

```
unsigned int wolfSSL_Atomic_Uint_AddFetch(
    wolfSSL_Atomic_Uint * c,
    unsigned int i
)
```

Atomically adds to unsigned integer, returns new value.

Parameters:

- **c** Atomic unsigned integer pointer
- **i** Value to add

See: wolfSSL_Atomic_Uint_FetchAdd

Return: New value after addition

Example

```
wolfSSL_Atomic_Uint counter;
unsigned int new_val = wolfSSL_Atomic_Uint_AddFetch(&counter, 1);
```

C.65.2.13 function wolfSSL_Atomic_Uint_SubFetch

```
unsigned int wolfSSL_Atomic_Uint_SubFetch(
    wolfSSL_Atomic_Uint * c,
    unsigned int i
)
```

Atomically subtracts from unsigned integer, returns new value.

Parameters:

- **c** Atomic unsigned integer pointer
- **i** Value to subtract

See: wolfSSL_Atomic_Uint_FetchSub

Return: New value after subtraction

Example

```
wolfSSL_Atomic_Uint counter;
unsigned int new_val = wolfSSL_Atomic_Uint_SubFetch(&counter, 1);
```

C.65.2.14 function wolfSSL_Atomic_Uint_CompareExchange

```
int wolfSSL_Atomic_Uint_CompareExchange(
    wolfSSL_Atomic_Uint * c,
    unsigned int * expected_i,
    unsigned int new_i
)
```

Atomically compares and exchanges unsigned integer.

Parameters:

- **c** Atomic unsigned integer pointer
- **expected_i** Pointer to expected value
- **new_i** New value to set

See: wolfSSL_Atomic_Uint_FetchAdd

Return: 1 if exchange occurred, 0 otherwise

Example

```
wolfSSL_Atomic_Uint counter;
unsigned int expected = 0;
int ret = wolfSSL_Atomic_Uint_CompareExchange(&counter, &expected, 1);
```

C.65.2.15 function wolfSSL_Atomic_Ptr_CompareExchange

```
int wolfSSL_Atomic_Ptr_CompareExchange(
    void ** c,
    void ** expected_ptr,
    void * new_ptr
)
```

Atomically compares and exchanges pointer.

Parameters:

- **c** Pointer to pointer
- **expected_ptr** Pointer to expected pointer value
- **new_ptr** New pointer value

See: wolfSSL_Atomic_Int_CompareExchange

Return: 1 if exchange occurred, 0 otherwise

Example

```
void* ptr = NULL;
void* expected = NULL;
void* new_val = malloc(100);
int ret = wolfSSL_Atomic_Ptr_CompareExchange(&ptr, &expected, new_val);
```

C.65.2.16 function wc_InitMutex

```
int wc_InitMutex(
    wolfSSL_Mutex * m
)
```

Initializes mutex.

Parameters:

- **m** Mutex pointer

See: wc_FreeMutex

Return:

- 0 on success
- negative on error

Example

```
wolfSSL_Mutex mutex;
int ret = wc_InitMutex(&mutex);
```

C.65.2.17 function wc_FreeMutex

```
int wc_FreeMutex(
    wolfSSL_Mutex * m
)
```

Frees mutex resources.

Parameters:

- **m** Mutex pointer

See: wc_InitMutex

Return:

- 0 on success
- negative on error

Example

```
wolfSSL_Mutex mutex;
wc_InitMutex(&mutex);
int ret = wc_FreeMutex(&mutex);
```

C.65.2.18 function wc_LockMutex

```
int wc_LockMutex(
    wolfSSL_Mutex * m
)
```

Locks mutex.

Parameters:

- **m** Mutex pointer

See: wc_UnLockMutex

Return:

- 0 on success
- negative on error

Example

```
wolfSSL_Mutex mutex;
int ret = wc_LockMutex(&mutex);
```

C.65.2.19 function wc_UnLockMutex

```
int wc_UnLockMutex(
    wolfSSL_Mutex * m
)
```

Unlocks mutex.

Parameters:

- **m** Mutex pointer

See: wc_LockMutex

Return:

- 0 on success
- negative on error

Example

```
wolfSSL_Mutex mutex;
wc_LockMutex(&mutex);
int ret = wc_UnLockMutex(&mutex);
```

C.65.2.20 function wc_InitAndAllocMutex

```
wolfSSL_Mutex * wc_InitAndAllocMutex(
    void
)
```

Initializes and allocates mutex.

Parameters:

- **none** No parameters

See: wc_InitMutex

Return:

- Pointer to mutex on success
- NULL on error

Example

```
wolfSSL_Mutex* mutex = wc_InitAndAllocMutex();
if (mutex != NULL) {
    wc_LockMutex(mutex);
}
```

C.65.2.21 function wc_InitRwLock

```
int wc_InitRwLock(
    wolfSSL_RwLock * m
)
```

Initializes read-write lock.

Parameters:

- **m** Read-write lock pointer

See: wc_FreeRwLock

Return:

- 0 on success
- negative on error

Example

```
wolfSSL_RwLock lock;
int ret = wc_InitRwLock(&lock);
```

C.65.2.22 function wc_FreeRwLock

```
int wc_FreeRwLock(
    wolfSSL_RwLock * m
)
```

Frees read-write lock resources.

Parameters:

- **m** Read-write lock pointer

See: wc_InitRwLock

Return:

- 0 on success
- negative on error

Example

```
wolfSSL_RwLock lock;
wc_InitRwLock(&lock);
int ret = wc_FreeRwLock(&lock);
```

C.65.2.23 function wc_LockRwLock_Wr

```
int wc_LockRwLock_Wr(
    wolfSSL_RwLock * m
)
```

Locks read-write lock for writing.

Parameters:

- **m** Read-write lock pointer

See: wc_UnLockRwLock

Return:

- 0 on success
- negative on error

Example

```
wolfSSL_RwLock lock;
int ret = wc_LockRwLock_Wr(&lock);
```

C.65.2.24 function wc_LockRwLock_Rd

```
int wc_LockRwLock_Rd(
    wolfSSL_RwLock * m
)
```

Locks read-write lock for reading.

Parameters:

- **m** Read-write lock pointer

See: wc_UnLockRwLock

Return:

- 0 on success
- negative on error

Example

```
wolfSSL_RwLock lock;
int ret = wc_LockRwLock_Rd(&lock);
```

C.65.2.25 function wc_UnLockRwLock

```
int wc_UnLockRwLock(
    wolfSSL_RwLock * m
)
```

Unlocks read-write lock.

Parameters:

- **m** Read-write lock pointer

See: wc_LockRwLock_Rd

Return:

- 0 on success
- negative on error

Example

```
wolfSSL_RwLock lock;
wc_LockRwLock_Rd(&lock);
int ret = wc_UnLockRwLock(&lock);
```

C.65.2.26 function wc_LockMutex_ex

```
int wc_LockMutex_ex(
    int flag,
    int type,
    const char * file,
    int line
)
```

Locks mutex with debug info.

Parameters:

- **flag** Lock flag
- **type** Lock type

- **file** Source file name
- **line** Source line number

See: wc_LockMutex

Return:

- 0 on success
- negative on error

Example

```
int ret = wc_LockMutex_ex(0, 0, __FILE__, __LINE__);
```

C.65.2.27 function wc_SetMutexCb

```
int wc_SetMutexCb(
    mutex_cb * cb
)
```

Sets mutex callback.

Parameters:

- **cb** Mutex callback pointer

See: wc_GetMutexCb

Return:

- 0 on success
- negative on error

Example

```
mutex_cb cb;
int ret = wc_SetMutexCb(&cb);
```

C.65.2.28 function wc_GetMutexCb

```
mutex_cb * wc_GetMutexCb(
    void
)
```

Gets mutex callback.

Parameters:

- **none** No parameters

See: wc_SetMutexCb

Return: Pointer to mutex callback

Example

```
mutex_cb* cb = wc_GetMutexCb();
```

C.65.2.29 function wolfCrypt_heap_peakAllocs_checkpoint

```
long wolfCrypt_heap_peakAllocs_checkpoint(
    void
)
```

Checkpoints peak heap allocations.

Parameters:

- **none** No parameters

See: wolfCrypt_heap_peakBytes_checkpoint

Return: Peak allocation count

Example

```
long peak = wolfCrypt_heap_peakAllocs_checkpoint();
```

C.65.2.30 function wolfCrypt_heap_peakBytes_checkpoint

```
long wolfCrypt_heap_peakBytes_checkpoint(
    void
)
```

Checkpoints peak heap bytes.

Parameters:

- **none** No parameters

See: wolfCrypt_heap_peakAllocs_checkpoint

Return: Peak bytes allocated

Example

```
long peak = wolfCrypt_heap_peakBytes_checkpoint();
```

C.65.2.31 function wc_FileLoad

```
int wc_FileLoad(
    const char * fname,
    unsigned char ** buf,
    size_t * bufLen,
    void * heap
)
```

Loads file into buffer.

Parameters:

- **fname** File name
- **buf** Buffer pointer
- **bufLen** Buffer length pointer
- **heap** Heap hint

See: wc_FileExists

Return:

- 0 on success
- negative on error

Example

```
unsigned char* buf = NULL;
size_t len = 0;
int ret = wc_FileLoad("file.txt", &buf, &len, NULL);
```

C.65.2.32 function wc_ReadDirFirst

```
int wc_ReadDirFirst(
    ReadDirCtx * ctx,
    const char * path,
    char ** name
)
```

Reads first entry in directory.

Parameters:

- **ctx** Directory context
- **path** Directory path
- **name** Pointer to store entry name

See: wc_ReadDirNext

Return:

- 0 on success
- negative on error

Example

```
ReadDirCtx ctx;
char* name;
int ret = wc_ReadDirFirst(&ctx, "/path", &name);
```

C.65.2.33 function wc_ReadDirNext

```
int wc_ReadDirNext(
    ReadDirCtx * ctx,
    const char * path,
    char ** name
)
```

Reads next entry in directory.

Parameters:

- **ctx** Directory context
- **path** Directory path
- **name** Pointer to store entry name

See: wc_ReadDirFirst

Return:

- 0 on success
- negative on error

Example

```
ReadDirCtx ctx;
char* name;
int ret = wc_ReadDirNext(&ctx, "/path", &name);
```

C.65.2.34 function wc_ReadDirClose

```
void wc_ReadDirClose(
    ReadDirCtx * ctx
)
```

Closes directory reading.

Parameters:

- **ctx** Directory context

See: wc_ReadDirFirst

Return: none No returns

Example

```
ReadDirCtx ctx;
wc_ReadDirClose(&ctx);
```

C.65.2.35 function wc_FileExists

```
int wc_FileExists(
    const char * fname
)
```

Checks if file exists.

Parameters:

- **fname** File name

See: wc_FileLoad

Return:

- 1 if file exists
- 0 if file does not exist

Example

```
if (wc_FileExists("file.txt")) {
    // file exists
}
```

C.65.2.36 function wolfSSL_GetHandleCbSet

```
int wolfSSL_GetHandleCbSet(
    void
)
```

Checks if handle callback is set.

Parameters:

- **none** No parameters

See: wolfSSL_SetHandleCb

Return:

- 1 if set
- 0 if not set

Example

```
if (wolfSSL_GetHandleCbSet()) {
    // callback is set
}
```

C.65.2.37 function wolfSSL_SetHandleCb

```
int wolfSSL_SetHandleCb(
    wolfSSL_DSP_Handle_cb in
)
```

Sets handle callback.

Parameters:

- **in** Handle callback

See: wolfSSL_GetHandleCbSet

Return:

- 0 on success
- negative on error

Example

```
int ret = wolfSSL_SetHandleCb(myHandleCallback);
```

C.65.3 Source code

```
int wolfCrypt_Init(void);

int wolfCrypt_Cleanup(void);

void wolfSSL_Atomic_Int_Init(wolfSSL_Atomic_Int* c, int i);

void wolfSSL_Atomic_Uint_Init(wolfSSL_Atomic_Uint* c, unsigned int i);

int wolfSSL_Atomic_Int_FetchAdd(wolfSSL_Atomic_Int* c, int i);

int wolfSSL_Atomic_Int_FetchSub(wolfSSL_Atomic_Int* c, int i);

int wolfSSL_Atomic_Int_AddFetch(wolfSSL_Atomic_Int* c, int i);

int wolfSSL_Atomic_Int_SubFetch(wolfSSL_Atomic_Int* c, int i);

int wolfSSL_Atomic_Int_CompareExchange(wolfSSL_Atomic_Int* c,
                                       int *expected_i, int new_i);

unsigned int wolfSSL_Atomic_Uint_FetchAdd(wolfSSL_Atomic_Uint* c,
                                          unsigned int i);

unsigned int wolfSSL_Atomic_Uint_FetchSub(wolfSSL_Atomic_Uint* c,
                                          unsigned int i);

C.66 wc_she.h

C.66.1 Functions

	Name
int	**wc_SHE_Init**(wc_SHE * she, void * heap, int devId)Initialize a SHE context with a heap hint and device ID.
int	**wc_SHE_Init_Id**(wc_SHE * she, unsigned char * id, int len, void * heap, int devId)Initialize a SHE context with an opaque hardware key identifier. Useful when using crypto callbacks and additional info needs to be attached to the SHE context to determine slot or key group information.
int	**wc_SHE_Init_Label**(wc_SHE * she, const char * label, void * heap, int devId)Initialize a SHE context with a human-readable key label. Useful when using crypto callbacks and additional info needs to be attached to the SHE context to determine slot or key group information.
void	**wc_SHE_Free**(wc_SHE * she)Scrub all data and zero the SHE context. Safe to call on a NULL pointer.
int	**wc_SHE_GetUID**(wc_SHE * she, byte * uid, word32 uidSz, const void * ctx)Retrieve the UID from hardware via a crypto callback. Requires WOLF_CRYPTO_CB and that NO_WC_SHE_GETUID is not defined.
int	**wc_SHE_GetCounter**(wc_SHE * she, word32 * counter, const void * ctx)Retrieve the monotonic counter value from hardware via a crypto callback. The SHE spec uses a 28-bit counter. The caller should increment this value before passing to GenerateM1M2M3 or GenerateM4M5. Requires WOLF_CRYPTO_CB and that NO_WC_SHE_GETCOUNTER is not defined.
int	**wc_SHE_SetKdfConstants**(wc_SHE * she, const byte * encC, word32 encCSz, const byte * macC, word32 macCSz)Set custom KDF constants used in Miyaguchi-Preneel key derivation. Defaults are KEY_UPDATE_ENC_C and KEY_UPDATE_MAC_C from the SHE spec. Either pointer may be NULL to leave that constant unchanged. Requires WOLFSSL_SHE_EXTENDED.

	Name
int	**wc_SHE_SetM2Header**(wc_SHE * she, const byte * header, word32 headerSz)Override the M2 cleartext header (first 16 bytes of M2 before encryption). When set, GenerateM1M2M3 uses this instead of auto-building from counter and flags. Requires WOLFSSL_SHE_EXTENDED.
int	**wc_SHE_SetM4Header**(wc_SHE * she, const byte * header, word32 headerSz)Override the M4 cleartext counter block (16_byte block encrypted with K3). When set, GenerateM4M5 uses this instead of auto-building from counter. Requires WOLFSSL_SHE_EXTENDED.
int	**wc_SHE_ImportM1M2M3**(wc_SHE * she, const byte * m1, word32 m1Sz, const byte * m2, word32 m2Sz, const byte * m3, word32 m3Sz)Import externally-provided M1/M2/M3 into the SHE context. Sets the generated flag so the callback for GenerateM4M5 can read M1/M2/M3 from the context to send to hardware. Requires WOLF_CRYPTO_CB and that NO_WC_SHE_IMPORT_M123 is not defined.
int	**wc_SHE_GenerateM1M2M3**(wc_SHE * she, const byte * uid, word32 uidSz, byte authKeyId, const byte * authKey, word32 authKeySz, byte targetKeyId, const byte * newKey, word32 newKeySz, word32 counter, byte flags, byte * m1, word32 m1Sz, byte * m2, word32 m2Sz, byte * m3, word32 m3Sz)Generate SHE key update messages M1, M2, and M3 and write them to caller_provided buffers. Uses Miyaguchi_Preneel AES_128 KDF to derive K1 and K2 from the authorizing key, AES_CBC to encrypt the new key (M2), and AES_CMAC for authentication (M3).
int	**wc_SHE_GenerateM4M5**(wc_SHE * she, const byte * uid, word32 uidSz, byte authKeyId, byte targetKeyId, const byte * newKey, word32 newKeySz, word32 counter, byte * m4, word32 m4Sz, byte * m5, word32 m5Sz)Generate SHE verification messages M4 and M5 and write them to caller-provided buffers. Uses Miyaguchi-Preneel AES-128 KDF to derive K3 and K4 from the new key, AES-ECB for the M4 counter block, and AES-CMAC for M5. Independent of M1/M2/M3 and can be called on a separate context.

	Name
int	**wc_SHE_LoadKey**(void * heap, int devId, const byte * m1, word32 m1Sz, const byte * m2, word32 m2Sz, const byte * m3, word32 m3Sz, byte * m4, word32 m4Sz, byte * m5, word32 m5Sz)One_shot convenience wrapper: Init, ImportM1M2M3, GenerateM4M5 (via callback), Free. Dispatches to a hardware crypto callback that sends M1/M2/M3 to the HSM and returns M4/M5. Requires a valid devId (not INVALID_DEVID). Define NO_WC_SHE_LOADKEY to compile out.
int	**wc_SHE_LoadKey_Id**(unsigned char * id, int idLen, void * heap, int devId, const byte * m1, word32 m1Sz, const byte * m2, word32 m2Sz, const byte * m3, word32 m3Sz, byte * m4, word32 m4Sz, byte * m5, word32 m5Sz)One-shot Load Key with an opaque hardware key identifier. Same as wc_SHE_LoadKey but initializes the context with wc_SHE_Init_Id. Define NO_WC_SHE_LOADKEY to compile out.
int	**wc_SHE_LoadKey_Label**(const char * label, void * heap, int devId, const byte * m1, word32 m1Sz, const byte * m2, word32 m2Sz, const byte * m3, word32 m3Sz, byte * m4, word32 m4Sz, byte * m5, word32 m5Sz)One-shot Load Key with a human-readable key label. Same as wc_SHE_LoadKey but initializes the context with wc_SHE_Init_Label. Define NO_WC_SHE_LOADKEY to compile out.
int	**wc_SHE_LoadKey_Verify**(void * heap, int devId, const byte * m1, word32 m1Sz, const byte * m2, word32 m2Sz, const byte * m3, word32 m3Sz, byte * m4, word32 m4Sz, byte * m5, word32 m5Sz, const byte * m4Expected, word32 m4ExpectedSz, const byte * m5Expected, word32 m5ExpectedSz)One-shot Load Key with M4/M5 verification. Same as wc_SHE_LoadKey but also compares the M4/M5 returned by the HSM against caller-provided expected values using constant-time comparison. Returns SIG_VERIFY_E on mismatch. The actual M4/M5 are still written to the output buffers on failure. Define NO_WC_SHE_LOADKEY to compile out.

	Name
int	**wc_SHE_LoadKey_Verify_Id**(unsigned char * id, int idLen, void * heap, int devId, const byte * m1, word32 m1Sz, const byte * m2, word32 m2Sz, const byte * m3, word32 m3Sz, byte * m4, word32 m4Sz, byte * m5, word32 m5Sz, const byte * m4Expected, word32 m4ExpectedSz, const byte * m5Expected, word32 m5ExpectedSz)One-shot Load Key with opaque key identifier and M4/M5 verification. Combines wc_SHE_LoadKey_Id and wc_SHE_LoadKey_Verify. Define NO_WC_SHE_LOADKEY to compile out.
int	**wc_SHE_LoadKey_Verify_Label**(const char * label, void * heap, int devId, const byte * m1, word32 m1Sz, const byte * m2, word32 m2Sz, const byte * m3, word32 m3Sz, byte * m4, word32 m4Sz, byte * m5, word32 m5Sz, const byte * m4Expected, word32 m4ExpectedSz, const byte * m5Expected, word32 m5ExpectedSz)One-shot Load Key with key label and M4/M5 verification. Combines wc_SHE_LoadKey_Label and wc_SHE_LoadKey_Verify. Define NO_WC_SHE_LOADKEY to compile out.
int	**wc_SHE_ExportKey**(wc_SHE * she, byte * m1, word32 m1Sz, byte * m2, word32 m2Sz, byte * m3, word32 m3Sz, byte * m4, word32 m4Sz, byte * m5, word32 m5Sz, const void * ctx)Export a key from hardware in SHE loadable format (M1_M5). Some HSMs allow exporting certain key slots (e.g. RAM key) so they can be re-loaded later via the SHE key update protocol. Requires WOLF_CRYPTO_CB and that NO_WC_SHE_EXPORTKEY is not defined. Any output buffer may be NULL to skip that message.
int	**wc_SHE_AesMp16**(Aes * aes, const byte * in, word32 inSz, byte * out)Miyaguchi_Preneel AES_128 one_way compression function. H_0 = 0, H_i = E_{H_{i_1}}(M_i) XOR M_i XOR H_{i-1}. Only valid for AES-128 where key size equals block size. This is an internal function exposed for testing purposes.

C.66.2 Functions Documentation

C.66.2.1 function wc_SHE_Init

```
int wc_SHE_Init(
    wc_SHE * she,
    void * heap,
    int devId
```

)

Initialize a SHE context with a heap hint and device ID.

Parameters:

- **she** pointer to a wc_SHE structure to initialize
- **heap** heap hint for internal allocations, or NULL
- **devId** crypto callback device ID, or INVALID_DEVID for software-only operation

See:

- wc_SHE_Init_Id
- wc_SHE_Init_Label
- wc_SHE_Free

Return:

- 0 on success
- BAD_FUNC_ARG if she is NULL

Example

```
wc_SHE she;
int ret;
ret = wc_SHE_Init(&she, NULL, INVALID_DEVID);
if (ret == 0) {
    // use she context
}
wc_SHE_Free(&she);
```

C.66.2.2 function wc_SHE_Init_Id

```
int wc_SHE_Init_Id(
    wc_SHE * she,
    unsigned char * id,
    int len,
    void * heap,
    int devId
)
```

Initialize a SHE context with an opaque hardware key identifier. Useful when using crypto callbacks and additional info needs to be attached to the SHE context to determine slot or key group information.

Parameters:

- **she** pointer to a wc_SHE structure to initialize
- **id** opaque key identifier bytes
- **len** length of id in bytes (0 to WC_SHE_MAX_ID_LEN)
- **heap** heap hint for internal allocations, or NULL
- **devId** crypto callback device ID

See:

- wc_SHE_Init
- wc_SHE_Init_Label
- wc_SHE_Free

Return:

- 0 on success
- BAD_FUNC_ARG if she is NULL, id is NULL when len > 0, or len exceeds WC_SHE_MAX_ID_LEN

Example

```
wc_SHE she;
unsigned char myId[] = { 0x01, 0x02, 0x03 };
int ret;
ret = wc_SHE_Init_Id(&she, myId, sizeof(myId), NULL, myDevId);
```

C.66.2.3 function wc_SHE_Init_Label

```
int wc_SHE_Init_Label(
    wc_SHE * she,
    const char * label,
    void * heap,
    int devId
)
```

Initialize a SHE context with a human-readable key label. Useful when using crypto callbacks and additional info needs to be attached to the SHE context to determine slot or key group information.

Parameters:

- **she** pointer to a wc_SHE structure to initialize
- **label** NUL-terminated key label string
- **heap** heap hint for internal allocations, or NULL
- **devId** crypto callback device ID

See:

- wc_SHE_Init
- wc_SHE_Init_Id
- wc_SHE_Free

Return:

- 0 on success
- BAD_FUNC_ARG if she or label is NULL, or label length exceeds WC_SHE_MAX_LABEL_LEN

Example

```
wc_SHE she;
int ret;
ret = wc_SHE_Init_Label(&she, "ecu-master-key", NULL, myDevId);
```

C.66.2.4 function wc_SHE_Free

```
void wc_SHE_Free(
    wc_SHE * she
)
```

Scrub all data and zero the SHE context. Safe to call on a NULL pointer.

Parameters:

- **she** pointer to a wc_SHE structure, or NULL

See: wc_SHE_Init

Example

```
wc_SHE she;
wc_SHE_Init(&she, NULL, INVALID_DEVID);
```

```
// ... use context ...
wc_SHE_Free(&she);
```

C.66.2.5 function wc_SHE_GetUID

```
int wc_SHE_GetUID(
    wc_SHE * she,
    byte * uid,
    word32 uidSz,
    const void * ctx
)
```

Retrieve the UID from hardware via a crypto callback. Requires WOLF_CRYPTO_CB and that NO_WC_SHE_GETUID is not defined.

Parameters:

- **she** initialized SHE context
- **uid** buffer to receive the 15-byte (120-bit) SHE UID
- **uidSz** size of uid buffer in bytes (must be >= WC_SHE_UID_SZ)
- **ctx** read-only caller context passed to the callback (e.g. challenge buffer, HSM handle)

See: wc_SHE_GetCounter

Return:

- 0 on success
- BAD_FUNC_ARG if she, uid, or uidSz is invalid
- CRYPTOCB_UNAVAILABLE if no callback is registered

Example

```
byte uid[WC_SHE_UID_SZ];
int ret;
ret = wc_SHE_GetUID(&she, uid, sizeof(uid), NULL);
```

C.66.2.6 function wc_SHE_GetCounter

```
int wc_SHE_GetCounter(
    wc_SHE * she,
    word32 * counter,
    const void * ctx
)
```

Retrieve the monotonic counter value from hardware via a crypto callback. The SHE spec uses a 28-bit counter. The caller should increment this value before passing to GenerateM1M2M3 or GenerateM4M5. Requires WOLF_CRYPTO_CB and that NO_WC_SHE_GETCOUNTER is not defined.

Parameters:

- **she** initialized SHE context
- **counter** pointer to receive the current counter value
- **ctx** read-only caller context passed to the callback

See: wc_SHE_GetUID

Return:

- 0 on success
- BAD_FUNC_ARG if she or counter is NULL
- CRYPTOCB_UNAVAILABLE if no callback is registered

Example

```
word32 counter;
int ret;
ret = wc_SHE_GetCounter(&she, &counter, NULL);
```

C.66.2.7 function wc_SHE_SetKdfConstants

```
int wc_SHE_SetKdfConstants(
    wc_SHE * she,
    const byte * encC,
    word32 encCSz,
    const byte * macC,
    word32 macCSz
)
```

Set custom KDF constants used in Miyaguchi-Preneel key derivation. Defaults are KEY_UPDATE_ENC_C and KEY_UPDATE_MAC_C from the SHE spec. Either pointer may be NULL to leave that constant unchanged. Requires WOLFSSL_SHE_EXTENDED.

Parameters:

- **she** initialized SHE context
- **encC** 16-byte encryption derivation constant (CENC), or NULL
- **encCSz** must be WC_SHE_KEY_SZ (16) when encC is non-NULL
- **macC** 16-byte MAC derivation constant (CMAC), or NULL
- **macCSz** must be WC_SHE_KEY_SZ (16) when macC is non-NULL

See:

- wc_SHE_SetM2Header
- wc_SHE_SetM4Header
- wc_SHE_GenerateM1M2M3

Return:

- 0 on success
- BAD_FUNC_ARG if she is NULL or sizes are not WC_SHE_KEY_SZ when corresponding pointer is non-NULL

Example

```
byte myEncC[WC_SHE_KEY_SZ] = { ... };
byte myMacC[WC_SHE_KEY_SZ] = { ... };
int ret;
ret = wc_SHE_SetKdfConstants(&she, myEncC, WC_SHE_KEY_SZ,
                             myMacC, WC_SHE_KEY_SZ);
```

C.66.2.8 function wc_SHE_SetM2Header

```
int wc_SHE_SetM2Header(
    wc_SHE * she,
    const byte * header,
    word32 headerSz
)
```

Override the M2 cleartext header (first 16 bytes of M2 before encryption). When set, GenerateM1M2M3 uses this instead of auto-building from counter and flags. Requires WOLFSSL_SHE_EXTENDED.

Parameters:

- **she** initialized SHE context
- **header** 16-byte cleartext header block
- **headerSz** must be WC_SHE_KEY_SZ (16)

See:

- wc_SHE_SetKdfConstants
- wc_SHE_SetM4Header
- wc_SHE_GenerateM1M2M3

Return:

- 0 on success
- BAD_FUNC_ARG if she or header is NULL, or headerSz is not WC_SHE_KEY_SZ

Example

```
byte header[WC_SHE_KEY_SZ] = { ... };
int ret;
ret = wc_SHE_SetM2Header(&she, header, WC_SHE_KEY_SZ);
```

C.66.2.9 function wc_SHE_SetM4Header

```
int wc_SHE_SetM4Header(
    wc_SHE * she,
    const byte * header,
    word32 headerSz
)
```

Override the M4 cleartext counter block (16-byte block encrypted with K3). When set, GenerateM4M5 uses this instead of auto-building from counter. Requires WOLFSSL_SHE_EXTENDED.

Parameters:

- **she** initialized SHE context
- **header** 16-byte cleartext counter block
- **headerSz** must be WC_SHE_KEY_SZ (16)

See:

- wc_SHE_SetKdfConstants
- wc_SHE_SetM2Header
- wc_SHE_GenerateM4M5

Return:

- 0 on success
- BAD_FUNC_ARG if she or header is NULL, or headerSz is not WC_SHE_KEY_SZ

Example

```
byte header[WC_SHE_KEY_SZ] = { ... };
int ret;
ret = wc_SHE_SetM4Header(&she, header, WC_SHE_KEY_SZ);
```

C.66.2.10 function wc_SHE_ImportM1M2M3

```
int wc_SHE_ImportM1M2M3(
    wc_SHE * she,
    const byte * m1,
```

```
    word32 m1Sz,
    const byte * m2,
    word32 m2Sz,
    const byte * m3,
    word32 m3Sz
)
```

Import externally-provided M1/M2/M3 into the SHE context. Sets the generated flag so the callback for GenerateM4M5 can read M1/M2/M3 from the context to send to hardware. Requires WOLF_CRYPTO_CB and that NO_WC_SHE_IMPORT_M123 is not defined.

Parameters:

- **she** initialized SHE context
- **m1** 16-byte M1 message (UID | KeyID | AuthID)
- **m1Sz** must be WC_SHE_M1_SZ (16)
- **m2** 32-byte M2 message (encrypted counter|flags|pad|newkey)
- **m2Sz** must be WC_SHE_M2_SZ (32)
- **m3** 16-byte M3 message (CMAC over M1|M2)
- **m3Sz** must be WC_SHE_M3_SZ (16)

See:

- wc_SHE_GenerateM1M2M3
- wc_SHE_GenerateM4M5
- wc_SHE_LoadKey

Return:

- 0 on success
- BAD_FUNC_ARG if she is NULL or any message size is incorrect

Example

```
int ret;
ret = wc_SHE_ImportM1M2M3(&she,
          m1, WC_SHE_M1_SZ,
          m2, WC_SHE_M2_SZ,
          m3, WC_SHE_M3_SZ);
```

C.66.2.11 function wc_SHE_GenerateM1M2M3

```
int wc_SHE_GenerateM1M2M3(
    wc_SHE * she,
    const byte * uid,
    word32 uidSz,
    byte authKeyId,
    const byte * authKey,
    word32 authKeySz,
    byte targetKeyId,
    const byte * newKey,
    word32 newKeySz,
    word32 counter,
    byte flags,
    byte * m1,
    word32 m1Sz,
    byte * m2,
    word32 m2Sz,
    byte * m3,
```

```
    word32 m3Sz
)
```

Generate SHE key update messages M1, M2, and M3 and write them to caller-provided buffers. Uses Miyaguchi-Preneel AES-128 KDF to derive K1 and K2 from the authorizing key, AES-CBC to encrypt the new key (M2), and AES-CMAC for authentication (M3).

Parameters:

- **she** initialized SHE context
- **uid** 15-byte SHE UID (120-bit ECU/module identifier)
- **uidSz** must be WC_SHE_UID_SZ (15)
- **authKeyId** 4-bit slot ID of the authorizing key
- **authKey** 16-byte value of the authorizing key
- **authKeySz** must be WC_SHE_KEY_SZ (16)
- **targetKeyId** 4-bit slot ID of the key being loaded
- **newKey** 16-byte value of the new key to load
- **newKeySz** must be WC_SHE_KEY_SZ (16)
- **counter** 28-bit monotonic counter value (must be strictly greater than the counter stored in the target slot)
- **flags** key protection flags (lower 4 bits)
- **m1** output buffer for M1 (16 bytes)
- **m1Sz** size of m1 buffer, must be >= WC_SHE_M1_SZ
- **m2** output buffer for M2 (32 bytes)
- **m2Sz** size of m2 buffer, must be >= WC_SHE_M2_SZ
- **m3** output buffer for M3 (16 bytes)
- **m3Sz** size of m3 buffer, must be >= WC_SHE_M3_SZ

See:

- wc_SHE_GenerateM4M5
- wc_SHE_ImportM1M2M3
- wc_SHE_LoadKey

Return:

- 0 on success
- BAD_FUNC_ARG if any required pointer is NULL, sizes are incorrect, or counter, flags, authKeyId or targetKeyId is wider than its packed field

Example

```
byte m1[WC_SHE_M1_SZ], m2[WC_SHE_M2_SZ], m3[WC_SHE_M3_SZ];
int ret;
ret = wc_SHE_GenerateM1M2M3(&she,
          uid, WC_SHE_UID_SZ,
          authKeyId, authKey, WC_SHE_KEY_SZ,
          targetKeyId, newKey, WC_SHE_KEY_SZ,
          counter, flags,
          m1, WC_SHE_M1_SZ,
          m2, WC_SHE_M2_SZ,
          m3, WC_SHE_M3_SZ);
```

C.66.2.12 function wc_SHE_GenerateM4M5

```
int wc_SHE_GenerateM4M5(
    wc_SHE * she,
    const byte * uid,
    word32 uidSz,
```

```
    byte authKeyId,
    byte targetKeyId,
    const byte * newKey,
    word32 newKeySz,
    word32 counter,
    byte * m4,
    word32 m4Sz,
    byte * m5,
    word32 m5Sz
)
```

Generate SHE verification messages M4 and M5 and write them to caller-provided buffers. Uses Miyaguchi-Preneel AES-128 KDF to derive K3 and K4 from the new key, AES-ECB for the M4 counter block, and AES-CMAC for M5. Independent of M1/M2/M3 and can be called on a separate context.

Parameters:

- **she** initialized SHE context
- **uid** 15-byte SHE UID (same UID used for M1)
- **uidSz** must be WC_SHE_UID_SZ (15)
- **authKeyId** 4-bit slot ID of the authorizing key (same as in M1)
- **targetKeyId** 4-bit slot ID of the key being loaded (same as in M1)
- **newKey** 16-byte value of the new key
- **newKeySz** must be WC_SHE_KEY_SZ (16)
- **counter** 28-bit monotonic counter (same value as in M2)
- **m4** output buffer for M4 (32 bytes)
- **m4Sz** size of m4 buffer, must be >= WC_SHE_M4_SZ
- **m5** output buffer for M5 (16 bytes)
- **m5Sz** size of m5 buffer, must be >= WC_SHE_M5_SZ

See:

- wc_SHE_GenerateM1M2M3
- wc_SHE_LoadKey_Verify

Return:

- 0 on success
- BAD_FUNC_ARG if any required pointer is NULL, sizes are incorrect, or counter, authKeyId or targetKeyId is wider than its packed field

Example

```
byte m4[WC_SHE_M4_SZ], m5[WC_SHE_M5_SZ];
int ret;
ret = wc_SHE_GenerateM4M5(&she,
          uid, WC_SHE_UID_SZ,
          authKeyId, targetKeyId,
          newKey, WC_SHE_KEY_SZ,
          counter,
          m4, WC_SHE_M4_SZ,
          m5, WC_SHE_M5_SZ);
```

C.66.2.13 function wc_SHE_LoadKey

```
int wc_SHE_LoadKey(
    void * heap,
    int devId,
    const byte * m1,
```

```
    word32 m1Sz,
    const byte * m2,
    word32 m2Sz,
    const byte * m3,
    word32 m3Sz,
    byte * m4,
    word32 m4Sz,
    byte * m5,
    word32 m5Sz
)
```

One-shot convenience wrapper: Init, ImportM1M2M3, GenerateM4M5 (via callback), Free. Dispatches to a hardware crypto callback that sends M1/M2/M3 to the HSM and returns M4/M5. Requires a valid devId (not INVALID_DEVID). Define NO_WC_SHE_LOADKEY to compile out.

Parameters:

- **heap** heap hint for internal allocations, or NULL
- **devId** crypto callback device ID (must not be INVALID_DEVID)
- **m1** 16-byte M1 input message
- **m1Sz** must be WC_SHE_M1_SZ (16)
- **m2** 32-byte M2 input message
- **m2Sz** must be WC_SHE_M2_SZ (32)
- **m3** 16-byte M3 input message
- **m3Sz** must be WC_SHE_M3_SZ (16)
- **m4** output buffer for M4 (32 bytes)
- **m4Sz** size of m4 buffer, must be >= WC_SHE_M4_SZ
- **m5** output buffer for M5 (16 bytes)
- **m5Sz** size of m5 buffer, must be >= WC_SHE_M5_SZ

See:

- wc_SHE_LoadKey_Id
- wc_SHE_LoadKey_Label
- wc_SHE_LoadKey_Verify
- wc_SHE_ImportM1M2M3
- wc_SHE_GenerateM4M5

Return:

- 0 on success
- BAD_FUNC_ARG if any required pointer is NULL or sizes are incorrect

Example

```
byte m4[WC_SHE_M4_SZ], m5[WC_SHE_M5_SZ];
int ret;
ret = wc_SHE_LoadKey(NULL, myDevId,
          m1, WC_SHE_M1_SZ,
          m2, WC_SHE_M2_SZ,
          m3, WC_SHE_M3_SZ,
          m4, WC_SHE_M4_SZ,
          m5, WC_SHE_M5_SZ);
```

C.66.2.14 function wc_SHE_LoadKey_Id

```
int wc_SHE_LoadKey_Id(
    unsigned char * id,
    int idLen,
```

```
    void * heap,
    int devId,
    const byte * m1,
    word32 m1Sz,
    const byte * m2,
    word32 m2Sz,
    const byte * m3,
    word32 m3Sz,
    byte * m4,
    word32 m4Sz,
    byte * m5,
    word32 m5Sz
)
```

One-shot Load Key with an opaque hardware key identifier. Same as wc_SHE_LoadKey but initializes the context with wc_SHE_Init_Id. Define NO_WC_SHE_LOADKEY to compile out.

Parameters:

- **id** opaque key identifier bytes
- **idLen** length of id in bytes
- **heap** heap hint for internal allocations, or NULL
- **devId** crypto callback device ID (must not be INVALID_DEVID)
- **m1** 16-byte M1 input message
- **m1Sz** must be WC_SHE_M1_SZ (16)
- **m2** 32-byte M2 input message
- **m2Sz** must be WC_SHE_M2_SZ (32)
- **m3** 16-byte M3 input message
- **m3Sz** must be WC_SHE_M3_SZ (16)
- **m4** output buffer for M4 (32 bytes)
- **m4Sz** size of m4 buffer, must be >= WC_SHE_M4_SZ
- **m5** output buffer for M5 (16 bytes)
- **m5Sz** size of m5 buffer, must be >= WC_SHE_M5_SZ

See:

- wc_SHE_LoadKey
- wc_SHE_LoadKey_Label
- wc_SHE_LoadKey_Verify_Id

Return:

- 0 on success
- BAD_FUNC_ARG if any required pointer is NULL or sizes are incorrect

Example

```
byte m4[WC_SHE_M4_SZ], m5[WC_SHE_M5_SZ];
unsigned char keyId[] = { 0x01, 0x02 };
int ret;
ret = wc_SHE_LoadKey_Id(keyId, sizeof(keyId), NULL, myDevId,
          m1, WC_SHE_M1_SZ,
          m2, WC_SHE_M2_SZ,
          m3, WC_SHE_M3_SZ,
          m4, WC_SHE_M4_SZ,
          m5, WC_SHE_M5_SZ);
```

C.66.2.15 function wc_SHE_LoadKey_Label

```
int wc_SHE_LoadKey_Label(
    const char * label,
    void * heap,
    int devId,
    const byte * m1,
    word32 m1Sz,
    const byte * m2,
    word32 m2Sz,
    const byte * m3,
    word32 m3Sz,
    byte * m4,
    word32 m4Sz,
    byte * m5,
    word32 m5Sz
)
```

One-shot Load Key with a human-readable key label. Same as wc_SHE_LoadKey but initializes the context with wc_SHE_Init_Label. Define NO_WC_SHE_LOADKEY to compile out.

Parameters:

- **label** NUL-terminated key label string
- **heap** heap hint for internal allocations, or NULL
- **devId** crypto callback device ID (must not be INVALID_DEVID)
- **m1** 16-byte M1 input message
- **m1Sz** must be WC_SHE_M1_SZ (16)
- **m2** 32-byte M2 input message
- **m2Sz** must be WC_SHE_M2_SZ (32)
- **m3** 16-byte M3 input message
- **m3Sz** must be WC_SHE_M3_SZ (16)
- **m4** output buffer for M4 (32 bytes)
- **m4Sz** size of m4 buffer, must be >= WC_SHE_M4_SZ
- **m5** output buffer for M5 (16 bytes)
- **m5Sz** size of m5 buffer, must be >= WC_SHE_M5_SZ

See:

- wc_SHE_LoadKey
- wc_SHE_LoadKey_Id
- wc_SHE_LoadKey_Verify_Label

Return:

- 0 on success
- BAD_FUNC_ARG if any required pointer is NULL or sizes are incorrect

Example

```
byte m4[WC_SHE_M4_SZ], m5[WC_SHE_M5_SZ];
int ret;
ret = wc_SHE_LoadKey_Label("ecu-master", NULL, myDevId,
          m1, WC_SHE_M1_SZ,
          m2, WC_SHE_M2_SZ,
          m3, WC_SHE_M3_SZ,
          m4, WC_SHE_M4_SZ,
          m5, WC_SHE_M5_SZ);
```

C.66.2.16 function wc_SHE_LoadKey_Verify

```
int wc_SHE_LoadKey_Verify(
    void * heap,
    int devId,
    const byte * m1,
    word32 m1Sz,
    const byte * m2,
    word32 m2Sz,
    const byte * m3,
    word32 m3Sz,
    byte * m4,
    word32 m4Sz,
    byte * m5,
    word32 m5Sz,
    const byte * m4Expected,
    word32 m4ExpectedSz,
    const byte * m5Expected,
    word32 m5ExpectedSz
)
```

One-shot Load Key with M4/M5 verification. Same as wc_SHE_LoadKey but also compares the M4/M5 returned by the HSM against caller-provided expected values using constant-time comparison. Returns SIG_VERIFY_E on mismatch. The actual M4/M5 are still written to the output buffers on failure. Define NO_WC_SHE_LOADKEY to compile out.

Parameters:

- **heap** heap hint for internal allocations, or NULL
- **devId** crypto callback device ID (must not be INVALID_DEVID)
- **m1** 16-byte M1 input message
- **m1Sz** must be WC_SHE_M1_SZ (16)
- **m2** 32-byte M2 input message
- **m2Sz** must be WC_SHE_M2_SZ (32)
- **m3** 16-byte M3 input message
- **m3Sz** must be WC_SHE_M3_SZ (16)
- **m4** output buffer for M4 (32 bytes)
- **m4Sz** size of m4 buffer, must be >= WC_SHE_M4_SZ
- **m5** output buffer for M5 (16 bytes)
- **m5Sz** size of m5 buffer, must be >= WC_SHE_M5_SZ
- **m4Expected** expected M4 verification message to compare against
- **m4ExpectedSz** must be WC_SHE_M4_SZ (32)
- **m5Expected** expected M5 verification message to compare against
- **m5ExpectedSz** must be WC_SHE_M5_SZ (16)

See:

- wc_SHE_LoadKey
- wc_SHE_LoadKey_Verify_Id
- wc_SHE_LoadKey_Verify_Label

Return:

- 0 on success
- SIG_VERIFY_E if M4/M5 do not match expected values
- BAD_FUNC_ARG if any required pointer is NULL or sizes are incorrect

Example

```
byte m4[WC_SHE_M4_SZ], m5[WC_SHE_M5_SZ];
int ret;
```

```
ret = wc_SHE_LoadKey_Verify(NULL, myDevId,
          m1, WC_SHE_M1_SZ,
          m2, WC_SHE_M2_SZ,
          m3, WC_SHE_M3_SZ,
          m4, WC_SHE_M4_SZ,
          m5, WC_SHE_M5_SZ,
          expectedM4, WC_SHE_M4_SZ,
          expectedM5, WC_SHE_M5_SZ);
if (ret == SIG_VERIFY_E) {
    // M4/M5 mismatch
}
```

C.66.2.17 function wc_SHE_LoadKey_Verify_Id

```
int wc_SHE_LoadKey_Verify_Id(
    unsigned char * id,
    int idLen,
    void * heap,
    int devId,
    const byte * m1,
    word32 m1Sz,
    const byte * m2,
    word32 m2Sz,
    const byte * m3,
    word32 m3Sz,
    byte * m4,
    word32 m4Sz,
    byte * m5,
    word32 m5Sz,
    const byte * m4Expected,
    word32 m4ExpectedSz,
    const byte * m5Expected,
    word32 m5ExpectedSz
)
```

One-shot Load Key with opaque key identifier and M4/M5 verification. Combines wc_SHE_LoadKey_Id and wc_SHE_LoadKey_Verify. Define NO_WC_SHE_LOADKEY to compile out.

Parameters:

- **id** opaque key identifier bytes
- **idLen** length of id in bytes
- **heap** heap hint for internal allocations, or NULL
- **devId** crypto callback device ID (must not be INVALID_DEVID)
- **m1** 16-byte M1 input message
- **m1Sz** must be WC_SHE_M1_SZ (16)
- **m2** 32-byte M2 input message
- **m2Sz** must be WC_SHE_M2_SZ (32)
- **m3** 16-byte M3 input message
- **m3Sz** must be WC_SHE_M3_SZ (16)
- **m4** output buffer for M4 (32 bytes)
- **m4Sz** size of m4 buffer, must be >= WC_SHE_M4_SZ
- **m5** output buffer for M5 (16 bytes)
- **m5Sz** size of m5 buffer, must be >= WC_SHE_M5_SZ
- **m4Expected** expected M4 verification message
- **m4ExpectedSz** must be WC_SHE_M4_SZ (32)

- **m5Expected** expected M5 verification message
- **m5ExpectedSz** must be WC_SHE_M5_SZ (16)

See:

- wc_SHE_LoadKey_Id
- wc_SHE_LoadKey_Verify
- wc_SHE_LoadKey_Verify_Label

Return:

- 0 on success
- SIG_VERIFY_E if M4/M5 do not match expected values
- BAD_FUNC_ARG if any required pointer is NULL or sizes are incorrect

Example

```
byte m4[WC_SHE_M4_SZ], m5[WC_SHE_M5_SZ];
unsigned char keyId[] = { 0x01, 0x02 };
int ret;
ret = wc_SHE_LoadKey_Verify_Id(keyId, sizeof(keyId), NULL, myDevId,
          m1, WC_SHE_M1_SZ, m2, WC_SHE_M2_SZ, m3, WC_SHE_M3_SZ,
          m4, WC_SHE_M4_SZ, m5, WC_SHE_M5_SZ,
          expectedM4, WC_SHE_M4_SZ, expectedM5, WC_SHE_M5_SZ);
```

C.66.2.18 function wc_SHE_LoadKey_Verify_Label

```
int wc_SHE_LoadKey_Verify_Label(
    const char * label,
    void * heap,
    int devId,
    const byte * m1,
    word32 m1Sz,
    const byte * m2,
    word32 m2Sz,
    const byte * m3,
    word32 m3Sz,
    byte * m4,
    word32 m4Sz,
    byte * m5,
    word32 m5Sz,
    const byte * m4Expected,
    word32 m4ExpectedSz,
    const byte * m5Expected,
    word32 m5ExpectedSz
)
```

One-shot Load Key with key label and M4/M5 verification. Combines wc_SHE_LoadKey_Label and wc_SHE_LoadKey_Verify. Define NO_WC_SHE_LOADKEY to compile out.

Parameters:

- **label** NUL-terminated key label string
- **heap** heap hint for internal allocations, or NULL
- **devId** crypto callback device ID (must not be INVALID_DEVID)
- **m1** 16-byte M1 input message
- **m1Sz** must be WC_SHE_M1_SZ (16)
- **m2** 32-byte M2 input message
- **m2Sz** must be WC_SHE_M2_SZ (32)

- **m3** 16-byte M3 input message
- **m3Sz** must be WC_SHE_M3_SZ (16)
- **m4** output buffer for M4 (32 bytes)
- **m4Sz** size of m4 buffer, must be >= WC_SHE_M4_SZ
- **m5** output buffer for M5 (16 bytes)
- **m5Sz** size of m5 buffer, must be >= WC_SHE_M5_SZ
- **m4Expected** expected M4 verification message
- **m4ExpectedSz** must be WC_SHE_M4_SZ (32)
- **m5Expected** expected M5 verification message
- **m5ExpectedSz** must be WC_SHE_M5_SZ (16)

See:

- wc_SHE_LoadKey_Label
- wc_SHE_LoadKey_Verify
- wc_SHE_LoadKey_Verify_Id

Return:

- 0 on success
- SIG_VERIFY_E if M4/M5 do not match expected values
- BAD_FUNC_ARG if any required pointer is NULL or sizes are incorrect

Example

```
byte m4[WC_SHE_M4_SZ], m5[WC_SHE_M5_SZ];
int ret;
ret = wc_SHE_LoadKey_Verify_Label("ecu-master", NULL, myDevId,
          m1, WC_SHE_M1_SZ, m2, WC_SHE_M2_SZ, m3, WC_SHE_M3_SZ,
          m4, WC_SHE_M4_SZ, m5, WC_SHE_M5_SZ,
          expectedM4, WC_SHE_M4_SZ, expectedM5, WC_SHE_M5_SZ);
```

C.66.2.19 function wc_SHE_ExportKey

```
int wc_SHE_ExportKey(
    wc_SHE * she,
    byte * m1,
    word32 m1Sz,
    byte * m2,
    word32 m2Sz,
    byte * m3,
    word32 m3Sz,
    byte * m4,
    word32 m4Sz,
    byte * m5,
    word32 m5Sz,
    const void * ctx
)
```

Export a key from hardware in SHE loadable format (M1-M5). Some HSMs allow exporting certain key slots (e.g. RAM key) so they can be re-loaded later via the SHE key update protocol. Requires WOLF_CRYPTO_CB and that NO_WC_SHE_EXPORTKEY is not defined. Any output buffer may be NULL to skip that message.

Parameters:

- **she** initialized SHE context
- **m1** output buffer for M1 (16 bytes), or NULL to skip
- **m1Sz** size of m1 buffer

- **m2** output buffer for M2 (32 bytes), or NULL to skip
- **m2Sz** size of m2 buffer
- **m3** output buffer for M3 (16 bytes), or NULL to skip
- **m3Sz** size of m3 buffer
- **m4** output buffer for M4 (32 bytes), or NULL to skip
- **m4Sz** size of m4 buffer
- **m5** output buffer for M5 (16 bytes), or NULL to skip
- **m5Sz** size of m5 buffer
- **ctx** read-only caller context passed to the callback

See:

- wc_SHE_ImportM1M2M3
- wc_SHE_LoadKey

Return:

- 0 on success
- BAD_FUNC_ARG if she is NULL
- CRYPTOCB_UNAVAILABLE if no callback is registered

Example

```
byte m1[WC_SHE_M1_SZ], m2[WC_SHE_M2_SZ], m3[WC_SHE_M3_SZ];
byte m4[WC_SHE_M4_SZ], m5[WC_SHE_M5_SZ];
int ret;
ret = wc_SHE_ExportKey(&she,
          m1, WC_SHE_M1_SZ,
          m2, WC_SHE_M2_SZ,
          m3, WC_SHE_M3_SZ,
          m4, WC_SHE_M4_SZ,
          m5, WC_SHE_M5_SZ,
          NULL);
```

C.66.2.20 function wc_SHE_AesMp16

```
int wc_SHE_AesMp16(
    Aes * aes,
    const byte * in,
    word32 inSz,
    byte * out
)
```

Miyaguchi-Preneel AES-128 one-way compression function. H_0 = 0, H_i = E_{H_{i-1}}(M_i) XOR M_i XOR H_{i-1}. Only valid for AES-128 where key size equals block size. This is an internal function exposed for testing purposes.

Parameters:

- **aes** caller-owned, already-initialized Aes structure
- **in** input data (e.g. BaseKey || KDF_Constant, 32 bytes)
- **inSz** length of input in bytes (zero-padded to block boundary)
- **out** output buffer for 16-byte compressed result

See:

- wc_SHE_GenerateM1M2M3
- wc_SHE_GenerateM4M5

Return:

- 0 on success
- BAD_FUNC_ARG if any pointer is NULL

Example

```
Aes aes;
byte input[32] = { ... };
byte output[WC_SHE_KEY_SZ];
int ret;
wc_AesInit(&aes, NULL, INVALID_DEVID);
ret = wc_SHE_AesMp16(&aes, input, sizeof(input), output);
wc_AesFree(&aes);
```

    const byte* m5Expected, word32 m5ExpectedSz);

int wc_SHE_ExportKey(wc_SHE* she,
                     byte* m1, word32 m1Sz,
                     byte* m2, word32 m2Sz,
                     byte* m3, word32 m3Sz,
                     byte* m4, word32 m4Sz,
                     byte* m5, word32 m5Sz,
                     const void* ctx);

int wc_SHE_AesMp16(Aes* aes, const byte* in, word32 inSz,
                   byte* out);
```

C.67 wc_slhdsa.h

C.67.1 Functions

	Name
int	**wc_SlhDsaKey_Init**(SlhDsaKey * key, enum SlhDsaParam param, void * heap, int devId)Initializes an SLH_DSA key object with the specified parameter set. Must be called before any other SLH_DSA operation. Use wc_SlhDsaKey_Free() to release resources when done.
int	**wc_SlhDsaKey_Init_id**(SlhDsaKey * key, enum SlhDsaParam param, const unsigned char * id, int len, void * heap, int devId)Initializes an SLH_DSA key with a device_side key identifier (id). Equivalent to wc_SlhDsaKey_Init() but also stashes a binary id that a crypto callback can use to look up the underlying key material on the device. Only available when wolfSSL is built with WOLF_PRIVATE_KEY_ID.

	Name
int	**wc_SlhDsaKey_Init_label**(SlhDsaKey * key, enum SlhDsaParam param, const char * label, void * heap, int devId)Initializes an SLH_DSA key with a device_side key label. Equivalent to wc_SlhDsaKey_Init() but also stashes a label string that a crypto callback can use to look up the underlying key material on the device. Only available when wolfSSL is built with WOLF_PRIVATE_KEY_ID.
void	**wc_SlhDsaKey_Free**(SlhDsaKey * key)Frees resources associated with an SLH-DSA key object.
int	**wc_SlhDsaKey_MakeKey**(SlhDsaKey * key, WC_RNG * rng)Generates a new SLH_DSA key pair using the RNG for randomness. The key must have been initialized with wc_SlhDsaKey_Init() first.
int	**wc_SlhDsaKey_MakeKeyWithRandom**(SlhDsaKey * key, const byte * sk_seed, word32 sk_seed_len, const byte * sk_prf, word32 sk_prf_len, const byte * pk_seed, word32 pk_seed_len)Generates an SLH-DSA key pair from caller-provided seed material. This is the deterministic key generation interface — given the same seeds, the same key pair is produced.
int	**wc_SlhDsaKey_SignDeterministic**(SlhDsaKey * key, const byte * ctx, byte ctxSz, const byte * msg, word32 msgSz, byte * sig, word32 * sigSz)Signs a message using the SLH_DSA external (pure) interface with deterministic randomness. This is FIPS 205 Algorithm 22 with opt_rand set to PK.seed. The message M is wrapped internally as M' = 0x00
int	**wc_SlhDsaKey_SignWithRandom**(SlhDsaKey * key, const byte * ctx, byte ctxSz, const byte * msg, word32 msgSz, byte * sig, word32 * sigSz, const byte * addRnd)Signs a message using the SLH_DSA external (pure) interface with caller-provided additional randomness. This is FIPS 205 Algorithm 22 with an explicit opt_rand value.
int	**wc_SlhDsaKey_Sign**(SlhDsaKey * key, const byte * ctx, byte ctxSz, const byte * msg, word32 msgSz, byte * sig, word32 * sigSz, WC_RNG * rng)Signs a message using the SLH_DSA external (pure) interface with RNG-provided randomness. This is the general-purpose signing function that uses the WC_RNG for opt_rand.

	Name
int	**wc_SlhDsaKey_Verify**(SlhDsaKey * key, const byte * ctx, byte ctxSz, const byte * msg, word32 msgSz, const byte * sig, word32 sigSz)Verifies an SLH_DSA signature over a message using the external (pure) interface. This is FIPS 205 Algorithm 24. The message is wrapped internally as M' = 0x00
int	**wc_SlhDsaKey_SignMsgDeterministic**(SlhDsaKey * key, const byte * mprime, word32 mprimeSz, byte * sig, word32 * sigSz)Signs using the SLH_DSA internal interface with deterministic randomness. Unlike the external interface, M' is provided directly by the caller — no wrapping is performed. This corresponds to FIPS 205 Algorithm 19 (slh_sign_internal) with opt_rand set to PK.seed.
int	**wc_SlhDsaKey_SignMsgWithRandom**(SlhDsaKey * key, const byte * mprime, word32 mprimeSz, byte * sig, word32 * sigSz, const byte * addRnd)Signs using the SLH_DSA internal interface with caller_provided additional randomness. M' is provided directly — no wrapping is performed. This corresponds to FIPS 205 Algorithm 19 (slh_sign_internal) with an explicit opt_rand value. See wc_SlhDsaKey_SignMsgDeterministic for the M' layout used by HashSLH-DSA.
int	**wc_SlhDsaKey_VerifyMsg**(SlhDsaKey * key, const byte * mprime, word32 mprimeSz, const byte * sig, word32 sigSz)Verifies an SLH_DSA signature using the internal interface. M' is provided directly — no wrapping is performed. This corresponds to FIPS 205 Algorithm 20 (slh_verify_internal).
int	**wc_SlhDsaKey_SignHashDeterministic**(SlhDsaKey * key, const byte * ctx, byte ctxSz, const byte * hash, word32 hashSz, enum wc_HashType hashType, byte * sig, word32 * sigSz)Signs a caller_pre_hashed message digest using the SLH_DSA external (HashSLH_DSA) interface with deterministic randomness, per FIPS 205 Algorithm 23 with the pre_hash domain separator (0x01). The caller must hash the application message with hashType first and pass the digest as hash; this function does NOT hash its input.

	Name
int	**wc_SlhDsaKey_SignHashWithRandom**(SlhDsaKey * key, const byte * ctx, byte ctxSz, const byte * hash, word32 hashSz, enum wc_HashType hashType, byte * sig, word32 * sigSz, const byte * addRnd)Signs a caller_pre_hashed message digest using the SLH_DSA external (HashSLH_DSA) interface with caller-provided additional randomness. The caller must hash the application message with hashType first and pass the digest as hash; this function does NOT hash its input.
int	**wc_SlhDsaKey_SignHash**(SlhDsaKey * key, const byte * ctx, byte ctxSz, const byte * hash, word32 hashSz, enum wc_HashType hashType, byte * sig, word32 * sigSz, WC_RNG * rng)Signs a caller_pre_hashed message digest using the SLH_DSA external (HashSLH_DSA) interface with RNG-provided randomness. The caller must hash the application message with hashType first and pass the digest as hash; this function does NOT hash its input.
int	**wc_SlhDsaKey_VerifyHash**(SlhDsaKey * key, const byte * ctx, byte ctxSz, const byte * hash, word32 hashSz, enum wc_HashType hashType, const byte * sig, word32 sigSz)Verifies an SLH_DSA signature using the external HashSLH_DSA interface (FIPS 205 Algorithm 25). The caller must hash the application message with hashType first and pass the digest as hash; this function does NOT hash its input.
int	**wc_SlhDsaKey_ImportPrivate**(SlhDsaKey * key, const byte * in, word32 inLen)Imports an SLH_DSA private key from a raw byte buffer. The buffer must contain the full private key (4*n bytes: SK.seed
int	**wc_SlhDsaKey_ImportPublic**(SlhDsaKey * key, const byte * in, word32 inLen)Imports an SLH_DSA public key from a raw byte buffer. The buffer must contain PK.seed
int	**wc_SlhDsaKey_CheckKey**(SlhDsaKey * key)Checks the consistency of an SLH-DSA key. For a key with both private and public components, verifies that the public key matches the private key.
int	**wc_SlhDsaKey_ExportPrivate**(SlhDsaKey * key, byte * out, word32 * outLen)Exports the private key from an SLH_DSA key object into a raw byte buffer (4*n bytes).
int	**wc_SlhDsaKey_ExportPublic**(SlhDsaKey * key, byte * out, word32 * outLen)Exports the public key from an SLH_DSA key object into a raw byte buffer (2*n bytes: PK.seed

	Name
int	**wc_SlhDsaKey_PrivateSize**(SlhDsaKey * key)Returns the private key size in bytes for the key's parameter set.
int	**wc_SlhDsaKey_PublicSize**(SlhDsaKey * key)Returns the public key size in bytes for the key's parameter set.
int	**wc_SlhDsaKey_SigSize**(SlhDsaKey * key)Returns the signature size in bytes for the key's parameter set.
int	**wc_SlhDsaKey_PrivateSizeFromParam**(enum SlhDsaParam param)Returns the private key size in bytes for the given parameter set without needing an initialized key object.
int	**wc_SlhDsaKey_PublicSizeFromParam**(enum SlhDsaParam param)Returns the public key size in bytes for the given parameter set without needing an initialized key object.
int	**wc_SlhDsaKey_SigSizeFromParam**(enum SlhDsaParam param)Returns the signature size in bytes for the given parameter set without needing an initialized key object.
int	**wc_SlhDsaKey_PrivateKeyDecode**(const byte * input, word32 * inOutIdx, SlhDsaKey * key, word32 inSz)Decodes a DER_encoded SLH_DSA private key in the PKCS#8 OneAsymmetricKey format defined by RFC 9909. The privateKey OCTET STRING contains the raw concatenation SK.seed
int	**wc_SlhDsaKey_PublicKeyDecode**(const byte * input, word32 * inOutIdx, SlhDsaKey * key, word32 inSz)Decodes a DER_encoded SLH_DSA public key in the SubjectPublicKeyInfo (SPKI) format. The SLH-DSA parameter set is detected from the AlgorithmIdentifier OID and key->params is updated accordingly.
int	**wc_SlhDsaKey_KeyToDer**(SlhDsaKey * key, byte * output, word32 inLen)Encodes an SLH_DSA private key to DER in the PKCS#8 OneAsymmetricKey format defined by RFC 9909. The privateKey OCTET STRING contains the raw 4*n bytes (SK.seed
int	**wc_SlhDsaKey_PrivateKeyToDer**(SlhDsaKey * key, byte * output, word32 inLen)Encodes an SLH-DSA private key to DER. RFC 9909 packs SK.seed

	Name
int	**wc_SlhDsaKey_PublicKeyToDer**(SlhDsaKey * key, byte * output, word32 inLen, int withAlg)Encodes an SLH_DSA public key to DER. When withAlg is non_zero the output is a full SubjectPublicKeyInfo structure (AlgorithmIdentifier plus BIT STRING). When withAlg is zero the output contains the raw public key bytes without the SPKI wrapping.

C.67.2 Functions Documentation

C.67.2.1 function wc_SlhDsaKey_Init

```
int wc_SlhDsaKey_Init(
    SlhDsaKey * key,
    enum SlhDsaParam param,
    void * heap,
    int devId
)
```

Initializes an SLH-DSA key object with the specified parameter set. Must be called before any other SLH-DSA operation. Use wc_SlhDsaKey_Free() to release resources when done.

Parameters:

- **key** Pointer to the SlhDsaKey to initialize.
- **param** Parameter set to use. One of: SLHDSA_SHAKE128S, SLHDSA_SHAKE128F, SLHDSA_SHAKE192S, SLHDSA_SHAKE192F, SLHDSA_SHAKE256S, SLHDSA_SHAKE256F, SLHDSA_SHA2_128S, SLHDSA_SHA2_128F, SLHDSA_SHA2_192S, SLHDSA_SHA2_192F, SLHDSA_SHA2_256S, SLHDSA_SHA2_256F.
- **heap** Pointer to heap hint for dynamic memory allocation. May be NULL.
- **devId** Device identifier for hardware crypto callbacks. Use INVALID_DEVID for software-only.

See:

- wc_SlhDsaKey_Free
- wc_SlhDsaKey_MakeKey

Return:

- 0 on success.
- BAD_FUNC_ARG if key is NULL or param is invalid.

SLH-DSA (FIPS 205) is a stateless hash-based digital signature algorithm. Parameter sets control the hash function (SHAKE or SHA2), security level (128, 192, 256), and speed/size tradeoff (s = small signatures, f = fast signing).

Example

```
SlhDsaKey key;
int ret;

ret = wc_SlhDsaKey_Init(&key, SLHDSA_SHAKE128F, NULL, INVALID_DEVID);
if (ret != 0) {
    // error initializing key
}
```

```
// ... use key ...
wc_SlhDsaKey_Free(&key);
```

C.67.2.2 function wc_SlhDsaKey_Init_id

```
int wc_SlhDsaKey_Init_id(
    SlhDsaKey * key,
    enum SlhDsaParam param,
    const unsigned char * id,
    int len,
    void * heap,
    int devId
)
```

Initializes an SLH-DSA key with a device-side key identifier (id). Equivalent to wc_SlhDsaKey_Init() but also stashes a binary id that a crypto callback can use to look up the underlying key material on the device. Only available when wolfSSL is built with WOLF_PRIVATE_KEY_ID.

Parameters:

- **key** Pointer to the SlhDsaKey to initialize.
- **param** Parameter set to use (see wc_SlhDsaKey_Init).
- **id** Pointer to the device-side key identifier bytes. May be NULL if len is 0.
- **len** Number of bytes in id. Must be in [0, SLHDSA_MAX_ID_LEN].
- **heap** Pointer to heap hint for dynamic memory allocation. May be NULL.
- **devId** Device identifier for the crypto callback. Should be a registered cb devId, not INVALID_DEVID, for the id to be meaningful.

See:

- wc_SlhDsaKey_Init
- wc_SlhDsaKey_Init_label
- wc_SlhDsaKey_Free

Return:

- 0 on success.
- BAD_FUNC_ARG if key is NULL, or if id is NULL while len > 0.
- BUFFER_E if len is negative or greater than SLHDSA_MAX_ID_LEN.

The id is copied into the key object; the caller may free its buffer immediately after this call returns.

Example

```
SlhDsaKey key;
unsigned char id[8] = { 0x01, 0x02, 0x03, 0x04,
                        0x05, 0x06, 0x07, 0x08 };
int ret;

ret = wc_SlhDsaKey_Init_id(&key, SLHDSA_SHAKE128F, id, sizeof(id),
    NULL, devId);
if (ret != 0) {
    // error initializing key with id
}
// ... use key, the cb resolves id -> device key ...
wc_SlhDsaKey_Free(&key);
```

C.67.2.3 function wc_SlhDsaKey_Init_label

```
int wc_SlhDsaKey_Init_label(
    SlhDsaKey * key,
    enum SlhDsaParam param,
    const char * label,
    void * heap,
    int devId
)
```

Initializes an SLH-DSA key with a device-side key label. Equivalent to wc_SlhDsaKey_Init() but also stashes a label string that a crypto callback can use to look up the underlying key material on the device. Only available when wolfSSL is built with WOLF_PRIVATE_KEY_ID.

Parameters:

- **key** Pointer to the SlhDsaKey to initialize.
- **param** Parameter set to use (see wc_SlhDsaKey_Init).
- **label** NUL-terminated device-side key label string.
- **heap** Pointer to heap hint for dynamic memory allocation. May be NULL.
- **devId** Device identifier for the crypto callback. Should be a registered cb devId, not INVALID_DEVID, for the label to be meaningful.

See:

- wc_SlhDsaKey_Init
- wc_SlhDsaKey_Init_id
- wc_SlhDsaKey_Free

Return:

- 0 on success.
- BAD_FUNC_ARG if key or label is NULL.
- BUFFER_E if label is empty or longer than SLHDSA_MAX_LABEL_LEN.

The label length is taken via XSTRLEN, so embedded NUL bytes terminate the label. The copy stored in key->label is NOT guaranteed to be NUL-terminated (when the input is exactly SLHDSA_MAX_LABEL_LEN bytes the entire array is consumed). Consumers must read at most key->labelLen bytes — do not pass key->label to C-string APIs.

Example

```
SlhDsaKey key;
int ret;

ret = wc_SlhDsaKey_Init_label(&key, SLHDSA_SHAKE128F,
    "device-key-1", NULL, devId);
if (ret != 0) {
    // error initializing key with label
}
// ... use key, the cb resolves label -> device key ...
wc_SlhDsaKey_Free(&key);
```

C.67.2.4 function wc_SlhDsaKey_Free

```
void wc_SlhDsaKey_Free(
    SlhDsaKey * key
)
```

Frees resources associated with an SLH-DSA key object.

Parameters:

- **key** Pointer to the SlhDsaKey to free. May be NULL.

See: wc_SlhDsaKey_Init

Example

```
SlhDsaKey key;
wc_SlhDsaKey_Init(&key, SLHDSA_SHAKE128F, NULL, INVALID_DEVID);
// ... use key ...
wc_SlhDsaKey_Free(&key);
```

C.67.2.5 function wc_SlhDsaKey_MakeKey

```
int wc_SlhDsaKey_MakeKey(
    SlhDsaKey * key,
    WC_RNG * rng
)
```

Generates a new SLH-DSA key pair using the RNG for randomness. The key must have been initialized with wc_SlhDsaKey_Init() first.

Parameters:

- **key** Pointer to an initialized SlhDsaKey.
- **rng** Pointer to an initialized WC_RNG.

See:

- wc_SlhDsaKey_Init
- wc_SlhDsaKey_MakeKeyWithRandom

Return:

- 0 on success.
- BAD_FUNC_ARG if key or rng is NULL, or key is not initialized.

Example

```
SlhDsaKey key;
WC_RNG rng;
int ret;

wc_InitRng(&rng);
wc_SlhDsaKey_Init(&key, SLHDSA_SHAKE128F, NULL, INVALID_DEVID);
ret = wc_SlhDsaKey_MakeKey(&key, &rng);
if (ret != 0) {
    // error generating key
}
```

C.67.2.6 function wc_SlhDsaKey_MakeKeyWithRandom

```
int wc_SlhDsaKey_MakeKeyWithRandom(
    SlhDsaKey * key,
    const byte * sk_seed,
    word32 sk_seed_len,
    const byte * sk_prf,
    word32 sk_prf_len,
    const byte * pk_seed,
    word32 pk_seed_len
)
```

Generates an SLH-DSA key pair from caller-provided seed material. This is the deterministic key generation interface — given the same seeds, the same key pair is produced.

Parameters:

- **key** Pointer to an initialized SlhDsaKey.
- **sk_seed** Secret key seed (n bytes).
- **sk_seed_len** Length of sk_seed.
- **sk_prf** Secret key PRF seed (n bytes).
- **sk_prf_len** Length of sk_prf.
- **pk_seed** Public key seed (n bytes).
- **pk_seed_len** Length of pk_seed.

See: wc_SlhDsaKey_MakeKey

Return:

- 0 on success.
- BAD_FUNC_ARG if key or any seed pointer is NULL, or lengths do not match the parameter set's n value.

Example

```
SlhDsaKey key;
byte sk_seed[16], sk_prf[16], pk_seed[16]; // n=16 for 128-bit params
int ret;

// fill seeds with known values (e.g. from NIST test vectors)
wc_SlhDsaKey_Init(&key, SLHDSA_SHAKE128F, NULL, INVALID_DEVID);
ret = wc_SlhDsaKey_MakeKeyWithRandom(&key,
    sk_seed, sizeof(sk_seed),
    sk_prf, sizeof(sk_prf),
    pk_seed, sizeof(pk_seed));
```

C.67.2.7 function wc_SlhDsaKey_SignDeterministic

```
int wc_SlhDsaKey_SignDeterministic(
    SlhDsaKey * key,
    const byte * ctx,
    byte ctxSz,
    const byte * msg,
    word32 msgSz,
    byte * sig,
    word32 * sigSz
)
```

Signs a message using the SLH-DSA external (pure) interface with deterministic randomness. This is FIPS 205 Algorithm 22 with opt_rand set to PK.seed. The message M is wrapped internally as M' = 0x00 || len(ctx) || ctx || M before signing.

Parameters:

- **key** Pointer to a private SlhDsaKey.
- **ctx** Context string for domain separation. May be NULL if ctxSz is 0.
- **ctxSz** Length of the context string (0-255).
- **msg** Pointer to the message to sign. May be NULL if msgSz is 0.
- **msgSz** Length of the message.
- **sig** Buffer to receive the signature.
- **sigSz** On input, size of sig buffer. On output, actual signature length.

See:

- wc_SlhDsaKey_SignWithRandom
- wc_SlhDsaKey_Sign
- wc_SlhDsaKey_Verify

Return:

- 0 on success.
- BAD_FUNC_ARG if key, sig, or sigSz is NULL, or msg is NULL but msgSz is greater than 0.
- BAD_LENGTH_E if the output buffer is too small.

Example

```
SlhDsaKey key;
byte sig[WC_SLHDSA_MAX_SIG_LEN];
word32 sigSz = sizeof(sig);
byte msg[] = "Hello World!";
int ret;

// key already generated via wc_SlhDsaKey_MakeKey()
ret = wc_SlhDsaKey_SignDeterministic(&key, NULL, 0,
    msg, sizeof(msg), sig, &sigSz);
```

C.67.2.8 function wc_SlhDsaKey_SignWithRandom

```
int wc_SlhDsaKey_SignWithRandom(
    SlhDsaKey * key,
    const byte * ctx,
    byte ctxSz,
    const byte * msg,
    word32 msgSz,
    byte * sig,
    word32 * sigSz,
    const byte * addRnd
)
```

Signs a message using the SLH-DSA external (pure) interface with caller-provided additional randomness. This is FIPS 205 Algorithm 22 with an explicit opt_rand value.

Parameters:

- **key** Pointer to a private SlhDsaKey.
- **ctx** Context string. May be NULL if ctxSz is 0.
- **ctxSz** Length of the context string (0-255).
- **msg** Pointer to the message to sign. May be NULL if msgSz is 0.
- **msgSz** Length of the message.
- **sig** Buffer to receive the signature.
- **sigSz** On input, size of sig buffer. On output, actual signature length.
- **addRnd** Additional randomness (n bytes, where n is the parameter set's security parameter).

See:

- wc_SlhDsaKey_SignDeterministic
- wc_SlhDsaKey_Sign

Return:

- 0 on success.

- BAD_FUNC_ARG if key, sig, sigSz, or addRnd is NULL, or msg is NULL but msgSz is greater than 0.

Example

```
SlhDsaKey key;
byte sig[WC_SLHDSA_MAX_SIG_LEN];
word32 sigSz = sizeof(sig);
byte msg[] = "Hello World!";
byte addRnd[16]; // n=16 for 128-bit params
int ret;

wc_RNG_GenerateBlock(&rng, addRnd, sizeof(addRnd));
ret = wc_SlhDsaKey_SignWithRandom(&key, NULL, 0,
    msg, sizeof(msg), sig, &sigSz, addRnd);
```

C.67.2.9 function wc_SlhDsaKey_Sign

```
int wc_SlhDsaKey_Sign(
    SlhDsaKey * key,
    const byte * ctx,
    byte ctxSz,
    const byte * msg,
    word32 msgSz,
    byte * sig,
    word32 * sigSz,
    WC_RNG * rng
)
```

Signs a message using the SLH-DSA external (pure) interface with RNG-provided randomness. This is the general-purpose signing function that uses the WC_RNG for opt_rand.

Parameters:

- **key** Pointer to a private SlhDsaKey.
- **ctx** Context string. May be NULL if ctxSz is 0.
- **ctxSz** Length of the context string (0-255).
- **msg** Pointer to the message to sign. May be NULL if msgSz is 0.
- **msgSz** Length of the message.
- **sig** Buffer to receive the signature.
- **sigSz** On input, size of sig buffer. On output, actual signature length.
- **rng** Pointer to an initialized WC_RNG.

See:

- wc_SlhDsaKey_SignDeterministic
- wc_SlhDsaKey_Verify

Return:

- 0 on success.
- BAD_FUNC_ARG if key, sig, sigSz, or rng is NULL, or msg is NULL but msgSz is greater than 0.

Example

```
SlhDsaKey key;
WC_RNG rng;
byte sig[WC_SLHDSA_MAX_SIG_LEN];
word32 sigSz = sizeof(sig);
byte msg[] = "Hello World!";
```

```
int ret;

ret = wc_SlhDsaKey_Sign(&key, NULL, 0,
    msg, sizeof(msg), sig, &sigSz, &rng);
```

C.67.2.10 function wc_SlhDsaKey_Verify

```
int wc_SlhDsaKey_Verify(
    SlhDsaKey * key,
    const byte * ctx,
    byte ctxSz,
    const byte * msg,
    word32 msgSz,
    const byte * sig,
    word32 sigSz
)
```

Verifies an SLH-DSA signature over a message using the external (pure) interface. This is FIPS 205 Algorithm 24. The message is wrapped internally as M' = 0x00 || len(ctx) || ctx || M before verification.

Parameters:

- **key** Pointer to a public SlhDsaKey.
- **ctx** Context string. May be NULL if ctxSz is 0.
- **ctxSz** Length of the context string (0-255).
- **msg** Pointer to the message to verify. May be NULL if msgSz is 0.
- **msgSz** Length of the message.
- **sig** Pointer to the signature to verify.
- **sigSz** Length of the signature.

See:

- wc_SlhDsaKey_Sign
- wc_SlhDsaKey_SignDeterministic

Return:

- 0 on success (signature valid).
- BAD_FUNC_ARG if key or sig is NULL, or ctx is NULL but ctxSz is greater than 0, or msg is NULL but msgSz is greater than 0.
- BAD_LENGTH_E if sigSz does not match the parameter set's signature length.
- MISSING_KEY if the public key has not been set.
- SIG_VERIFY_E if the signature is invalid.

Example

```
SlhDsaKey key;
byte sig[...]; // previously generated signature
word32 sigSz;
byte msg[] = "Hello World!";
int ret;

ret = wc_SlhDsaKey_Verify(&key, NULL, 0,
    msg, sizeof(msg), sig, sigSz);
if (ret == 0) {
    // signature is valid
}
```

C.67.2.11 function wc_SlhDsaKey_SignMsgDeterministic

```
int wc_SlhDsaKey_SignMsgDeterministic(
    SlhDsaKey * key,
    const byte * mprime,
    word32 mprimeSz,
    byte * sig,
    word32 * sigSz
)
```

Signs using the SLH-DSA internal interface with deterministic randomness. Unlike the external interface, M' is provided directly by the caller — no wrapping is performed. This corresponds to FIPS 205 Algorithm 19 (slh_sign_internal) with opt_rand set to PK.seed.

Parameters:

- **key** Pointer to a private SlhDsaKey.
- **mprime** Pointer to the pre-constructed M' message.
- **mprimeSz** Length of M'.
- **sig** Buffer to receive the signature.
- **sigSz** On input, size of sig buffer. On output, actual signature length.

See:

- wc_SlhDsaKey_SignMsgWithRandom
- wc_SlhDsaKey_VerifyMsg
- wc_SlhDsaKey_SignDeterministic
- wc_SlhDsaKey_SignHashDeterministic

Return:

- 0 on success.
- BAD_FUNC_ARG if key, mprime, sig, or sigSz is NULL.
- BAD_LENGTH_E if sigSz is less than the parameter set's signature length.
- MISSING_KEY if the private key has not been set.

Use this when the ACVP signatureInterface=internal test framework or a protocol layer has already constructed M'. For HashSLH-DSA the caller builds M' as 0x01 || ctxSz || ctx || OID(hashType) || PHM and passes it in here, where PHM is the hash of the application message under hashType.

Example

```
SlhDsaKey key;
byte sig[WC_SLHDSA_MAX_SIG_LEN];
word32 sigSz = sizeof(sig);
byte mprime[] = { ... }; // pre-constructed M'
int ret;

ret = wc_SlhDsaKey_SignMsgDeterministic(&key,
    mprime, sizeof(mprime), sig, &sigSz);
```

C.67.2.12 function wc_SlhDsaKey_SignMsgWithRandom

```
int wc_SlhDsaKey_SignMsgWithRandom(
    SlhDsaKey * key,
    const byte * mprime,
    word32 mprimeSz,
    byte * sig,
    word32 * sigSz,
```

```
    const byte * addRnd
)
```

Signs using the SLH-DSA internal interface with caller-provided additional randomness. M' is provided directly — no wrapping is performed. This corresponds to FIPS 205 Algorithm 19 (slh_sign_internal) with an explicit opt_rand value. See wc_SlhDsaKey_SignMsgDeterministic for the M' layout used by HashSLH-DSA.

Parameters:

- **key** Pointer to a private SlhDsaKey.
- **mprime** Pointer to the pre-constructed M' message.
- **mprimeSz** Length of M'.
- **sig** Buffer to receive the signature.
- **sigSz** On input, size of sig buffer. On output, actual signature length.
- **addRnd** Additional randomness (n bytes).

See:

- wc_SlhDsaKey_SignMsgDeterministic
- wc_SlhDsaKey_VerifyMsg
- wc_SlhDsaKey_SignHashWithRandom

Return:

- 0 on success.
- BAD_FUNC_ARG if key, mprime, sig, sigSz, or addRnd is NULL.
- BAD_LENGTH_E if sigSz is less than the parameter set's signature length.
- MISSING_KEY if the private key has not been set.

Example

```
SlhDsaKey key;
byte sig[WC_SLHDSA_MAX_SIG_LEN];
word32 sigSz = sizeof(sig);
byte mprime[] = { ... };
byte addRnd[16];
int ret;

wc_RNG_GenerateBlock(&rng, addRnd, sizeof(addRnd));
ret = wc_SlhDsaKey_SignMsgWithRandom(&key,
    mprime, sizeof(mprime), sig, &sigSz, addRnd);
```

C.67.2.13 function wc_SlhDsaKey_VerifyMsg

```
int wc_SlhDsaKey_VerifyMsg(
    SlhDsaKey * key,
    const byte * mprime,
    word32 mprimeSz,
    const byte * sig,
    word32 sigSz
)
```

Verifies an SLH-DSA signature using the internal interface. M' is provided directly — no wrapping is performed. This corresponds to FIPS 205 Algorithm 20 (slh_verify_internal).

Parameters:

- **key** Pointer to a public SlhDsaKey.
- **mprime** Pointer to the pre-constructed M' message.

- **mprimeSz** Length of M'.
- **sig** Pointer to the signature to verify.
- **sigSz** Length of the signature.

See:

- wc_SlhDsaKey_SignMsgDeterministic
- wc_SlhDsaKey_Verify
- wc_SlhDsaKey_VerifyHash

Return:

- 0 on success (signature valid).
- BAD_FUNC_ARG if key, mprime, or sig is NULL.
- BAD_LENGTH_E if sigSz does not match the parameter set's signature length.
- MISSING_KEY if the public key has not been set.
- SIG_VERIFY_E if the signature is invalid.

Example

```
SlhDsaKey key;
byte sig[...]; // previously generated signature
word32 sigSz;
byte mprime[] = { ... };
int ret;

ret = wc_SlhDsaKey_VerifyMsg(&key,
    mprime, sizeof(mprime), sig, sigSz);
if (ret == 0) {
    // signature is valid
}
```

C.67.2.14 function wc_SlhDsaKey_SignHashDeterministic

```
int wc_SlhDsaKey_SignHashDeterministic(
    SlhDsaKey * key,
    const byte * ctx,
    byte ctxSz,
    const byte * hash,
    word32 hashSz,
    enum wc_HashType hashType,
    byte * sig,
    word32 * sigSz
)
```

Signs a caller-pre-hashed message digest using the SLH-DSA external (HashSLH-DSA) interface with deterministic randomness, per FIPS 205 Algorithm 23 with the pre-hash domain separator (0x01). The caller must hash the application message with hashType first and pass the digest as hash; this function does NOT hash its input.

Parameters:

- **key** Pointer to a private SlhDsaKey.
- **ctx** Context string. May be NULL if ctxSz is 0.
- **ctxSz** Length of the context string (0-255).
- **hash** Pointer to the pre-hashed message digest. hashSz must equal the digest size for hashType.
- **hashSz** Length of the digest in bytes.
- **hashType** Hash algorithm used for pre-hashing (selects OID). Supported: WC_HASH_TYPE_SHA224, WC_HASH_TYPE_SHA256, WC_HASH_TYPE_SHA384, WC_HASH_TYPE_SHA512, WC_HASH_TYPE_SHA512_224,

WC_HASH_TYPE_SHA512_256, WC_HASH_TYPE_SHAKE128, WC_HASH_TYPE_SHAKE256, WC_HASH_TYPE_SHA3_22
WC_HASH_TYPE_SHA3_256, WC_HASH_TYPE_SHA3_384, WC_HASH_TYPE_SHA3_512.
- **sig** Buffer to receive the signature.
- **sigSz** On input, size of sig buffer. On output, actual signature length.

See:

- wc_SlhDsaKey_SignHashWithRandom
- wc_SlhDsaKey_SignHash
- wc_SlhDsaKey_VerifyHash
- wc_SlhDsaKey_SignMsgDeterministic

Return:

- 0 on success.
- BAD_FUNC_ARG if key, hash, sig, or sigSz is NULL.
- BAD_FUNC_ARG if hashType is WC_HASH_TYPE_NONE, or if the pre-hash gives less collision strength than the parameter set's security category (FIPS 205 sec. 10.2).
- BAD_LENGTH_E if hashSz does not equal the digest size for hashType (32 for SHAKE128, 64 for SHAKE256 per FIPS 205 Section 10.2.2).
- NOT_COMPILED_IN if hashType is not supported in this build.
- MISSING_KEY if the private key has not been set.

Example

```
SlhDsaKey key;
byte sig[WC_SLHDSA_MAX_SIG_LEN];
word32 sigSz = sizeof(sig);
byte msg[] = "Hello World!";
byte digest[WC_SHA256_DIGEST_SIZE];
int ret;

wc_Sha256Hash(msg, sizeof(msg), digest);
ret = wc_SlhDsaKey_SignHashDeterministic(&key, NULL, 0,
    digest, sizeof(digest), WC_HASH_TYPE_SHA256, sig, &sigSz);
```

C.67.2.15 function wc_SlhDsaKey_SignHashWithRandom

```
int wc_SlhDsaKey_SignHashWithRandom(
    SlhDsaKey * key,
    const byte * ctx,
    byte ctxSz,
    const byte * hash,
    word32 hashSz,
    enum wc_HashType hashType,
    byte * sig,
    word32 * sigSz,
    const byte * addRnd
)
```

Signs a caller-pre-hashed message digest using the SLH-DSA external (HashSLH-DSA) interface with caller-provided additional randomness. The caller must hash the application message with hashType first and pass the digest as hash; this function does NOT hash its input.

Parameters:

- **key** Pointer to a private SlhDsaKey.
- **ctx** Context string. May be NULL if ctxSz is 0.
- **ctxSz** Length of the context string (0-255).

- **hash** Pointer to the pre-hashed message digest. hashSz must equal the digest size for hashType.
- **hashSz** Length of the digest in bytes.
- **hashType** Hash algorithm used for pre-hashing (selects OID).
- **sig** Buffer to receive the signature.
- **sigSz** On input, size of sig buffer. On output, actual signature length.
- **addRnd** Additional randomness (n bytes).

See:

- wc_SlhDsaKey_SignHashDeterministic
- wc_SlhDsaKey_VerifyHash
- wc_SlhDsaKey_SignMsgWithRandom

Return:

- 0 on success.
- BAD_FUNC_ARG if key, hash, sig, sigSz, or addRnd is NULL.
- BAD_FUNC_ARG if hashType is WC_HASH_TYPE_NONE, or if the pre-hash gives less collision strength than the parameter set's security category (FIPS 205 sec. 10.2).
- BAD_LENGTH_E if hashSz does not equal the digest size for hashType (32 for SHAKE128, 64 for SHAKE256 per FIPS 205 Section 10.2.2).
- NOT_COMPILED_IN if hashType is not supported in this build.

C.67.2.16 function wc_SlhDsaKey_SignHash

```
int wc_SlhDsaKey_SignHash(
    SlhDsaKey * key,
    const byte * ctx,
    byte ctxSz,
    const byte * hash,
    word32 hashSz,
    enum wc_HashType hashType,
    byte * sig,
    word32 * sigSz,
    WC_RNG * rng
)
```

Signs a caller-pre-hashed message digest using the SLH-DSA external (HashSLH-DSA) interface with RNG-provided randomness. The caller must hash the application message with hashType first and pass the digest as hash; this function does NOT hash its input.

Parameters:

- **key** Pointer to a private SlhDsaKey.
- **ctx** Context string. May be NULL if ctxSz is 0.
- **ctxSz** Length of the context string (0-255).
- **hash** Pointer to the pre-hashed message digest. hashSz must equal the digest size for hashType.
- **hashSz** Length of the digest in bytes.
- **hashType** Hash algorithm used for pre-hashing (selects OID).
- **sig** Buffer to receive the signature.
- **sigSz** On input, size of sig buffer. On output, actual signature length.
- **rng** Pointer to an initialized WC_RNG.

See:

- wc_SlhDsaKey_SignHashDeterministic
- wc_SlhDsaKey_VerifyHash
- wc_SlhDsaKey_SignMsgDeterministic

Return:

- 0 on success.
- BAD_FUNC_ARG if key, hash, sig, sigSz, or rng is NULL.
- BAD_FUNC_ARG if hashType is WC_HASH_TYPE_NONE, or if the pre-hash gives less collision strength than the parameter set's security category (FIPS 205 sec. 10.2).
- BAD_LENGTH_E if hashSz does not equal the digest size for hashType (32 for SHAKE128, 64 for SHAKE256 per FIPS 205 Section 10.2.2).
- NOT_COMPILED_IN if hashType is not supported in this build.

C.67.2.17 function wc_SlhDsaKey_VerifyHash

```
int wc_SlhDsaKey_VerifyHash(
    SlhDsaKey * key,
    const byte * ctx,
    byte ctxSz,
    const byte * hash,
    word32 hashSz,
    enum wc_HashType hashType,
    const byte * sig,
    word32 sigSz
)
```

Verifies an SLH-DSA signature using the external HashSLH-DSA interface (FIPS 205 Algorithm 25). The caller must hash the application message with hashType first and pass the digest as hash; this function does NOT hash its input.

Parameters:

- **key** Pointer to a public SlhDsaKey.
- **ctx** Context string. May be NULL if ctxSz is 0.
- **ctxSz** Length of the context string (0-255).
- **hash** Pointer to the pre-hashed message digest. hashSz must equal the digest size for hashType.
- **hashSz** Length of the digest in bytes.
- **hashType** Hash algorithm used for pre-hashing (selects OID). Must match the hash used during signing.
- **sig** Pointer to the signature to verify.
- **sigSz** Length of the signature.

See:

- wc_SlhDsaKey_SignHashDeterministic
- wc_SlhDsaKey_Verify
- wc_SlhDsaKey_VerifyMsg

Return:

- 0 on success (signature valid).
- BAD_FUNC_ARG if key, hash, or sig is NULL.
- BAD_FUNC_ARG if hashType is WC_HASH_TYPE_NONE, or if the pre-hash gives less collision strength than the parameter set's security category (FIPS 205 sec. 10.2).
- BAD_LENGTH_E if sigSz does not match the parameter set, or if hashSz does not equal the digest size for hashType (32 for SHAKE128, 64 for SHAKE256 per FIPS 205 Section 10.2.2).
- NOT_COMPILED_IN if hashType is not supported in this build.
- MISSING_KEY if the public key has not been set.
- SIG_VERIFY_E if the signature is invalid.

Example

```
SlhDsaKey key;
byte sig[...];
word32 sigSz;
byte msg[] = "Hello World!";
byte digest[WC_SHA256_DIGEST_SIZE];
int ret;

wc_Sha256Hash(msg, sizeof(msg), digest);
ret = wc_SlhDsaKey_VerifyHash(&key, NULL, 0,
    digest, sizeof(digest), WC_HASH_TYPE_SHA256, sig, sigSz);
if (ret == 0) {
    // signature is valid
}
```

C.67.2.18 function wc_SlhDsaKey_ImportPrivate

```
int wc_SlhDsaKey_ImportPrivate(
    SlhDsaKey * key,
    const byte * in,
    word32 inLen
)
```

Imports an SLH-DSA private key from a raw byte buffer. The buffer must contain the full private key (4*n bytes: SK.seed || SK.prf || PK.seed || PK.root). After import, the key can be used for signing.

Parameters:

- **key** Pointer to an initialized SlhDsaKey.
- **in** Buffer containing the raw private key bytes.
- **inLen** Length of the input buffer.

See:

- wc_SlhDsaKey_ExportPrivate
- wc_SlhDsaKey_ImportPublic

Return:

- 0 on success.
- BAD_FUNC_ARG if key or in is NULL, or inLen does not match the expected private key size for the parameter set.

Example

```
SlhDsaKey key;
byte privKey[...]; // 4*n bytes
int ret;

wc_SlhDsaKey_Init(&key, SLHDSA_SHAKE128F, NULL, INVALID_DEVID);
ret = wc_SlhDsaKey_ImportPrivate(&key, privKey, sizeof(privKey));
```

C.67.2.19 function wc_SlhDsaKey_ImportPublic

```
int wc_SlhDsaKey_ImportPublic(
    SlhDsaKey * key,
    const byte * in,
    word32 inLen
)
```

Imports an SLH-DSA public key from a raw byte buffer. The buffer must contain PK.seed || PK.root (2*n bytes). After import, the key can be used for verification.

Parameters:

- **key** Pointer to an initialized SlhDsaKey.
- **in** Buffer containing the raw public key bytes.
- **inLen** Length of the input buffer.

See:

- wc_SlhDsaKey_ExportPublic
- wc_SlhDsaKey_ImportPrivate

Return:

- 0 on success.
- BAD_FUNC_ARG if key or in is NULL, or inLen does not match the expected public key size.

Example

```
SlhDsaKey key;
byte pubKey[...]; // 2*n bytes
int ret;

wc_SlhDsaKey_Init(&key, SLHDSA_SHAKE128F, NULL, INVALID_DEVID);
ret = wc_SlhDsaKey_ImportPublic(&key, pubKey, sizeof(pubKey));
```

C.67.2.20 function wc_SlhDsaKey_CheckKey

```
int wc_SlhDsaKey_CheckKey(
    SlhDsaKey * key
)
```

Checks the consistency of an SLH-DSA key. For a key with both private and public components, verifies that the public key matches the private key.

Parameters:

- **key** Pointer to the SlhDsaKey to check.

See:

- wc_SlhDsaKey_MakeKey
- wc_SlhDsaKey_ImportPrivate

Return:

- 0 on success (key is valid).
- BAD_FUNC_ARG if key is NULL.

C.67.2.21 function wc_SlhDsaKey_ExportPrivate

```
int wc_SlhDsaKey_ExportPrivate(
    SlhDsaKey * key,
    byte * out,
    word32 * outLen
)
```

Exports the private key from an SLH-DSA key object into a raw byte buffer (4*n bytes).

Parameters:

- **key** Pointer to the SlhDsaKey containing a private key.
- **out** Buffer to receive the raw private key bytes.
- **outLen** On input, size of out buffer. On output, bytes written.

See:

- wc_SlhDsaKey_ImportPrivate
- wc_SlhDsaKey_ExportPublic

Return:

- 0 on success.
- BAD_FUNC_ARG if key, out, or outLen is NULL.
- MISSING_KEY if the key object holds no private key.
- BUFFER_E if the output buffer is too small.

Example

```
SlhDsaKey key;
byte privKey[4 * 32]; // 4*n for 256-bit params
word32 privKeySz = sizeof(privKey);
int ret;

ret = wc_SlhDsaKey_ExportPrivate(&key, privKey, &privKeySz);
```

C.67.2.22 function wc_SlhDsaKey_ExportPublic

```
int wc_SlhDsaKey_ExportPublic(
    SlhDsaKey * key,
    byte * out,
    word32 * outLen
)
```

Exports the public key from an SLH-DSA key object into a raw byte buffer (2*n bytes: PK.seed || PK.root).

Parameters:

- **key** Pointer to the SlhDsaKey containing a public key.
- **out** Buffer to receive the raw public key bytes.
- **outLen** On input, size of out buffer. On output, bytes written.

See:

- wc_SlhDsaKey_ImportPublic
- wc_SlhDsaKey_ExportPrivate

Return:

- 0 on success.
- BAD_FUNC_ARG if key, out, or outLen is NULL.
- MISSING_KEY if the key object holds no public key.
- BUFFER_E if the output buffer is too small.

Example

```
SlhDsaKey key;
byte pubKey[2 * 32];
word32 pubKeySz = sizeof(pubKey);
int ret;

ret = wc_SlhDsaKey_ExportPublic(&key, pubKey, &pubKeySz);
```

C.67.2.23 function wc_SlhDsaKey_PrivateSize

```
int wc_SlhDsaKey_PrivateSize(
    SlhDsaKey * key
)
```

Returns the private key size in bytes for the key's parameter set.

Parameters:

- **key** Pointer to an initialized SlhDsaKey.

See:

- wc_SlhDsaKey_PublicSize
- wc_SlhDsaKey_SigSize
- wc_SlhDsaKey_PrivateSizeFromParam

Return:

- Private key size in bytes (4*n) on success.
- BAD_FUNC_ARG if key is NULL or not initialized.

C.67.2.24 function wc_SlhDsaKey_PublicSize

```
int wc_SlhDsaKey_PublicSize(
    SlhDsaKey * key
)
```

Returns the public key size in bytes for the key's parameter set.

Parameters:

- **key** Pointer to an initialized SlhDsaKey.

See:

- wc_SlhDsaKey_PrivateSize
- wc_SlhDsaKey_SigSize
- wc_SlhDsaKey_PublicSizeFromParam

Return:

- Public key size in bytes (2*n) on success.
- BAD_FUNC_ARG if key is NULL or not initialized.

C.67.2.25 function wc_SlhDsaKey_SigSize

```
int wc_SlhDsaKey_SigSize(
    SlhDsaKey * key
)
```

Returns the signature size in bytes for the key's parameter set.

Parameters:

- **key** Pointer to an initialized SlhDsaKey.

See:

- wc_SlhDsaKey_PrivateSize
- wc_SlhDsaKey_PublicSize
- wc_SlhDsaKey_SigSizeFromParam

Return:

- Signature size in bytes on success.
- BAD_FUNC_ARG if key is NULL or not initialized.

C.67.2.26 function wc_SlhDsaKey_PrivateSizeFromParam

```
int wc_SlhDsaKey_PrivateSizeFromParam(
    enum SlhDsaParam param
)
```

Returns the private key size in bytes for the given parameter set without needing an initialized key object.

Parameters:

- **param** The SLH-DSA parameter set.

See: wc_SlhDsaKey_PrivateSize

Return:

- Private key size in bytes (4*n) on success.
- BAD_FUNC_ARG if param is invalid.

C.67.2.27 function wc_SlhDsaKey_PublicSizeFromParam

```
int wc_SlhDsaKey_PublicSizeFromParam(
    enum SlhDsaParam param
)
```

Returns the public key size in bytes for the given parameter set without needing an initialized key object.

Parameters:

- **param** The SLH-DSA parameter set.

See: wc_SlhDsaKey_PublicSize

Return:

- Public key size in bytes (2*n) on success.
- BAD_FUNC_ARG if param is invalid.

C.67.2.28 function wc_SlhDsaKey_SigSizeFromParam

```
int wc_SlhDsaKey_SigSizeFromParam(
    enum SlhDsaParam param
)
```

Returns the signature size in bytes for the given parameter set without needing an initialized key object.

Parameters:

- **param** The SLH-DSA parameter set.

See: wc_SlhDsaKey_SigSize

Return:

- Signature size in bytes on success.
- BAD_FUNC_ARG if param is invalid.

C.67.2.29 function wc_SlhDsaKey_PrivateKeyDecode

```
int wc_SlhDsaKey_PrivateKeyDecode(
    const byte * input,
    word32 * inOutIdx,
    SlhDsaKey * key,
    word32 inSz
)
```

Decodes a DER-encoded SLH-DSA private key in the PKCS#8 OneAsymmetricKey format defined by RFC 9909. The privateKey OCTET STRING contains the raw concatenation SK.seed || SK.prf || PK.seed || PK.root (4*n bytes) directly, without a nested OCTET STRING wrapper as used by Ed25519/Ed448. The SLH-DSA parameter set is detected from the AlgorithmIdentifier OID and key->params is updated to match. Available only when WOLFSSL_SLHDSA_VERIFY_ONLY is not defined.

Parameters:

- **input** DER-encoded key data.
- **inOutIdx** On input, starting offset into input. On output, advanced past the parsed key (unchanged on failure).
- **key** SLH-DSA key. Parameter set is auto-detected from the encoded OID.
- **inSz** Total size of input in bytes.

See:

- wc_SlhDsaKey_KeyToDer
- wc_SlhDsaKey_PublicKeyDecode
- wc_SlhDsaKey_ImportPrivate

Return:

- 0 on success.
- BAD_FUNC_ARG if input, inOutIdx, or key is NULL, or inSz is 0.
- ASN_PARSE_E if the DER cannot be parsed as an SLH-DSA private key (malformed input, wrong key size, or trailing-field violation).
- NOT_COMPILED_IN if the OID names an SLH-DSA variant that is not built into this library.

On a failure that is detected before any write to key->sk (BAD_FUNC_ARG, header/OID parse errors, or wrong privateKey length), the key state is left untouched. On a failure detected after wc_SlhDsaKey_ImportPrivate has populated key->sk (a SHA-2 precompute error, or a trailing-field validation error), key->sk is scrubbed with ForceZero and the WC_SLHDSA_FLAG_PRIVATE/PUBLIC flags are cleared so flags can never claim valid bytes that were zeroed. In both rollback cases, key->params and inOutIdx are restored to their pre-call values.

C.67.2.30 function wc_SlhDsaKey_PublicKeyDecode

```
int wc_SlhDsaKey_PublicKeyDecode(
    const byte * input,
    word32 * inOutIdx,
    SlhDsaKey * key,
    word32 inSz
)
```

Decodes a DER-encoded SLH-DSA public key in the SubjectPublicKeyInfo (SPKI) format. The SLH-DSA parameter set is detected from the AlgorithmIdentifier OID and key->params is updated accordingly.

Parameters:

- **input** DER-encoded key data, or a raw 2*n public key when key->params is already set.

- **inOutIdx** On input, starting offset into input. On output, advanced past the parsed key (unchanged on failure).
- **key** SLH-DSA key. Parameter set is auto-detected from the encoded OID, or honored as-is in the raw fast path.
- **inSz** Total size of input in bytes.

See:

- wc_SlhDsaKey_PublicKeyToDer
- wc_SlhDsaKey_PrivateKeyDecode
- wc_SlhDsaKey_ImportPublic

Return:

- 0 on success.
- BAD_FUNC_ARG if input, inOutIdx, or key is NULL, or inSz is 0.
- ASN_PARSE_E if the DER cannot be parsed as an SLH-DSA public key.
- NOT_COMPILED_IN if the OID names an SLH-DSA variant that is not built into this library.

As a fast path, if key->params is already set the function first hands the entire window from inOutIdx to inSz to wc_SlhDsaKey_ImportPublic. ImportPublic's length check is the disambiguator: a window of exactly 2*n bytes is accepted as a raw public key (PK.seed || PK.root) and consumed in full; any other length is rejected and the function falls through to SPKI parsing. SPKI input always carries enough AlgorithmIdentifier/BIT STRING overhead that it never collides with the 2*n raw length, so it falls through cleanly. The caller does not need to pre-trim the window to 2*n.

On a failure detected before any write (BAD_FUNC_ARG or a malformed SPKI), the key state is left untouched. On a failure detected after ImportPublic has populated the public half of key->sk (a SHA-2 precompute error), the public half sk[2*n .. 4*n] is scrubbed and WC_SLHDSA_FLAG_PUBLIC is cleared from the flags; the private half is left intact in case the caller imported it earlier. key->params and inOutIdx are restored to their pre-call values.

C.67.2.31 function wc_SlhDsaKey_KeyToDer

```
int wc_SlhDsaKey_KeyToDer(
    SlhDsaKey * key,
    byte * output,
    word32 inLen
)
```

Encodes an SLH-DSA private key to DER in the PKCS#8 OneAsymmetricKey format defined by RFC 9909. The privateKey OCTET STRING contains the raw 4*n bytes (SK.seed || SK.prf || PK.seed || PK.root) directly, without the nested OCTET STRING wrapping used by Ed25519/Ed448.

Parameters:

- **key** SLH-DSA key with a populated private key.
- **output** Buffer to receive the DER encoding, or NULL to query the required size.
- **inLen** Size of output in bytes (ignored when output is NULL).

See:

- wc_SlhDsaKey_PrivateKeyDecode
- wc_SlhDsaKey_PrivateKeyToDer
- wc_SlhDsaKey_PublicKeyToDer

Return:

- Size of the encoded DER in bytes on success. Pass NULL as output to query the required buffer size without writing.
- BAD_FUNC_ARG if key or key->params is NULL.

- MISSING_KEY if the private key has not been set.
- BUFFER_E if output is non-NULL and inLen is smaller than the required size.
- NOT_COMPILED_IN if key->params names an SLH-DSA variant whose parameter set is not built in.

Available only when WOLFSSL_SLHDSA_VERIFY_ONLY is not defined and WC_ENABLE_ASYM_KEY_EXPORT is set.

C.67.2.32 function wc_SlhDsaKey_PrivateKeyToDer

```
int wc_SlhDsaKey_PrivateKeyToDer(
    SlhDsaKey * key,
    byte * output,
    word32 inLen
)
```

Encodes an SLH-DSA private key to DER. RFC 9909 packs SK.seed || SK.prf || PK.seed || PK.root into a single OCTET STRING, so SLH-DSA has no distinct private-only encoding. This function is an intentional alias of wc_SlhDsaKey_KeyToDer, kept for API parity with Ed25519/Ed448 which do have a separate private form.

Parameters:

- **key** SLH-DSA key with a populated private key.
- **output** Buffer to receive the DER encoding, or NULL to query the required size.
- **inLen** Size of output in bytes (ignored when output is NULL).

See:

- wc_SlhDsaKey_KeyToDer
- wc_SlhDsaKey_PrivateKeyDecode

Return:

- Size of the encoded DER in bytes on success. Pass NULL as output to query the required buffer size.
- BAD_FUNC_ARG if key or key->params is NULL.
- MISSING_KEY if the private key has not been set.
- BUFFER_E if output is non-NULL and inLen is smaller than the required size.
- NOT_COMPILED_IN if key->params names an SLH-DSA variant whose parameter set is not built in.

Available only when WOLFSSL_SLHDSA_VERIFY_ONLY is not defined and WC_ENABLE_ASYM_KEY_EXPORT is set.

Return codes are inherited unchanged from wc_SlhDsaKey_KeyToDer.

C.67.2.33 function wc_SlhDsaKey_PublicKeyToDer

```
int wc_SlhDsaKey_PublicKeyToDer(
    SlhDsaKey * key,
    byte * output,
    word32 inLen,
    int withAlg
)
```

Encodes an SLH-DSA public key to DER. When withAlg is non-zero the output is a full SubjectPublicKeyInfo structure (AlgorithmIdentifier plus BIT STRING). When withAlg is zero the output contains the raw public key bytes without the SPKI wrapping.

Parameters:

- **key** SLH-DSA key with a populated public key.
- **output** Buffer to receive the DER encoding, or NULL to query the required size.
- **inLen** Size of output in bytes (ignored when output is NULL).
- **withAlg** Non-zero to emit SubjectPublicKeyInfo (with AlgorithmIdentifier); zero to emit the raw public key only.

See:

- wc_SlhDsaKey_PublicKeyDecode
- wc_SlhDsaKey_KeyToDer

Return:

- Size of the encoded DER in bytes on success. Pass NULL as output to query the required buffer size.
- BAD_FUNC_ARG if key or key->params is NULL.
- BUFFER_E if output is non-NULL and inLen is smaller than the required size.
- NOT_COMPILED_IN if key->params names an SLH-DSA variant whose parameter set is not built in.

Available only when WC_ENABLE_ASYM_KEY_EXPORT is set.

C.68 wc_xmss.h

C.68.1 Functions

	Name
int	**wc_XmssKey_Init**(XmssKey * key, void * heap, int devId)Initializes an XmssKey object. Must be called before any other XMSS/XMSS^MT operation. Use wc_XmssKey_Free() to release resources when done.
int	**wc_XmssKey_InitId**(XmssKey * key, const unsigned char * id, int len, void * heap, int devId)Initializes an XmssKey with a device_side key identifier. Equivalent to wc_XmssKey_Init() but also stashes a binary id that a crypto callback can use to look up the underlying key material on the device. Only available when wolfSSL is built with WOLF_PRIVATE_KEY_ID.
int	**wc_XmssKey_InitLabel**(XmssKey * key, const char * label, void * heap, int devId)Initializes an XmssKey with a device_side key label. Equivalent to wc_XmssKey_Init() but also stashes a label string that a crypto callback can use to look up the underlying key material on the device. Only available when wolfSSL is built with WOLF_PRIVATE_KEY_ID.
int	**wc_XmssKey_SetParamStr**(XmssKey * key, const char * str)Selects an XMSS or XMSS^MT parameter set by its RFC 8391 name. Accepted names take the form “XMSS_” (single_tree) or “XMSSMT_/” (multi_tree), for example “XMSS-SHA2_10_256” or “XMSSMT-SHA2_20/2_256”. The set of names actually accepted depends on the hash families and tree heights enabled at build time.

	Name
int	**wc_XmssKey_GetParamStr**(const XmssKey * key, const char ** str)Retrieves the parameter set name currently selected on this key. The returned pointer is a static string and must not be freed by the caller.
int	**wc_XmssKey_SetWriteCb**(XmssKey * key, wc_xmss_write_private_key_cb write_cb)Registers the callback that wolfSSL invokes to persist updated private key state. Because XMSS/XMSS^MT is stateful, the application MUST persist the private key after each successful sign before the signature is released; otherwise a crash or restart can lead to one-time key reuse and break the scheme.
int	**wc_XmssKey_SetReadCb**(XmssKey * key, wc_xmss_read_private_key_cb read_cb)Registers the callback that wolfSSL invokes to load persisted private key state. Used by wc_XmssKey_Reload() to bring a saved key back into memory for further signing.
int	**wc_XmssKey_SetContext**(XmssKey * key, void * context)Sets the opaque context pointer passed to both the read and write private-key callbacks.
int	**wc_XmssKey_MakeKey**(XmssKey * key, WC_RNG * rng)Generates a fresh XMSS/XMSS^MT key pair. The parameter set must already be selected via wc_XmssKey_SetParamStr() and the read/write callbacks must be registered. The newly generated private key is persisted via the write callback before the function returns; on success the key transitions to state WC_XMSS_STATE_OK.
int	**wc_XmssKey_Reload**(XmssKey * key)Reloads a previously generated XMSS/XMSS^MT private key from persistent storage using the registered read callback, restoring the key to a state where it can sign further messages. On success the key is in state WC_XMSS_STATE_OK.
int	**wc_XmssKey_GetPrivLen**(const XmssKey * key, word32 * len)Returns the size in bytes of the encoded private key for the parameter set selected on this key.
int	**wc_XmssKey_GetPubLen**(const XmssKey * key, word32 * len)Returns the size in bytes of the XMSS/XMSS^MT public key for the parameter set selected on this key.
int	**wc_XmssKey_GetSigLen**(const XmssKey * key, word32 * len)Returns the signature size in bytes for the parameter set selected on this key.

	Name
int	**wc_XmssKey_Sign**(XmssKey * key, byte * sig, word32 * sigSz, const byte * msg, int msgSz)Signs msg with the XMSS/XMSS^MT private key in key. On entry *sigSz is the size of the sig buffer; on success it is updated to the bytes written.
int	**wc_XmssKey_SigsLeft**(XmssKey * key)Reports whether this key can create another signature. It does not return a count. A key whose one-time keys are used up returns 0 and should be retired.
void	**wc_XmssKey_Free**(XmssKey * key)Releases resources held by an XmssKey. Safe to call with a NULL pointer. After this call the key is in state WC_XMSS_STATE_FREED and must be re-initialized before reuse.
int	**wc_XmssKey_ExportPub**(XmssKey * keyDst, const XmssKey * keySrc)Copies the public part of keySrc into keyDst. The destination key inherits the same parameter set and may be used for verification; it does not carry the private key state and cannot sign. Useful for handing a verifier the minimal data it needs.
int	**wc_XmssKey_ExportPub_ex**(XmssKey * keyDst, const XmssKey * keySrc, void * heap, int devId)Like wc_XmssKey_ExportPub() but the destination key is initialized fresh with the supplied heap and devId.
int	**wc_XmssKey_ExportPubRaw**(const XmssKey * key, byte * out, word32 * outLen)Exports the XMSS/XMSS^MT public key as a raw byte string. On entry *outLen is the size of out; on success it is updated to the bytes written.
int	**wc_XmssKey_ImportPubRaw**(XmssKey * key, const byte * in, word32 inLen)Imports a raw XMSS public key into key. The key must be in state WC_XMSS_STATE_INITED and the parameter set must already be selected (the raw encoding does NOT carry the parameter set, so the caller must apply it via wc_XmssKey_SetParamStr() first). On success the key transitions to state WC_XMSS_STATE_VERIFYONLY.
int	**wc_XmssKey_ImportPubRaw_ex**(XmssKey * key, const byte * in, word32 inLen, int is_xmssmt)Like wc_XmssKey_ImportPubRaw() but explicitly declares whether the encoded key is single_tree XMSS or multi_tree XMSS^MT (pass non_zero for XMSS^MT, zero for XMSS).

	Name
int	**wc_XmssKey_Verify**(XmssKey * key, const byte * sig, word32 sigSz, const byte * msg, int msgSz)Verifies an XMSS/XMSS^MT signature against msg using the public key held in key. The function returns 0 only when the signature is valid; any other value indicates the signature was rejected.

C.68.2 Functions Documentation

C.68.2.1 function wc_XmssKey_Init

```
int wc_XmssKey_Init(
    XmssKey * key,
    void * heap,
    int devId
)
```

Initializes an XmssKey object. Must be called before any other XMSS/XMSS^MT operation. Use wc_XmssKey_Free() to release resources when done.

Parameters:

- **key** Pointer to the XmssKey to initialize.
- **heap** Heap hint for dynamic memory allocation. May be NULL.
- **devId** Device identifier for hardware crypto callbacks. Use INVALID_DEVID for software-only.

See:

- wc_XmssKey_Free
- wc_XmssKey_SetParamStr
- wc_XmssKey_MakeKey

Return:

- 0 on success.
- BAD_FUNC_ARG if key is NULL.

XMSS (eXtended Merkle Signature Scheme) and its multi-tree variant XMSS^MT (RFC 8391, NIST SP 800-208) are STATEFUL hash-based signature schemes: each call to wc_XmssKey_Sign() consumes a one_time component of the private key, and reusing a one_time key destroys the security of the scheme. Applications MUST persist the private key state between sign calls; see wc_XmssKey_SetWriteCb() and wc_XmssKey_SetReadCb().

After init the key is in state WC_XMSS_STATE_INITED. The parameter set must be selected by name with wc_XmssKey_SetParamStr() before generating or reloading a key.

Example

```
XmssKey key;
int ret;

ret = wc_XmssKey_Init(&key, NULL, INVALID_DEVID);
if (ret != 0) {
    // error initializing key
}
wc_XmssKey_SetParamStr(&key, "XMSS-SHA2_10_256");
```

```
// ... use key ...
wc_XmssKey_Free(&key);
```

C.68.2.2 function wc_XmssKey_InitId

```
int wc_XmssKey_InitId(
    XmssKey * key,
    const unsigned char * id,
    int len,
    void * heap,
    int devId
)
```

Initializes an XmssKey with a device-side key identifier. Equivalent to wc_XmssKey_Init() but also stashes a binary id that a crypto callback can use to look up the underlying key material on the device. Only available when wolfSSL is built with WOLF_PRIVATE_KEY_ID.

Parameters:

- **key** Pointer to the XmssKey to initialize.
- **id** Pointer to the device-side key identifier bytes.
- **len** Number of bytes in id; must be in [0, XMSS_MAX_ID_LEN].
- **heap** Heap hint for dynamic memory allocation.
- **devId** Device identifier for the crypto callback.

See:

- wc_XmssKey_Init
- wc_XmssKey_InitLabel
- wc_XmssKey_Free

Return:

- 0 on success.
- BAD_FUNC_ARG if key is NULL, or id is NULL while len > 0.
- BUFFER_E if len is negative or greater than XMSS_MAX_ID_LEN.

The id is copied into the key object; the caller may free its buffer immediately after this call returns.

C.68.2.3 function wc_XmssKey_InitLabel

```
int wc_XmssKey_InitLabel(
    XmssKey * key,
    const char * label,
    void * heap,
    int devId
)
```

Initializes an XmssKey with a device-side key label. Equivalent to wc_XmssKey_Init() but also stashes a label string that a crypto callback can use to look up the underlying key material on the device. Only available when wolfSSL is built with WOLF_PRIVATE_KEY_ID.

Parameters:

- **key** Pointer to the XmssKey to initialize.
- **label** NUL-terminated device-side key label.
- **heap** Heap hint for dynamic memory allocation.
- **devId** Device identifier for the crypto callback.

See:

- wc_XmssKey_Init
- wc_XmssKey_InitId

Return:

- 0 on success.
- BAD_FUNC_ARG if key or label is NULL.
- BUFFER_E if label is empty or longer than XMSS_MAX_LABEL_LEN.

C.68.2.4 function wc_XmssKey_SetParamStr

```
int wc_XmssKey_SetParamStr(
    XmssKey * key,
    const char * str
)
```

Selects an XMSS or XMSS^MT parameter set by its RFC 8391 name. Accepted names take the form "XMSS-" (single-tree) or "XMSSMT-/" (multi-tree), for example "XMSS-SHA2_10_256" or "XMSSMT-SHA2_20/2_256". The set of names actually accepted depends on the hash families and tree heights enabled at build time.

Parameters:

- **key** Pointer to an XmssKey in state WC_XMSS_STATE_INITED.
- **str** Parameter set name (NUL-terminated).

See:

- wc_XmssKey_GetParamStr
- wc_XmssKey_MakeKey

Return:

- 0 on success.
- BAD_FUNC_ARG if key or str is NULL, or if the named parameter set is unknown or not compiled in.
- BAD_STATE_E if key is not in state WC_XMSS_STATE_INITED.

Example

```
XmssKey key;

wc_XmssKey_Init(&key, NULL, INVALID_DEVID);
wc_XmssKey_SetParamStr(&key, "XMSS-SHA2_10_256");
```

C.68.2.5 function wc_XmssKey_GetParamStr

```
int wc_XmssKey_GetParamStr(
    const XmssKey * key,
    const char ** str
)
```

Retrieves the parameter set name currently selected on this key. The returned pointer is a static string and must not be freed by the caller.

Parameters:

- **key** Pointer to an XmssKey with a parameter set selected.
- **str** Receives a pointer to a static parameter name string.

See: wc_XmssKey_SetParamStr

Return:

- 0 on success.
- BAD_FUNC_ARG if key or str is NULL, or no parameter set has been selected.

C.68.2.6 function wc_XmssKey_SetWriteCb

```
int wc_XmssKey_SetWriteCb(
    XmssKey * key,
    wc_xmss_write_private_key_cb write_cb
)
```

Registers the callback that wolfSSL invokes to persist updated private key state. Because XMSS/XMSS^MT is stateful, the application MUST persist the private key after each successful sign before the signature is released; otherwise a crash or restart can lead to one-time key reuse and break the scheme.

Parameters:

- **key** Pointer to an XmssKey.
- **write_cb** Callback invoked to persist the private key.

See:

- wc_XmssKey_SetReadCb
- wc_XmssKey_SetContext
- wc_XmssKey_Sign

Return:

- 0 on success.
- BAD_FUNC_ARG if key or write_cb is NULL.

The callback returns one of the wc_XmssRc codes; WC_XMSS_RC_SAVED_TO_NV_MEMORY signals a durable write.

C.68.2.7 function wc_XmssKey_SetReadCb

```
int wc_XmssKey_SetReadCb(
    XmssKey * key,
    wc_xmss_read_private_key_cb read_cb
)
```

Registers the callback that wolfSSL invokes to load persisted private key state. Used by wc_XmssKey_Reload() to bring a saved key back into memory for further signing.

Parameters:

- **key** Pointer to an XmssKey.
- **read_cb** Callback invoked to load the private key.

See:

- wc_XmssKey_SetWriteCb
- wc_XmssKey_Reload

Return:

- 0 on success.
- BAD_FUNC_ARG if key or read_cb is NULL.

C.68.2.8 function wc_XmssKey_SetContext

```
int wc_XmssKey_SetContext(
    XmssKey * key,
    void * context
)
```

Sets the opaque context pointer passed to both the read and write private-key callbacks.

Parameters:

- **key** Pointer to an XmssKey.
- **context** Application-defined pointer; may be NULL.

See:

- wc_XmssKey_SetReadCb
- wc_XmssKey_SetWriteCb

Return:

- 0 on success.
- BAD_FUNC_ARG if key is NULL.

C.68.2.9 function wc_XmssKey_MakeKey

```
int wc_XmssKey_MakeKey(
    XmssKey * key,
    WC_RNG * rng
)
```

Generates a fresh XMSS/XMSS^MT key pair. The parameter set must already be selected via wc_XmssKey_SetParamStr() and the read/write callbacks must be registered. The newly generated private key is persisted via the write callback before the function returns; on success the key transitions to state WC_XMSS_STATE_OK.

Parameters:

- **key** Pointer to an XmssKey in state WC_XMSS_STATE_PARMSET with callbacks set.
- **rng** Pointer to an initialized WC_RNG.

See:

- wc_XmssKey_Sign
- wc_XmssKey_Reload

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL.
- MEMORY_E on allocation failure.

Key generation can be slow for large tree heights; XMSS^MT variants amortize the cost over multiple smaller trees and generate noticeably faster than equivalent single-tree XMSS parameter sets.

Example

```
XmssKey key;
WC_RNG rng;

wc_XmssKey_Init(&key, NULL, INVALID_DEVID);
wc_XmssKey_SetParamStr(&key, "XMSS-SHA2_10_256");
wc_XmssKey_SetWriteCb(&key, my_write_cb);
```

```
wc_XmssKey_SetReadCb(&key, my_read_cb);
wc_XmssKey_SetContext(&key, &my_storage);
wc_InitRng(&rng);

if (wc_XmssKey_MakeKey(&key, &rng) != 0) {
    // error generating key
}
```

C.68.2.10 function wc_XmssKey_Reload

```
int wc_XmssKey_Reload(
    XmssKey * key
)
```

Reloads a previously generated XMSS/XMSS^MT private key from persistent storage using the registered read callback, restoring the key to a state where it can sign further messages. On success the key is in state WC_XMSS_STATE_OK.

Parameters:

- **key** Pointer to an XmssKey with parameters and read callback set.

See:

- wc_XmssKey_MakeKey
- wc_XmssKey_SetReadCb

Return:

- 0 on success, including the device-backed no-op.
- BAD_FUNC_ARG if any required pointer is NULL.
- WC_XMSS_RC_* mapped error if the read callback fails.
- IO_FAILED_E if the private key could not be read.
- NO_VALID_DEVID with WOLF_CRYPTO_CB_ONLY_XMSS when the key is not device-backed.

The same parameter set selected at key-generation time must be reapplied with wc_XmssKey_SetParamStr() before calling Reload.

With WOLF_CRYPTO_CB, a key on a devId with no read callback is taken to be device-backed and Reload is a no-op. With a read callback the software reload runs as usual, which needs the write callback set too.

WOLF_CRYPTO_CB_ONLY_XMSS removes the software reload, so the read callback is never called and only the device-backed no-op succeeds.

A reloaded key holds no public key: neither arm populates it. Call wc_XmssKey_ImportPubRaw() on a separate key to verify, or keep the public key exported at generation time.

C.68.2.11 function wc_XmssKey_GetPrivLen

```
int wc_XmssKey_GetPrivLen(
    const XmssKey * key,
    word32 * len
)
```

Returns the size in bytes of the encoded private key for the parameter set selected on this key.

Parameters:

- **key** Pointer to an XmssKey with parameters set.
- **len** Receives the private key size in bytes.

See:

- wc_XmssKey_GetPubLen
- wc_XmssKey_GetSigLen

Return:

- 0 on success.
- BAD_FUNC_ARG if key or len is NULL.

C.68.2.12 function wc_XmssKey_GetPubLen

```
int wc_XmssKey_GetPubLen(
    const XmssKey * key,
    word32 * len
)
```

Returns the size in bytes of the XMSS/XMSS^MT public key for the parameter set selected on this key.

Parameters:

- **key** Pointer to an XmssKey with parameters set.
- **len** Receives the public key size in bytes.

See: wc_XmssKey_ExportPubRaw

Return:

- 0 on success.
- BAD_FUNC_ARG if key or len is NULL.

C.68.2.13 function wc_XmssKey_GetSigLen

```
int wc_XmssKey_GetSigLen(
    const XmssKey * key,
    word32 * len
)
```

Returns the signature size in bytes for the parameter set selected on this key.

Parameters:

- **key** Pointer to an XmssKey with parameters set.
- **len** Receives the signature size in bytes.

See: wc_XmssKey_Sign

Return:

- 0 on success.
- BAD_FUNC_ARG if key or len is NULL.

C.68.2.14 function wc_XmssKey_Sign

```
int wc_XmssKey_Sign(
    XmssKey * key,
    byte * sig,
    word32 * sigSz,
    const byte * msg,
    int msgSz
)
```

Signs msg with the XMSS/XMSS^MT private key in key. On entry *sigSz is the size of the sig buffer; on success it is updated to the bytes written.

Parameters:

- **key** Pointer to an XmssKey in state WC_XMSS_STATE_OK.
- **sig** Buffer that receives the signature.
- **sigSz** In: size of sig. Out: bytes written.
- **msg** Message to sign.
- **msgSz** Length of msg in bytes.

See:

- wc_XmssKey_Verify
- wc_XmssKey_SigsLeft
- wc_XmssKey_SetWriteCb

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL.
- BUFFER_E if *sigSz is smaller than the signature size.
- Negative error if all one-time keys have been used.

Each successful sign call consumes a one-time component of the private key. The updated key state is persisted via the registered write callback BEFORE the new signature is returned to the caller. If the write callback fails the sign call fails and the signature is not released. When the supply of one-time keys is exhausted the key transitions to state WC_XMSS_STATE_NOSIGS and further sign attempts fail – query wc_XmssKey_SigsLeft() to detect this condition in advance.

C.68.2.15 function wc_XmssKey_SigsLeft

```
int wc_XmssKey_SigsLeft(
    XmssKey * key
)
```

Reports whether this key can create another signature. It does not return a count. A key whose one-time keys are used up returns 0 and should be retired.

Parameters:

- **key** Pointer to an XmssKey in state WC_XMSS_STATE_OK.

See: wc_XmssKey_Sign

Return:

- 1 if at least one signature remains.
- 0 if the one-time keys are exhausted, if key is NULL or not in state WC_XMSS_STATE_OK, if the read callback cannot load the private key, or if a crypto callback device returns an error. A key bound to a device that handles the request gets the device's answer.

C.68.2.16 function wc_XmssKey_Free

```
void wc_XmssKey_Free(
    XmssKey * key
)
```

Releases resources held by an XmssKey. Safe to call with a NULL pointer. After this call the key is in state WC_XMSS_STATE_FREED and must be re-initialized before reuse.

Parameters:

- **key** Pointer to the XmssKey to free.

See: wc_XmssKey_Init

C.68.2.17 function wc_XmssKey_ExportPub

```
int wc_XmssKey_ExportPub(
    XmssKey * keyDst,
    const XmssKey * keySrc
)
```

Copies the public part of keySrc into keyDst. The destination key inherits the same parameter set and may be used for verification; it does not carry the private key state and cannot sign. Useful for handing a verifier the minimal data it needs.

Parameters:

- **keyDst** Pointer to an initialized destination XmssKey.
- **keySrc** Pointer to an XmssKey with the public key.

See:

- wc_XmssKey_ExportPub_ex
- wc_XmssKey_ExportPubRaw

Return:

- 0 on success.
- BAD_FUNC_ARG if keyDst or keySrc is NULL.
- BAD_STATE_E if keySrc holds no public key.

C.68.2.18 function wc_XmssKey_ExportPub_ex

```
int wc_XmssKey_ExportPub_ex(
    XmssKey * keyDst,
    const XmssKey * keySrc,
    void * heap,
    int devId
)
```

Like wc_XmssKey_ExportPub() but the destination key is initialized fresh with the supplied heap and devId.

Parameters:

- **keyDst** Pointer to an XmssKey to populate.
- **keySrc** Pointer to an XmssKey with the public key.
- **heap** Heap hint for keyDst.
- **devId** Device identifier for keyDst.

See: wc_XmssKey_ExportPub

Return:

- 0 on success.
- BAD_FUNC_ARG if keyDst or keySrc is NULL.
- BAD_STATE_E if keySrc holds no public key.

C.68.2.19 function wc_XmssKey_ExportPubRaw

```
int wc_XmssKey_ExportPubRaw(
    const XmssKey * key,
    byte * out,
    word32 * outLen
)
```

Exports the XMSS/XMSS^MT public key as a raw byte string. On entry *outLen is the size of out; on success it is updated to the bytes written.

Parameters:

- **key** Pointer to an XmssKey.
- **out** Buffer that receives the public key.
- **outLen** In: size of out. Out: bytes written.

See:

- wc_XmssKey_ImportPubRaw
- wc_XmssKey_GetPubLen

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL.
- BAD_STATE_E if key holds no public key.
- BUFFER_E if *outLen is smaller than the public key size.

C.68.2.20 function wc_XmssKey_ImportPubRaw

```
int wc_XmssKey_ImportPubRaw(
    XmssKey * key,
    const byte * in,
    word32 inLen
)
```

Imports a raw XMSS public key into key. The key must be in state WC_XMSS_STATE_INITED and the parameter set must already be selected (the raw encoding does NOT carry the parameter set, so the caller must apply it via wc_XmssKey_SetParamStr() first). On success the key transitions to state WC_XMSS_STATE_VERIFYONLY.

Parameters:

- **key** Pointer to an XmssKey with a parameter set.
- **in** Raw public key bytes.
- **inLen** Length of in in bytes.

See:

- wc_XmssKey_ImportPubRaw_ex
- wc_XmssKey_ExportPubRaw
- wc_XmssKey_Verify

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL.
- BUFFER_E if inLen does not match the expected public key size.

C.68.2.21 function wc_XmssKey_ImportPubRaw_ex

```
int wc_XmssKey_ImportPubRaw_ex(
    XmssKey * key,
    const byte * in,
    word32 inLen,
    int is_xmssmt
)
```

Like wc_XmssKey_ImportPubRaw() but explicitly declares whether the encoded key is single_tree XMSS or multi_tree XMSS^MT (pass non_zero for XMSS^MT, zero for XMSS).

Parameters:

- **key** Pointer to an XmssKey with a parameter set.
- **in** Raw public key bytes.
- **inLen** Length of in in bytes.
- **is_xmssmt** Non-zero if the key is XMSS^MT, zero if plain XMSS.

See: wc_XmssKey_ImportPubRaw

Return:

- 0 on success.
- BAD_FUNC_ARG if any required pointer is NULL.
- BUFFER_E if inLen does not match the expected public key size.

C.68.2.22 function wc_XmssKey_Verify

```
int wc_XmssKey_Verify(
    XmssKey * key,
    const byte * sig,
    word32 sigSz,
    const byte * msg,
    int msgSz
)
```

Verifies an XMSS/XMSS^MT signature against msg using the public key held in key. The function returns 0 only when the signature is valid; any other value indicates the signature was rejected.

Parameters:

- **key** Pointer to an XmssKey with the public key.
- **sig** Signature bytes to verify.
- **sigSz** Length of sig in bytes.
- **msg** Message that was signed.
- **msgSz** Length of msg in bytes.

See:

- wc_XmssKey_Sign
- wc_XmssKey_ImportPubRaw

Return:

- 0 on a valid signature.
- BAD_FUNC_ARG if any required pointer is NULL.
- BAD_STATE_E if key holds no public key.
- SIG_VERIFY_E (or similar) if the signature is invalid or malformed.

C.68.3 Source code

```
int wc_XmssKey_Init(XmssKey* key, void* heap, int devId);

int wc_XmssKey_InitId(XmssKey* key, const unsigned char* id, int len,

C.69 wolfio.h

C.69.1 Functions

	Name
int	**EmbedReceive**(WOLFSSL * ssl, char * buf, int sz, void * ctx)This function is the receive embedded callback.
int	**EmbedSend**(WOLFSSL * ssl, char * buf, int sz, void * ctx)This function is the send embedded callback.
int	**EmbedReceiveFrom**(WOLFSSL * ssl, char * buf, int sz, void * ctx)This function is the receive embedded callback.
int	**EmbedSendTo**(WOLFSSL * ssl, char * buf, int sz, void * ctx)This function is the send embedded callback.
int	**EmbedGenerateCookie**(WOLFSSL * ssl, byte * buf, int sz, void * ctx)This function is the DTLS Generate Cookie callback.
void	**EmbedOcspRespFree**(void * ctx, byte * resp)This function frees the response buffer.
void	**wolfSSL_CTX_SetIORecv**(WOLFSSL_CTX * ctx, CallbackIORecv CBIORecv)This function registers a receive callback for wolfSSL to get input data. By default, wolfSSL uses EmbedReceive() as the callback which uses the system's TCP recv() function. The user can register a function to get input from memory, some other network module, or from anywhere. Please see the EmbedReceive() function in src/io.c as a guide for how the function should work and for error codes. In particular, IO_ERR_WANT_READ should be returned for non blocking receive when no data is ready.
void	**wolfSSL_SetIOReadCtx**(WOLFSSL * ssl, void * ctx)This function registers a context for the SSL session's receive callback function. By default, wolfSSL sets the file descriptor passed to wolfSSL_set_fd() as the context when wolfSSL is using the system's TCP library. If you've registered your own receive callback you may want to set a specific context for the session. For example, if you're using memory buffers the context may be a pointer to a structure describing where and how to access the memory buffers.

	Name
void	**wolfSSL_SetIOWriteCtx**(WOLFSSL * ssl, void * ctx)This function registers a context for the SSL session's send callback function. By default, wolfSSL sets the file descriptor passed to wolfSSL_set_fd() as the context when wolfSSL is using the system's TCP library. If you've registered your own send callback you may want to set a specific context for the session. For example, if you're using memory buffers the context may be a pointer to a structure describing where and how to access the memory buffers.
void *	**wolfSSL_GetIOReadCtx**(WOLFSSL * ssl)This function returns the IOCB_ReadCtx member of the WOLFSSL struct.
void *	**wolfSSL_GetIOWriteCtx**(WOLFSSL * ssl)This function returns the IOCB_WriteCtx member of the WOLFSSL structure.
void	**wolfSSL_SetIOReadFlags**(WOLFSSL * ssl, int flags)This function sets the flags for the receive callback to use for the given SSL session. The receive callback could be either the default wolfSSL EmbedReceive callback, or a custom callback specified by the user (see wolfSSL_CTX_SetIORecv). The default flag value is set internally by wolfSSL to the value of 0. The default wolfSSL receive callback uses the recv() function to receive data from the socket. From the recv() man page: "The flags argument to a recv() function is formed by or'ing one or more of the values: MSG_OOB process out-of-band data, MSG_PEEK peek at incoming message, MSG_WAITALL wait for full request or error. The MSG_OOB flag requests receipt of out-of-band data that would not be received in the normal data stream. Some protocols place expedited data at the head of the normal data queue, and thus this flag cannot be used with such protocols. The MSG_PEEK flag causes the receive operation to return data from the beginning of the receive queue without removing that data from the queue. Thus, a subsequent receive call will return the same data. The MSG_WAITALL flag requests that the operation block until the full request is satisfied. However, the call may still return less data than requested if a signal is caught, an error or disconnect occurs, or the next data to be received is of a different type than that returned."

	Name
void	**wolfSSL_SetIOWriteFlags**(WOLFSSL * ssl, int flags)This function sets the flags for the send callback to use for the given SSL session. The send callback could be either the default wolfSSL EmbedSend callback, or a custom callback specified by the user (see wolfSSL_CTX_SetIOSend). The default flag value is set internally by wolfSSL to the value of 0. The default wolfSSL send callback uses the send() function to send data from the socket. From the send() man page: “The flags parameter may include one or more of the following: #define MSG_OOB 0x1 // process out_of_band data, #define MSG_DONTROUTE 0x4 // bypass routing, use direct interface. The flag MSG_OOB is used to send ‘out_of_band’ data on sockets that support this notion (e.g. SOCK_STREAM); the underlying protocol must also support ‘out-of-band’ data. MSG_DONTROUTE is usually used only by diagnostic or routing programs.”
void	**wolfSSL_SetIO_NetX**(WOLFSSL * ssl, NX_TCP_SOCKET * nxsocket, ULONG waitoption)This function sets the nxTcpSocket and nxWait members of the nxCtx struct within the WOLFSSL structure.
void	**wolfSSL_SetIO_NetX_Dtls**(WOLFSSL * ssl, NX_UDP_SOCKET * nxsocket, NXD_ADDRESS nxdip, USHORT nxport, ULONG waitoption)This function configures the NetX Duo UDP context for a DTLS session. It stores the UDP socket, destination IP address (by value), destination port, and wait option into the WOLFSSL nxCtx structure. Requires WOLFSSL_NETX_DUO to be defined (ThreadX NetX Duo SDK).
void	**wolfSSL_CTX_SetGenCookie**(WOLFSSL_CTX * ctx, CallbackGenCookie cb)This function sets the callback for the CBIOCookie member of the WOLFSSL_CTX structure. The CallbackGenCookie type is a function pointer and has the signature: int (*CallbackGenCookie)(WOLFSSL* ssl, unsigned char* buf, int sz, void* ctx);.
void *	**wolfSSL_GetCookieCtx**(WOLFSSL * ssl)This function returns the IOCB_CookieCtx member of the WOLFSSL structure.

	Name
int	**wolfSSL_SetIO_ISOTP**(WOLFSSL * ssl, isotp_wolfssl_ctx * ctx, can_recv_fn recv_fn, can_send_fn send_fn, can_delay_fn delay_fn, word32 receive_delay, char * receive_buffer, int receive_buffer_size, void * arg)This function sets up the ISO-TP context if wolfSSL, for use when wolfSSL is compiled with WOLFSSL_ISOTP.
void	**wolfSSL_SSLDisableRead**(WOLFSSL * ssl)This function disables reading from the IO layer.
void	**wolfSSL_SSLEnableRead**(WOLFSSL * ssl)This function enables reading from the IO layer. Reading is enabled by default and should be used to undo wolfSSL_SSLDisableRead();.
WOLFSSL_API void	**wolfSSL_SetRecvFrom**(WOLFSSL * ssl, WolfSSLRecvFrom recvFrom)Set a custom DTLS recvfrom callback for a WOLFSSL session.
WOLFSSL_API void	**wolfSSL_SetSendTo**(WOLFSSL * ssl, WolfSSLSento sendTo)Set a custom DTLS sendto callback for a WOLFSSL session.
int	**wolfIO_Select**(SOCKET_T sockfd, int to_sec)Waits for socket to be ready for I/O with timeout.
int	**wolfIO_TcpConnect**(SOCKET_T * sockfd, const char * ip, unsigned short port, int to_sec)Connects to TCP server with timeout.
int	**wolfIO_TcpAccept**(SOCKET_T sockfd, SOCKADDR * peer_addr, XSOCKLENT * peer_len)Accepts TCP connection.
int	**wolfIO_TcpBind**(SOCKET_T * sockfd, word16 port)Binds TCP socket to port.
int	**wolfIO_Send**(SOCKET_T sd, char * buf, int sz, int wrFlags)Sends data on socket.
int	**wolfIO_Recv**(SOCKET_T sd, char * buf, int sz, int rdFlags)Receives data from socket.
int	**wolfIO_SendTo**(SOCKET_T sd, WOLFSSL_BIO_ADDR * addr, char * buf, int sz, int wrFlags)Sends datagram to address.
int	**wolfIO_RecvFrom**(SOCKET_T sd, WOLFSSL_BIO_ADDR * addr, char * buf, int sz, int rdFlags)Receives datagram from address.
int	**wolfSSL_BioSend**(WOLFSSL * ssl, char * buf, int sz, void * ctx)BIO send callback.
int	**wolfSSL_BioReceive**(WOLFSSL * ssl, char * buf, int sz, void * ctx)BIO receive callback.
int	**EmbedReceiveFromMcast**(WOLFSSL * ssl, char * buf, int sz, void * ctx)Receives multicast datagram.
int	**wolfIO_HttpBuildRequestOcsp**(const char * domainName, const char * path, int ocspReqSz, unsigned char * buf, int bufSize)Builds HTTP OCSP request.

	Name
int	**wolfIO_HttpProcessResponseOcspGenericIO**(WolfSSLGenericI ioCb, void * ioCbCtx, unsigned char ** respBuf, unsigned char * httpBuf, int httpBufSz, void * heap)Processes HTTP OCSP response with generic I/O.
int	**wolfIO_HttpProcessResponseOcsp**(int sfd, unsigned char ** respBuf, unsigned char * httpBuf, int httpBufSz, void * heap)Processes HTTP OCSP response.
int	**EmbedOcspLookup**(void * ctx, const char * url, int urlSz, byte * ocspReqBuf, int ocspReqSz, byte ** ocspRespBuf)OCSP lookup callback.
int	**wolfIO_HttpBuildRequestCrl**(const char * url, int urlSz, const char * domainName, unsigned char * buf, int bufSize)Builds HTTP CRL request.
int	**wolfIO_HttpProcessResponseCrl**(WOLFSSL_CRL * crl, int sfd, unsigned char * httpBuf, int httpBufSz)Processes HTTP CRL response.
int	**EmbedCrlLookup**(WOLFSSL_CRL * crl, const char * url, int urlSz)CRL lookup callback.
int	**wolfIO_DecodeUrl**(const char * url, int urlSz, char * outName, char * outPath, unsigned short * outPort)Decodes URL into components.
int	**wolfIO_HttpBuildRequest**(const char * reqType, const char * domainName, const char * path, int pathLen, int reqSz, const char * contentType, unsigned char * buf, int bufSize)Builds generic HTTP request.
int	**wolfIO_HttpProcessResponseGenericIO**(WolfSSLGenericIORecv ioCb, void * ioCbCtx, const char ** appStrList, unsigned char ** respBuf, unsigned char * httpBuf, int httpBufSz, int dynType, void * heap)Processes HTTP response with generic I/O.
int	**wolfIO_HttpProcessResponse**(int sfd, const char ** appStrList, unsigned char ** respBuf, unsigned char * httpBuf, int httpBufSz, int dynType, void * heap)Processes HTTP response.
void	**wolfSSL_CTX_SetIOSend**(WOLFSSL_CTX * ctx, CallbackIOSend CBIOSend)Sets I/O send callback for context.
void	**wolfSSL_SSLSetIORecv**(WOLFSSL * ssl, CallbackIORecv CBIORecv)Sets I/O receive callback for SSL object.
void	**wolfSSL_SSLSetIOSend**(WOLFSSL * ssl, CallbackIOSend CBIOSend)Sets I/O send callback for SSL object.
void	**wolfSSL_SetIO_Mynewt**(WOLFSSL * ssl, struct mn_socket * mnSocket, struct mn_sockaddr_in * mnSockAddrIn)Sets I/O for Mynewt platform.

	Name
int	**wolfSSL_SetIO_LwIP**(WOLFSSL * ssl, void * pcb, tcp_recv_fn recv, tcp_sent_fn sent, void * arg)Sets I/O for LwIP platform.
void	**wolfSSL_SetCookieCtx**(WOLFSSL * ssl, void * ctx)Sets cookie context for DTLS.
void	**wolfSSL_CTX_SetIOGetPeer**(WOLFSSL_CTX * ctx, CallbackGetPeer cb)Sets get peer callback for context.
void	**wolfSSL_CTX_SetIOSetPeer**(WOLFSSL_CTX * ctx, CallbackSetPeer cb)Sets set peer callback for context.
int	**EmbedGetPeer**(WOLFSSL * ssl, char * ip, int * ipSz, unsigned short * port, int * fam)Gets peer information.
int	**EmbedSetPeer**(WOLFSSL * ssl, char * ip, int ipSz, unsigned short port, int fam)Sets peer information.

C.69.2 Functions Documentation

C.69.2.1 function EmbedReceive

```
int EmbedReceive(
    WOLFSSL * ssl,
    char * buf,
    int sz,
    void * ctx
)
```

This function is the receive embedded callback.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **buf** a char pointer representation of the buffer.
- **sz** the size of the buffer.
- **ctx** a void pointer to user registered context. In the default case the ctx is a socket descriptor pointer.

See:

- EmbedSend
- wolfSSL_CTX_SetIORecv
- wolfSSL_SSLSetIORecv

Return:

- Success This function returns the number of bytes read.
- WOLFSSL_CBIO_ERR_WANT_READ returned with a “Would block” message if the last error was SOCKET_EWOULDBLCOK or SOCKET_EAGAIN.
- WOLFSSL_CBIO_ERR_TIMEOUT returned with a “Socket timeout” message.
- WOLFSSL_CBIO_ERR_CONN_RST returned with a “Connection reset” message if the last error was SOCKET_ECONNRESET.
- WOLFSSL_CBIO_ERR_ISR returned with a “Socket interrupted” message if the last error was SOCKET_EINTR.

- WOLFSSL_CBIO_ERR_WANT_READ returned with a “Connection refused” message if the last error was SOCKET_ECONNREFUSED.
- WOLFSSL_CBIO_ERR_CONN_CLOSE returned with a “Connection aborted” message if the last error was SOCKET_ECONNABORTED.
- WOLFSSL_CBIO_ERR_GENERAL returned with a “General error” message if the last error was not specified.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
WOLFSSL* ssl = wolfSSL_new(ctx);
char* buf;
int sz;
void* ctx;
int bytesRead = EmbedReceive(ssl, buf, sz, ctx);
if(bytesRead <= 0){
    // There were no bytes read. Failure case.
}
```

C.69.2.2 function EmbedSend

```
int EmbedSend(
    WOLFSSL * ssl,
    char * buf,
    int sz,
    void * ctx
)
```

This function is the send embedded callback.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **buf** a char pointer representing the buffer.
- **sz** the size of the buffer.
- **ctx** a void pointer to user registered context.

See:

- EmbedReceive
- wolfSSL_CTX_SetIOSend
- wolfSSL_SSLSetIOSend

Return:

- Success This function returns the number of bytes sent.
- WOLFSSL_CBIO_ERR_WANT_WRITE returned with a “Would block” message if the last error was SOCKET_EWOULDBLOCK or SOCKET_EAGAIN.
- WOLFSSL_CBIO_ERR_CONN_RST returned with a “Connection reset” message if the last error was SOCKET_ECONNRESET.
- WOLFSSL_CBIO_ERR_ISR returned with a “Socket interrupted” message if the last error was SOCKET_EINTR.
- WOLFSSL_CBIO_ERR_CONN_CLOSE returned with a “Socket EPIPE” message if the last error was SOCKET_EPIPE.
- WOLFSSL_CBIO_ERR_GENERAL returned with a “General error” message if the last error was not specified.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
char* buf;
int sz;
void* ctx;
int dSent = EmbedSend(ssl, buf, sz, ctx);
if(dSent <= 0){
    // No byes sent. Failure case.
}
```

C.69.2.3 function EmbedReceiveFrom

```
int EmbedReceiveFrom(
    WOLFSSL * ssl,
    char * buf,
    int sz,
    void * ctx
)
```

This function is the receive embedded callback.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **buf** a constant char pointer to the buffer.
- **sz** an int type representing the size of the buffer.
- **ctx** a void pointer to the WOLFSSL_CTX context.

See:

- EmbedSendTo
- wolfSSL_CTX_SetIORecv
- wolfSSL_SSLSetIORecv
- wolfSSL_dtls_get_current_timeout

Return:

- Success This function returns the nb bytes read if the execution was successful.
- WOLFSSL_CBIO_ERR_WANT_READ if the connection refused or if a 'would block' error was thrown in the function.
- WOLFSSL_CBIO_ERR_TIMEOUT returned if the socket timed out.
- WOLFSSL_CBIO_ERR_CONN_RST returned if the connection reset.
- WOLFSSL_CBIO_ERR_ISR returned if the socket was interrupted.
- WOLFSSL_CBIO_ERR_GENERAL returned if there was a general error.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( protocol method );
WOLFSSL* ssl = WOLFSSL_new(ctx);
char* buf;
int sz = sizeof(buf)/sizeof(char);
(void*)ctx;
…
int nb = EmbedReceiveFrom(ssl, buf, sz, ctx);
if(nb > 0){
    // nb is the number of bytes written and is positive
}
```

C.69.2.4 function EmbedSendTo

```
int EmbedSendTo(
    WOLFSSL * ssl,
    char * buf,
    int sz,
    void * ctx
)
```

This function is the send embedded callback.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **buf** a char pointer representing the buffer.
- **sz** the size of the buffer.
- **ctx** a void pointer to the user registered context. The default case is a WOLFSSL_DTLS_CTX structure.

See:

- EmbedReceiveFrom
- wolfSSL_CTX_SetIOSend
- wolfSSL_SSLSetIOSend

Return:

- Success This function returns the number of bytes sent.
- WOLFSSL_CBIO_ERR_WANT_WRITE returned with a "Would Block" message if the last error was either SOCKET_EWOULDBLOCK or SOCKET_EAGAIN error.
- WOLFSSL_CBIO_ERR_CONN_RST returned with a "Connection reset" message if the last error was SOCKET_ECONNRESET.
- WOLFSSL_CBIO_ERR_ISR returned with a "Socket interrupted" message if the last error was SOCKET_EINTR.
- WOLFSSL_CBIO_ERR_CONN_CLOSE returned with a "Socket EPIPE" message if the last error was WOLFSSL_CBIO_ERR_CONN_CLOSE.
- WOLFSSL_CBIO_ERR_GENERAL returned with a "General error" message if the last error was not specified.

Example

```
WOLFSSL* ssl;
…
char* buf;
int sz;
void* ctx;

int sEmbed = EmbedSendto(ssl, buf, sz, ctx);
if(sEmbed <= 0){
    // No bytes sent. Failure case.
}
```

C.69.2.5 function EmbedGenerateCookie

```
int EmbedGenerateCookie(
    WOLFSSL * ssl,
    byte * buf,
    int sz,
```

```
    void * ctx
)
```

This function is the DTLS Generate Cookie callback.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **buf** byte pointer representing the buffer. It is the destination from XMEMCPY().
- **sz** the size of the buffer.
- **ctx** a void pointer to user registered context.

See: wolfSSL_CTX_SetGenCookie

Return:

- Success This function returns the number of bytes copied into the buffer.
- GEN_COOKIE_E returned if the getpeername failed in EmbedGenerateCookie.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
byte buffer[BUFFER_SIZE];
int sz = sizeof(buffer)/sizeof(byte);
void* ctx;
…
int ret = EmbedGenerateCookie(ssl, buffer, sz, ctx);

if(ret > 0){
    // EmbedGenerateCookie code block for success
}
```

C.69.2.6 function EmbedOcspRespFree

```
void EmbedOcspRespFree(
    void * ctx,
    byte * resp
)
```

This function frees the response buffer.

Parameters:

- **ctx** a void pointer to heap hint.
- **resp** a byte pointer representing the response.

See:

- wolfSSL_CertManagerSetOCSP_Cb
- wolfSSL_CertManagerEnableOCSPStapling
- wolfSSL_CertManagerEnableOCSP

Return: none No returns.

Example

```
void* ctx;
byte* resp; // Response buffer.
…
EmbedOcspRespFree(ctx, resp);
```

C.69.2.7 function wolfSSL_CTX_SetIORecv

```
void wolfSSL_CTX_SetIORecv(
    WOLFSSL_CTX * ctx,
    CallbackIORecv CBIORecv
)
```

This function registers a receive callback for wolfSSL to get input data. By default, wolfSSL uses EmbedReceive() as the callback which uses the system's TCP recv() function. The user can register a function to get input from memory, some other network module, or from anywhere. Please see the EmbedReceive() function in src/io.c as a guide for how the function should work and for error codes. In particular, IO_ERR_WANT_READ should be returned for non blocking receive when no data is ready.

Parameters:

- **ctx** pointer to the SSL context, created with wolfSSL_CTX_new().
- **callback** function to be registered as the receive callback for the wolfSSL context, ctx. The signature of this function must follow that as shown above in the Synopsis section.

See:

- wolfSSL_CTX_SetIOSend
- wolfSSL_SetIOReadCtx
- wolfSSL_SetIOWriteCtx

Return: none no Returns.

Example

```
WOLFSSL_CTX* ctx = 0;
// Receive callback prototype
int MyEmbedReceive(WOLFSSL* ssl, char* buf, int sz, void* ctx);
// Register the custom receive callback with wolfSSL
wolfSSL_CTX_SetIORecv(ctx, MyEmbedReceive);
int MyEmbedReceive(WOLFSSL* ssl, char* buf, int sz, void* ctx)
{
    // custom EmbedReceive function
}
```

C.69.2.8 function wolfSSL_SetIOReadCtx

```
void wolfSSL_SetIOReadCtx(
    WOLFSSL * ssl,
    void * ctx
)
```

This function registers a context for the SSL session's receive callback function. By default, wolfSSL sets the file descriptor passed to wolfSSL_set_fd() as the context when wolfSSL is using the system's TCP library. If you've registered your own receive callback you may want to set a specific context for the session. For example, if you're using memory buffers the context may be a pointer to a structure describing where and how to access the memory buffers.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **rctx** pointer to the context to be registered with the SSL session's (ssl) receive callback function.

See:

- wolfSSL_CTX_SetIORecv
- wolfSSL_CTX_SetIOSend

- wolfSSL_SetIOWriteCtx

Return: none No returns.

Example

```
int sockfd;
WOLFSSL* ssl = 0;
...
// Manually setting the socket fd as the receive CTX, for example
wolfSSL_SetIOReadCtx(ssl, &sockfd);
...
```

C.69.2.9 function wolfSSL_SetIOWriteCtx

```
void wolfSSL_SetIOWriteCtx(
    WOLFSSL * ssl,
    void * ctx
)
```

This function registers a context for the SSL session's send callback function. By default, wolfSSL sets the file descriptor passed to wolfSSL_set_fd() as the context when wolfSSL is using the system's TCP library. If you've registered your own send callback you may want to set a specific context for the session. For example, if you're using memory buffers the context may be a pointer to a structure describing where and how to access the memory buffers.

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **wctx** pointer to the context to be registered with the SSL session's (ssl) send callback function.

See:

- wolfSSL_CTX_SetIORecv
- wolfSSL_CTX_SetIOSend
- wolfSSL_SetIOReadCtx

Return: none No returns.

Example

```
int sockfd;
WOLFSSL* ssl = 0;
...
// Manually setting the socket fd as the send CTX, for example
wolfSSL_SetIOWriteCtx(ssl, &sockfd);
...
```

C.69.2.10 function wolfSSL_GetIOReadCtx

```
void * wolfSSL_GetIOReadCtx(
    WOLFSSL * ssl
)
```

This function returns the IOCB_ReadCtx member of the WOLFSSL struct.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_GetIOWriteCtx
- wolfSSL_SetIOReadFlags
- wolfSSL_SetIOWriteCtx
- wolfSSL_SetIOReadCtx
- wolfSSL_CTX_SetIOSend

Return:

- pointer This function returns a void pointer to the IOCB_ReadCtx member of the WOLFSSL structure.
- NULL returned if the WOLFSSL struct is NULL.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
void* ioRead;
...
ioRead = wolfSSL_GetIOReadCtx(ssl);
if(ioRead == NULL){
    // Failure case. The ssl object was NULL.
}
```

C.69.2.11 function wolfSSL_GetIOWriteCtx

```
void * wolfSSL_GetIOWriteCtx(
    WOLFSSL * ssl
)
```

This function returns the IOCB_WriteCtx member of the WOLFSSL structure.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().

See:

- wolfSSL_GetIOReadCtx
- wolfSSL_SetIOWriteCtx
- wolfSSL_SetIOReadCtx
- wolfSSL_CTX_SetIOSend

Return:

- pointer This function returns a void pointer to the IOCB_WriteCtx member of the WOLFSSL structure.
- NULL returned if the WOLFSSL struct is NULL.

Example

```
WOLFSSL* ssl;
void* ioWrite;
...
ioWrite = wolfSSL_GetIOWriteCtx(ssl);
if(ioWrite == NULL){
    // The function returned NULL.
}
```

C.69.2.12 function wolfSSL_SetIOReadFlags

```
void wolfSSL_SetIOReadFlags(
    WOLFSSL * ssl,
```

```
    int flags
)
```

This function sets the flags for the receive callback to use for the given SSL session. The receive callback could be either the default wolfSSL EmbedReceive callback, or a custom callback specified by the user (see wolfSSL_CTX_SetIORecv). The default flag value is set internally by wolfSSL to the value of 0. The default wolfSSL receive callback uses the recv() function to receive data from the socket. From the recv() man page: "The flags argument to a recv() function is formed by or'ing one or more of the values: MSG_OOB process out-of-band data, MSG_PEEK peek at incoming message, MSG_WAITALL wait for full request or error. The MSG_OOB flag requests receipt of out-of-band data that would not be received in the normal data stream. Some protocols place expedited data at the head of the normal data queue, and thus this flag cannot be used with such protocols. The MSG_PEEK flag causes the receive operation to return data from the beginning of the receive queue without removing that data from the queue. Thus, a subsequent receive call will return the same data. The MSG_WAITALL flag requests that the operation block until the full request is satisfied. However, the call may still return less data than requested if a signal is caught, an error or disconnect occurs, or the next data to be received is of a different type than that returned."

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **flags** value of the I/O read flags for the specified SSL session (ssl).

See:

- wolfSSL_CTX_SetIORecv
- wolfSSL_CTX_SetIOSend
- wolfSSL_SetIOReadCtx

Return: none No returns.

Example

```
WOLFSSL* ssl = 0;
...
// Manually setting recv flags to 0
wolfSSL_SetIOReadFlags(ssl, 0);
...
```

C.69.2.13 function wolfSSL_SetIOWriteFlags

```
void wolfSSL_SetIOWriteFlags(
    WOLFSSL * ssl,
    int flags
)
```

This function sets the flags for the send callback to use for the given SSL session. The send callback could be either the default wolfSSL EmbedSend callback, or a custom callback specified by the user (see wolfSSL_CTX_SetIOSend). The default flag value is set internally by wolfSSL to the value of 0. The default wolfSSL send callback uses the send() function to send data from the socket. From the send() man page: "The flags parameter may include one or more of the following: #define MSG_OOB 0x1 // process out-of-band data, #define MSG_DONTROUTE 0x4 // bypass routing, use direct interface. The flag MSG_OOB is used to send 'out-of-band' data on sockets that support this notion (e.g. SOCK_STREAM); the underlying protocol must also support 'out-of-band' data. MSG_DONTROUTE is usually used only by diagnostic or routing programs."

Parameters:

- **ssl** pointer to the SSL session, created with wolfSSL_new().
- **flags** value of the I/O send flags for the specified SSL session (ssl).

See:

- wolfSSL_CTX_SetIORecv
- wolfSSL_CTX_SetIOSend
- wolfSSL_SetIOReadCtx

Return: none No returns.

Example

```
WOLFSSL* ssl = 0;
...
// Manually setting send flags to 0
wolfSSL_SetIOWriteFlags(ssl, 0);
...
```

C.69.2.14 function wolfSSL_SetIO_NetX

```
void wolfSSL_SetIO_NetX(
    WOLFSSL * ssl,
    NX_TCP_SOCKET * nxsocket,
    ULONG waitoption
)
```

This function sets the nxTcpSocket and nxWait members of the nxCtx struct within the WOLFSSL structure.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **nxsocket** a pointer to type NX_TCP_SOCKET that is set to the nxTcpSocket member of the nxCtx structure.
- **waitoption** a ULONG type that is set to the nxWait member of the nxCtx structure. With NX_NO_WAIT, or any wait option that can expire, the callbacks report WANT_READ/WANT_WRITE instead of a fatal error, so the wolfSSL call can be retried.

See:

- set_fd
- NetX_Send
- NetX_Receive

Return: none No returns.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
NX_TCP_SOCKET* nxsocket;
ULONG waitoption;
…
if(ssl != NULL || nxsocket != NULL || waitoption <= 0){
wolfSSL_SetIO_NetX(ssl, nxsocket, waitoption);
} else {
    // You need to pass in good parameters.
}
```

C.69.2.15 function wolfSSL_SetIO_NetX_Dtls

```
void wolfSSL_SetIO_NetX_Dtls(
    WOLFSSL * ssl,
```

```
    NX_UDP_SOCKET * nxsocket,
    NXD_ADDRESS nxdip,
    USHORT nxport,
    ULONG waitoption
)
```

This function configures the NetX Duo UDP context for a DTLS session. It stores the UDP socket, destination IP address (by value), destination port, and wait option into the WOLFSSL nxCtx structure. Requires WOLFSSL_NETX_DUO to be defined (ThreadX NetX Duo SDK).

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **nxsocket** a pointer to an NX_UDP_SOCKET already created and bound.
- **nxdip** the destination NXD_ADDRESS (passed by value; IPv4 or IPv6).
- **nxport** the destination UDP port number.
- **waitoption** a ULONG NetX wait option (e.g. NX_WAIT_FOREVER or ticks). With NX_NO_WAIT, or any wait option that can expire, NetX_SendTo reports WANT_WRITE instead of a fatal error. A receive that expires reports WANT_READ when the session is set non blocking, and a timeout otherwise so that DTLS can retransmit.

See:

- wolfSSL_SetIO_NetX
- NetX_SendTo
- NetX_ReceiveFrom

Return: none No returns.

Example

```
WOLFSSL* ssl = wolfSSL_new(ctx);
NX_UDP_SOCKET udpsocket;
NXD_ADDRESS   peeraddr;
USHORT        peerport = 4433;
ULONG         wait     = NX_WAIT_FOREVER;
// … initialise udpsocket and peeraddr …
wolfSSL_SetIO_NetX_Dtls(ssl, &udpsocket, peeraddr, peerport, wait);
```

C.69.2.16 function wolfSSL_CTX_SetGenCookie

```
void wolfSSL_CTX_SetGenCookie(
    WOLFSSL_CTX * ctx,
    CallbackGenCookie cb
)
```

This function sets the callback for the CBIOCookie member of the WOLFSSL_CTX structure. The CallbackGenCookie type is a function pointer and has the signature: int (*CallbackGenCookie)(WOLFSSL* ssl, unsigned char* buf, int sz, void* ctx);.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **cb** a CallbackGenCookie type function pointer with the signature of CallbackGenCookie.

See: CallbackGenCookie

Return: none No returns.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
…
int SetGenCookieCB(WOLFSSL* ssl, unsigned char* buf, int sz, void* ctx){
// Callback function body.
}
…
wolfSSL_CTX_SetGenCookie(ssl->ctx, SetGenCookieCB);
```

C.69.2.17 function wolfSSL_GetCookieCtx

```
void * wolfSSL_GetCookieCtx(
    WOLFSSL * ssl
)
```

This function returns the IOCB_CookieCtx member of the WOLFSSL structure.

Parameters:

- **ssl** a pointer to a WOLFSSL structure, created using wolfSSL_new().
- **ssl** SSL object

See:

- wolfSSL_SetCookieCtx
- wolfSSL_CTX_SetGenCookie
- wolfSSL_SetCookieCtx

Return:

- pointer The function returns a void pointer value stored in the IOCB_CookieCtx.
- NULL if the WOLFSSL struct is NULL
- Cookie context pointer

Gets cookie context for DTLS.

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new( method );
WOLFSSL* ssl = wolfSSL_new(ctx);
void* cookie;
...
cookie = wolfSSL_GetCookieCtx(ssl);
if(cookie != NULL){
// You have the cookie
}
```

Example

```
WOLFSSL* ssl;
void* ctx = wolfSSL_GetCookieCtx(ssl);
```

C.69.2.18 function wolfSSL_SetIO_ISOTP

```
int wolfSSL_SetIO_ISOTP(
    WOLFSSL * ssl,
    isotp_wolfssl_ctx * ctx,
    can_recv_fn recv_fn,
    can_send_fn send_fn,
    can_delay_fn delay_fn,
```

```
    word32 receive_delay,
    char * receive_buffer,
    int receive_buffer_size,
    void * arg
)
```

This function sets up the ISO-TP context if wolfSSL, for use when wolfSSL is compiled with WOLFSSL_ISOTP.

Parameters:

- **ssl** the wolfSSL context
- **ctx** a user created ISOTP context which this function initializes
- **recv_fn** a user CAN bus receive callback, returning the frame length, 0 if none arrived within timeout (ms), or negative on error
- **send_fn** a user CAN bus send callback
- **delay_fn** a user microsecond granularity delay function
- **receive_delay** a set amount of microseconds to delay each CAN bus packet
- **receive_buffer** a user supplied buffer to receive data, recommended that is allocated to ISOTP_DEFAULT_BUFFER_SIZE bytes
- **receive_buffer_size** - The size of receive_buffer
- **arg** an arbitrary pointer sent to recv_fn and send_fn

Return: 0 on success, WOLFSSL_CBIO_ERR_GENERAL on failure

Example

```
struct can_info can_con_info;
isotp_wolfssl_ctx isotp_ctx;
char *receive_buffer = malloc(ISOTP_DEFAULT_BUFFER_SIZE);
WOLFSSL_CTX* ctx = wolfSSL_CTX_new(method);
WOLFSSL* ssl = wolfSSL_new(ctx);
...
wolfSSL_SetIO_ISOTP(ssl, &isotp_ctx, can_receive, can_send, can_delay, 0,
        receive_buffer, ISOTP_DEFAULT_BUFFER_SIZE, &can_con_info);
```

C.69.2.19 function wolfSSL_SSLDisableRead

```
void wolfSSL_SSLDisableRead(
    WOLFSSL * ssl
)
```

This function disables reading from the IO layer.

Parameters:

- **ssl** the wolfSSL context

See:

- wolfSSL_CTX_SetIORecv
- wolfSSL_SSLSetIORecv
- wolfSSL_SSLEnableRead

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new(method);
WOLFSSL* ssl = wolfSSL_new(ctx);
wolfSSL_SSLDisableRead(ssl);
```

C.69.2.20 function wolfSSL_SSLEnableRead

```
void wolfSSL_SSLEnableRead(
    WOLFSSL * ssl
)
```

This function enables reading from the IO layer. Reading is enabled by default and should be used to undo wolfSSL_SSLDisableRead();.

Parameters:

- **ssl** the wolfSSL context

See:

- wolfSSL_CTX_SetIORecv
- wolfSSL_SSLSetIORecv
- wolfSSL_SSLEnableRead

Example

```
WOLFSSL_CTX* ctx = wolfSSL_CTX_new(method);
WOLFSSL* ssl = wolfSSL_new(ctx);
wolfSSL_SSLDisableRead(ssl);
...
wolfSSL_SSLEnableRead(ssl);
```

C.69.2.21 function wolfSSL_SetRecvFrom

```
WOLFSSL_API void wolfSSL_SetRecvFrom(
    WOLFSSL * ssl,
    WolfSSLRecvFrom recvFrom
)
```

Set a custom DTLS recvfrom callback for a WOLFSSL session.

Parameters:

- **ssl** A pointer to a WOLFSSL structure, created using wolfSSL_new().
- **recvFrom** The custom callback function to use for DTLS datagram receive.

See:

- WolfSSLRecvFrom
- wolfSSL_SetSendTo
- EmbedReceiveFrom
- wolfSSL_CTX_SetIORecv
- wolfSSL_SSLSetIORecv

This function allows you to specify a custom callback function for receiving datagrams (DTLS) using the `recvfrom`-style interface. The callback must match the WolfSSLRecvFrom function pointer type and is expected to behave like the POSIX `recvfrom()` function, including its return values and error handling.

Example

```
wolfSSL_SetRecvFrom(ssl, my_recvfrom_cb);
```

C.69.2.22 function wolfSSL_SetSendTo

```
WOLFSSL_API void wolfSSL_SetSendTo(
    WOLFSSL * ssl,
```

```
    WolfSSLSento sendTo
)
```

Set a custom DTLS sendto callback for a WOLFSSL session.

Parameters:

- **ssl** A pointer to a WOLFSSL structure, created using wolfSSL_new().
- **sendTo** The custom callback function to use for DTLS datagram send.

See:

- WolfSSLSento
- wolfSSL_SetRecvFrom
- EmbedSendTo
- wolfSSL_CTX_SetIOSend
- wolfSSL_SSLSetIOSend

This function allows you to specify a custom callback function for sending datagrams (DTLS) using the `sendto`-style interface. The callback must match the WolfSSLSento function pointer type and is expected to behave like the POSIX `sendto()` function, including its return values and error handling.

Example

```
wolfSSL_SetSendTo(ssl, my_sendto_cb);
```

C.69.2.23 function wolfIO_Select

```
int wolfIO_Select(
    SOCKET_T sockfd,
    int to_sec
)
```

Waits for socket to be ready for I/O with timeout.

Parameters:

- **sockfd** Socket file descriptor
- **to_sec** Timeout in seconds

See: wolfIO_TcpConnect

Return:

- 0 on success
- negative on error

Example

```
SOCKET_T sockfd;
int ret = wolfIO_Select(sockfd, 5);
```

C.69.2.24 function wolfIO_TcpConnect

```
int wolfIO_TcpConnect(
    SOCKET_T * sockfd,
    const char * ip,
    unsigned short port,
    int to_sec
)
```

Connects to TCP server with timeout.

Parameters:

- **sockfd** Pointer to socket file descriptor
- **ip** IP address string
- **port** Port number
- **to_sec** Timeout in seconds

See: wolfIO_TcpBind

Return:

- 0 on success
- negative on error

Example

```
SOCKET_T sockfd;
int ret = wolfIO_TcpConnect(&sockfd, "127.0.0.1", 443, 5);
```

C.69.2.25 function wolfIO_TcpAccept

```
int wolfIO_TcpAccept(
    SOCKET_T sockfd,
    SOCKADDR * peer_addr,
    XSOCKLENT * peer_len
)
```

Accepts TCP connection.

Parameters:

- **sockfd** Socket file descriptor
- **peer_addr** Peer address structure
- **peer_len** Peer address length

See: wolfIO_TcpBind

Return:

- Socket descriptor on success
- negative on error

Example

```
SOCKET_T sockfd;
SOCKADDR peer;
XSOCKLENT len = sizeof(peer);
int ret = wolfIO_TcpAccept(sockfd, &peer, &len);
```

C.69.2.26 function wolfIO_TcpBind

```
int wolfIO_TcpBind(
    SOCKET_T * sockfd,
    word16 port
)
```

Binds TCP socket to port.

Parameters:

- **sockfd** Pointer to socket file descriptor

- **port** Port number

See: wolfIO_TcpAccept

Return:

- 0 on success
- negative on error

Example

```
SOCKET_T sockfd;
int ret = wolfIO_TcpBind(&sockfd, 443);
```

C.69.2.27 function wolfIO_Send

```
int wolfIO_Send(
    SOCKET_T sd,
    char * buf,
    int sz,
    int wrFlags
)
```

Sends data on socket.

Parameters:

- **sd** Socket descriptor
- **buf** Buffer to send
- **sz** Buffer size
- **wrFlags** Write flags

See: wolfIO_Recv

Return:

- Number of bytes sent on success
- negative on error

Example

```
SOCKET_T sd;
char buf[100];
int ret = wolfIO_Send(sd, buf, sizeof(buf), 0);
```

C.69.2.28 function wolfIO_Recv

```
int wolfIO_Recv(
    SOCKET_T sd,
    char * buf,
    int sz,
    int rdFlags
)
```

Receives data from socket.

Parameters:

- **sd** Socket descriptor
- **buf** Buffer to receive into
- **sz** Buffer size
- **rdFlags** Read flags

See: wolfIO_Send

Return:

- Number of bytes received on success
- negative on error

Example

```
SOCKET_T sd;
char buf[100];
int ret = wolfIO_Recv(sd, buf, sizeof(buf), 0);
```

C.69.2.29 function wolfIO_SendTo

```
int wolfIO_SendTo(
    SOCKET_T sd,
    WOLFSSL_BIO_ADDR * addr,
    char * buf,
    int sz,
    int wrFlags
)
```

Sends datagram to address.

Parameters:

- **sd** Socket descriptor
- **addr** Destination address
- **buf** Buffer to send
- **sz** Buffer size
- **wrFlags** Write flags

See: wolfIO_RecvFrom

Return:

- Number of bytes sent on success
- negative on error

Example

```
SOCKET_T sd;
WOLFSSL_BIO_ADDR addr;
char buf[100];
int ret = wolfIO_SendTo(sd, &addr, buf, sizeof(buf), 0);
```

C.69.2.30 function wolfIO_RecvFrom

```
int wolfIO_RecvFrom(
    SOCKET_T sd,
    WOLFSSL_BIO_ADDR * addr,
    char * buf,
    int sz,
    int rdFlags
)
```

Receives datagram from address.

Parameters:

- **sd** Socket descriptor

- **addr** Source address
- **buf** Buffer to receive into
- **sz** Buffer size
- **rdFlags** Read flags

See: wolfIO_SendTo

Return:

- Number of bytes received on success
- negative on error

Example

```
SOCKET_T sd;
WOLFSSL_BIO_ADDR addr;
char buf[100];
int ret = wolfIO_RecvFrom(sd, &addr, buf, sizeof(buf), 0);
```

C.69.2.31 function wolfSSL_BioSend

```
int wolfSSL_BioSend(
    WOLFSSL * ssl,
    char * buf,
    int sz,
    void * ctx
)
```

BIO send callback.

Parameters:

- **ssl** SSL object
- **buf** Buffer to send
- **sz** Buffer size
- **ctx** Context pointer

See: wolfSSL_BioReceive

Return:

- Number of bytes sent on success
- negative on error

Example

```
WOLFSSL* ssl;
char buf[100];
int ret = wolfSSL_BioSend(ssl, buf, sizeof(buf), NULL);
```

C.69.2.32 function wolfSSL_BioReceive

```
int wolfSSL_BioReceive(
    WOLFSSL * ssl,
    char * buf,
    int sz,
    void * ctx
)
```

BIO receive callback.

Parameters:

- **ssl** SSL object
- **buf** Buffer to receive into
- **sz** Buffer size
- **ctx** Context pointer

See: wolfSSL_BioSend

Return:

- Number of bytes received on success
- negative on error

Example

```
WOLFSSL* ssl;
char buf[100];
int ret = wolfSSL_BioReceive(ssl, buf, sizeof(buf), NULL);
```

C.69.2.33 function EmbedReceiveFromMcast

```
int EmbedReceiveFromMcast(
    WOLFSSL * ssl,
    char * buf,
    int sz,
    void * ctx
)
```

Receives multicast datagram.

Parameters:

- **ssl** SSL object
- **buf** Buffer to receive into
- **sz** Buffer size
- **ctx** Context pointer

See: EmbedReceiveFrom

Return:

- Number of bytes received on success
- negative on error

Example

```
WOLFSSL* ssl;
char buf[100];
int ret = EmbedReceiveFromMcast(ssl, buf, sizeof(buf), NULL);
```

C.69.2.34 function wolfIO_HttpBuildRequestOcsp

```
int wolfIO_HttpBuildRequestOcsp(
    const char * domainName,
    const char * path,
    int ocspReqSz,
    unsigned char * buf,
    int bufSize
)
```

Builds HTTP OCSP request.

Parameters:

- **domainName** Domain name
- **path** URL path
- **ocspReqSz** OCSP request size
- **buf** Output buffer
- **bufSize** Buffer size

See: wolfIO_HttpProcessResponseOcsp

Return:

- Request size on success
- negative on error

Example

```
char buf[1024];
int ret = wolfIO_HttpBuildRequestOcsp("example.com", "/ocsp", 100,
                                      (unsigned char*)buf, sizeof(buf));
```

C.69.2.35 function wolfIO_HttpProcessResponseOcspGenericIO

```
int wolfIO_HttpProcessResponseOcspGenericIO(
    WolfSSLGenericIORecvCb ioCb,
    void * ioCbCtx,
    unsigned char ** respBuf,
    unsigned char * httpBuf,
    int httpBufSz,
    void * heap
)
```

Processes HTTP OCSP response with generic I/O.

Parameters:

- **ioCb** I/O callback
- **ioCbCtx** I/O callback context
- **respBuf** Response buffer pointer
- **httpBuf** HTTP buffer
- **httpBufSz** HTTP buffer size
- **heap** Heap hint

See: wolfIO_HttpProcessResponseOcsp

Return:

- 0 on success
- negative on error

Example

```
unsigned char* resp = NULL;
unsigned char httpBuf[1024];
int ret = wolfIO_HttpProcessResponseOcspGenericIO(myIoCb, ctx, &resp,
                                                  httpBuf,
                                                  sizeof(httpBuf), NULL);
```

C.69.2.36 function wolfIO_HttpProcessResponseOcsp

```
int wolfIO_HttpProcessResponseOcsp(
    int sfd,
    unsigned char ** respBuf,
```

```
    unsigned char * httpBuf,
    int httpBufSz,
    void * heap
)
```

Processes HTTP OCSP response.

Parameters:

- **sfd** Socket file descriptor
- **respBuf** Response buffer pointer
- **httpBuf** HTTP buffer
- **httpBufSz** HTTP buffer size
- **heap** Heap hint

See: wolfIO_HttpBuildRequestOcsp

Return:

- 0 on success
- negative on error

Example

```
int sfd;
unsigned char* resp = NULL;
unsigned char httpBuf[1024];
int ret = wolfIO_HttpProcessResponseOcsp(sfd, &resp, httpBuf,
                                         sizeof(httpBuf), NULL);
```

C.69.2.37 function EmbedOcspLookup

```
int EmbedOcspLookup(
    void * ctx,
    const char * url,
    int urlSz,
    byte * ocspReqBuf,
    int ocspReqSz,
    byte ** ocspRespBuf
)
```

OCSP lookup callback.

Parameters:

- **ctx** Context pointer
- **url** URL string
- **urlSz** URL size
- **ocspReqBuf** OCSP request buffer
- **ocspReqSz** OCSP request size
- **ocspRespBuf** OCSP response buffer pointer

See: EmbedOcspRespFree

Return:

- 0 on success
- negative on error

Example

```
byte* resp = NULL;
byte req[100];
int ret = EmbedOcspLookup(NULL, "http://example.com/ocsp", 25, req,
                          sizeof(req), &resp);
```

C.69.2.38 function wolfIO_HttpBuildRequestCrl

```
int wolfIO_HttpBuildRequestCrl(
    const char * url,
    int urlSz,
    const char * domainName,
    unsigned char * buf,
    int bufSize
)
```

Builds HTTP CRL request.

Parameters:

- **url** URL string
- **urlSz** URL size
- **domainName** Domain name
- **buf** Output buffer
- **bufSize** Buffer size

See: wolfIO_HttpProcessResponseCrl

Return:

- Request size on success
- negative on error

Example

```
char buf[1024];
int ret = wolfIO_HttpBuildRequestCrl("http://example.com/crl", 22,
                                     "example.com",
                                     (unsigned char*)buf, sizeof(buf));
```

C.69.2.39 function wolfIO_HttpProcessResponseCrl

```
int wolfIO_HttpProcessResponseCrl(
    WOLFSSL_CRL * crl,
    int sfd,
    unsigned char * httpBuf,
    int httpBufSz
)
```

Processes HTTP CRL response.

Parameters:

- **crl** CRL object
- **sfd** Socket file descriptor
- **httpBuf** HTTP buffer
- **httpBufSz** HTTP buffer size

See: wolfIO_HttpBuildRequestCrl

Return:

- 0 on success
- negative on error

Example

```
WOLFSSL_CRL crl;
int sfd;
unsigned char httpBuf[1024];
int ret = wolfIO_HttpProcessResponseCrl(&crl, sfd, httpBuf,
                                        sizeof(httpBuf));
```

C.69.2.40 function EmbedCrlLookup

```
int EmbedCrlLookup(
    WOLFSSL_CRL * crl,
    const char * url,
    int urlSz
)
```

CRL lookup callback.

Parameters:

- **crl** CRL object
- **url** URL string
- **urlSz** URL size

See: wolfIO_HttpBuildRequestCrl

Return:

- 0 on success
- negative on error

Example

```
WOLFSSL_CRL crl;
int ret = EmbedCrlLookup(&crl, "http://example.com/crl", 22);
```

C.69.2.41 function wolfIO_DecodeUrl

```
int wolfIO_DecodeUrl(
    const char * url,
    int urlSz,
    char * outName,
    char * outPath,
    unsigned short * outPort
)
```

Decodes URL into components.

Parameters:

- **url** URL string
- **urlSz** URL size
- **outName** Output domain name
- **outPath** Output path
- **outPort** Output port

See: wolfIO_HttpBuildRequest

Return:

- 0 on success
- negative on error

Example

```
char name[256], path[256];
unsigned short port;
int ret = wolfIO_DecodeUrl("http://example.com:443/path", 28, name,
                           path, &port);
```

C.69.2.42 function wolfIO_HttpBuildRequest

```
int wolfIO_HttpBuildRequest(
    const char * reqType,
    const char * domainName,
    const char * path,
    int pathLen,
    int reqSz,
    const char * contentType,
    unsigned char * buf,
    int bufSize
)
```

Builds generic HTTP request.

Parameters:

- **reqType** Request type (GET, POST, etc.)
- **domainName** Domain name
- **path** URL path
- **pathLen** Path length
- **reqSz** Request body size
- **contentType** Content type
- **buf** Output buffer
- **bufSize** Buffer size

See: wolfIO_HttpProcessResponse

Return:

- Request size on success
- negative on error

Example

```
char buf[1024];
int ret = wolfIO_HttpBuildRequest("POST", "example.com", "/api", 4,
                                  100, "application/json",
                                  (unsigned char*)buf, sizeof(buf));
```

C.69.2.43 function wolfIO_HttpProcessResponseGenericIO

```
int wolfIO_HttpProcessResponseGenericIO(
    WolfSSLGenericIORecvCb ioCb,
    void * ioCbCtx,
    const char ** appStrList,
    unsigned char ** respBuf,
    unsigned char * httpBuf,
    int httpBufSz,
```

```
    int dynType,
    void * heap
)
```

Processes HTTP response with generic I/O.

Parameters:

- **ioCb** I/O callback
- **ioCbCtx** I/O callback context
- **appStrList** Application string list
- **respBuf** Response buffer pointer
- **httpBuf** HTTP buffer
- **httpBufSz** HTTP buffer size
- **dynType** Dynamic type
- **heap** Heap hint

See: wolfIO_HttpProcessResponse

Return:

- 0 on success
- negative on error

Example

```
unsigned char* resp = NULL;
unsigned char httpBuf[1024];
const char* appStrs[] = {"200 OK", NULL};
int ret = wolfIO_HttpProcessResponseGenericIO(myIoCb, ctx, appStrs,
                                              &resp, httpBuf,
                                              sizeof(httpBuf), 0, NULL);
```

C.69.2.44 function wolfIO_HttpProcessResponse

```
int wolfIO_HttpProcessResponse(
    int sfd,
    const char ** appStrList,
    unsigned char ** respBuf,
    unsigned char * httpBuf,
    int httpBufSz,
    int dynType,
    void * heap
)
```

Processes HTTP response.

Parameters:

- **sfd** Socket file descriptor
- **appStrList** Application string list
- **respBuf** Response buffer pointer
- **httpBuf** HTTP buffer
- **httpBufSz** HTTP buffer size
- **dynType** Dynamic type
- **heap** Heap hint

See: wolfIO_HttpBuildRequest

Return:

- 0 on success
- negative on error

Example

```
int sfd;
unsigned char* resp = NULL;
unsigned char httpBuf[1024];
const char* appStrs[] = {"200 OK", NULL};
int ret = wolfIO_HttpProcessResponse(sfd, appStrs, &resp, httpBuf,
                                     sizeof(httpBuf), 0, NULL);
```

C.69.2.45 function wolfSSL_CTX_SetIOSend

```
void wolfSSL_CTX_SetIOSend(
    WOLFSSL_CTX * ctx,
    CallbackIOSend CBIOSend
)
```

Sets I/O send callback for context.

Parameters:

- **ctx** SSL context
- **CBIOSend** Send callback

See: wolfSSL_SSLSetIOSend

Return: none No returns

Example

```
WOLFSSL_CTX* ctx;
wolfSSL_CTX_SetIOSend(ctx, mySendCallback);
```

C.69.2.46 function wolfSSL_SSLSetIORecv

```
void wolfSSL_SSLSetIORecv(
    WOLFSSL * ssl,
    CallbackIORecv CBIORecv
)
```

Sets I/O receive callback for SSL object.

Parameters:

- **ssl** SSL object
- **CBIORecv** Receive callback

See: wolfSSL_CTX_SetIORecv

Return: none No returns

Example

```
WOLFSSL* ssl;
wolfSSL_SSLSetIORecv(ssl, myRecvCallback);
```

C.69.2.47 function wolfSSL_SSLSetIOSend

```
void wolfSSL_SSLSetIOSend(
    WOLFSSL * ssl,
    CallbackIOSend CBIOSend
)
```

Sets I/O send callback for SSL object.

Parameters:

- **ssl** SSL object
- **CBIOSend** Send callback

See: wolfSSL_CTX_SetIOSend

Return: none No returns

Example

```
WOLFSSL* ssl;
wolfSSL_SSLSetIOSend(ssl, mySendCallback);
```

C.69.2.48 function wolfSSL_SetIO_Mynewt

```
void wolfSSL_SetIO_Mynewt(
    WOLFSSL * ssl,
    struct mn_socket * mnSocket,
    struct mn_sockaddr_in * mnSockAddrIn
)
```

Sets I/O for Mynewt platform.

Parameters:

- **ssl** SSL object
- **mnSocket** Mynewt socket
- **mnSockAddrIn** Mynewt socket address

See: wolfSSL_SetIO_LwIP

Return: none No returns

Example

```
WOLFSSL* ssl;
struct mn_socket sock;
struct mn_sockaddr_in addr;
wolfSSL_SetIO_Mynewt(ssl, &sock, &addr);
```

C.69.2.49 function wolfSSL_SetIO_LwIP

```
int wolfSSL_SetIO_LwIP(
    WOLFSSL * ssl,
    void * pcb,
    tcp_recv_fn recv,
    tcp_sent_fn sent,
    void * arg
)
```

Sets I/O for LwIP platform.

Parameters:

- **ssl** SSL object
- **pcb** Protocol control block
- **recv** Receive callback
- **sent** Sent callback
- **arg** Argument pointer

See: wolfSSL_SetIO_Mynewt

Return:

- 0 on success
- negative on error

Example

```
WOLFSSL* ssl;
struct tcp_pcb* pcb;
int ret = wolfSSL_SetIO_LwIP(ssl, pcb, myRecv, mySent, NULL);
```

C.69.2.50 function wolfSSL_SetCookieCtx

```
void wolfSSL_SetCookieCtx(
    WOLFSSL * ssl,
    void * ctx
)
```

Sets cookie context for DTLS.

Parameters:

- **ssl** SSL object
- **ctx** Cookie context

See: wolfSSL_GetCookieCtx

Return: none No returns

Example

```
WOLFSSL* ssl;
void* ctx;
wolfSSL_SetCookieCtx(ssl, ctx);
```

C.69.2.51 function wolfSSL_CTX_SetIOGetPeer

```
void wolfSSL_CTX_SetIOGetPeer(
    WOLFSSL_CTX * ctx,
    CallbackGetPeer cb
)
```

Sets get peer callback for context.

Parameters:

- **ctx** SSL context
- **cb** Get peer callback

See: wolfSSL_CTX_SetIOSetPeer

Return: none No returns

Example

```
WOLFSSL_CTX* ctx;
wolfSSL_CTX_SetIOGetPeer(ctx, myGetPeerCallback);
```

C.69.2.52 function wolfSSL_CTX_SetIOSetPeer

```
void wolfSSL_CTX_SetIOSetPeer(
    WOLFSSL_CTX * ctx,
    CallbackSetPeer cb
)
```

Sets set peer callback for context.

Parameters:

- **ctx** SSL context
- **cb** Set peer callback

See: wolfSSL_CTX_SetIOGetPeer

Return: none No returns

Example

```
WOLFSSL_CTX* ctx;
wolfSSL_CTX_SetIOSetPeer(ctx, mySetPeerCallback);
```

C.69.2.53 function EmbedGetPeer

```
int EmbedGetPeer(
    WOLFSSL * ssl,
    char * ip,
    int * ipSz,
    unsigned short * port,
    int * fam
)
```

Gets peer information.

Parameters:

- **ssl** SSL object
- **ip** IP address buffer
- **ipSz** IP address buffer size pointer
- **port** Port number pointer
- **fam** Address family pointer

See: EmbedSetPeer

Return:

- 0 on success
- negative on error

Example

```
WOLFSSL* ssl;
char ip[46];
int ipSz = sizeof(ip);
unsigned short port;
int fam;
int ret = EmbedGetPeer(ssl, ip, &ipSz, &port, &fam);
```

C.69.2.54 function EmbedSetPeer

```
int EmbedSetPeer(
    WOLFSSL * ssl,
    char * ip,
    int ipSz,
    unsigned short port,
    int fam
)
```

Sets peer information.

Parameters:

- **ssl** SSL object
- **ip** IP address string
- **ipSz** IP address string size
- **port** Port number
- **fam** Address family

See: EmbedGetPeer

Return:

- 0 on success
- negative on error

Example

```
WOLFSSL* ssl;
int ret = EmbedSetPeer(ssl, "127.0.0.1", 9, 443, AF_INET);
```

C.69.3 Source code

                 int* fam);

int EmbedSetPeer(WOLFSSL* ssl, char* ip, int ipSz, unsigned short port,
                 int fam);
```

D SSL/TLS Overview

D.1 General Architecture

The wolfSSL (formerly CyaSSL) embedded SSL library implements SSL 3.0, TLS 1.0, TLS 1.1, TLS 1.2, and TLS 1.3 protocols. TLS 1.3 is currently the most secure and up to date version of the standard. wolfSSL does not support SSL 2.0 due to the fact that it has been insecure for several years.

The TLS protocol in wolfSSL is implemented as defined in RFC 5246 (https://tools.ietf.org/html/rfc5246). Two record layer protocols exist within SSL - the message layer and the handshake layer. Handshake messages are used to negotiate a common cipher suite, create secrets, and enable a secure connection. The message layer encapsulates the handshake layer while also supporting alert processing and application data transfer.

A general diagram of how the SSL protocol fits into existing protocols can be seen in **Figure 1**. SSL sits in between the Transport and Application layers of the OSI model, where any number of protocols (including TCP/IP, Bluetooth, etc.) may act as the transport medium. Application protocols are layered on top of SSL (such as HTTP, FTP, and SMTP).

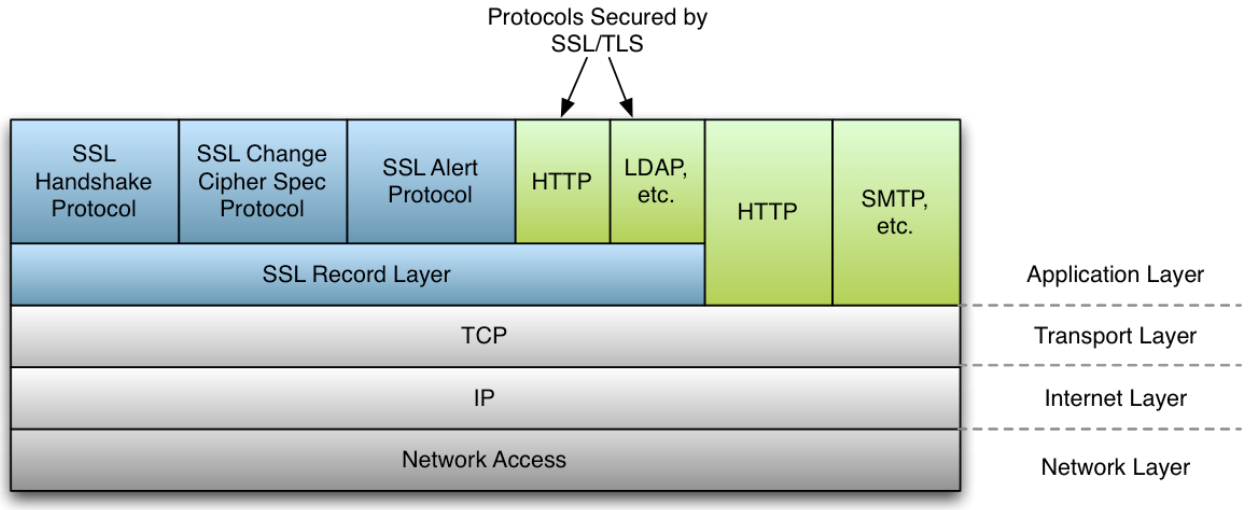

Figure 5: SSL Protocol Diagram

D.2 SSL Handshake

The SSL handshake involves several steps, some of which are optional depending on what options the SSL client and server have been configured with. Below, in **Figure 2**, you will find a simplified diagram of the SSL handshake process.

D.3 Differences between SSL and TLS Protocol Versions

SSL (Secure Sockets Layer) and TLS (Transport Security Layer) are both cryptographic protocols which provide secure communication over networks. These two protocols (and the several versions of each) are in widespread use today in applications ranging from web browsing to e-mail to instant messaging and VoIP. Each protocol, and the underlying versions of each, are slightly different from the other.

Below you will find both an explanation of, and the major differences between the different SSL and TLS protocol versions. For specific details about each protocol, please reference the RFC specification mentioned.

D.3.1 SSL 3.0

This protocol was released in 1996 but began with the creation of SSL 1.0 developed by Netscape. Version 1.0 wasn't released, and version 2.0 had a number of security flaws, thus leading to the release of SSL 3.0. Some major improvements of SSL 3.0 over SSL 2.0 are:

- Separation of the transport of data from the message layer
- Use of a full 128 bits of keying material even when using the Export cipher
- Ability of the client and server to send chains of certificates, thus allowing organizations to use certificate hierarchy which is more than two certificates deep.
- Implementing a generalized key exchange protocol, allowing Diffie-Hellman and Fortezza key exchanges as well as non-RSA certificates.
- Allowing for record compression and decompression
- Ability to fall back to SSL 2.0 when a 2.0 client is encountered

D.3.2 TLS 1.0

This protocol was first defined in RFC 2246 in January of 1999. This was an upgrade from SSL 3.0 and the differences were not dramatic, but they are significant enough that SSL 3.0 and TLS 1.0 don't interoperate. Some of the major differences between SSL 3.0 and TLS 1.0 are:

- Key derivation functions are different
- MACs are different - SSL 3.0 uses a modification of an early HMAC while TLS 1.0 uses HMAC.
- The Finished messages are different
- TLS has more alerts
- TLS requires DSS/DH support

D.3.3 TLS 1.1

This protocol was defined in RFC 4346 in April of 2006, and is an update to TLS 1.0. The major changes are:

- The Implicit Initialization Vector (IV) is replaced with an explicit IV to protect against Cipher block chaining (CBC) attacks.
- Handling of padded errors is changed to use the `bad_record_mac` alert rather than the `decryption_failed` alert to protect against CBC attacks.
- IANA registries are defined for protocol parameters
- Premature closes no longer cause a session to be non-resumable.

D.3.4 TLS 1.2

This protocol was defined in RFC 5246 in August of 2008. Based on TLS 1.1, TLS 1.2 contains improved flexibility. The major differences include:

- The MD5/SHA-1 combination in the pseudorandom function (PRF) was replaced with cipher-suite-specified PRFs.
- The MD5/SHA-1 combination in the digitally-signed element was replaced with a single hash. Signed elements include a field explicitly specifying the hash algorithm used.
- There was substantial cleanup to the client's and server's ability to specify which hash and signature algorithms they will accept.
- Addition of support for authenticated encryption with additional data modes.
- TLS Extensions definition and AES Cipher Suites were merged in.
- Tighter checking of EncryptedPreMasterSecret version numbers.
- Many of the requirements were tightened
- `Verify_data` length depends on the cipher suite
- Description of Bleichenbacher/Dlima attack defenses cleaned up.

COPYRIGHT ©2024 wolfSSL Inc.

D.3.5 TLS 1.3

This protocol was defined in RFC 8446 in August of 2018. TLS 1.3 contains improved security and speed. The major differences include:

- The list of supported symmetric algorithms has been pruned of all legacy algorithms. The remaining algorithms all use Authenticated Encryption with Associated Data (AEAD) algorithms.
- A zero-RTT (0-RTT) mode was added, saving a round-trip at connection setup for some application data at the cost of certain security properties.
- All handshake messages after the ServerHello are now encrypted.
- Key derivation functions have been re-designed, with the HMAC-based Extract-and-Expand Key Derivation Function (HKDF) being used as a primitive.
- The handshake state machine has been restructured to be more consistent and remove superfluous messages.
- ECC is now in the base spec and includes new signature algorithms. Point format negotiation has been removed in favor of single point format for each curve.
- Compression, custom DHE groups, and DSA have been removed, RSA padding now uses PSS.
- TLS 1.2 version negotiation verification mechanism was deprecated in favor of a version list in an extension.
- Session resumption with and without server-side state and the PSK-based ciphersuites of earlier versions of TLS have been replaced by a single new PSK exchange.

F Error Codes

F.1 wolfSSL Error Codes

wolfSSL (formerly CyaSSL) error codes can be found in `wolfssl/ssl.h`. For detailed descriptions of the following errors, see the OpenSSL man page for `SSL_get_error` (`man SSL_get_error`).

Error Code Enum	Error Code	Error Description
SSL_ERROR_WANT_READ	2	
SSL_ERROR_WANT_WRITE	3	
SSL_ERROR_WANT_CONNECT	7	
SSL_ERROR_WANT_ACCEPT	8	
SSL_ERROR_SYSCALL	5	
SSL_ERROR_WANT_X509_LOOKUP	83	
SSL_ERROR_ZERO_RETURN	6	
SSL_ERROR_SSL	85	

Additional wolfSSL error codes can be found in `wolfssl/error-ssl.h`

Error Code Enum	Error Code	Error Description
INPUT_CASE_ERROR	-301	process input state error
PREFIX_ERROR	-302	bad index to key rounds
MEMORY_ERROR	-303	out of memory
VERIFY_FINISHED_ERROR	-304	verify problem on finished
VERIFY_MAC_ERROR	-305	verify mac problem
PARSE_ERROR	-306	parse error on header
UNKNOWN_HANDSHAKE_TYPE	-307	weird handshake type
SOCKET_ERROR_E	-308	error state on socket
SOCKET_NODATA	-309	expected data, not there
INCOMPLETE_DATA	-310	don't have enough data to complete task
UNKNOWN_RECORD_TYPE	-311	unknown type in record hdr
DECRYPT_ERROR	-312	error during decryption
FATAL_ERROR	-313	revcd alert fatal error
ENCRYPT_ERROR	-314	error during encryption
FREAD_ERROR	-315	fread problem
NO_PEER_KEY	-316	need peer's key
NO_PRIVATE_KEY	-317	need the private key
RSA_PRIVATE_ERROR	-318	error during rsa priv op
NO_DH_PARAMS	-319	server missing DH params
BUILD_MSG_ERROR	-320	build message failure
BAD_HELLO	-321	client hello malformed
DOMAIN_NAME_MISMATCH	-322	peer subject name mismatch
WANT_READ	-323	want read, call again
NOT_READY_ERROR	-324	handshake layer not ready
VERSION_ERROR	-326	record layer version error
WANT_WRITE	-327	want write, call again
BUFFER_ERROR	-328	malformed buffer input
VERIFY_CERT_ERROR	-329	verify cert error
VERIFY_SIGN_ERROR	-330	verify sign error
CLIENT_ID_ERROR	-331	psk client identity error
SERVER_HINT_ERROR	-332	psk server hint error

COPYRIGHT ©2024 wolfSSL Inc.

Error Code Enum	Error Code	Error Description
PSK_KEY_ERROR	-333	psk key error
GETTIME_ERROR	-337	gettimeofday failed ???
GETITIMER_ERROR	-338	getitimer failed ???
SIGACT_ERROR	-339	sigaction failed ???
SETITIMER_ERROR	-340	setitimer failed ???
LENGTH_ERROR	-341	record layer length error
PEER_KEY_ERROR	-342	cant decode peer key
ZERO_RETURN	-343	peer sent close notify
SIDE_ERROR	-344	wrong client/server type
NO_PEER_CERT	-345	peer didn't send key
ECC_CURVETYPE_ERROR	-350	Bad ECC Curve Type
ECC_CURVE_ERROR	-351	Bad ECC Curve
ECC_PEERKEY_ERROR	-352	Bad Peer ECC Key
ECC_MAKEKEY_ERROR	-353	Bad Make ECC Key
ECC_EXPORT_ERROR	-354	Bad ECC Export Key
ECC_SHARED_ERROR	-355	Bad ECC Shared Secret
NOT_CA_ERROR	-357	Not CA cert error
BAD_CERT_MANAGER_ERROR	-359	Bad Cert Manager
OCSP_CERT_REVOKED	-360	OCSP Certificate revoked
CRL_CERT_REVOKED	-361	CRL Certificate revoked
CRL_MISSING	-362	CRL Not loaded
MONITOR_SETUP_E	-363	CRL Monitor setup error
THREAD_CREATE_E	-364	Thread Create Error
OCSP_NEED_URL	-365	OCSP need an URL for lookup
OCSP_CERT_UNKNOWN	-366	OCSP responder doesn't know
OCSP_LOOKUP_FAIL	-367	OCSP lookup not successful
MAX_CHAIN_ERROR	-368	max chain depth exceeded
COOKIE_ERROR	-369	dtls cookie error
SEQUENCE_ERROR	-370	dtls sequence error
SUITES_ERROR	-371	suites pointer error
OUT_OF_ORDER_E	-373	out of order message
BAD_KEA_TYPE_E	-374	bad KEA type found
SANITY_CIPHER_E	-375	sanity check on cipher error
RECV_OVERFLOW_E	-376	RXCB returned more than rqed
GEN_COOKIE_E	-377	Generate Cookie Error
NO_PEER_VERIFY	-378	Need peer cert verify Error
FWRITE_ERROR	-379	fwrite problem
CACHE_MATCH_ERROR	-380	cache hrd match error
UNKNOWN_SNI_HOST_NAME_E	-381	Unrecognized host name Error
UNKNOWN_MAX_FRAG_LEN_E	-382	Unrecognized max frag len Error
KEYUSE_SIGNATURE_E	-383	KeyUse digSignature error
KEYUSE_ENCIPHER_E	-385	KeyUse KeyEncipher error
EXTKEYUSE_AUTH_E	-386	ExtKeyUse server|client_auth
SEND_OOB_READ_E	-387	Send Cb out of bounds read
SECURE_RENEGOTIATION_E	-388	Invalid renegotiation info
SESSION_TICKET_LEN_E	-389	Session Ticket too large
SESSION_TICKET_EXPECT_E	-390	Session Ticket missing
SCR_DIFFERENT_CERT_E	-391	SCR Different cert error
SESSION_SECRET_CB_E	-392	Session secret CB fcn failure
NO_CHANGE_CIPHER_E	-393	Finished before change cipher
SANITY_MSG_E	-394	Sanity check on msg order error
DUPLICATE_MST_E	-395	Duplicate message error

Error Code Enum	Error Code	Error Description
SNI_UNSUPPORTED	-396	SSL 3.0 does not support SNI
SOCKET_PEER_CLOSED_E	-397	Underlying transport closed
BAD_TICKET_KEY_CB_SZ	-398	Bad session ticket key cb size
BAD_TICKET_MSG_SZ	-399	Bad session ticket msg size
BAD_TICKET_ENCRYPT	-400	Bad user ticket encrypt
DH_KEY_SIZE_E	-401	DH key too small
SNI_ABSENT_ERROR	-402	No SNI request
RSA_SIGN_FAULT	-403	RSA sign fault
HANDSHAKE_SIZE_ERROR	-404	Handshake message too large
UNKNOWN_ALPN_PROTOCOL_NAME_E	-405	Unrecognized protocol name error
BAD_CERTIFICATE_STATUS_ERROR	-406	Bad certificate status message
OCSP_INVALID_STATUS	-407	Invalid OCSP status
OCSP_WANT_READ	-408	OCSP callback response
RSA_KEY_SIZE_E	-409	RSA key too small
ECC_KEY_SIZE_E	-410	ECC key too small
DTLS_EXPORT_VER_E	-411	Export version error
INPUT_SIZE_E	-412	Input size too big error
CTX_INIT_MUTEX_E	-413	Initialize ctx mutex error
EXT_MASTER_SECRET_NEEDED_E	-414	Need EMS enabled to resume
DTLS_POOL_SZ_E	-415	Exceeded DTLS pool size
DECODE_E	-416	Decode handshake message error
HTTP_TIMEOUT	-417	HTTP timeout for OCSP or CRL req
WRITE_DUP_READ_E	-418	Write dup write side can't read
WRITE_DUP_WRITE_E	-419	Write dup read side can't write
INVALID_CERT_CTX_E	-420	TLS cert ctx not matching
BAD_KEY_SHARE_DATA	-421	Key share data invalid
MISSING_HANDSHAKE_DATA	-422	Handshake message missing data
BAD_BINDER	-423	Binder does not match
EXT_NOT_ALLOWED	-424	Extension not allowed in msg
INVALID_PARAMETER	-425	Security parameter invalid
MCAST_HIGHWATER_CB_E	-426	Multicast highwater cb err
ALERT_COUNT_E	-427	Alert count exceeded err
EXT_MISSING	-428	Required extension not found
UNSUPPORTED_EXTENSION	-429	TLSX not requested by client
PRF_MISSING	-430	PRF not compiled in
DTLS_RETX_OVER_TX	-431	Retransmit DTLS flight over
DH_PARAMS_NOT_FFDHE_E	-432	DH params from server not FFDHE
TCA_INVALID_ID_TYPE	-433	TLSX TCA ID type invalid
TCA_ABSENT_ERROR	-434	TLSX TCA ID no response

Negotiation Parameter Errors

Error Code Enum	Error Code	Error Description
UNSUPPORTED_SUITE	-500	Unsupported cipher suite
MATCH_SUITE_ERROR	-501	Can't match cipher suite
COMPRESSION_ERROR	-502	Compression mismatch
KEY_SHARE_ERROR	-503	Key share mismatch
POST_HAND_AUTH_ERROR	-504	Client won't do post-hand auth
HRR_COOKIE_ERROR	-505	HRR msg cookie mismatch

F.2 wolfCrypt Error Codes

wolfCrypt error codes can be found in `wolfssl/wolfcrypt/error.h`.

Error Code Enum	Error Code	Error Description
OPEN_RAN_E	-101	opening random device error
READ_RAN_E	-102	reading random device error
WINCRYPT_E	-103	windows crypt init error
CRYPTGEN_E	-104	windows crypt generation error
RAN_BLOCK_E	-105	reading random device would block
BAD_MUTEX_E	-106	Bad mutex operation
MP_INIT_E	-110	mp_init error state
MP_READ_E	-111	mp_read error state
MP_EXPTMOD_E	-112	mp_exptmod error state
MP_TO_E	-113	mp_to_xxx error state, can't convert
MP_SUB_E	-114	mp_sub error state, can't subtract
MP_ADD_E	-115	mp_add error state, can't add
MP_MUL_E	-116	mp_mul error state, can't multiply
MP_MULMOD_E	-117	mp_mulmod error state, can't multiply mod
MP_MOD_E	-118	mp_mod error state, can't mod
MP_INVMOD_E	-119	mp_invmod error state, can't inv mod
MP_CMP_E	-120	mp_cmp error state
MP_ZERO_E	-121	got a mp zero result, not expected
MEMORY_E	-125	out of memory error
RSA_WRONG_TYPE_E	-130	RSA wrong block type for RSA function
RSA_BUFFER_E	-131	RSA buffer error, output too small or input too large
BUFFER_E	-132	output buffer too small or input too large
ALGO_ID_E	-133	setting algo id error

ASN_PARSE_E	-140	ASN parsing error, invalid input
ASN_VERSION_E	-141	ASN version error, invalid number
ASN_GETINT_E	-142	ASN get big int error, invalid data
ASN_RSA_KEY_E	-143	ASN key init error, invalid input
ASN_OBJECT_ID_E	-144	ASN object id error, invalid id
ASN_TAG_NULL_E	-145	ASN tag error, not null
ASN_EXPECT_0_E	-146	ASN expect error, not zero
ASN_BITSTR_E	-147	ASN bit string error, wrong id
ASN_UNKNOWN_OID_E	-148	ASN oid error, unknown sum id
ASN_DATE_SZ_E	-149	ASN date error, bad size
ASN_BEFORE_DATE_E	-150	ASN date error, current date before
ASN_AFTER_DATE_E	-151	ASN date error, current date after
ASN_SIG_OID_E	-152	ASN signature error, mismatched oid
ASN_TIME_E	-153	ASN time error, unknown time type
ASN_INPUT_E	-154	ASN input error, not enough data
ASN_SIG_CONFIRM_E	-155	ASN sig error, confirm failure
ASN_SIG_HASH_E	-156	ASN sig error, unsupported hash type
ASN_SIG_KEY_E	-157	ASN sig error, unsupported key type
ASN_DH_KEY_E	-158	ASN key init error, invalid input
ASN_CRIT_EXT_E	-160	ASN unsupported critical extension

Error Code Enum	Error Code	Error Description
ECC_BAD_ARG_E	-170	ECC input argument of wrong type
ASN_ECC_KEY_E	-171	ASN ECC bad input
ECC_CURVE_OID_E	-172	Unsupported ECC OID curve type
BAD_FUNC_ARG	-173	Bad function argument provided
NOT_COMPILED_IN	-174	Feature not compiled in
UNICODE_SIZE_E	-175	Unicode password too big
NO_PASSWORD	-176	no password provided by user
ALT_NAME_E	-177	alt name size problem, too big
AES_GCM_AUTH_E	-180	AES-GCM Authentication check failure
AES_CCM_AUTH_E	-181	AES-CCM Authentication check failure

WC_HW_E	-248	Error with hardware crypto use
WC_HW_WAIT_E	-249	Hardware waiting on resource
PSS_SALTLEN_E	-250	PSS length of salt is too long for hash
PRIME_GEN_E	-251	Failure finding a prime
BER_INDEF_E	-252	Cannot decode indefinite length BER
RSA_OUT_OF_RANGE_E	-253	Ciphertext to decrypt out of range
RSAPSS_PAT_FIPS_E	-254	RSA-PSS PAT failure
ECDSA_PAT_FIPS_E	-255	ECDSA PAT failure
DH_KAT_FIPS_E	-256	DH KAT failure
AESCCM_KAT_FIPS_E	-257	AESCCM KAT failure
SHA3_KAT_FIPS_E	-258	SHA-3 KAT failure
ECDHE_KAT_FIPS_E	-259	ECDHE KAT failure
AES_GCM_OVERFLOW_E	-260	AES-GCM invocation counter overflow
AES_CCM_OVERFLOW_E	-261	AES-CCM invocation counter overflow
RSA_KEY_PAIR_E	-262	RSA Key Pair-Wise consistency check fail
DH_CHECK_PRIVE_E	-263	DH check private key error
WC_AFALG_SOCK_E	-264	AF_ALG socket error
WC_DEVCRYPTO_E	-265	/dev/crypto error
ZLIB_INIT_ERROR	-266	Zlib init error
ZLIB_COMPRESS_ERROR	-267	Zlib compression error
ZLIB_DECOMPRESS_ERROR	-268	Zlib decompression error
PKCS7_NO_SIGNER_E	-269	No signer in PKCS7 signed data msg
WC_PKCS7_WANT_READ_E	-270	PKCS7 stream operation wants more input
CRYPTOCB_UNAVAILABLE	-271	Crypto callback unavailable
PKCS7_SIGNEEDS_CHECK	-272	Signature needs verified by caller
ASN_SELF_SIGNED_E	-275	ASN self-signed certificate error
MIN_CODE_E	-300	errors -101 - -299

F.3 Common Error Codes and their Solution

There are several error codes that commonly happen when getting an application up and running with wolfSSL.

F.3.1 ASN_NO_SIGNER_E (-188)

This error occurs when using a certificate and the signing CA certificate was not loaded. This can be seen using the wolfSSL example server or client against another client or server, for example connecting to Google using the wolfSSL example client:

```
./examples/client/client -g -h www.google.com -p 443
```

This fails with error -188 because Google's CA certificate wasn't loaded with the "-A" command line option.

F.3.2 WANT_READ (-323)

The WANT_READ error happens often when using non-blocking sockets, and isn't actually an error when using non-blocking sockets, but it is passed up to the caller as an error. When a call to receive data from the I/O callback would block as there isn't data currently available to receive, the I/O callback returns WANT_READ. The caller should wait and try receiving again later. This is usually seen from calls to wolfSSL_read(), wolfSSL_negotiate(), wolfSSL_accept(), and wolfSSL_connect(). The example client and server will indicate the WANT_READ incidents when debugging is enabled.

G Supported Cipher Suites, Key Exchange Groups, and Signature Algorithms

G.1 A. Cipher Suites

G.1.1 A-1. TLS 1.3

IANA Name	Wire Value	Default	configure Option
TLS_AES_128_GCM_SHA256	0x13,0x01	**Enabled**	--enable-tls13 + --enable-aesgcm
TLS_AES_256_GCM_SHA384	0x13,0x02	**Enabled**	--enable-tls13 + --enable-aesgcm + --enable-sha384
TLS_CHACHA20_POLY1305_SHA256	0x13,0x03	**Enabled**	--enable-tls13 + --enable-chacha + --enable-poly1305
TLS_AES_128_CCM_SHA256	0x13,0x04	Disabled	--enable-aesccm
TLS_AES_128_CCM_8_SHA256	0x13,0x05	Disabled	--enable-aesccm
TLS_SM4_GCM_SM3	0x00,0xC6	Disabled	--enable-sm4-gcm + --enable-sm3
TLS_SM4_CCM_SM3	0x00,0xC7	Disabled	--enable-sm4-ccm + --enable-sm3
TLS_SHA256_SHA256	0xC0,0xB4	Disabled	--enable-nullcipher
TLS_SHA384_SHA384	0xC0,0xB5	Disabled	--enable-nullcipher + --enable-sha384

G.1.2 A-2. TLS 1.2 ECDHE-ECDSA

IANA Name	Wire Value	Default	configure Option
TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256	0xC0,0x2B	**Enabled**	—
TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384	0xC0,0x2C	**Enabled**	—
TLS_ECDHE_ECDSA_WITH_CHACHA20_POLY1305_SHA256	0xCC,0xA9	**Enabled**	—

H.2 B. SP Math Library (Public Key Cryptography)

Architecture	Algorithms	user_settings.h Macro	configure Option
x86-64 assembly	RSA 2048/3072/4096, ECC P-256/P-384/P-521, DH	WOLFSSL_SP_X86_64_ASM	Auto-detected
ARM AArch64 assembly	RSA, ECC, DH	WOLFSSL_SP_ARM64_ASM	Auto-detected
ARM 32-bit assembly	RSA, ECC, DH	WOLFSSL_SP_ARM32_ASM	Auto-detected
ARM Thumb assembly	RSA, ECC, DH	WOLFSSL_SP_ARM_THUMB_ASM	Auto-detected
Cortex-M assembly	RSA, ECC, DH	WOLFSSL_SP_ARM_CORTEX_M_ASM	Auto-detected
Generic C (32-bit / 64-bit)	RSA, ECC, DH	WOLFSSL_SP_MATH	--enable-sp

H.2.1 sp_int.c Inline Assembly Speedups

sp_int.c contains small inline assembly helpers for multi-precision multiply/add operations used when the dedicated per-algorithm SP files (e.g. sp_x86_64.c) are absent or for non-RSA/ECC key sizes. These are controlled by the following macros (auto-detected; can also be set in user_settings.h):

Architecture	user_settings.h Macro
Intel x86-64	WOLFSSL_SP_X86_64
Intel x86 (32-bit)	WOLFSSL_SP_X86
ARM AArch64	WOLFSSL_SP_ARM64
ARM 32-bit	WOLFSSL_SP_ARM32
ARM Thumb	WOLFSSL_SP_ARM_THUMB
RISC-V 64-bit	WOLFSSL_SP_RISCV64
RISC-V 32-bit	WOLFSSL_SP_RISCV32
MIPS 64-bit	WOLFSSL_SP_MIPS64
MIPS 32-bit	WOLFSSL_SP_MIPS
s390x	WOLFSSL_SP_S390X

H.2.2 SP Key Size Configuration

```
#define WOLFSSL_SP_MATH
#define WOLFSSL_SP_X86_64_ASM         /* x86-64 */
#define WOLFSSL_SP_ARM64_ASM          /* AArch64 */

I Experimenting with Post-Quantum Cryptography

A while back, the wolfSSL team integrated experimental post-quantum cryptographic algorithms into the wolfSSL library. This was done by integrating with the Open Quantum Safe team's liboqs. Currently, wolfCrypt implements LMS, XMSS, ML-DSA and ML-KEM. So, for the purpose of code size reduction and ease of maintenance, the wolfSSL team removed the integration with liboqs.

This appendix is intended for anyone that wants to start learning about post-quantum cryptography in the context of (D)TLS 1.3. It explains why post-quantum algorithms are important, what we have done in response to the quantum threat and how you can start experimenting with these new algorithms.

Note: Some of the post-quantum algorithms are not fully standardized yet. Some OIDs and codepoints are temporary and expected to change in the future. You should have no expectation of backwards compatibility until they are fully standardized.

I.1 A Gentle Introduction to Post-Quantum Cryptography

I.1.1 Why Post-Quantum Cryptography?

For some time now, many resources have been devoted to the development of quantum computers. So much so that commercialization of cloud quantum computing resources has already begun. While the current state of the art is still not in the realm of being cryptographically relevant, some threat models such as "harvest now, decrypt later" mean that preparations need to happen sooner than the appearance of cryptographically relevant quantum computers.

NIST is leading the way for standardization of a new class of algorithms designed to replace the public key cryptography algorithms that will become vulnerable to quantum computers. At the time of the writing of this passage, NIST has already standardized ML-DSA, ML-KEM, and SLH-DSA.

ML-KEM (Module Lattice Key Encapsulation Mechanism) is a NIST-standardized, lattice-based post-quantum algorithm derived from Kyber. It enables two parties to establish a shared key over an insecure channel using a key encapsulation mechanism, protecting against both classical and quantum adversaries.

ML-DSA (Module Lattice Digital Signature Algorithm) is a NIST-standardized, lattice-based post-quantum digital signature scheme derived from Dilithium. It enables a sender to produce a verifiable signature that proves the origin and integrity of a message.

Both ML-KEM and ML-DSA are public-key algorithms designed to resist cryptographically relevant quantum computers. They are part of NIST's Post-Quantum Cryptography standards (FIPS 203 and FIPS 204) and can be deployed today, often in hybrid form, to prepare for the post-quantum era.

Currently, standards organizations have various draft documents describing OIDs and codepoints. NIST is working on bringing these algorithms under the ubmbrella of the CMVP regulatory framework allowing for FIPS-140-3 validations of implementations of these algorithms.

I.1.2 How do we Protect Ourselves?

From a high level perspective, for every TLS 1.3 connection, authentication, integrity and confidentiality are the main security goals that protect each connection. Authentication is maintained via signature schemes such as ECDSA. Confidentiality and integrity are maintained by key establishment algorithms such as ECDHE and then using the established key with symmetric encryption algorithms such as AES to encrypt a communication stream. We can thus decompose the security of the TLS 1.3 protocol into 3 types of cryptographic algorithms:

- authentication algorithms
- key establishment algorithms

COPYRIGHT ©2024 wolfSSL Inc.

- symmetric cipher algorithms

The threat of quantum computers to conventional cryptography takes two forms. Grover's algorithm reduces the security of modern symmetric cipher algorithms by approximately half while Shor's algorithm completely breaks the security of modern authentication and key establishment algorithms. As a result, we can continue to protect our communications using the AES-256 symmetric cipher which is considered sufficiently secure even in the presence of a cryptographically relevant quantum computer. We can then replace our conventional authentication and key establishment algorithms with post-quantum algorithms. Note that during TLS 1.3 handshakes, the ciphersuite specifies the symmetric cipher to be used for the duration of the connection. Both CNSA (Commercial National Security Algorithm Suite) 1.0 and 2.0 prescribe using the AES_256_GCM_SHA384 ciphersuite. For key establishment and authentication, there are post-quantum KEMs (Key Encapsulation Mechanisms) and signature schemes.

These use different kinds of math from the conventional algorithms. They are designed specifically for resistance to quantum-computers. The authentication algorithm and KEM that NIST has standardized for use with network protocols are lattice-based algorithms.

- ML-DSA (Dilithium) Signature Scheme
- ML-KEM (KYBER) KEM

Note: SABER KEM and NTRU KEM were deprecated and removed as they did not move on to standardization.

Note: KYBER KEM 90s variants were deprecated and removed as NIST is not considering them for standardization.

Note: Dilithium Signature Scheme's AES variants were deprecated and removed as NIST is not considering them for standardization.

Note: When the liboqs integration was removed, we also removed the FALCON and SPHINCS+ signature schemes. We will have our own implementations in the future.

An explanation of lattice-based cryptography would fall outside the scope of this document but more information about these algorithms can be found in their NIST submissions at https://csrc.nist.gov/projects/post-quantum-cryptography/round-3-submissions.

Unfortunately, it might come as a shock, but we do not actually know that these algorithms will resist attacks from quantum computers. In fact, we do not even know that these algorithms are safe against a conventional computer. Its getting less and less likely, but someone could break lattice-based cryptography. However, as security experts will tell you, this is how cryptography has always worked. Algorithms are good when we start using them, but weaknesses and vulnerabilities are discovered and technology gets better. The post-quantum algorithms are somewhat problematic in that they are relatively new and could use a bit more attention from the community.

One solution is to not put our full faith into these new algorithms. For now, we can hedge our bets by hybridizing post-quantum algorithms with the conventional algorithms that we actually trust. ECC with NIST standardized curves seem like good candidates as we have to keep using them since FIPS 140-3 compliance is a priority. For this reason, we have not only implemented post-quantum KEMs but also hybridized them with ECDH over NIST approved curves. Please see our list of hybrid groups below.

I.2 Getting Started with Post-Quantum algorithms in wolfSSL

The following instructions will get you started from a clean Linux development environment and lead you step by step to performing a quantum-safe TLS 1.3 connection.

I.2.1 Build Instructions

Please see the wolfSSL repo's INSTALL file (https://github.com/wolfSSL/wolfssl/blob/master/INSTALL). Item 15 has instructions on how to configure and build wolfSSL with ML-KEM and ML-DSA enabled.

You will need the patched OQS OpenSSL Provider fork in order to generate X.509 certificates with post-quantum cryptographic keys and signatures. Instructions can be found at https://github.com/wolfSSL/osp/tree/maste For your convenience, pre-generated certificates can be found there as well.

I.2.2 Making a Quantum Safe TLS Connection

You can run the server and client like this in separate terminals:

```
examples/server/server -v 4 -l TLS_AES_256_GCM_SHA384 \
      -A ../osp/oqs/mldsa87_root_cert.pem \
      -c ../osp/oqs/mldsa44_entity_cert.pem \
      -k ../osp/oqs/mldsa44_entity_key.pem \
      --pqc SecP521r1MLKEM1024
```

```
examples/client/client -v 4 -l TLS_AES_256_GCM_SHA384 \
      -A ../osp/oqs/mldsa44_root_cert.pem \
      -c ../osp/oqs/mldsa87_entity_cert.pem \
      -k ../osp/oqs/mldsa87_entity_key.pem \
      --pqc SecP521r1MLKEM1024
```

You have just achieved a fully quantum-safe TLS 1.3 connection using AES-256 for symmetric encryption, the ML-DSA signature scheme for authentication and ECDHE hybridized with ML-KEM for key establishment.

Further information about other post-quantum examples can be found at https://github.com/wolfSSL/wolfssl-examples/blob/master/pq/README.md.

I.3 Post Quantum Algorithm Variant Names

Post-Quantum algorithm variant names:

NIST Security Level	PQC Variant Name
2	ML_DSA_44
3	ML_DSA_65
5	ML_DSA_87
1	ML_KEM_512
3	ML_KEM_768
5	ML_KEM_1024

Post-Quantum hybrid KEM names:

wolfSSL Variant Name	NIST ECC Curve and PQC Submission Variant Name
SecP256r1MLKEM512	ECDSA P-256 and KYBER512
SecP384r1MLKEM768	ECDSA P-384 and KYBER768
SecP521r1MLKEM1024	ECDSA P-521 and KYBER1024

COPYRIGHT ©2024 wolfSSL Inc.

I.4 Cryptographic Artifact Sizes

All sizes are in bytes.

Post-Quantum Signature Scheme Artifact Sizes:

PQC Variant Name	Public Key Size	Private Key Size	Maximum Signature Size
ML_DSA_44	1312	2560	2420
ML_DSA_65	1952	4032	3309
ML_DSA_87	2592	4896	4627

Post-Quantum KEM Artifact Sizes:

PQC Variant Name	Public Key Size	Private Key Size	Ciphertext Size	Shared Secret Size
ML_KEM_512	800	1632	768	32
ML_KEM_768	1184	2400	1088	32
ML_KEM_1024	1568	3168	1568	32

I.5 Statistics

The following statistics and benchmarks were taken on an 11th GenIntel Core i7-1185G7@3-GHz with 8 cores running Ubuntu 22.04.5 LTS

wolfSSL:

```
./configure --enable-kyber \
            --enable-dilithium \
            --disable-psk \
            --disable-shared \
            --enable-intelasm \
            --enable-aesni \
            --enable-sp-math-all \
            --enable-sp-asm \
            CFLAGS="-Os"
```

Note: We are primarily benchmarking the post-quantum algorithms, but leave some conventional algorithms for comparison purposes.

I.5.1 Runtime Binary Sizes

The `tls_bench` example application binary file is 2498432 bytes after being built then stripped (Approximately 2.4M). Without `--enable-kyber --enable-dilithium` it is 2290912 bytes after being built then stripped (Approximately 2.2M). This is a difference of 207520 bytes (Approximately 200K).

I.5.2 TLS 1.3 Data Transmission Sizes

The following results were taken by running the example server and client and recording all information being transmitted via wireshark. This includes the TLS 1.3 handshake with mutual authentication, “hello wolfssl!” and “I hear you fa shizzle!” messages. The `tcp.len` of all packets were summed:

Ciphersuite	Authentication	Key Establishment	Total Bytes
TLS_AES_256_GCM_SHA384	RSA 2048 bit	ECC SECP256R1	5455
TLS_AES_256_GCM_SHA384	RSA 2048 bit	ML_KEM_512	6633
TLS_AES_256_GCM_SHA384	RSA 2048 bit	ML_KEM_768	7337
TLS_AES_256_GCM_SHA384	RSA 2048 bit	ML_KEM_1024	8201
TLS_AES_256_GCM_SHA384	RSA 2048 bit	SecP256r1MLKEM512	6763
TLS_AES_256_GCM_SHA384	RSA 2048 bit	SecP384r1MLKEM768	7531
TLS_AES_256_GCM_SHA384	RSA 2048 bit	SecP521r1MLKEM1024	8467
TLS_AES_256_GCM_SHA384	ML_DSA_44	ECC SECP256R1	7918
TLS_AES_256_GCM_SHA384	ML_DSA_65	ECC SECP256R1	10233
TLS_AES_256_GCM_SHA384	ML_DSA_87	ECC SECP256R1	13477

I.5.3 Heap and Stack Usage

NOTE: This is out of date. These were obtained when wolfSSL was using the liboqs implementations of these algorithms. This is left here for historical purposes.

These statistics were obtained by adding the following configuration flags: `--enable-trackmemory --enable-stacksize`.

Memory use for server sign and client verify without server authentication of the client, TLS13-AES256-GCM-SHA384 ciphersuite and ECC SECP256R1 for key exchange.

I.6 Documentation

Technical documentation and other resources such as known answer tests can be found at the NIST PQC website:

https://csrc.nist.gov/projects/post-quantum-cryptography/round-3-submissions.

For more algorithm-specific benchmarking information, the OQS Project has benchmarking information at their website:

https://openquantumsafe.org/benchmarking/

I.7 Post-Quantum Stateful Hash-Based Signatures

This section covers post-quantum stateful hash-based signature (HBS) schemes such as LMS/HSS, and XMSS/XMSS^MT, for which wolfSSL has recently added support.

I.7.1 Motivation

Stateful HBS schemes are of growing interest for a number of reasons. The primary motivation for stateful HBS schemes is post-quantum security. As discussed previously in this appendix, Shor's algorithm would allow a quantum computer to efficiently factorize large integers and compute discrete logarithms, thus completely breaking public-key cryptography schemes such as RSA and ECC.

In contrast, stateful HBS schemes are founded on the security of their underlying hash functions and Merkle trees (typically implemented with SHA256), which are not expected to be broken by the advent of cryptographically relevant quantum computers. For these reasons they have been recommended by NIST SP 800-208 and the NSA's CNSA 2.0 suite. See these two links for more info:

- https://csrc.nist.gov/publications/detail/sp/800-208/final
- https://media.defense.gov/2022/Sep/07/2003071834/-1/-1/0/CSA_CNSA_2.0_ALGORITHMS_.PDF

Furthermore, the CNSA 2.0 timeline has specified that post-quantum stateful HBS schemes should be used exclusively by 2030, and adoption should begin *immediately*. In fact, adoption of LMS is the earliest requirement in the CNSA 2.0 suite timeline.

However, the nature of stateful HBS schemes requires that significant care is given to their use and tracking their state. In a stateful HBS system, the private key is actually a finite set of one-time signature (OTS) keys, which may never be reused. If the same OTS key were used to sign two different messages, it would be possible for an attacker to fabricate signatures, and the security of the entire scheme would unravel. Therefore, stateful HBS schemes are not suitable for general use such as the public internet.

Instead, because of these unique strengths and characteristics, and NIST and NSA backing, stateful HBS schemes such as LMS/HSS are of particular interest for offline firmware authentication and signature verification, especially on embedded or constrained systems that are expected to have a long operational lifetime and thus need to be resilient against a cryptographically relevant quantum computer.

I.7.2 LMS/HSS signatures

wolfSSL is adding support for the LMS/HSS hash-based signature scheme to our wolfCrypt embedded crypto engine. This will be achieved by experimental integration with the hash-sigs LMS/HSS library (https://github.com/cisco/hash-sigs), similar to our previous libOQS integration.

Leighton-Micali Signatures (LMS), and its multi-tree variant, the Hierarchical Signature System (HSS), is a post-quantum, stateful hash-based signature scheme. It is noted for having small public and private keys, and fast signing and verifying. Its signature sizes are larger, but are tunable via its Winternitz parameter. See these two links from RFC8554 for more details:

- LMS: https://datatracker.ietf.org/doc/html/rfc8554
- HSS: https://datatracker.ietf.org/doc/html/rfc8554#section-6

As previously discussed, the LMS/HSS signature system consists of a finite number of one-time signature (OTS) keys, and thus may only safely generate a finite number of signatures. However the number of signatures, and the signature size, are tunable via a set of defined parameters, which will be discussed next.

I.7.2.1 Supported Parameters LMS/HSS signatures are defined by 3 parameters: - levels: number of levels of Merkle trees. - height: height of an individual Merkle tree. - Winternitz: number of bits from hash used in a Winternitz chain. Used as a space-time tradeoff for the signature size.

wolfSSL supports all LMS/HSS parameters defined in RFC8554:

- levels = {1..8}
- height = {5, 10, 15, 20, 25}
- Winternitz = {1, 2, 4, 8}

The number of available signatures is: - N = 2 ** (levels * height)

For convenience some parameter sets have been predefined in the enum `wc_LmsParm`. Its values are shown in the table below:

COPYRIGHT ©2024 wolfSSL Inc.

parameter set	description
WC_LMS_PARM_NONE	Not set, use default (WC_LMS_PARM_L1_H15_W2)
WC_LMS_PARM_L1_H15_W2	1 level Merkle tree of 15 height, Winternitz 2
WC_LMS_PARM_L1_H15_W4	same as above, Winternitz 4
WC_LMS_PARM_L2_H10_W2	2 level Merkle tree of 10 height, Winternitz 4
WC_LMS_PARM_L2_H10_W4	same as above, Winternitz 4
WC_LMS_PARM_L2_H10_W8	same as above, Winternitz 8
WC_LMS_PARM_L3_H5_W2	3 level Merkle tree of 5 height, Winternitz 2
WC_LMS_PARM_L3_H5_W4	same as above, Winternitz 4
WC_LMS_PARM_L3_H5_W8	same as above, Winternitz 8
WC_LMS_PARM_L3_H10_W4	3 level Merkle tree of 10 height, Winternitz 4
WC_LMS_PARM_L4_H5_W8	4 level Merkle tree of 5 height, Winternitz 8

The signature size and number of signatures is shown with respect to the parameter set here:

parameter set	signature size	number of signatures
WC_LMS_PARM_L1_H15_W2	4784	32768
WC_LMS_PARM_L1_H15_W4	2672	32768
WC_LMS_PARM_L2_H10_W2	9300	1048576
WC_LMS_PARM_L2_H10_W4	5076	1048576
WC_LMS_PARM_L2_H10_W8	2964	1048576
WC_LMS_PARM_L3_H5_W2	13496	32768
WC_LMS_PARM_L3_H5_W4	7160	32768
WC_LMS_PARM_L3_H5_W8	3992	32768
WC_LMS_PARM_L3_H10_W4	7640	1073741824
WC_LMS_PARM_L4_H5_W8	5340	1048576

As can be seen from the tables, signature sizes are primarily determined by the levels and Winternitz parameters, and height to a lesser extent: - Larger levels values increase signature size significantly. - Larger height values increase signature size modestly. - Larger winternitz values will reduce the signature size, at the expense of longer key generation and sign/verify times.

Key generation time is strongly determined by the height of the first level tree. A 3 level, 5 height tree is much faster than 1 level, 15 height at initial key gen, even if the number of available signatures is the same.

I.7.2.2 LMS/HSS Build Instructions Please see the wolfSSL repo's INSTALL file (https://github.com/wolfSSL/wolfssl/ Item 17 (Building with hash-sigs lib for LMS/HSS support [EXPERIMENTAL]) has instructions on how to configure and build wolfSSL and the hash-sigs LMS/HSS library.

I.7.2.3 Benchmark Data The following benchmark data was taken on an 8-core Intel i7-8700 CPU @ 3.20GHz, on Fedora 38 (`6.2.9-300.fc38.x86_64`). The multi-threaded example used 4 worker threads and 4 cores, while the single-threaded example used only a single core.

As discussed in item 17 of the INSTALL file, the hash-sigs lib offers two static libraries: - `hss_lib.a`: a single-threaded version. - `hss_lib_thread.a`: a multi-threaded version.

The multi-threaded version will spawn worker threads to accelerate cpu intensive tasks, such as key generation. This will mainly speedup key generation and signing for all parameter values, and to a lesser extent will speedup verifying for larger levels values.

For reference, wolfSSL was built with the following to obtain both benchmarks:

```
  ./configure \
    --enable-static \
    --disable-shared \
    --enable-lms=yes \
    --with-liblms=<path to hash sigs install>
```

multi-threaded benchmark

The following is benchmark data obtained when built against the multi-threaded `hss_lib_thread.a`, which used 4 worker threads to parallelize intensive tasks, and used 4 cores.

```
./wolfcrypt/benchmark/benchmark -lms_hss

I.7.3 XMSS/XMSS^MT signatures

wolfSSL is adding support for XMSS/XMSS^MT stateful hash-based signatures. Similar to LMS, this will be done by experimental integration with the xmss-reference repository (https://github.com/XMSS/xmss-reference.git), from RFC 8391 (https://www.rfc-editor.org/rfc/rfc8391.html).

The xmss-reference supports `xmss_core_fast`, and `xmss_core` implementations. The `xmss_core_fast` implementation was designed to prioritize performance with larger private key sizes as a tradeoff. Our integration uses `xmss_core_fast`, with a patch applied so that the wolfCrypt SHA256 implementation may be used instead.

The patch may be found here

```
in the wolfssl-examples repository: https://github.com/wolfSSL/wolfssl-
   examples.

Overall, XMSS/XMSS^MT is similar to LMS/HSS. For a more detailed comparison
   see
"LMS vs XMSS: Comparison of two Hash-Based Signature Standards" (https://
   eprint.iacr.org/2017/349.pdf).

XMSS^MT is the Multi-Tree generalization of XMSS,
analogous to HSS with LMS, with the distinction that the Winternitz value is
   fixed to `w=16` in
XMSS/XMSS^MT. The public key is slightly larger in XMSS/XMSS^MT (at 68 bytes
   in XMSS/XMSS^MT, vs 60 bytes in LMS/HSS), while signatures are slightly
   smaller.

#### Supported Parameters
```

wolfSSL supports the SHA256 XMSS/XMSS^MT parameter sets from Tables 10 and 11 from NIST SP 800-208 (https://csrc.nist.gov/pubs/sp/800/208/final).

parameter set name	Oid	n	w	h	d	h/d	Sig len
XMSS							
"XMSS-SHA2_10_256"	0x00000001	32	16	10	1	10	2500
"XMSS-SHA2_16_256"	0x00000002	32	16	16	1	16	2692
"XMSS-SHA2_20_256"	0x00000003	32	16	20	1	20	2820
XMSS^MT							
"XMSSMT-SHA2_20/2_256"	0x00000001	32	16	20	2	10	4963
"XMSSMT-SHA2_20/4_256"	0x00000002	32	16	20	4	5	9251
"XMSSMT-SHA2_40/2_256"	0x00000003	32	16	40	2	20	5605
"XMSSMT-SHA2_40/4_256"	0x00000004	32	16	40	4	10	9893
"XMSSMT-SHA2_40/8_256"	0x00000005	32	16	40	8	5	18469
"XMSSMT-SHA2_60/3_256"	0x00000006	32	16	60	3	20	8392
"XMSSMT-SHA2_60/6_256"	0x00000007	32	16	60	6	10	14824
"XMSSMT-SHA2_60/12_256"	0x00000008	32	16	60	12	5	27688

In the table above, `n` is the number of bytes in the HASH function, `w` the Winternitz value, `h` the total height of the tree system, and `d` the number of levels of trees.

Key generation time is strongly determined by the height of the
first level tree (or `h/d`), while signature length grows primarily with `d` (the number of hyper
tree levels).

Similar to LMS/HSS, the number of available signatures grows as `2**h`, where h is the
total height of the tree system.

Benchmark Data

In the following, benchmark data is shown for several XMSS/XMSS^MT parameter sets,
for intel x86_64 and aarch64. The SHA256 performance on these systems is also listed for reference,
as computing the large number of required hash chains will constitute the bulk of the CPU
work for XMSS/XMSS^MT. Additionally, our patch to xmss-reference substitutes wolfCrypt's SHA256 implementation, and therefore benefits from the same ASM speedups.

As previously mentioned, our xmss integration is using the `xmss_core_fast` implementation from xmss-reference, which has faster performance at the tradeoff of larger private key sizes.

x86_64

The following x86_64 benchmark data were taken on an 8-core Intel i7-8700 CPU @ 3.20GHz, on Fedora 38 (`6.2.9-300.fc38.x86_64`). This CPU has `avx avx2` flags, which can accelerate hash operations and be utilized with `--enable-intelasm`.

I.7.4 Developer Notes

- If you are trying to thwart the “harvest now, decrypt later” threat model and you are willing to sacrifice some interoperability, then you do not want to advertise support for conventional algorithms in the Supported Groups extension. Be sure to call `wolfSSL_UseKeyShare()` and `wolfSSL_set_groups()` with your chosen algorithms. Only calling `wolfSSL_UseKeyShare()` is insufficient as that will advertise your support for quantum-vulnerable algorithms. If your peer does not support post-quantum algorithms, they will then send a HelloRetryRequest which will then result in a connection with a conventional algorithm.

J wolfSSL Porting Guide

J.1 Purpose

This guide provides a reference for developers and engineers porting the wolfSSL lightweight SSL/TLS library to new embedded platforms, operating systems, or transport mediums (TCP/IP, bluetooth, etc.). It calls out areas in the wolfSSL codebase which typically require modification when porting wolfSSL. It should be considered a "guide" and as such, it is an evolving work. If there is something you find missing, please let us know and we'll be happy to add instructions or clarification to the document.

J.2 Audience

This guide caters to developers or engineers porting the wolfSSL and wolfCrypt to new platforms or environments that are not supported by default.

J.3 Introduction

Several steps need to be iterated through when getting wolfSSL to run on an embedded platform. Some of these steps are outlined in Section 2.4.

Apart from steps in Chapter 2 of the wolfSSL Manual, there are areas in the code which may need porting or modifications in order to accommodate a specific platform. wolfSSL abstracts many of these areas - attempting to make it as easy as possible to port wolfSSL to a new platform.

In the `./wolfssl/wolfcrypt/settings.h` file, there are several defines specific to different operating systems, TCP/IP stacks, and chipsets (ex: MBED, FREESCALE_MQX, MICROCHIP_PIC32, MICRIUM, EBSNET, etc.). There are two main locations to put `#defines` when compiling and porting wolfSSL to a new platform:

1. New defines for a Operating System or TCP/IP stack port are typically added to the `settings.h` file when a new port of wolfSSL is completed. This provides an easy way to turn on/off features as well as customize build settings that should be "default" for that build. New custom defines can be added in this file when doing a port of wolfSSL to a new platform. We encourage users to contribute ports of wolfSSL back to the master open source code branch on GitHub. This helps keep wolfSSL up to date and allows different ports to remain updated as the wolfSSL project improves and moves forward.
2. For users not wanting to contribute back their changes to wolfSSL proper, or for users who want to customize the wolfSSL build with additional preprocessor defines, wolfSSL recommends the use of a custom `user_settings.h` header file. If `WOLFSSL_USER_SETTINGS` is defined when compiling the wolfSSL source files, wolfSSL will automatically include a custom header file called `user_settings.h`. This header should be created by the user and placed on the include path. This allows users to maintain one single file for their wolfSSL build, and makes it much easier to update to newer versions of wolfSSL.

wolfSSL encourages the submission of patches and code changes through either direct email (facts@wolfssl.com), or through GitHub pull request.

J.4 Porting wolfSSL

J.4.1 Data Types

Q: When do I need to read this section?

A: Setting the correct data type size for your platform is always important.

wolfSSL benefits speed-wise from having a 64-bit type available. Define SIZEOF_LONG and SIZEOF_LONG_LONG to match the result of sizeof(long) and sizeof(long long) on your platform. This can be added to a custom define in the settings.h file or to user_settings.h. For example, in settings.h under a sample define of MY_NEW_PLATFORM:

```
#ifdef MY_NEW_PLATFORM
    #define SIZEOF_LONG 4
    #define SIZEOF_LONG_LONG 8
    ...
#endif
```

There are two additional data types used by wolfSSL and wolfCrypt, called word32 and word16. The default type mappings for these are:

```
#ifndef WOLFSSL_TYPES
#ifndef byte
    typedef unsigned char  byte;
#endif
    typedef unsigned short word16;
    typedef unsigned int   word32;
    typedef byte           word24[3];
#endif
```

word32 should be mapped to the compiler's 32-bit type, and word16 to the compiler's 16-bit type. If these default mappings are incorrect for your platform, you should define WOLFSSL_TYPES in settings.h or user_settings.h and assign your own custom typedefs for word32 and word16.

The fastmath library in wolfSSL uses the fp_digit and fp_word types. By default these are mapped in <wolfssl/wolfcrypt/tfm.h> depending on build configuration.

fp_word should be twice the size of fp_digit. If the default cases do not hold true for your platform, you should define WOLFSSL_BIGINT_TYPES in settings.h or user_settings.h and assign your own custom typedefs for fp_word and fp_digit.

wolfSSL does use a 64-bit type when available for some operations. The wolfSSL build tries to detect and set up the correct underlying data type for word64 based on what SIZEOF_LONG and SIZEOF_LONG_LONG have been set to. On some platforms that don't have a true 64-bit type, where two 32-bit types are used in conjunction, performance can be slow. To compile out the use of 64-bit types, define NO_64BIT.

J.4.2 Endianness

Q: When do I need to read this section?

A: Your platform is a big endian system.

Is your platform big endian or little endian? wolfSSL defaults to a little endian system. If your system is big endian, define BIG_ENDIAN_ORDER when building wolfSSL. Example of setting this in settings.h:

```
#ifdef MY_NEW_PLATFORM
    ...
    #define BIG_ENDIAN_ORDER
    ...
#endif
```

J.4.3 writev

Q: When do I need to read this section?

A: <sys/uio.h> is not available.

By default, the wolfSSL API makes available wolfSSL_writev() to applications, which simulates writev() semantics. On systems that don't have the <sys/uio.h> header available, define NO_WRITEV to exclude this feature.

J.4.4 Input / Output

Q: When do I need to read this section?

A: A BSD-style socket API is not available, you are using a custom transport layer or TCP/IP stack, or only want to use static buffers.

wolfSSL defaults to using a BSD-style socket interface. If your transport layer provides a BSD socket interface, wolfSSL should integrate into it as-is, unless custom headers are needed.

wolfSSL provides a custom I/O abstraction layer which allows users to tailor wolfSSL's I/O functionality to their system. Full details can be found in Section 5.1.2.

Simply put, you can define WOLFSSL_USER_IO, then write your own I/O callback functions using wolfSSL's default EmbedSend() and EmbedReceive() as templates. These two functions are located in ./src/io.c.

wolfSSL uses dynamic buffers for input and output, which default to 0 bytes. If an input record is received that is greater in size than the buffer, then a dynamic buffer is temporarily used to handle the request and then freed.

If you prefer using large, 16kB static buffers which will never need dynamic memory, you can enable this option by defining LARGE_STATIC_BUFFERS.

If dynamic buffers are used and the user requests an wolfSSL_write() that is bigger than the buffer size, then a dynamic block up to MAX_RECORD_SIZE is used to send the data. Users wishing to only send the data in chunks of the current buffer size at maximum, as defined by RECORD_SIZE, can do this by defining STATIC_CHUNKS_ONLY. When using this define, RECORD_SIZE defaults to 128 bytes.

J.4.5 Filesystem

Q: When do I need to read this section?

A: No file system is available, standard file system functions are not available, or you have a custom file system.

wolfSSL uses the filesystem for loading keys and certificates into the SSL session or context. wolfSSL also allows loading these from memory buffers. If strictly using memory buffers, a filesystem is not needed.

You can disable wolfSSL's usage of the filesystem by defining NO_FILESYSTEM when building the library. This means that certificates and keys will need to be loaded from memory buffers instead of files. An example of setting this in settings.h:

```
#ifdef MY_NEW_PLATFORM
    ...
    #define NO_FILESYSTEM
    ...
#endif
```

Test key and certificate buffers can be found in the ./wolfssl/certs_test.h header file. These will match up to corresponding certificates and keys found in the ./certs directory.

The certs_test.h header file can be updated using the ./gencertbuf.pl script if needed. Inside gencertbuf.pl, there are two arrays: fileList_1024 and fileList_2048. Additional certificates

or keys may be added to the respective array, depending on key size, and must be in DER format. The above mentioned arrays map a certificate/key file location with the desired buffer name. After modifying gencertbuf.pl, running it from the wolfSSL root directory will update the certificate and key buffers in ./wolfssl/certs_test.h:

```
./gencertbuf.pl
```

If you would like to use a filesystem other than the default, the filesystem abstraction layer is located in ./wolfssl/wolfcrypt/wc_port.h. Here you will see filesystem ports for various platforms including EBSNET, FREESCALE_MQX, and MICRIUM. You can add a custom define for your platform if needed - allowing you to define file system functions with XFILE, XFOPEN, XFSEEK, etc. For example, the filesystem layer in wc_port.h for Micrium's µC/OS (MICRIUM) is as follows:

```
#elif defined(MICRIUM)
#include <fs.h>
#define XFILE      FS_FILE*
#define XFOPEN     fs_fopen
#define XFSEEK     fs_fseek
#define XFTELL     fs_ftell
#define XREWIND    fs_rewind
#define XFREAD     fs_fread
#define XFCLOSE    fs_fclose
#define XSEEK_END  FS_SEEK_END
#define XBADFILE   NULL
```

J.4.6 Threading

Q: When do I need to read this section?

A: You want to use wolfSSL in a multithreaded environment, or want to just compile it in single threaded mode.

If wolfSSL will only be used in a single threaded environment, the wolfSSL mutex layer can be disabled when compiling wolfSSL by defining SINGLE_THREADED. This will negate the need to port the wolfSSL mutex layer.

If wolfSSL needs to be used in a multithreaded environment, the wolfSSL mutex layer will need to be ported to the new environment. The mutex layer can be found in ./wolfssl/wolfcrypt/wc_port.h and ./wolfcrypt/src/wc_port.c. wolfSSL_Mutex will need to be defined for the new system in wc_port.h and the mutex functions (wc_InitMutex, wc_FreeMutex, wc_LockMutex and wc_UnLockMutex) in wc_port.c. You can search in wc_port.h and wc_port.c to see an example for some existing platform port layers (EBSNET, FREESCALE_MQX, etc.).

J.4.7 Random Seed

Q: When do I need to read this section?

A: Either /dev/random or /dev/urandom is not available or you want to integrate into a hardware RNG.

By default, wolfSSL uses /dev/urandom or /dev/random to generate a RNG seed. The NO_DEV_RANDOM define can be used when building wolfSSL to disable the default GenerateSeed() function. If this is defined, you need to write a custom GenerateSeed() function in ./wolfcrypt/src/random.c, specific to your target platform. This allows you to seed wolfSSL's PRNG with a hardware-based random entropy source if available.

For examples of how GenerateSeed() needs to be written, reference wolfSSL's existing GenerateSeed() implementations in ./wolfcrypt/src/random.c.

J.4.8 Memory

Q: When do I need to read this section?

A: When you don't have standard memory functions available or are interested in memory usage differences between optional math libraries.

wolfSSL proper uses both `malloc()` and `free()` by default. When using the normal big integer math library, wolfCrypt will also use `realloc()`.

By default wolfSSL/wolfCrypt use the normal big integer math library, which uses quite a bit of dynamic memory. When building wolfSSL, the fastmath library can be enabled, which is both faster and uses no dynamic memory for crypto operations (all on the stack). By using fastmath, wolfSSL won't need a `realloc()` implementation at all. As the SSL layer of wolfSSL still uses some dynamic memory, `malloc()` and `free()` are still required.

For a comparison of resource usage (stack/heap) between the big integer math library and fastmath library, ask us to see our Resource Use document.

To enable fastmath, define `USE_FAST_MATH` and build in `./wolfcrypt/src/tfm.c` instead of `./wolfcrypt/src/integer.c`. Since the stack memory can be large when using fastmath, we recommend defining `TFM_TIMING_RESISTANT` as well.

If the normal `malloc()`, `free()`, and possibly `realloc()` functions are not available, define `XMALLOC_USER`, then provide custom memory function hooks in `./wolfssl/wolfcrypt/types.h` specific to the target environment.

Please read section 5.1.1.1 for details about using `XMALLOC_USER`.

J.4.9 Time

Q: When do I need to read this section?

A: When standard time functions (`time()`, `gmtime()`) are not available, or you need to specify a custom clock tick function.

By default, wolfSSL uses `time()`, `gmtime()`, and `ValidateDate()`, as specified in `./wolfcrypt/src/asn.c`. These are abstracted to `XTIME`, `XGMTIME`, and `XVALIDATE_DATE`. If the standard time functions, and `time.h`, are not available, the user can define `USER_TIME`. After defining `USER_TIME`, the user can define their own `XTIME`, `XGMTIME`, and `XVALIDATE_DATE` functions.

wolfSSL uses `time(0)` by default for the clock tick function. This is located in `./src/internal.c` inside of the `LowResTimer()` function.

Defining `USER_TICKS` allows the user to define their own clock tick function if `time(0)` is not wanted. The custom function needs second accuracy, but doesn't have to be correlated to EPOCH. See `LowResTimer()` function in `./src/internal.c` for reference.

J.4.10 C Standard Library

Q: When do I need to read this section?

A: When you don't have a C standard library available, or have a custom one.

wolfSSL can be built without the C standard library to provide a higher level of portability and flexibility to developers. When doing so, the user needs to map functions they wish to use instead of the C standard ones.

Section 7, above, covered memory functions. In addition to memory function abstraction, wolfSSL also abstracts string function and math functions, where the specific functions are typically abstracted to a define in the form of X<FUNC>, where <FUNC> is the name of the function being abstracted.

Please read Section 5.1 for details.

J.4.11 Logging

Q: When do I need to read this section?

A: You want to enable debug messages but don't have stderr available.

By default, wolfSSL provides debug output through stderr. In order for debug messages to be enabled, wolfSSL must be compiled with `DEBUG_WOLFSSL` defined, and `wolfSSL_Debugging_ON()` must be called from the application code. `wolfSSL_Debugging_OFF()` may be used by the application layer to turn off wolfSSL debug messages.

For environments which do not have stderr available, or wish to output debug messages over a different output stream or in a different format, wolfSSL allows applications to register a logging callback.

Please read Section 8.1 for details.

J.4.12 Public Key Operations

Q: When do I need to read this section?

A: You want to use your own public key implementation with wolfSSL.

wolfSSL allows users to write their own public key callbacks which will be called when the SSL/TLS layer needs to do public key operations. The user can optionally define 6 functions:

1. ECC sign callback
2. ECC verify callback
3. RSA sign callback
4. RSA verify callback
5. RSA encrypt callback
6. RSA decrypt callback

For full details, please read Section 6.4.

J.4.13 Atomic Record Layer Processing

Q: When do I need to read this section?

A: You want to do your own processing of record layers, specifically MAC/encrypt and decrypt/verify operations.

By default, wolfSSL handles record layer processing for the user using its cryptography library, wolfCrypt. wolfSSL provides Atomic Record Processing callbacks for users who wish to have more control over MAC/encrypt and decrypt/verify functionality during the SSL/TLS connection.

The user will need to define 2 functions:

1. MAC/encrypt callback function
2. Decrypt/verify callback function

For full details, please read Section 6.3.

J.4.14 Features

Q: When do I need to read this section?

A: When you want to disable features.

Features can be disabled when building wolfSSL by using the appropriate defines. For a list of defines available, please refer to Chapter 2.

J.5 Next Steps

J.5.1 wolfCrypt Test Application

After getting wolfSSL proper to build on the target platform, a good next step is to port the wolfCrypt test application. Running this application on the target system will verify that all the crypto algorithms are working correctly, using NIST test vectors.

If this step is skipped, and you instead proceed directly to establishing an SSL connection, it can be more difficult to debug problems caused by underlying crypto operations failing.

The wolfCrypt test application is located in `./wolfcrypt/test/test.c`. If an embedded application has its own `main()` function, then `NO_MAIN_DRIVER` must be defined when compiling `./wolfcrypt/test/test.c`. This will allow the application's `main()` to call each cipher/algorithm test individually on its own.

If an embedded device does not have enough resources to run the entire wolfCrypt test application, individual tests can be broken out of `test.c` and compiled individually. Please ensure that correct header files needed for the specific test case are included in the build when extracting isolated crypto tests from `test.c`.

J.6 Support

General support questions may be sent directly to wolfSSL either through email, support forums, or wolfSSL's Zendesk ticket tracking system.

Website: https://www.wolfssl.com

Support Email: support@wolfssl.com

Zendesk: https://wolfssl.zendesk.com

Forums: https://www.wolfssl.com/forums

wolfSSL offers several support packages as well as consulting services to help users and customers port wolfSSL to new environments.

Support Packages: https://www.wolfssl.com/wolfSSL/Support/support_tiers.php

Consulting Services: https://www.wolfssl.com/wolfSSL/wolfssl-consulting.html

General Inquiries: facts@wolfssl.com

K wolfSM (ShangMi)

This appendix provides information about the Chinese National Standard's cryptographic algorithms known as ShangMi (SM) in wolfSSL.

wolfSM support includes: * SM3 - Hash Function * SM4 - Cipher * SM2 - ECDH key agreement and a signature scheme using the specified 256-bit elliptic curve.

The code must be installed into wolfSSL in order to be used.

Note that the test and build configuration code is already in wolfSSL.

K.1 Getting and Installing wolfSM

K.1.1 Get wolfSM from GitHub

Clone the wolfSM repository from GitHub:

```
git clone https://github.com/wolfssl/wolfsm.git
```

K.1.2 Get wolfSSL from GitHub

wolfSSL is needed to build and test the SM algorithm implementations. Checkout the wolfSSL repository from GitHub beside wolfSM:

```
# Directory structure should be:
# <install-dir>
# ├── wolfsm
# └── wolfssl

cd .. # To directory containing wolfsm
git clone https://github.com/wolfssl/wolfssl.git
```

K.1.3 Install SM code into wolfSSL

To install the SM code into wolfSSL, use the install script:

```
cd wolfsm
./install.sh
```

K.2 Building wolfSM

Once the wolfSM files have been installed into wolfSSL, you can build SM algorithms into wolfSSL.

Choose which algorithms you require on the configure line: `* --enable-sm3 * --enable-sm4-ecb * --enable-sm4-cbc * --enable-sm4-ctr * --enable-sm4-gcm * --enable-sm4-ccm * --enable-sm2`

For example, to include SM3, SM4-GCM and SM2:

```
./autogen.sh
./configure --enable-sm3 --enable-sm4-gcm --enable-sm2
make
sudo make install
```

K.2.1 Optimized SM2

To use optimized implementations of SM2 you can either use C only code or C code with the faster assembly code.

For C code only: `--enable-sp` For C and assembly code: `--enable-sp --enable-sp-asm`

Optimized C code is available for 32 and 64 bit CPUs.

Assembly code is available for the following platforms: * Intel x64 * Aarch64 * ARM 32-bit * ARM Thumb2 * ARM Thumb

K.3 Testing wolfSM

To test that the SM ciphers are working use the following command:

```
make test
```

To benchmark the algorithms enabled:

```
./wolfcrypt/benchmark/benchmark
```

To benchmark specific algorithms, add to the command line the option/s matching the algorithm/s: * SM2: `-sm2` * SM3: `-sm3` * SM4: `-sm4` or * SM4-CBC: `-sm4-cbc` * SM4-GCM: `-sm4-gcm` * SM4-CCM: `-sm4-ccm`

K.3.1 Testing TLS

SM ciphers are able to be used with TLSv1.2 and TLSv1.3.

Note: SM2, SM3 and at least one SM4 cipher must be built in order for SM ciphers suite to work. All algorithms must be SM.

The cipher suites added are: - ECDHE-ECDSA-SM4-CBC-SM3 (TLSv1.2, `--enable-sm2 --enable-sm3 --enable-sm4-cbc`) - ECDHE-ECDSA-SM4-GCM-SM3 (TLSv1.2, `--enable-sm2 --enable-sm3 --enable-sm4-gcm`) - ECDHE-ECDSA-SM4-CCM-SM3 (TLSv1.2, `--enable-sm2 --enable-sm3 --enable-sm4-ccm`) - TLS13-SM4-GCM-SM3 (TLSv1.3, `--enable-sm2 --enable-sm3 --enable-sm4-gcm`) - TLS13-SM4-CCM-SM3 (TLSv1.3, `--enable-sm2 --enable-sm3 --enable-sm4-ccm`)

K.3.1.1 Example of using SM cipher suites with TLSv1.2 An example of testing TLSv1.2 with "ECDHE-ECDSA-SM4-CBC-SM3" cipher suite:

```
./examples/server/server -v 3 -l ECDHE-ECDSA-SM4-CBC-SM3 \
    -c ./certs/sm2/server-sm2.pem -k ./certs/sm2/server-sm2-priv.pem \
    -A ./certs/sm2/client-sm2.pem -V &
./examples/client/client -v 3 -l ECDHE-ECDSA-SM4-CBC-SM3 \
    -c ./certs/sm2/client-sm2.pem -k ./certs/sm2/client-sm2-priv.pem \
    -A ./certs/sm2/root-sm2.pem -C
```

The output using the commands above will be:

```
SSL version is TLSv1.2
SSL cipher suite is TLS_ECDHE_ECDSA_WITH_SM4_CBC_SM3
SSL curve name is SM2P256V1
SSL version is TLSv1.2
SSL cipher suite is TLS_ECDHE_ECDSA_WITH_SM4_CBC_SM3
SSL curve name is SM2P256V1
Client message: hello wolfssl!
I hear you fa shizzle!
```

K.3.1.2 Example of using SM cipher suites with TLSv1.3 An example of testing TLSv1.3 with "TLS13-SM4-GCM-SM3" cipher suite:

```
./examples/server/server -v 4 -l TLS13-SM4-GCM-SM3 \
    -c ./certs/sm2/server-sm2.pem -k ./certs/sm2/server-sm2-priv.pem \
    -A ./certs/sm2/client-sm2.pem -V &
./examples/client/client -v 4 -l TLS13-SM4-GCM-SM3 \
    -c ./certs/sm2/client-sm2.pem -k ./certs/sm2/client-sm2-priv.pem \
    -A ./certs/sm2/root-sm2.pem -C
```

The output using the commands above will be:

```
SSL version is TLSv1.3
SSL cipher suite is TLS_SM4_GCM_SM3
SSL curve name is SM2P256V1
SSL version is TLSv1.3
SSL cipher suite is TLS_SM4_GCM_SM3
SSL curve name is SM2P256V1
Client message: hello wolfssl!
I hear you fa shizzle!
```
