

WHO

cover-up of Vaccine Differences

by Craig Paardekooper

The World Health Organisation has its own database for adverse events of vaccines and drugs. This data is collected globally. They make this database publicly available at

<https://vigiaccess.org>

During the Covid jab rollout there were different Covid vaccines – Moderna, Pfizer, Janssen, Astrazeneca, Novavax and so on.

These vaccines varied from each another. Some were viral-vector vaccines, others were mRNA vaccines. The mRNA vaccines also varied with the type of lipid used for the lipid nano particle. They even varied in dosage size – Moderna used a larger dosage compared to Pfizer. And these were all experimental vaccines, so it would be important to know whether the differences mentioned above resulted in differences in adverse effects.

Unfortunately, the WHO decided that we should not see the differences in the adverse effects between these experimental vaccines. Consequently, if you search for MODERNA, or PFIZER, or JANSSEN or ASTRAZENECA covid vaccines, the WHO database will return identical results for each one.

However, we now know from independent sources that viral vector vaccines have a very different symptom profile from mRNA vaccines. See

The WHO has suppressed the data by simply not allowing the public to see these differences. And this was for EXPERIMENTAL vaccines, where seeing the differences as early on as possible was crucial for making an informed choice and for shaping public health policy.

Hiding data vital for informed choice and vital for public health policy !

Yet, the same organization, the WHO, wants to be the arbiter of global health policy, when they have so little respect for truth and for the informed choice of populations.
