This is a wrapper around the *lammps_extract_compute()* function of the C-library interface. This function returns None if either the compute id is not recognized, or an invalid combination of *cstyle* and *ctype* constants is used. The names and functionality of the constants are the same as for the corresponding C-library function. For requests to return a scalar or a size, the value is returned, otherwise a pointer.

Parameters

- **cid** (*string*) – compute ID
- **cstyle** (*int*) – style of the data retrieve (global, atom, or local), see *Style Constants*
- **ctype** (*int*) – type or size of the returned data (scalar, vector, or array), see *Type Constants*

Returns
requested data as scalar, pointer to 1d or 2d double array, or None

Return type
c_double, ctypes.POINTER(c_double), ctypes.POINTER(ctypes.POINTER(c_double)), or NoneType

extract_fix(*fid*, *fstyle*, *ftype*, *nrow=0*, *ncol=0*)

Retrieve data from a LAMMPS fix

This is a wrapper around the *lammps_extract_fix()* function of the C-library interface. This function returns None if either the fix id is not recognized, or an invalid combination of *fstyle* and *ftype* constants is used. The names and functionality of the constants are the same as for the corresponding C-library function. For requests to return a scalar or a size, the value is returned, also when accessing global vectors or arrays, otherwise a pointer.

Note

When requesting global data, the fix data can only be accessed one item at a time without access to the whole vector or array. Thus this function will always return a scalar. To access vector or array elements the "nrow" and "ncol" arguments need to be set accordingly (they default to 0).

Parameters

- **fid** (*string*) – fix ID
- **fstyle** (*int*) – style of the data retrieve (global, atom, or local), see *Style Constants*
- **ftype** (*int*) – type or size of the returned data (scalar, vector, or array), see *Type Constants*
- **nrow** (*int*) – index of global vector element or row index of global array element
- **ncol** (*int*) – column index of global array element

Returns
requested data or None

Return type
c_double, ctypes.POINTER(c_double), ctypes.POINTER(ctypes.POINTER(c_double)), or NoneType

`extract_variable`(*name*, *group=None*, *vartype=None*)

Evaluate a LAMMPS variable and return its data

This function is a wrapper around the function *lammps_extract_variable()* of the C library interface, evaluates variable name and returns a copy of the computed data. The memory temporarily allocated by the C-interface is deleted after the data is copied to a Python variable or list. The variable must be either an equal-style (or equivalent) variable or an atom-style variable. The variable type can be provided as the `vartype` parameter, which may be one of several constants: `LMP_VAR_EQUAL`, `LMP_VAR_ATOM`, `LMP_VAR_VECTOR`, or `LMP_VAR_STRING`. If omitted or `None`, LAMMPS will determine its value for you based on a call to *lammps_extract_variable_datatype()* from the C library interface. The group parameter is only used for atom-style variables and defaults to the group "all".

Parameters

- **name** (*string*) – name of the variable to execute
- **group** (*string, only for atom-style variables*) – name of group for atom-style variable
- **vartype** (*int*) – type of variable, see *Variable Type Constants*

Returns
the requested data

Return type
c_double, (c_double), or NoneType

`clearstep_compute`()

Call 'lammps_clearstep_compute()' from Python

`addstep_compute`(*nextstep*)

Call 'lammps_addstep_compute()' from Python

`addstep_compute_all`(*nextstep*)

Call 'lammps_addstep_compute_all()' from Python

`flush_buffers`()

Flush output buffers

This is a wrapper around the *lammps_flush_buffers()* function of the C-library interface.

`set_variable`(*name*, *value*)

Set a new value for a LAMMPS string style variable

Deprecated since version 7Feb2024.

This is a wrapper around the *lammps_set_variable()* function of the C-library interface.

Parameters

- **name** (*string*) – name of the variable
- **value** (*any. will be converted to a string*) – new variable value

Returns
either 0 on success or -1 on failure

Return type
int

`set_string_variable`(*name*, *value*)

Set a new value for a LAMMPS string style variable

Added in version 7Feb2024.

This is a wrapper around the *lammps_set_string_variable()* function of the C-library interface.

Parameters

- **name** (*string*) – name of the variable
- **value** (*any. will be converted to a string*) – new variable value

Returns
either 0 on success or -1 on failure

Return type
int

`set_internal_variable`(*name*, *value*)

Set a new value for a LAMMPS internal style variable

Added in version 7Feb2024.

This is a wrapper around the *lammps_set_internal_variable()* function of the C-library interface.

Parameters

- **name** (*string*) – name of the variable
- **value** (*float or compatible. will be converted to float*) – new variable value

Returns
either 0 on success or -1 on failure

Return type
int

`eval`(*expr*)

Evaluate a LAMMPS immediate variable expression

Added in version 4Feb2025.

This function is a wrapper around the function *lammps_eval()* of the C library interface. It evaluates and expression like in immediate variables and returns the value.

Parameters
expr – immediate variable expression

Returns
the result of the evaluation

Return type
c_double

`gather_bonds`()

Retrieve global list of bonds

Added in version 28Jul2021.

This is a wrapper around the *lammps_gather_bonds()* function of the C-library interface.

This function returns a tuple with the number of bonds and a flat list of ctypes integer values with the bond type, bond atom1, bond atom2 for each bond.

Returns
a tuple with the number of bonds and a list of c_int or c_long

Return type
(int, 3*nbonds*c_tagint)

`gather_angles`()

Retrieve global list of angles

Added in version 8Feb2023.

This is a wrapper around the *lammps_gather_angles()* function of the C-library interface.

This function returns a tuple with the number of angles and a flat list of ctypes integer values with the angle type, angle atom1, angle atom2, angle atom3 for each angle.

Returns
a tuple with the number of angles and a list of c_int or c_long

Return type
(int, 4*nangles*c_tagint)

`gather_dihedrals`()

Retrieve global list of dihedrals

Added in version 8Feb2023.

This is a wrapper around the *lammps_gather_dihedrals()* function of the C-library interface.

This function returns a tuple with the number of dihedrals and a flat list of ctypes integer values with the dihedral type, dihedral atom1, dihedral atom2, dihedral atom3, dihedral atom4 for each dihedral.

Returns
a tuple with the number of dihedrals and a list of c_int or c_long

Return type
(int, 5*ndihedrals*c_tagint)

`gather_impropers`()

Retrieve global list of impropers

Added in version 8Feb2023.

This is a wrapper around the *lammps_gather_impropers()* function of the C-library interface.

This function returns a tuple with the number of impropers and a flat list of ctypes integer values with the improper type, improper atom1, improper atom2, improper atom3, improper atom4 for each improper.

Returns
a tuple with the number of impropers and a list of c_int or c_long

Return type
(int, 5*nimpropers*c_tagint)

`encode_image_flags`(*ix*, *iy*, *iz*)

convert 3 integers with image flags for x-, y-, and z-direction into a single integer like it is used internally in LAMMPS

This method is a wrapper around the *lammps_encode_image_flags()* function of library interface.

Parameters

- **ix** (*int*) – x-direction image flag
- **iy** (*int*) – y-direction image flag
- **iz** (*int*) – z-direction image flag

Returns
encoded image flags

Return type
lammps.c_imageint

decode_image_flags(*image*)

Convert encoded image flag integer into list of three regular integers.

This method is a wrapper around the *lammps_decode_image_flags()* function of library interface.

Parameters
image (*lammps.c_imageint*) – encoded image flags

Returns
list of three image flags in x-, y-, and z- direction

Return type
list of 3 int

create_atoms(*n*, *atomid*, *atype*, *x*, *v=None*, *image=None*, *shrinkexceed=False*)

Create N atoms from list of coordinates and properties

This function is a wrapper around the *lammps_create_atoms()* function of the C-library interface, and the behavior is similar except that the *v*, *image*, and *shrinkexceed* arguments are optional and default to *None*, *None*, and *False*, respectively. With *None* being equivalent to a `NULL` pointer in C.

The lists of coordinates, types, atom IDs, velocities, image flags can be provided in any format that may be converted into the required internal data types. Also the list may contain more than *N* entries, but not fewer. In the latter case, the function will return without attempting to create atoms. You may use the *encode_image_flags* method to properly combine three integers with image flags into a single integer.

Parameters

- **n** (*int*) – number of atoms for which data is provided
- **atomid** (*list of lammps.tagint*) – list of atom IDs with at least n elements or None
- **atype** (*list of int*) – list of atom types
- **x** (*list of float*) – list of coordinates for x-, y-, and z (flat list of 3n entries)
- **v** (*list of float*) – list of velocities for x-, y-, and z (flat list of 3n entries) or None (optional)
- **image** (*list of lammps.imageint*) – list of encoded image flags (optional)
- **shrinkexceed** (*bool*) – whether to expand shrink-wrap boundaries if atoms are outside the box (optional)

Returns
number of atoms created. 0 if insufficient or invalid data

Return type
int

create_molecule(*molid*, *jsonstr*)

Create new molecule template from string with JSON data

Added in version 22Jul2025.

This is a wrapper around the *lammps_create_molecule()* function of the library interface.

Parameters

- **molid** – molecule-id of the new molecule template
- **jsonstr** (*string*) – JSON data defining a new molecule template

property has_mpi_support

Report whether the LAMMPS shared library was compiled with a real MPI library or in serial.

This is a wrapper around the *lammps_config_has_mpi_support()* function of the library interface.

Returns
False when compiled with MPI STUBS, otherwise True

Return type
bool

property has_omp_support

Report whether the LAMMPS shared library was compiled with OpenMP enabled.

This is a wrapper around the *lammps_config_has_omp_support()* function of the library interface.

Returns
True when compiled with OpenMP enabled, otherwise False

Return type
bool

property is_running

Report whether being called from a function during a run or a minimization

Added in version 9Oct2020.

Various LAMMPS commands must not be called during an ongoing run or minimization. This property allows to check for that. This is a wrapper around the *lammps_is_running()* function of the library interface.

Returns
True when called during a run otherwise false

Return type
bool

set_show_error(*flag*)

Enable or disable direct printing of error messages in C++ code

Added in version 2Apr2025.

This function allows to enable or disable printing of error message directly in the C++ code. Disabling the printing avoids printing error messages twice when detecting and re-throwing them in Python code.

This is a wrapper around the *lammps_set_show_error()* function of the library interface.

Parameters
flag (*int*) – enable (1) or disable (0) printing of error message

Returns
previous setting of the flag

Return type
int

`force_timeout()`

Trigger an immediate timeout, i.e. a "soft stop" of a run.

Added in version 9Oct2020.

This function allows to cleanly stop an ongoing run or minimization at the next loop iteration. This is a wrapper around the *lammps_force_timeout()* function of the library interface.

`property has_exceptions`

Report whether the LAMMPS shared library was compiled with C++ exceptions handling enabled

This is a wrapper around the *lammps_config_has_exceptions()* function of the library interface.

Returns
state of C++ exception support

Return type
bool

`property has_gzip_support`

Report whether the LAMMPS shared library was compiled with support for reading and writing compressed files through `gzip`.

This is a wrapper around the *lammps_config_has_gzip_support()* function of the library interface.

Returns
state of gzip support

Return type
bool

`property has_png_support`

Report whether the LAMMPS shared library was compiled with support for writing images in PNG format.

This is a wrapper around the *lammps_config_has_png_support()* function of the library interface.

Returns
state of PNG support

Return type
bool

`property has_jpeg_support`

Report whether the LAMMPS shared library was compiled with support for writing images in JPEG format.

This is a wrapper around the *lammps_config_has_jpeg_support()* function of the library interface.

Returns
state of JPEG support

Return type
bool

`property has_ffmpeg_support`

State of support for writing movies with `ffmpeg` in the LAMMPS shared library

This is a wrapper around the *lammps_config_has_ffmpeg_support()* function of the library interface.

Returns
state of ffmpeg support

Return type
bool

property has_curl_support

Report whether the LAMMPS shared library was compiled with support for downloading files through libcurl.

This is a wrapper around the `lammps_config_has_curl_support()` function of the library interface.

Returns
state of CURL support

Return type
bool

has_package(*name*)

Report if the named package has been enabled in the LAMMPS shared library.

Added in version 3Nov2022.

This is a wrapper around the *lammps_config_has_package()* function of the library interface.

Parameters
name (*string*) – name of the package

Returns
state of package availability

Return type
bool

property accelerator_config

Return table with available accelerator configuration settings.

This is a wrapper around the *lammps_config_accelerator()* function of the library interface which loops over all known packages and categories and returns enabled features as a nested dictionary with all enabled settings as list of strings.

Returns
nested dictionary with all known enabled settings as list of strings

Return type
dictionary

property has_gpu_device

Availability of GPU package compatible device

This is a wrapper around the *lammps_has_gpu_device()* function of the C library interface.

Returns
True if a GPU package compatible device is present, otherwise False

Return type
bool

get_gpu_device_info()

Return a string with detailed information about any devices that are usable by the GPU package.

This is a wrapper around the *lammps_get_gpu_device_info()* function of the C-library interface.

Returns
GPU device info string

Return type
string

property installed_packages

List of the names of enabled packages in the LAMMPS shared library

This is a wrapper around the functions *lammps_config_package_count()* and *lammps_config_package_name()* of the library interface.

:return

has_style(*category*, *name*)

Returns whether a given style name is available in a given category

This is a wrapper around the function *lammps_has_style()* of the library interface.

Parameters

- **category** (*string*) – name of category
- **name** (*string*) – name of the style

Returns
true if style is available in given category

Return type
bool

available_styles(*category*)

Returns a list of styles available for a given category

This is a wrapper around the functions *lammps_style_count()* and *lammps_style_name()* of the library interface.

Parameters
category (*string*) – name of category

Returns
list of style names in given category

Return type
list

has_id(*category*, *name*)

Returns whether a given ID name is available in a given category

Added in version 9Oct2020.

This is a wrapper around the function *lammps_has_id()* of the library interface.

Parameters

- **category** (*string*) – name of category
- **name** (*string*) – name of the ID

Returns
true if ID is available in given category

Return type
bool

available_ids(*category*)

Returns a list of IDs available for a given category

Added in version 9Oct2020.

This is a wrapper around the functions *lammps_id_count()* and *lammps_id_name()* of the library interface.

Changed in version 22Jul2025.

This function has a different behavior for the "group" category: rather than only listing the available groups, it will return a full list with LMP_MAX_GROUP elements. This is because the list may have "holes" when groups are deleted. The returned list has either the name of the group or "None" for empty entries. This way, the value of 1 << idx is the groupbit that can be compared to the per-atom "mask" property to determine if an atom is member of a group.

Parameters
category (*string*) – name of category

Returns
list of id names in given category

Return type
list

available_plugins(*category=None*)

Returns a list of plugins available for a given category

Added in version 10Mar2021.

This is a wrapper around the functions lammps_plugin_count() and lammps_plugin_name() of the library interface.

Returns
list of style/name pairs of loaded plugins

Return type
list

set_fix_external_callback(*fix_id*, *callback*, *caller=None*)

Set the callback function for a fix external instance with a given fix ID.

Optionally also set a reference to the calling object.

This is a wrapper around the *lammps_set_fix_external_callback()* function of the C-library interface. However this is set up to call a Python function with the following arguments.

- object is the value of the "caller" argument
- ntimestep is the current timestep
- nlocal is the number of local atoms on the current MPI process
- tag is a 1d NumPy array of integers representing the atom IDs of the local atoms
- x is a 2d NumPy array of doubles of the coordinates of the local atoms
- f is a 2d NumPy array of doubles of the forces on the local atoms that will be added

Changed in version 28Jul2021.

Parameters

- **fix_id** – Fix-ID of a fix external instance
- **callback** – Python function that will be called from fix external

- **caller** – reference to some object passed to the callback function

Type
string

Type
function

Type
object, optional

fix_external_get_force(*fix_id*)

Get access to the array with per-atom forces of a fix external instance with a given fix ID.

Added in version 28Jul2021.

This is a wrapper around the *lammps_fix_external_get_force()* function of the C-library interface.

Parameters
fix_id – Fix-ID of a fix external instance

Type
string

Returns
requested data

Return type
ctypes.POINTER(ctypes.POINTER(ctypes.double))

fix_external_set_energy_global(*fix_id*, *eng*)

Set the global energy contribution for a fix external instance with the given ID.

Added in version 28Jul2021.

This is a wrapper around the *lammps_fix_external_set_energy_global()* function of the C-library interface.

Parameters

- **fix_id** – Fix-ID of a fix external instance
- **eng** – potential energy value to be added by fix external

Type
string

Type
float

fix_external_set_virial_global(*fix_id*, *virial*)

Set the global virial contribution for a fix external instance with the given ID.

Added in version 28Jul2021.

This is a wrapper around the *lammps_fix_external_set_virial_global()* function of the C-library interface.

Parameters

- **fix_id** – Fix-ID of a fix external instance
- **eng** – list of 6 floating point numbers with the virial to be added by fix external

Type
string

Type
float

fix_external_set_energy_peratom(*fix_id*, *eatom*)

Set the per-atom energy contribution for a fix external instance with the given ID.

Added in version 28Jul2021.

This is a wrapper around the *lammps_fix_external_set_energy_peratom()* function of the C-library interface.

Parameters

- **fix_id** – Fix-ID of a fix external instance
- **eatom** – list of potential energy values for local atoms to be added by fix external

Type
string

Type
float

fix_external_set_virial_peratom(*fix_id*, *vatom*)

Set the per-atom virial contribution for a fix external instance with the given ID.

Added in version 28Jul2021.

This is a wrapper around the *lammps_fix_external_set_virial_peratom()* function of the C-library interface.

Parameters

- **fix_id** – Fix-ID of a fix external instance
- **vatom** – list of natoms lists with 6 floating point numbers to be added by fix external

Type
string

Type
float

fix_external_set_vector_length(*fix_id*, *length*)

Set the vector length for a global vector stored with fix external for analysis

Added in version 28Jul2021.

This is a wrapper around the *lammps_fix_external_set_vector_length()* function of the C-library interface.

Parameters

- **fix_id** – Fix-ID of a fix external instance
- **length** – length of the global vector

Type
string

Type
int

fix_external_set_vector(*fix_id*, *idx*, *val*)

Store a global vector value for a fix external instance with the given ID.

Added in version 28Jul2021.

This is a wrapper around the *lammps_fix_external_set_vector()* function of the C-library interface.

Parameters

- **fix_id** – Fix-ID of a fix external instance
- **idx** – 1-based index of the value in the global vector
- **val** – value to be stored in the global vector

Type
string

Type
int

Type
float

get_neighlist(*idx*)

Returns an instance of *NeighList* which wraps access to the neighbor list with the given index

See *lammps.numpy.get_neighlist()* if you want to use NumPy arrays instead of `c_int` pointers.

Parameters
idx (*int*) – index of neighbor list

Returns
an instance of *NeighList* wrapping access to neighbor list data

Return type
NeighList

get_neighlist_size(*idx*)

Return the number of elements in neighbor list with the given index

Parameters
idx (*int*) – neighbor list index

Returns
number of elements in neighbor list with index idx

Return type
int

get_neighlist_element_neighbors(*idx*, *element*)

Return data of neighbor list entry

Parameters

- **element** (*int*) – neighbor list index
- **element** – neighbor list element index

Returns
tuple with atom local index, number of neighbors and array of neighbor local atom indices

Return type
(int, int, POINTER(c_int))

find_pair_neighlist(*style*, *exact=True*, *nsub=0*, *reqid=0*)

Find neighbor list index of pair style neighbor list

Search for a neighbor list requested by a pair style instance that matches "style". If exact is True, the pair style name must match exactly. If exact is False, the pair style name is matched against "style" as regular expression or sub-string. If the pair style is a hybrid pair style, the style is instead matched against the hybrid sub-styles. If the same pair style is used as sub-style multiple types, you must set nsub to a value n > 0 which indicates the nth instance of that sub-style to be used (same as for the pair_coeff command). The default value of 0 will fail to match in that case.

Once the pair style instance has been identified, it may have requested multiple neighbor lists. Those are uniquely identified by a request ID > 0 as set by the pair style. Otherwise the request ID is 0.

Parameters

- **style** (*string*) – name of pair style that should be searched for
- **exact** (*bool, optional*) – controls whether style should match exactly or only must be contained in pair style name, defaults to True
- **nsub** (*int, optional*) – match nsub-th hybrid sub-style, defaults to 0
- **reqid** (*int, optional*) – list request id, > 0 in case there are more than one, defaults to 0

Returns
neighbor list index if found, otherwise -1

Return type
int

find_fix_neighlist(*fixid*, *reqid=0*)

Find neighbor list index of fix neighbor list

The fix instance requesting the neighbor list is uniquely identified by the fix ID. In case the fix has requested multiple neighbor lists, those are uniquely identified by a request ID > 0 as set by the fix. Otherwise the request ID is 0 (the default).

Parameters

- **fixid** (*string*) – name of fix
- **reqid** (*int, optional*) – id of neighbor list request, in case there are more than one request, defaults to 0

Returns
neighbor list index if found, otherwise -1

Return type
int

find_compute_neighlist(*computeid*, *reqid=0*)

Find neighbor list index of compute neighbor list

The compute instance requesting the neighbor list is uniquely identified by the compute ID. In case the compute has requested multiple neighbor lists, those are uniquely identified by a request ID > 0 as set by the compute. Otherwise the request ID is 0 (the default).

Parameters

- **computeid** (*string*) – name of compute
- **reqid** (*int, optional*) – index of neighbor list request, in case there are more than one request, defaults to 0

Returns
neighbor list index if found, otherwise -1

Return type
int

class lammps.numpy_wrapper.**numpy_wrapper**(*lmp*)

lammps API NumPy Wrapper

This is a wrapper class that provides additional methods on top of an existing *lammps* instance. The methods transform raw ctypes pointers into NumPy arrays, which give direct access to the original data while protecting against out-of-bounds accesses.

There is no need to explicitly instantiate this class. Each instance of *lammps* has a `numpy` property that returns an instance.

Parameters
lmp (*lammps*) – instance of the *lammps* class

extract_atom(*name*, *dtype=None*, *nelem=None*, *dim=None*)

Retrieve per-atom properties from LAMMPS as NumPy arrays

This is a wrapper around the `lammps.extract_atom()` method. It behaves the same as the original method, but returns NumPy arrays instead of `ctypes` pointers.

Note

The returned vectors or arrays of per-atom data are dimensioned according to the return value of `lammps.extract_atom_size()`. Except for the "mass" property, the underlying storage will always be dimensioned for the range [0:nmax]. The actual usable data may be only in the range [0:nlocal] or [0:nlocal][0:dim]. Whether there is valid data in the range [nlocal:nlocal+nghost] or [nlocal:local+nghost][0:dim] depends on whether the property of interest is also updated for ghost atoms. Also the value of *dim* depends on the value of *name*. By using the optional *nelem* and *dim* parameters the dimensions of the returned NumPy array can be overridden. There is no check whether the number of elements chosen is valid.

Parameters

- **name** (*string*) – name of the property
- **dtype** (*int, optional*) – type of the returned data (see *Data Types*)
- **nelem** (*int, optional*) – number of elements in array
- **dim** (*int, optional*) – dimension of each element

Returns
requested data as NumPy array with direct access to C data or None

Return type
numpy.array or NoneType

extract_compute(*cid*, *cstyle*, *ctype*)

Retrieve data from a LAMMPS compute

This is a wrapper around the *lammps.extract_compute()* method. It behaves the same as the original method, but returns NumPy arrays instead of `ctypes` pointers.

Parameters

- **cid** (*string*) – compute ID
- **cstyle** (*int*) – style of the data retrieve (global, atom, or local), see *Style Constants*
- **ctype** (*int*) – type of the returned data (scalar, vector, or array), see *Type Constants*

Returns
requested data either as float, as NumPy array with direct access to C data, or None

Return type
float, numpy.array, or NoneType

extract_fix(*fid*, *fstyle*, *ftype*, *nrow=0*, *ncol=0*)

Retrieve data from a LAMMPS fix

This is a wrapper around the *lammps.extract_fix()* method. It behaves the same as the original method, but returns NumPy arrays instead of `ctypes` pointers.

> **Note**
>
> When requesting global data, the fix data can only be accessed one item at a time without access to the whole vector or array. Thus this function will always return a scalar. To access vector or array elements the "nrow" and "ncol" arguments need to be set accordingly (they default to 0).

Parameters

- **fid** (*string*) – fix ID
- **fstyle** (*int*) – style of the data retrieve (global, atom, or local), see *Style Constants*
- **ftype** (*int*) – type or size of the returned data (scalar, vector, or array), see *Type Constants*
- **nrow** (*int*) – index of global vector element or row index of global array element
- **ncol** (*int*) – column index of global array element

Returns
requested data

Return type
integer or double value, pointer to 1d or 2d double array or None

extract_variable(*name*, *group=None*, *vartype=0*)

Evaluate a LAMMPS variable and return its data

This function is a wrapper around the function *lammps.extract_variable()* method. It behaves the same as the original method, but returns NumPy arrays instead of `ctypes` pointers.

Parameters

- **name** (*string*) – name of the variable to execute
- **group** (*string*) – name of group for atom-style variable (ignored for equal-style variables)
- **vartype** (*int*) – type of variable, see *Variable Type Constants*

Returns
the requested data or None

Return type
c_double, numpy.array, or NoneType

`gather_bonds`()

Retrieve global list of bonds as a NumPy array

Added in version 28Jul2021.

This is a wrapper around *lammps.gather_bonds()*. It behaves the same as the original method, but returns a NumPy array instead of a `ctypes` list.

Returns
the requested data as a 2d-integer numpy array

Return type
numpy.array(nbonds,3)

`gather_angles`()

Retrieve global list of angles as a NumPy array

Added in version 8Feb2023.

This is a wrapper around *lammps.gather_angles()*. It behaves the same as the original method, but returns a NumPy array instead of a `ctypes` list.

Returns
the requested data as a 2d-integer numpy array

Return type
numpy.array(nangles,4)

`gather_dihedrals`()

Retrieve global list of dihedrals as a NumPy array

Added in version 8Feb2023.

This is a wrapper around *lammps.gather_dihedrals()*. It behaves the same as the original method, but returns a NumPy array instead of a `ctypes` list.

Returns
the requested data as a 2d-integer numpy array

Return type
numpy.array(ndihedrals,5)

`gather_impropers`()

Retrieve global list of impropers as a NumPy array

Added in version 8Feb2023.

This is a wrapper around *lammps.gather_impropers()*. It behaves the same as the original method, but returns a NumPy array instead of a `ctypes` list.

Returns
the requested data as a 2d-integer numpy array

Return type
numpy.array(nimpropers,5)

`fix_external_get_force`(*fix_id*)

Get access to the array with per-atom forces of a fix external instance with a given fix ID.

Changed in version 28Jul2021.

This function is a wrapper around the *lammps.fix_external_get_force()* method. It behaves the same as the original method, but returns a NumPy array instead of a `ctypes` pointer.

Parameters
fix_id – Fix-ID of a fix external instance

Type
string

Returns
requested data

Return type
numpy.array

fix_external_set_energy_peratom(*fix_id*, *eatom*)

Set the per-atom energy contribution for a fix external instance with the given ID.

Added in version 28Jul2021.

This function is an alternative to *lammps.fix_external_set_energy_peratom()* method. It behaves the same as the original method, but accepts a NumPy array instead of a list as argument.

Parameters

- **fix_id** – Fix-ID of a fix external instance
- **eatom** – per-atom potential energy

Type
string

Type
numpy.array

fix_external_set_virial_peratom(*fix_id*, *vatom*)

Set the per-atom virial contribution for a fix external instance with the given ID.

Added in version 28Jul2021.

This function is an alternative to *lammps.fix_external_set_virial_peratom()* method. It behaves the same as the original method, but accepts a NumPy array instead of a list as argument.

Parameters

- **fix_id** – Fix-ID of a fix external instance
- **eatom** – per-atom potential energy

Type
string

Type
numpy.array

get_neighlist(*idx*)

Returns an instance of *NumPyNeighList* which wraps access to the neighbor list with the given index

Parameters
idx (*int*) – index of neighbor list

Returns
an instance of *NumPyNeighList* wrapping access to neighbor list data

Return type
NumPyNeighList

get_neighlist_element_neighbors(*idx*, *element*)

Return data of neighbor list entry

This function is a wrapper around the function *lammps.get_neighlist_element_neighbors()* method. It behaves the same as the original method, but returns a NumPy array containing the neighbors instead of a `ctypes` pointer.

Parameters

- **element** (*int*) – neighbor list index
- **element** – neighbor list element index

Returns
tuple with atom local index and numpy array of neighbor local atom indices

Return type
(int, numpy.array)

iarray(*c_int_type*, *raw_ptr*, *nelem*, *dim=1*)

Convert ctypes pointer to an array of integers into a corresponding numpy array

This will cast the raw pointer into a 1-d or 2-d numpy array and set its shape

Parameters

- **c_int_type** – type of integer (c_int32 or c_int64)
- **raw_ptr** – ctypes pointer to the array data
- **nelem** – length of the leading dimension
- **dim** – length of the second dimension

Type
ctypes type

Type
POINTER(c_int_type)

Type
integer

Type
integer, optional

Returns
ctypes array converted to numpy style array with proper shape

Return type
numpy.array

darray(*raw_ptr*, *nelem*, *dim=1*)

Convert ctypes pointer to an array of doubles into a corresponding numpy array

This will cast the raw pointer into a 1-d or 2-d numpy array and set its shape

Parameters

- **raw_ptr** – ctypes pointer to the array data
- **nelem** – length of the leading dimension
- **dim** – length of the second dimension

Type
POINTER(c_double)

Type
integer

Type
integer, optional

Returns
ctypes array converted to numpy style array with proper shape

Return type
numpy.array

class lammps.ipython.**wrapper**(*lmp*)

lammps API IPython Wrapper

This is a wrapper class that provides additional methods on top of an existing `lammps` instance. It provides additional methods that allow create and/or embed visualizations created by native LAMMPS commands.

There is no need to explicitly instantiate this class. Each instance of `lammps` has a `ipython` property that returns an instance.

Parameters
lmp (`lammps`) – instance of the `lammps` class

image(*filename='snapshot.png'*, *group='all'*, *color='type'*, *diameter='type'*, *size=None*, *view=None*, *center=None*, *up=None*, *zoom=1.0*, *background_color='white'*)

Generate image using write_dump command and display it

See *dump image* for more information.

Parameters

- **filename** (*string*) – Name of the image file that should be generated. The extension determines whether it is PNG or JPEG
- **group** (*string*) – the group of atoms write_image should use
- **color** (*string*) – name of property used to determine color
- **diameter** (*string*) – name of property used to determine atom diameter
- **size** (*tuple (width, height)*) – dimensions of image
- **view** (*tuple (theta, phi)*) – view parameters
- **center** (*tuple (flag, center_x, center_y, center_z)*) – center parameters
- **up** (*tuple (up_x, up_y, up_z)*) – vector pointing to up direction
- **zoom** (*float*) – zoom factor
- **background_color** (*string*) – background color of scene

Returns
Image instance used to display image in notebook

Return type
`IPython.core.display.Image`

video(*filename*)

Load video from file

Can be used to visualize videos from *dump movie*.

Parameters
filename (*string*) – Path to video file

Returns
HTML Video Tag used by notebook to embed a video

Return type
IPython.display.HTML

2.4.2 Additional components of the lammps module

The *lammps* module additionally contains several constants and the *NeighList* class:

Data Types

LAMMPS_INT, LAMMPS_INT_2D, LAMMPS_DOUBLE, LAMMPS_DOUBLE_2D, LAMMPS_INT64, LAMMPS_INT64_2D, LAMMPS_STRING

Constants in the *lammps* module to indicate how to cast data when the C library function returns a void pointer. Used in *lammps.extract_global()* and *lammps.extract_atom()*. See _LMP_DATATYPE_CONST for the equivalent constants in the C library interface.

Style Constants

LMP_STYLE_GLOBAL, LMP_STYLE_ATOM, LMP_STYLE_LOCAL

Constants in the *lammps* module to select what style of data to request from computes or fixes. See *_LMP_STYLE_CONST* for the equivalent constants in the C library interface. Used in *lammps.extract_compute()*, *lammps.extract_fix()*, and their NumPy variants *lammps.numpy.extract_compute()* and *lammps.numpy.extract_fix()*.

Type Constants

LMP_TYPE_SCALAR, LMP_TYPE_VECTOR, LMP_TYPE_ARRAY, LMP_SIZE_VECTOR, LMP_SIZE_ROWS, LMP_SIZE_COLS

Constants in the *lammps* module to select what type of data to request from computes or fixes. See *_LMP_TYPE_CONST* for the equivalent constants in the C library interface. Used in *lammps.extract_compute()*, *lammps.extract_fix()*, and their NumPy variants *lammps.numpy.extract_compute()* and *lammps.numpy.extract_fix()*.

Variable Type Constants

LMP_VAR_EQUAL, LMP_VAR_ATOM

Constants in the *lammps* module to select what type of variable to query when calling *lammps.extract_variable()*. See also: *variable command*.

Classes representing internal objects

class lammps.**NeighList**(*lmp*, *idx*)

This is a wrapper class that exposes the contents of a neighbor list.

It can be used like a regular Python list. Each element is a tuple of:

- the atom local index
- its number of neighbors
- and a pointer to an c_int array containing local atom indices of its neighbors

Internally it uses the lower-level LAMMPS C-library interface.

Parameters

- **lmp** (lammps) – reference to instance of *lammps*
- **idx** (*int*) – neighbor list index

property size

Returns
number of elements in neighbor list

get(*element*)

Access a specific neighbor list entry. "element" must be a number from 0 to the size-1 of the list

Returns
tuple with atom local index, number of neighbors and ctypes pointer to neighbor's local atom indices

Return type
(int, int, ctypes.POINTER(c_int))

find(*iatom*)

Find the neighbor list for a specific (local) atom iatom. If there is no list for iatom, (-1, None) is returned.

Returns
tuple with number of neighbors and ctypes pointer to neighbor's local atom indices

Return type
(int, ctypes.POINTER(c_int))

class lammps.numpy_wrapper.**NumPyNeighList**(*lmp*, *idx*)

This is a wrapper class that exposes the contents of a neighbor list.

It can be used like a regular Python list. Each element is a tuple of:

- the atom local index
- a NumPy array containing the local atom indices of its neighbors

Internally it uses the lower-level LAMMPS C-library interface.

Parameters

- **lmp** (lammps) – reference to instance of *lammps*
- **idx** (*int*) – neighbor list index

get(*element*)

Access a specific neighbor list entry. "element" must be a number from 0 to the size-1 of the list

Returns
tuple with atom local index, numpy array of neighbor local atom indices

Return type
(int, numpy.array)

find(*iatom*)

Find the neighbor list for a specific (local) atom iatom. If there is no list for iatom, None is returned.

Returns
numpy array of neighbor local atom indices

Return type
numpy.array or None

2.5 Extending the Python interface

As noted previously, most of the `lammps` Python class methods correspond one-to-one with the functions in the LAMMPS library interface in `src/library.cpp` and `library.h`. This means you can extend the Python wrapper by following these steps:

- Add a new interface function to `src/library.cpp` and `src/library.h`.
- Rebuild LAMMPS as a shared library.
- Add a wrapper method to `python/lammps/core.py` for this interface function.
- Define the corresponding `argtypes` list and `restype` in the `lammps.__init__()` function.
- Re-install the shared library and the python module, if needed
- You should now be able to invoke the new interface function from a Python script.

2.6 Calling Python from LAMMPS

LAMMPS has several commands which can be used to invoke Python code directly from an input script:

- *python*
- *python-style variables*
- *equal-style and atom-style variables with formulas containing Python function wrappers*
- *fix python/invoke*
- *pair_style python*

The *python* command can be used to define and execute a Python function that you write the code for. The Python function can also be assigned to a LAMMPS python-style variable via the *variable* command. Each time the variable is evaluated, either in the LAMMPS input script itself, or by another LAMMPS command that uses the variable, this will trigger the Python function to be invoked.

The Python function can also be referenced in the formula used to define an *equal-style or atom-style variable*, using the syntax for a *Python function wrapper*. This make it easy to pass LAMMPS-related arguments to the Python function, as well as to invoke it whenever the equal- or atom-style variable is evaluated. For an atom-style variable it means the Python function can be invoked once per atom, using per-atom properties as arguments to the function.

The Python code for the function can be included directly in the input script or in an auxiliary file. The function can have arguments which are mapped to LAMMPS variables (also defined in the input script) and it can return a value to a LAMMPS variable. This is thus a mechanism for your input script to pass information to a piece of Python code, ask Python to execute the code, and return information to your input script.

Note that a Python function can be arbitrarily complex. It can import other Python modules, instantiate Python classes, call other Python functions, etc. The Python code that you provide can contain more code than the single function. It can contain other functions or Python classes, as well as global variables or other mechanisms for storing state between calls from LAMMPS to the function.

The Python function you provide can consist of "pure" Python code that only performs operations provided by standard Python. However, the Python function can also "call back" to LAMMPS through its Python-wrapped library interface, in the manner described in the *Python run* doc page. This means it can issue LAMMPS input script commands or query and set internal LAMMPS state. As an example, this can be useful in an input script to create a more complex loop with branching logic, than can be created using the simple looping and branching logic enabled by the *next* and *if* commands.

See the *python* page and the *variable* doc page for its python-style variables for more info, including examples of Python code you can write for both pure Python operations and callbacks to LAMMPS.

2.7 Output Readers

The Python package contains the `lammps.formats` module, which provides classes to post-process some of the output files generated by LAMMPS.

Output formats for LAMMPS python module Written by Richard Berger <richard.berger@outlook.com> and Axel Kohlmeyer <akohlmey@gmail.com>

class lammps.formats.**LogFile**(*filename*)

Reads LAMMPS log files and extracts the thermo information

It supports the line, multi, and yaml thermo output styles.

Parameters
filename (*str*) – path to log file

Variables

- **runs** – List of LAMMPS runs in log file. Each run is a dictionary with thermo fields as keys, storing the values over time
- **errors** – List of error lines in log file

class lammps.formats.**AvgChunkFile**(*filename*)

Reads files generated by fix ave/chunk

Parameters
filename (*str*) – path to ave/chunk file

Variables

- **timesteps** – List of timesteps stored in file
- **total_count** – total count over time
- **chunks** – List of chunks. Each chunk is a dictionary containing its ID, the coordinates, and the averaged quantities

2.8 Example Python scripts

The `python/examples` directory has Python scripts which show how Python can run LAMMPS, grab data, change it, and put it back into LAMMPS.

These are the Python scripts included as demos in the `python/examples` directory of the LAMMPS distribution, to illustrate the kinds of things that are possible when Python wraps LAMMPS. If you create your own scripts, send them to us and we can include them in the LAMMPS distribution.

`trivial.py`	read/run a LAMMPS input script through Python
`demo.py`	invoke various LAMMPS library interface routines
`simple.py`	run in parallel, similar to `examples/COUPLE/simple/simple.cpp`
`split.py`	same as `simple.py` but running in parallel on a subset of procs
`gui.py`	GUI go/stop/temperature-slider to control LAMMPS
`plot.py`	real-time temperature plot with GnuPlot via Pizza.py
`viz_TOOL.py`	real-time viz via some viz package
`vizplotgui_TOOL.py`	combination of `viz_TOOL.py` and `plot.py` and `gui.py`

For the `viz_TOOL.py` and `vizplotgui_TOOL.py` commands, replace `TOOL` with `gl` or `atomeye` or `pymol` or `vmd`, depending on what visualization package you have installed.

Note that for GL, you need to be able to run the Pizza.py GL tool, which is included in the pizza subdirectory. See the Pizza.py doc pages for more info:

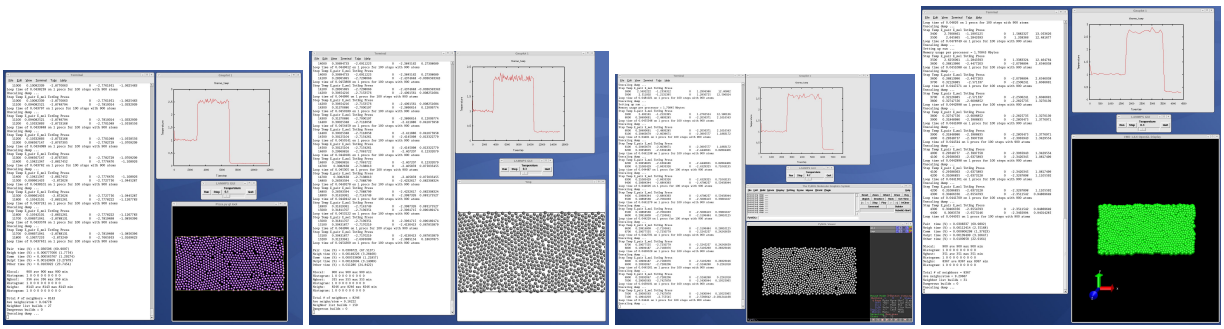
- https://sjplimp.github.io/pizza/

Note that for AtomEye, you need version 3, and there is a line in the scripts that specifies the path and name of the executable. See the AtomEye web pages for more details:

- http://li.mit.edu/Archive/Graphics/A/
- http://li.mit.edu/Archive/Graphics/A3/A3.html

The latter link is to AtomEye 3 which has the scripting capability needed by these Python scripts.

Note that for PyMol, you need to have built and installed the open-source version of PyMol in your Python, so that you can import it from a Python script. See the PyMol web pages for more details:



- https://www.pymol.org
- https://github.com/schrodinger/pymol-open-source

The latter link is to the open-source version.

Note that for VMD, you need a fairly current version (1.8.7 works for me) and there are some lines in the `pizza/vmd.py` script for 4 PIZZA variables that have to match the VMD installation on your system.

See the `python/README` file for instructions on how to run them and the source code for individual scripts for comments about what they do.

Here are screenshots of the `vizplotgui_tool.py` script in action for different visualization package options:

2.9 Using LAMMPS in IPython notebooks and Jupyter

If the LAMMPS Python package is installed for the same Python interpreter as IPython, you can use LAMMPS directly inside of an IPython notebook inside of Jupyter. Jupyter is a powerful integrated development environment (IDE) for many dynamic languages like Python, Julia and others, which operates inside of any web browser. Besides auto-completion and syntax highlighting it allows you to create formatted documents using Markup, mathematical formulas, graphics and animations intermixed with executable Python code. It is a great format for tutorials and showcasing your latest research.

The easiest way to install it is via `pip` from https://pypi.org/:

```
pip install --user jupyter
```

To launch an instance of Jupyter simply run the following command inside your Python environment:

```
jupyter notebook
```

2.9.1 Interactive Python Examples

Examples of IPython notebooks can be found in the `python/examples/ipython` subdirectory. They require LAMMPS to be compiled as shared library with PYTHON, PNG, JPEG and FFMPEG support.

To open these notebooks launch `jupyter notebook index.ipynb` inside this directory. The opened file provides an overview of the available examples.

- Example 1: Using LAMMPS with Python (`simple.ipynb`)
- Example 2: Analyzing LAMMPS thermodynamic data (`thermo.ipynb`)
- Example 3: Working with Per-Atom Data (`atoms.ipynb`)
- Example 4: Working with LAMMPS variables (`variables.ipynb`)
- Example 5: Validating a dihedral potential (`dihedrals/dihedral.ipynb`)
- Example 6: Running a Monte Carlo relaxation (`montecarlo/mc.ipynb`)

Note

Typically clicking a link in Jupyter will open a new tab, which might be blocked by your pop-up blocker.

2.10 Handling LAMMPS errors

LAMMPS and the LAMMPS library are compiled with *C++ exception support* to provide a better error handling experience. LAMMPS errors trigger throwing a C++ exception. These exceptions allow capturing errors on the C++ side and rethrowing them on the Python side. This way LAMMPS errors can be handled through the Python exception handling mechanism.

```
from lammps import lammps, MPIAbortException

lmp = lammps()

try:
   # LAMMPS will normally terminate itself and the running process if an error
   # occurs. This would kill the Python interpreter.  The library wrapper will
   # detect that an error has occurred and throw a Python exception

   lmp.command('unknown')
except MPIAbortException as ae:
   # Single MPI process got killed. This would normally be handled by an MPI abort
   pass
except Exception as e:
   # All (MPI) processes have reached this error
   pass
```

Warning

Capturing a LAMMPS exception in Python can still mean that the current LAMMPS process is in an illegal state and must be terminated. It is advised to save your data and terminate the Python instance as quickly as possible when running in parallel with MPI.

2.11 Troubleshooting

2.11.1 Testing if Python can launch LAMMPS

To test if LAMMPS is callable from Python, launch Python interactively and type:

```
>>> from lammps import lammps
>>> lmp = lammps()
```

If you get no errors, you're ready to use LAMMPS from Python. If the second command fails, the most common error to see is

```
OSError: Could not load LAMMPS dynamic library
```

which means Python was unable to load the LAMMPS shared library. This typically occurs if the system can't find the LAMMPS shared library or one of the auxiliary shared libraries it depends on, or if something about the library is incompatible with your Python. The error message should give you an indication of what went wrong.

If your shared library uses a suffix, such as `liblammps_mpi.so`, change the constructor call as follows (see *Creating or deleting a LAMMPS object* for more details):

```
>>> lmp = lammps(name='mpi')
```

You can also test the load directly in Python as follows, without first importing from the `lammps` module:

```
>>> from ctypes import CDLL
>>> CDLL("liblammps.so")
```

If an error occurs, carefully go through the steps in *Installing the LAMMPS Python Module and Shared Library* and on the *Build_basics* page about building a shared library.

If you are not familiar with Python, it is a powerful scripting and programming language which can do almost everything that compiled languages like C, C++, or Fortran can do in fewer lines of code. It also comes with a large collection of add-on modules for many purposes (either bundled or easily installed from Python code repositories). The major drawback is slower execution speed of the script code compared to compiled programming languages. But when the script code is interfaced to optimized compiled code, performance can be on par with a standalone executable, for as long as the scripting is restricted to high-level operations. Thus Python is also convenient to use as a "glue" language to "drive" a program through its library interface, or to hook multiple pieces of software together, such as a simulation code and a visualization tool, or to run a coupled multi-scale or multi-physics model.

See the *Coupling LAMMPS to other codes* page for more ideas about coupling LAMMPS to other codes. See the *LAMMPS Library Interfaces* page for a description of the LAMMPS library interfaces. That interface is exposed to Python either when calling LAMMPS from Python or when calling Python from a LAMMPS input script and then calling back to LAMMPS from Python code. The C-library interface is designed to be easy to add functionality to, thus the Python interface to LAMMPS is easy to extend as well.

If you create interesting Python scripts that run LAMMPS or interesting Python functions that can be called from a LAMMPS input script, that you think would be generally useful, please post them as a pull request to our GitHub site, and they can be added to the LAMMPS distribution or web page.

CHAPTER

THREE

MODIFYING & EXTENDING LAMMPS

LAMMPS has a modular design, so that it is easy to modify or extend with new functionality. In fact, about 95% of its source code is optional. The following pages give basic instructions on adding new features to LAMMPS. More in-depth explanations and documentation of individual functions and classes are given in *Information for Developers*.

If you add a new feature to LAMMPS and think it will be of general interest to other users, we encourage you to submit it for inclusion in LAMMPS. This process is explained in the following three pages:

- *how to prepare and submit your code*
- *requirements for submissions*
- *style guidelines*

A summary description of various types of styles in LAMMPS follows. A discussion of implementing specific styles from scratch is given in *writing new styles*.

3.1 Overview

The best way to add a new feature to LAMMPS is to find a similar feature and look at the corresponding source and header files to figure out what it does. You will need some knowledge of C++ to understand the high-level structure of LAMMPS and its class organization. Functions (class methods) that do actual computations are mostly written in C-style code and operate on simple C-style data structures (vectors and arrays). A high-level overview of the programming style choices in LAMMPS is *given elsewhere*.

Most of the new features described on the *Modify* doc page require you to write a new C++ derived class (excluding exceptions described below, this can often be done by making small edits to existing files). Creating a new class requires 2 files, a source code file (*.cpp) and a header file (*.h). The derived class must provide certain methods to work as a new option. Depending on how different your new feature is compared to existing features, you can either derive from the base class itself, or from a derived class that already exists. Enabling LAMMPS to invoke the new class is as simple as putting the two source files in the src directory and re-building LAMMPS.

The advantage of C++ and its object-orientation is that all the code and variables needed to define the new feature are in the 2 files you write. Thus, it should not make the rest of LAMMPS more complex or cause bugs through unwanted side effects.

Here is a concrete example. Suppose you write 2 files `pair_foo.cpp` and `pair_foo.h` that define a new class `PairFoo` which computes pairwise potentials described in the classic 1997 *paper* by Foo, *et al*. If you wish to invoke those potentials in a LAMMPS input script with a command like:

```
pair_style foo 0.1 3.5
```

then your `pair_foo.h` file should be structured as follows:

```
#ifdef PAIR_CLASS
// clang-format off
PairStyle(foo,PairFoo);
#else
// clang-format on
...
(class definition for PairFoo)
...
#endif
```

where "foo" is the style keyword in the pair_style command, and `PairFoo` is the class name defined in your `pair_foo.cpp` and `pair_foo.h` files.

When you re-build LAMMPS, your new pairwise potential becomes part of the executable and can be invoked with a pair_style command like the example above. Arguments like 0.1 and 3.5 can be defined and processed by your new class.

As illustrated by this example, many features referred to in the LAMMPS documentation are called a "style" of a particular command.

The *Modify page* lists all the common styles in LAMMPS, and discusses the header file for the base class that these styles derive from. Public variables in that file can be used and set by the derived classes, and may also be used by the base class. Sometimes they are also accessed by the rest of LAMMPS. Pure functions, which means functions declared as virtual in the base class header file and which are also set to 0, are functions you **must** implement in your new derived class to give it the functionality LAMMPS expects. Virtual functions that are not set to 0 are functions you may override or not. Those are usually defined with an empty function body.

Additionally, new output options can be added directly to the thermo.cpp, dump_custom.cpp, and variable.cpp files. These are also listed on the *Modify page*.

Here are additional guidelines for modifying LAMMPS and adding new functionality:

- Think about whether what you want to do would be better as a pre- or post-processing step. Many computations are more easily and more quickly done that way.
- Do not try to do anything within the timestepping of a run that is not parallel. For example, do not accumulate a bunch of data on a single processor and analyze it. That would run the risk of seriously degrading the parallel efficiency.
- If your new feature reads arguments or writes output, make sure you follow the unit conventions discussed by the *units* command.

(Foo) Foo, Morefoo, and Maxfoo, J of Classic Potentials, 75, 345 (1997).

3.2 Submitting new features for inclusion in LAMMPS

We encourage LAMMPS users to submit new features they write for LAMMPS to be included in the LAMMPS distribution and thus become easily accessible to all LAMMPS users. The LAMMPS source code is managed with git and public development is hosted on GitHub. You can monitor the repository to be notified of releases, follow the ongoing development, and comment on topics of interest to you.

This section contains general information regarding the preparation and submission of new features to LAMMPS. If you are new to development in LAMMPS, we recommend you read one of the tutorials on developing a new *pair style* or *fix style* which provide a friendly introduction to what LAMMPS development entails and common vocabulary used on this section.

3.2.1 Communication with the LAMMPS developers

For any larger modifications or programming project, you are encouraged to contact the LAMMPS developers ahead of time to discuss implementation strategies. That will make it easier to integrate your contribution and typically results in less work for everyone involved. You are also encouraged to search through the list of open issues on GitHub and submit a new issue for a planned feature, to avoid duplicating work (and possibly being scooped).

For informal communication with the LAMMPS developers, you may ask to join the LAMMPS developers on Slack. This slack work space is by invitation only. For access, please send an e-mail to `slack@lammps.org` explaining what part of LAMMPS you are working on. Only discussions related to LAMMPS development are tolerated in that work space, so this is **NOT** for people looking for help with compiling, installing, or using LAMMPS. Please post a message to the LAMMPS forum for those purposes.

3.2.2 Time and effort required

How quickly your contribution will be integrated can vary widely. It depends largely on how much effort is required by the LAMMPS developers to integrate and test it, if any and what kind of changes to the core code are required, how quickly you can address them, and how much interest the contribution is to the larger LAMMPS community. This process can be streamlined by following the *requirements* and *style guidelines*. A small, modular, well written contribution may be integrated within hours, but a complex change that requires a re-design of a core functionality in LAMMPS can take months before inclusion (though this is rare).

3.2.3 Submission procedure

All changes to LAMMPS (including those from LAMMPS developers) are integrated via pull requests on GitHub and cannot be merged without passing the automated testing and an approving review by a LAMMPS core developer. Before submitting your contribution, you should therefore first ensure that your added or modified code compiles and works correctly with the latest development version of LAMMPS and contains all bug fixes from it.

Once you have prepared everything, see the *LAMMPS GitHub Tutorial* page for instructions on how to submit your changes or new files through a GitHub pull request. If you are unable or unwilling to submit via GitHub yourself, you may also send patch files or full files to the LAMMPS developers and ask them to submit a pull request on GitHub on your behalf. If this is the case, create a gzipped tar file of all new or changed files or a corresponding patch file using 'diff -u' or 'diff -c' format and compress it with gzip. Please only use gzip compression, as this works well and is available on all platforms. This mode of submission may delay the integration as it depends more on the LAMMPS developers.

3.2.4 External contributions

If you prefer to do so, you can also develop and support your add-on feature **without** having it included in the LAMMPS distribution, for example as a download from a website of your own. See the External LAMMPS packages and tools page of the LAMMPS website for examples of groups that do this. We are happy to advertise your package and website from that page. Simply email the developers with info about your package, and we will post it there. We recommend naming external packages USER-<name> so they can be easily distinguished from packages in the LAMMPS distribution which do not have the USER- prefix.

3.2.5 Location of files: individual files and packages

We rarely accept new styles in the core src folder. Thus, please review the list of *available Packages* to see if your contribution should be added to one of them. It should fit into the general purpose of that package. If it does not fit well, it may be added to one of the EXTRA- packages or the MISC package.

However, if your project includes many related features that are not covered by one of the existing packages or is dependent on a library (bundled or external), it is best to create a new package with its own directory (with a name like FOO). In addition to your new files, the directory should contain a README text file containing your name and contact information and a brief description of what your new package does.

3.2.6 Changes to core LAMMPS files

If designed correctly, most additions do not require any changes to the core code of LAMMPS; they are simply add-on files that are compiled with the rest of LAMMPS. To make those styles work, you may need some trivial changes to the core code. An example of a trivial change is making a parent-class method "virtual" when you derive a new child class from it. If your features involve more substantive changes to the core LAMMPS files, it is particularly encouraged that you communicate with the LAMMPS developers early in development.

3.3 Requirements for contributions to LAMMPS

The following is a summary of the current requirements and recommendations for including contributed source code or documentation into the LAMMPS software distribution.

3.3.1 Motivation

The LAMMPS developers are committed to provide a software package that is versatile, reliable, high-quality, efficient, portable, and easy to maintain and modify. Achieving all of these goals is challenging since a large part of LAMMPS consists of contributed code from many different authors who may not be professionally trained programmers or familiar with the idiosyncrasies of maintaining a large software package. In addition, changes that interfere with the parallel efficiency of the core code must be avoided. As LAMMPS continues to grow and more features and functionality are added, it is necessary to follow established guidelines when accepting new contributions while also working at the same time to improve the existing code.

The following requirements and recommendations are provided as a guide. They indicate which individual requirements are strict, and which represent a preference and thus are negotiable or optional. Please feel free to contact the LAMMPS core developers in case you need additional explanations or clarifications, or you need assistance in implementing the (strict) requirements for your contributions. Requirements include:

- *Licensing requirements* (strict)
- *Integration testing* (strict)
- *Documentation* (strict)
- *Programming language standards* (strict)
- *Build system* (strict)
- *Command or style names* (strict)
- *Programming style requirements* (varied)
- *Examples* (preferred)
- *Error or warning messages and explanations* (preferred)
- *Citation reminder* (optional)
- *Testing* (optional)

3.3.2 Licensing requirements (strict)

Contributing authors agree when submitting a pull request that their contributions can be distributed under the LAMMPS license conditions. This is the GNU public license in version 2 (not 3 or later) for the publicly distributed versions, e.g. on the LAMMPS homepage or on GitHub. We also have a version of LAMMPS under LGPL 2.1 terms which is available on request; this will usually be the latest available or a previous stable version with a few LGPL 2.1 incompatible files removed. More details are found on the *LAMMPS open-source license page*.

Your new source files should have the LAMMPS copyright and GPL notice, followed by your name and email address at the top, like other user-contributed LAMMPS source files.

Contributions may be under a different license as long as that license does not conflict with the aforementioned terms. Contributions that use code with a conflicting license can be split into two parts:

1. the core parts (i.e. parts that must be in the *src* tree) that are licensed under compatible terms and bundled with the LAMMPS sources
2. an external library that must be downloaded and compiled (either separately or as part of the LAMMPS compilation)

Please note, that this split licensing mode may complicate including the contribution in binary packages.

3.3.3 Integration testing (strict)

Where possible we use available continuous integration tools to search for common programming mistakes, portability limitations, incompatible formatting, and undesired side effects. Contributed code must pass the automated tests on GitHub before it can be merged with the LAMMPS distribution. These tests compile LAMMPS in a variety of environments and settings and run the bundled unit tests. At the discretion of the LAMMPS developer managing the pull request, additional tests may be activated that test for "side effects" on running a collection of input decks and create consistent results. The translation of the documentation to HTML and PDF is also tested.

This means that contributed source code **must** compile with the most current version of LAMMPS with `-DLAMMPS_BIGBIG` in addition to the default setting of `-DLAMMPS_SMALLBIG`. The code needs to work correctly in both cases, and also in serial and parallel using MPI.

Some "disruptive" changes may break tests and require updates to the testing tools or scripts or tests themselves. This is rare. If in doubt, contact the LAMMPS developer that is assigned to the pull request.

3.3.4 Documentation (strict)

Contributions that add new styles or commands or augment existing ones must include the corresponding new or modified documentation in ReStructuredText format (.rst files in the `doc/src/` folder). The documentation should be written in American English and the .rst file must only use ASCII characters, so it can be cleanly translated to PDF files (via sphinx and PDFLaTeX). Special characters may be included via embedded math expression typeset in a LaTeX subset.

When adding new commands, they need to be integrated into the sphinx documentation system, and the corresponding command tables and lists updated. When translating the documentation into html files there should be no warnings. When adding a new package, some lists describing packages must also be updated as well as a package specific description added. Likewise, if necessary, some package specific build instructions should be included.

A detailed, step-by-step guide for what a documentation page must contain, how to register a new style in the command tables and overview lists, how to document accelerated variants, and which consistency checks to run is given on the *Writing or updating documentation* page.

As appropriate, the text files with the documentation can include inline mathematical expressions or figures (see `doc/JPG` for examples). Additional PDF files with further details may also be included; see `doc/PDF` for examples. The page should also include literature citations as appropriate; see the bottom of `doc/fix_nh.rst` for examples and the earlier part of the same file for how to format the cite itself. Citation labels must be unique across **all** .rst files. The "Restrictions" section of the page should indicate if your command is only available if LAMMPS is built with the appropriate package. See other command doc files for examples of how to do this.

Please run at least "make html" and "make spelling" from within the doc/src directory, and carefully inspect and proofread the resulting HTML format doc page before submitting your code. Upon submission of a pull request, checks for error free completion of the HTML and PDF build will be performed and also a spell check, a check for correct anchors and labels, and a check for completeness of references to all styles in their corresponding tables and lists is run. In case the spell check reports false positives, they can be added to the file `doc/utils/sphinx-config/false_positives.txt`

Contributions that add or modify the library interface or "public" APIs from the C++ code or the Fortran module must include suitable doxygen comments in the source and corresponding changes to the documentation sources for the "Programmer Guide" guide section of the LAMMPS manual.

If your feature requires some more complex steps and explanations to be used correctly or some external or bundled tools or scripts, we recommend that you also contribute a *Howto document* providing some more background information and some tutorial material. This can also be used to provide more in-depth explanations of models that require use of multiple commands.

As a rule-of-thumb, the more clear and self-explanatory you make your documentation, README files and examples, and the easier you make it for people to get started, the more likely it is that users will try out your new feature.

Programming language standards (strict)

The core of LAMMPS is written in C++17 in a style that can be mostly described as "C with classes". Advanced C++ features like operator overloading or excessive use of templates are avoided with the intent to keep the code readable to programmers that have limited C++ programming experience. C++ constructs are acceptable when they help improve the readability and reliability of the code, e.g. when using the *std::string* class instead of manipulating pointers and calling the string functions of the C library or when using *auto* to avoid redundant data type specifications. In addition, a collection of convenient *utility functions and classes* for recurring tasks and a collection of *platform neutral functions* for improved portability are provided. Containers from C++ standard library have to be used with caution, but *std::vector* can be useful and is compatible with efficient communication via MPI. Contributions with code requiring more recent C++ standards are only accepted as packages with the post C++17 standard code confined to the package so that it is optional.

Included Fortran code has to be compatible with the Fortran 2003 standard. Since not all platforms supported by LAMMPS provide good support for compiling Fortran files, it should be considered to rewrite these parts as C++ code, if possible, and thus allow for a wider adoption of the contribution. As of January 2023, all previously included Fortran code for the LAMMPS executable has been replaced by equivalent C++ code.

Python code currently must be compatible with Python 3.6. If a later version or Python is required, it needs to be documented.

Compatibility with older programming language standards is very important to maintain portability and availability of LAMMPS on many platforms. This applies especially to HPC cluster environments, which tend to be running older software stacks and where LAMMPS users may be required to use those older tools for access to advanced hardware features or not have the option to install newer compilers or libraries.

3.3.5 Build system (strict)

LAMMPS currently supports two build systems: one that is based on *traditional Makefiles* and one that is based on *CMake*. As of fall 2025, it is no longer required to support the traditional *traditional GNU make build system*. New packages may choose to only support *building with CMake*. Additions to existing packages must follow the requirements set by that package.

For a single pair of header and implementation files that are an independent feature, it is usually only required to add them to `src/.gitignore`.

For traditional make, if your contributed files or package depend on other LAMMPS style files or packages also being installed (e.g. because your file is a derived class from the other LAMMPS class), then an `Install.sh` file is also needed to check for those dependencies and modifications to `src/Depend.sh` to trigger the checks. See other README and Install.sh files in other directories as examples.

Similarly, for CMake support, changes may need to be made to `cmake/CMakeLists.txt`, some of the files in `cmake/presets`, and possibly a file with specific instructions needs to be added to `cmake/Modules/Packages/`. Please check out how this is handled for existing packages and ask the LAMMPS developers if you need assistance.

3.3.6 Command or style names, file names, and keywords (strict)

All user-visible command or style names should be all lower case and should only use letters, numbers, or forward slashes. They should be descriptive and initialisms should be avoided unless they are well established (e.g. lj for Lennard-Jones). For a compute style "some/name" the source files must be called `compute_some_name.h` and `compute_some_name.cpp`. The "include guard" in the header file would then be `LMP_COMPUTE_SOME_NAME_H` and the class name `ComputeSomeName`.

3.3.7 Programming style requirements (varied)

To maintain source code consistency across contributions from many people, there are various programming style requirements for contributions to LAMMPS. Some of these requirements are strict and must be followed, while others are only preferred and thus may be skipped. An in-depth discussion of the style guidelines is provided in the *programming style doc page*.

3.3.8 Examples (preferred)

For many new features, it is preferred that example scripts (simple, small, fast to complete on 1 CPU) are included that demonstrate the use of new or extended functionality. These are typically include under the examples or examples/PACKAGES directory and are further described on the *examples page*. Guidelines for input scripts include:

- commands that generate output should be commented out (except when the output is the sole purpose or the feature, e.g. for a new compute)
- commands like *log*, *echo*, *package*, *processors*, *suffix* may **not** be used in the input file (exception: "processors * * 1" or similar is acceptable when used to avoid unwanted domain decomposition of empty volumes)
- outside of the log files, no generated output should be included
- custom thermo_style settings may not include output measuring CPU or other time as it complicates comparisons between different runs
- input files should be named `in.name`, data files should be named `data.name` and log files should be named `log.version.name.<compiler>.<ncpu>`
- the total file size of all the inputs and outputs should be small
- where possible, potential files from the "potentials" folder or data file from other folders should be reused through symbolic links

3.3.9 Error or warning messages and explanations (preferred)

Changed in version 4May2022.

Starting with LAMMPS version 4 May 2022, the LAMMPS developers have agreed on a new policy for error and warning messages.

Previously, all error and warning strings were supposed to be listed in the class header files with an explanation. Those would then be regularly "harvested" and transferred to alphabetically sorted lists in the manual. To avoid excessively long lists and to reduce effort, this came with a requirement to have rather generic error messages (e.g. "Illegal ... command"). To identify the specific cause, the name of the source file and the line number of the error location would be printed, so that one could look up the cause by reading the source code.

The new policy encourages more specific error messages that ideally indicate the cause directly, and requiring no further lookup. This is aided by either the {fmt} library or the C++ format library (for C++20 and later) enabling `LAMMPS_NS::Error` class methods that take a variable number of arguments and an error text that will be treated like a C++ format string. Error messages should still preferably be kept to a single line or two lines at most.

For more complex explanations or errors that have multiple possible reasons, a paragraph should be added to the *Error_details* page with an error code reference (e.g. `.. _err0001:`) then the utility function *utils::errorurl()*

can be used to generate a URL that will directly lead to that paragraph. An error for missing arguments can be easily generated using the *utils::missing_cmd_args()* convenience function. An example for this approach would be the `src/read_data.cpp` and `src/atom.cpp` files that implement the *read_data* and *atom_modify* commands and that may create *"Unknown identifier in data file"* errors that may have multiple possible reasons which complicates debugging, and thus require some additional explanation.

The transformation of existing LAMMPS code to this new scheme is ongoing. Given the size of the LAMMPS code base, it will take a significant amount of time to complete. For new code, however, following the new approach is strongly preferred. The expectation is that the new scheme will make understanding errors easier for LAMMPS users, developers, and maintainers.

3.3.10 Citation reminder (optional)

If there is a paper of yours describing your feature (either the algorithm/science behind the feature itself, or its initial usage, or its implementation in LAMMPS), you can add the citation to the `.cpp` source file. A description of how to add the reminder is *available elsewhere in this manual*.

If there is additional functionality (which may have been added later) described in a different publication, additional citation descriptions may be added so long as they are only registered when the corresponding keyword activating this functionality is used.

With these options, it is possible to have LAMMPS output a specific citation reminder whenever a user invokes your feature from their input script. Please note that you should *only* use this for the *most* relevant paper for a feature and a publication that you or your group authored. E.g. adding a citation in the source code for a paper by Nose and Hoover if you write a fix that implements their integrator is not the intended usage. That kind of citation should just be included in the documentation page you provide describing your contribution. If you are not sure what the best option would be, please contact the LAMMPS developers for advice.

3.3.11 Testing (optional)

If your contribution contains new utility functions or a supporting class (i.e. anything that does not depend on a LAMMPS object), new unit tests should be added to a suitable folder in the `unittest` tree. When adding a new LAMMPS style computing forces or selected fixes, a `.yaml` file with a test configuration and reference data should be added for the styles where a suitable tester program already exists (e.g. pair styles, bond styles, etc.). Please see *this section in the manual* for more information on how to enable, run, and expand testing.

3.4 LAMMPS programming style

The aim of the LAMMPS developers is to use a consistent programming style and naming conventions across the entire code base, as this helps with maintenance, debugging, and understanding the code, both for developers and users. This page provides a list of standard style choices used in LAMMPS. Some of these standards are required, while others are just preferred. Following these conventions will make it much easier to integrate your contribution. If you are uncertain, please ask.

The files *pair_lj_cut.h*, *pair_lj_cut.cpp*, *utils.h*, and *utils.cpp* may serve as representative examples.

3.4.1 Include files (varied)

- Header files that define a new LAMMPS style (i.e. that have a `SomeStyle(some/name,SomeName);` macro in them) should only use the include file for the base class and otherwise use forward declarations and pointers; when interfacing to a library use the PIMPL (pointer to implementation) approach where you have a pointer to a struct that contains all library specific data (and thus requires the library header) but use a forward declaration and define the struct only in the implementation file. This is a **strict** requirement since this is where type clashes between packages and hard-to-find bugs have regularly manifested in the past.

- Header files, especially those defining a "style", should only use the absolute minimum number of include files and **must not** contain any `using` statements. Typically, that would only be the header for the base class. Instead, any include statements should be put in the corresponding implementation files and forward declarations be used. For implementation files, the "include what you use" principle should be employed. However, there is the notable exception that when the `pointers.h` header is included (or the header of one of the classes derived from it), certain headers will *always* be included and thus do not need to be explicitly specified. These are: *mpi.h*, *cstddef*, *cstdio*, *cstdlib*, *string*, *utils.h*, *vector*, *fmt/format.h* (or *format* when using C++20 and later), *climits*, *cinttypes*. This also means any such file can assume that *FILE*, *NULL*, and *INT_MAX* are defined.
- Class members variables should not be initialized in the header file, but instead should be initialized either in the initializer list of the constructor or explicitly assigned in the body of the constructor. If the member variable is relevant to the functionality of a class (for example when it stores a value from a command-line argument), the member variable declaration is followed by a brief comment explaining its purpose and what its values can be. Class members that are pointers should always be initialized to `nullptr` in the initializer list of the constructor. This reduces clutter in the header and avoids accessing uninitialized pointers, which leads to hard to debug issues, class members are often implicitly initialized to `NULL` on the first use (but *not* after a *clear command*). Please see the files `reset_atoms_mol.h` and `reset_atoms_mol.cpp` as an example.
- System headers or headers from installed libraries are included with angular brackets (example: `#include <vector>`), while local include files use double quotes (example: `#include "atom.h"`)
- When including system header files from the C library use the C++-style names (`<cstdlib>` or `<cstring>`) instead of the C-style names (`<stdlib.h>` or `<string.h>`)
- The order of `#include` statements in a file `some_name.cpp` that implements a class `SomeName` defined in a header file `some_name.h` should be as follows:
  - `#include "some_name.h"` followed by an empty line
  - LAMMPS include files e.g. `#include "comm.h"` or `#include "modify.h"` in alphabetical order followed by an empty line
  - System header files from the C++ or C standard library followed by an empty line
  - `using namespace LAMMPS_NS` or other namespace imports.

3.4.2 Whitespace (preferred)

Source files should not contain TAB characters unless required by the syntax (e.g. in makefiles) and no trailing whitespace. Text files should have Unix-style line endings (LF-only). Git will automatically convert those in both directions when running on Windows; use dos2unix on Linux machines to convert files to Unix-style line endings. The last line of text files include a line ending.

You can check for these issues with the python scripts in the *"tools/coding_standard"* folder. When run normally with a source file or a source folder as argument, they will list all non-conforming lines. By adding the *-f* flag to the command line, they will modify the flagged files to try to remove the detected issues.

3.4.3 Constants (strongly preferred)

Global or per-file constants should be declared as *static constexpr* variables rather than via the pre-processor with *#define*. The name of constants should be all uppercase. This has multiple advantages:

- constants are easily identified as such by their all upper case name
- rather than a pure text substitution during pre-processing, *constexpr variables* have a type associated with them and are processed later in the parsing process where the syntax checks and type specific processing (e.g. via overloads) can be applied to them.
- compilers can emit a warning if the constant is not used and thus can be removed (we regularly check for and remove dead code like this)

- there are no unexpected substitutions and thus confusing syntax errors when compiling leading to, for instance, conflicts so that LAMMPS cannot be compiled with certain combinations of packages (this *has* happened multiple times in the past).

Pre-processor defines should be limited to macros (but consider C++ templates) and conditional compilation. If a pre-processor define must be used, it should be defined at the top of the .cpp file after the include statements and at all cost it should be avoided to put them into header files.

Some sets of commonly used constants are provided in the `MathConst` and `EwaldConst` namespaces and implemented in the files `math_const.h` and `ewald_const.h`, respectively.

There are always exceptions, special cases, and legacy code in LAMMPS, so please contact the LAMMPS developers if you are not sure.

3.4.4 Placement of braces (strongly preferred)

For new files added to the "src" tree, a clang-format configuration file is provided under the name *.clang-format*. This file is compatible with clang-format version 8 and later. With that file present, files can be reformatted according to the configuration with a command like: *clang-format -i new-file.cpp*. Ideally, this is done while writing the code or before a pull request is submitted. Blocks of code where the reformatting from clang-format yields hard-to-read or otherwise undesirable output may be protected with placing a pair *// clang-format off* and *// clang-format on* comments around that block.

3.4.5 Miscellaneous standards (varied)

- I/O is done via the C-style stdio library and **not** iostreams.
- Do not use so-called "alternative tokens" like `and`, `or`, `not` and similar, but rather use the corresponding operators `&&`, `||`, and `!`. The alternative tokens are not available by default on all compilers.
- Output to the screen and the logfile should use the corresponding FILE pointers and only be done on MPI rank 0. Use the *`utils::logmesg()`* convenience function where possible.
- Usage of C++ *virtual*, *override*, *final* keywords: Please follow the C++ Core Guideline C.128. That means, you should only use *virtual* to declare a new virtual function, *override* to indicate you are overriding an existing virtual function, and *final* to prevent any further overriding.
- Trivial destructors: Do not write destructors when they are empty and *default*.

```
// don't write destructors for A or B like this

class A : protected Pointers {
 public:
   A();
   ~A() override {}
};

class B : protected Pointers {
 public:
   B();
   ~B() override = default;
};

// instead, let the compiler create the implicit default destructor by not writing␣
↪it

class A : protected Pointers {
```

(continues on next page)

(continued from previous page)

```
 public:
   A();
};

class B : protected Pointers {
 public:
   B();
};
```

- Please use clang-format only to reformat files that you have contributed. For header files containing a `SomeStyle(keyword, ClassName)` macros it is required to have this macro embedded with a pair of `// clang-format off`, `// clang-format on` comments and the line must be terminated with a semicolon (;). Example:

```
#ifdef COMMAND_CLASS
// clang-format off
CommandStyle(run,Run);
// clang-format on
#else

#ifndef LMP_RUN_H
[...]
```

  You may also use `// clang-format on/off` throughout your files to protect individual sections from being reformatted.

- All files should have 0644 permissions, i.e. writable by the user only and readable by all and no executable permissions. Executable permissions (0755) should only be for shell scripts or python or similar scripts for interpreted script languages.

3.5 Atom styles

Classes that define an *atom style* are derived from the AtomVec class and managed by the Atom class. The atom style determines what attributes are associated with an atom and communicated when it is a ghost atom or migrates to a new processor. A new atom style can be created if one of the existing atom styles does not define all the attributes you need to store and communicate with atoms.

The file `atom_vec_atomic.cpp` is the simplest example of an atom style. Examining the code for others will make these instructions more clear.

Note that the *atom style hybrid* command can be used to define atoms or particles which have the union of properties of individual styles. Also the *fix property/atom* command can be used to add a single property (e.g. charge or a molecule ID) to a style that does not have it. It can also be used to add custom properties to an atom, with options to communicate them with ghost atoms or read them from a data file. Other LAMMPS commands can access these custom properties, as can new pair, fix, compute styles that are written to work with these properties. For example, the *set* command can be used to set the values of custom per-atom properties from an input script. All of these methods are less work than writing and testing(!) code for a new atom style.

If you follow these directions your new style will automatically work in tandem with others via the *atom_style hybrid* command.

The first step is to define a set of string lists in the constructor of the new derived class. Each list will have zero or more comma-separated strings that correspond to the variable names used in the `atom.h` header file for per-atom properties. Note that some represent per-atom vectors (q, molecule) while other are per-atom arrays (x,v). For all but the last two lists you do not need to specify any of (id,type,x,v,f). Those are included automatically as needed in the other lists.

fields_grow	full list of properties which is allocated and stored
fields_copy	list of properties to copy atoms are rearranged on-processor
fields_comm	list of properties communicated to ghost atoms every step
fields_comm_vel	additional properties communicated if *comm_modify vel* is used
fields_reverse	list of properties summed from ghost atoms every step
fields_border	list of properties communicated with ghost atoms every reneighboring step
fields_border_vel	additional properties communicated if *comm_modify vel* is used
fields_exchange	list of properties communicated when an atom migrates to another processor
fields_restart	list of properties written/read to/from a restart file
fields_create	list of properties defined when an atom is created by *create_atoms*
fields_data_atom	list of properties (in order) in the Atoms section of a data file, as read by *read_data*
fields_data_vel	list of properties (in order) in the Velocities section of a data file, as read by *read_data*

In these lists you can list variable names which LAMMPS already defines (in some other atom style), or you can create new variable names. You should not reuse a LAMMPS variable in your atom style that is used for something with a different meaning in another atom style. If the meaning is related, but interpreted differently by your atom style, then using the same variable name means a user must not use your style and the other style together in a *atom_style hybrid* command. Because there will only be one value of the variable and different parts of LAMMPS will then likely use it differently. LAMMPS has no way of checking for this.

If you are defining new variable names then make them descriptive and unique to your new atom style. For example choosing "e" for energy is a bad choice; it is too generic. A better choice would be "e_foo", where "foo" is specific to your style.

If any of the variable names in your new atom style do not exist in LAMMPS, you need to add them to the src/atom.h and atom.cpp files.

Search for the word "customize" or "customization" in these 2 files to see where to add your variable. Adding a flag to the 2nd customization section in `atom.h` is only necessary if your code (e.g. a pair style) needs to check that a per-atom property is defined. These flags should also be set in the constructor of the atom style child class.

In `atom.cpp`, aside from the constructor and destructor, there are 3 methods that a new variable name or flag needs to be added to.

In `Atom::peratom_create()` when using the `Atom::add_peratom()` method, a cols argument of 0 is for per-atom vectors, a length > 1 is for per-atom arrays. Note the use of the extra per-thread flag and the add_peratom_vary() method when the last dimension of the array is variable-length.

Adding the variable name to Atom::extract() enables the per-atom data to be accessed through the *LAMMPS library interface* by a calling code, including from *Python*.

The constructor of the new atom style will also typically set a few flags which are defined at the top of `atom_vec.h`. If these are unclear, see how other atom styles use them.

The grow_pointers() method is also required to make a copy of peratom data pointers, as explained in the code.

There are a number of other optional methods which your atom style can implement. These are only needed if you need to do something out-of-the-ordinary which the default operation of the AtomVec parent class does not take care of. The best way to figure out why they are sometimes useful is to look at how other atom styles use them.

- process_args = use if the atom style has arguments
- init = called before each run
- force_clear = called before force computations each timestep

A few atom styles define "bonus" data associated with some or all of their particles, such as *atom_style ellipsoid or tri*. These methods work with that data:

- copy_bonus
- clear_bonus
- pack_comm_bonus
- unpack_comm_bonus
- pack_border_bonus
- unpack_border_bonus
- pack_exchange_bonus
- unpack_exchange_bonus
- size_restart_bonus
- pack_restart_bonus
- unpack_restart_bonus
- data_atom_bonus
- memory_usage_bonus

The *atom_style body* command can define a particle geometry with an arbitrary number of values. This method reads it from a data file:

- data_body

These methods are called before or after operations handled by the parent AtomVec class. They allow an atom style to do customized operations on the per-atom values. For example *atom_style sphere* reads a diameter and density of each particle from a data file. But these need to be converted internally to a radius and mass. That operation is done in the data_atom_post() method.

- pack_restart_pre
- pack_restart_post
- unpack_restart_init
- create_atom_post
- data_atom_post
- pack_data_pre
- pack_data_post

These methods enable the *compute property/atom* command to access per-atom variables it does not already define as arguments, so that they can be written to a dump file or used by other LAMMPS commands.

- property_atom
- pack_property_atom

3.6 Pair styles

Classes that compute pairwise non-bonded interactions are derived from the `Pair` class. In LAMMPS, pairwise force calculations include many-body potentials such as EAM, Tersoff, or ReaxFF where particles interact without an explicit bond topology but include interactions beyond pairwise non-bonded contributions. New styles can be created to add support for additional pair potentials to LAMMPS. When the modifications are small, sometimes it is more effective to derive from an existing pair style class. This latter approach is also used by *Accelerator packages* where the accelerated style names differ from their base classes by an appended suffix.

The file `src/pair_lj_cut.cpp` is an example of a Pair class with a very simple potential function. It includes several optional methods to enable its use with *run_style respa* and *compute group/group*. *Writing new pair styles* contains a detailed discussion of writing new pair styles from scratch, and how simple and more complex pair styles can be implemented with examples from existing pair styles.

Here is a brief list of some the class methods in the Pair class that *must* be or *may* be overridden in a derived class for a new pair style.

Required	"pure" methods that *must* be overridden in a derived class
compute	workhorse routine that computes pairwise interactions
settings	processes the arguments to the pair_style command
coeff	set coefficients for one i,j type pair, called from pair_coeff

Optional	methods that have a default or dummy implementation
init_one	perform initialization for one i,j type pair
init_style	style initialization: request neighbor list(s), error checks
init_list	Neighbor class callback function to pass neighbor list to pair style
single	force/r and energy of a single pairwise interaction between two atoms
compute_inner/middle/outer	versions of compute used by rRESPA
compute_atomic_energy	energy of one atom, equivalent to per-atom energy
memory_usage	return estimated amount of memory used by the pair style
modify_params	process arguments to pair_modify command
extract	provide access to internal scalar or per-type data like cutoffs
extract_peratom	provide access to internal per-atom data
setup	initialization at the beginning of a run
finish	called at the end of a run, e.g. to print
write & read_restart	write/read i,j pair coeffs to restart files
write & read_restart_settings	write/read global settings to restart files
write_data	write Pair Coeffs section to data file
write_data_all	write PairIJ Coeffs section to data file
pack & unpack_forward_comm	copy data to and from buffer if style uses forward communication
pack & unpack_reverse_comm	copy data to and from buffer if style uses reverse communication
reinit	reset all type-based parameters, called by fix adapt for example
reset_dt	called when the time step is changed by timestep or fix reset/dt
born_matrix	compute Born matrix elements for elasticity (optional)
single_hessian	compute the per-pair Hessian (optional)

Here is a list of flags or settings that should be set in the constructor of the derived pair class when they differ from the default setting.

Name of flag	Description	default
single_enable	1 if single() method is implemented, 0 if missing	1
respa_enable	1 if pair style has compute_inner/middle/outer()	0
restartinfo	1 if pair style writes its settings to a restart	1
one_coeff	1 if only a pair_coeff * * command is allowed	0
manybody_flag	1 if pair style is a manybody potential	0
unit_convert_flag	value != 0 indicates support for unit conversion	0
no_virial_fdotr_compute	1 if pair style does not call virial_fdotr_compute()	0
writedata	1 if write_data() and write_data_all() are implemented	0
comm_forward	size of buffer (in doubles) for forward communication	0
comm_reverse	size of buffer (in doubles) for reverse communication	0
ghostneigh	1 if cutghost is set and style uses neighbors of ghosts	0
finitecutflag	1 if cutoff depends on diameter of atoms	0
reinitflag	1 if style has reinit() and is compatible with fix adapt	0
ewaldflag	1 if compatible with kspace_style ewald	0
pppmflag	1 if compatible with kspace_style pppm	0
msmflag	1 if compatible with kspace_style msm	0
dispersionflag	1 if compatible with ewald/disp or pppm/disp	0
tip4pflag	1 if compatible with kspace_style pppm/tip4p	0
dipoleflag	1 if compatible with dipole kspace_style	0
spinflag	1 if compatible with spin kspace_style	0
atomic_energy_enable	1 if compute_atomic_energy() routine exists	0
born_matrix_enable	1 if born_matrix() routine exists	0
single_hessian_enable	1 if single_hessian() routine exists	0
centroidstressflag	CENTROID_SAME/CENTROID_AVAIL/CENTROID_NOTAVAIL	SAME

3.7 Bond, angle, dihedral, improper styles

Classes that compute molecular interactions are derived from the Bond, Angle, Dihedral, and Improper classes. New styles can be created to add new potentials to LAMMPS.

Writing new bond, angle, dihedral, and improper styles contains a detailed discussion of writing new bond, angle, dihedral, and improper styles from scratch with examples from the existing harmonic styles.

Bond_harmonic.cpp is the simplest example of a bond style. Ditto for the harmonic forms of the angle, dihedral, and improper style commands.

Here is a brief description of common methods you define in your new derived class. See bond.h, angle.h, dihedral.h, and improper.h for details and specific additional methods.

Required	"pure" methods that *must* be overridden in a derived class
compute	compute the molecular interactions for all listed items
coeff	set coefficients for one type
equilibrium_distance	length of bond, used by SHAKE (bond styles only)
equilibrium_angle	opening of angle, used by SHAKE (angle styles only)
write & read_restart	writes/reads coeffs to restart files
single	force/r (bond styles only) and energy of a single bond or angle

Optional	methods that have a default or dummy implementation
init	check if all coefficients are set, calls init_style()
init_style	check if style specific conditions are met
settings	apply global settings for all types
write & read_restart_settings	writes/reads global style settings to restart files
write_data	write corresponding Coeffs section(s) in data file
memory_usage	tally memory allocated by the style
extract	provide access to internal data
born_matrix	compute Born matrix elements for elasticity
reinit	reset all type-based parameters, called by fix adapt (bonds only)
pack & unpack_forward_comm	copy data to and from buffer in forward communication (bonds only)
pack & unpack_reverse_comm	copy data to and from buffer in reverse communication (bonds only)

Here is a list of flags or settings that should be set in the constructor of the derived class when they differ from the default setting.

Name of flag	Description	default
writedata	1 if write_data() is implemented	1
single_extra	number of extra single values calculated (bond styles only)	0
partial_flag	1 if bond type can be set to 0 and deleted (bond styles only)	0
reinitflag	1 if style has reinit() and is compatible with fix adapt	1
comm_forward	size of buffer (in doubles) for forward communication (bond styles only)	0
comm_reverse	size of buffer (in doubles) for reverse communication (bond styles only)	0
comm_reverse_off	size of buffer for reverse communication with newton off (bond styles only)	0
born_matrix_enable	1 if born_matrix() is implemented	0
centroidstressflag	CENTROID_AVAIL if centroid stress is different and implemented	varies

The default value of `centroidstressflag` is `CENTROID_SAME` for bond styles and `CENTROID_AVAIL` for angle, dihedral, and improper styles. It should be set to `CENTROID_NOTAVAIL` when the centroid stress differs from the two-body virial but has not yet been implemented.

3.8 Compute styles

Classes that compute scalar and vector quantities like temperature and the pressure tensor, as well as classes that compute per-atom quantities like kinetic energy and the centro-symmetry parameter are derived from the Compute class. New styles can be created to add new calculations to LAMMPS.

Writing new compute styles contains a detailed discussion of writing new compute styles from scratch with examples from existing styles.

The `src/compute_temp.cpp` file is a simple example of computing a scalar temperature. The `src/compute_ke_atom.cpp` file is a simple example of computing per-atom kinetic energy.

Here is a brief description of methods you define in your new derived class. See `src/compute.h` for additional details.

post_constructor	perform tasks that cannot be run in the constructor (optional)
init	perform one time setup (required)
init_list	neighbor list setup, if needed (optional)
setup	called before the first timestep of a run (optional)

continues on next page

Table 1 – continued from previous page

compute_scalar	compute a scalar quantity (optional)
compute_vector	compute a vector of quantities (optional)
compute_array	compute a 2d array of quantities (optional)
compute_peratom	compute one or more quantities per atom (optional)
compute_local	compute one or more quantities per processor (optional)
compute_pergrid	compute one or more quantities per grid cell (optional)
compute_image	compute image data for dump image (optional)
set_arrays	initialize per-atom arrays when a new atom is created (optional)
pack_forward_comm	pack a buffer with items to communicate (optional)
unpack_forward_comm	unpack the buffer (optional)
pack_reverse_comm	pack a buffer with items to reverse communicate (optional)
unpack_reverse_comm	unpack the buffer (optional)
dof_remove_pre	pre-check before removing atoms from temperature DOF (optional)
dof_remove	return 1 to exclude an atom from temperature DOF count (optional)
remove_bias	remove velocity bias from one atom (optional)
remove_bias_all	remove velocity bias from all atoms in group (optional)
reapply_bias_all	reapply velocity bias to all atoms in group (optional)
restore_bias	restore velocity bias for one atom after remove_bias (optional)
restore_bias_all	same as before, but for all atoms in group (optional)
lock_enable	enable locking mechanism for fix ave/time (optional)
lock_disable	disable locking mechanism (optional)
refresh	refresh internal state (e.g. for dump_modify refresh) (optional)
pair_setup_callback	callback invoked during pair-style setup (optional)
pair_tally_callback	callback function for *tally*-style computes (optional).
get_thermo_colname	return custom column label for thermo output (optional)
modify_param	called when a compute_modify request is executed (optional)
memory_usage	tally memory usage (optional)

Tally-style computes are a special case, as their computation is done in two stages: the callback function is registered with the pair style and then called from the Pair::ev_tally() function, which is called for each pair after force and energy has been computed for this pair. Then the tallied values are retrieved with the standard compute_scalar or compute_vector or compute_peratom methods. The *compute styles in the TALLY package* provide *examples* for utilizing this mechanism.

3.9 Fix styles

In LAMMPS, a "fix" is any operation that is computed during timestepping that alters some property of the system. Essentially everything that happens during a simulation besides force computation, neighbor list construction, and output, is a "fix". This includes time integration (update of coordinates and velocities), force constraints or boundary conditions (SHAKE or walls), and diagnostics (compute a diffusion coefficient). New styles can be created to add new options to LAMMPS.

The file `src/fix_setforce.cpp` is a simple example of setting forces on atoms to prescribed values. There are dozens of fix options already in LAMMPS; choose one as a template that is similar to what you want to implement. There also is a detailed discussion of *how to write new fix styles* in LAMMPS.

Here is a brief description of methods you can define in your new derived class. See `src/fix.h` for additional details.

Required	"pure" method that *must* be overridden in a derived class
setmask	determines when the fix is called during the timestep

Optional	methods that have a default or empty implementation
post_constructor	perform tasks that cannot be run in the constructor
init	initialization before a run
init_list	store pointer to neighbor list; called by neighbor list code
setup_pre_exchange	called before atom exchange in setup
setup_pre_neighbor	called before neighbor list build in setup
setup_post_neighbor	called after neighbor list build in setup
setup_pre_force	called before force computation in setup
setup_pre_reverse	called before reverse communication in setup
setup	called immediately before the first timestep and after forces are computed
min_setup	like setup, but for minimizations instead of MD runs
initial_integrate	called at very beginning of each timestep
post_integrate	called after the first half-step position/velocity update
pre_exchange	called before atom exchange on re-neighboring steps
pre_neighbor	called before neighbor list build
post_neighbor	called after neighbor list build
pre_force	called before pair & molecular forces are computed
pre_reverse	called before reverse communication of forces
post_force	called after pair & molecular forces are computed and communicated
final_integrate	called at end of each timestep
end_of_step	called at very end of timestep
post_run	called at the end of each run command
write_restart	dumps fix info to restart file
restart	uses info from restart file to re-initialize the fix
grow_arrays	allocate memory for atom-based arrays used by fix
copy_arrays	copy atom info when an atom migrates to a new processor
set_arrays	set per-atom values when a new atom is created
pack_exchange	store atom's data in a buffer
unpack_exchange	retrieve atom's data from a buffer
pack_restart	store atom's data for writing to restart file
unpack_restart	retrieve atom's data from a restart file buffer
size_restart	size of atom's data
maxsize_restart	max size of atom's data
setup_pre_force_respa	same as setup_pre_force, but for rRESPA
initial_integrate_respa	same as initial_integrate, but for rRESPA
post_integrate_respa	called after the first half integration step is done in rRESPA
pre_force_respa	same as pre_force, but for rRESPA
post_force_respa	same as post_force, but for rRESPA
final_integrate_respa	same as final_integrate, but for rRESPA
min_pre_exchange	called before atom exchange during minimization

continues on next page

Table 2 – continued from previous page

Optional	methods that have a default or empty implementation
min_pre_neighbor	called before neighbor list build during minimization
min_post_neighbor	called after neighbor list build during minimization
min_pre_force	called before pair & molecular forces are computed in minimizer
min_pre_reverse	called before reverse communication during minimization
min_post_force	called after pair & molecular forces are computed and communicated in minimizer
min_energy	return an extra energy contribution during minimization
min_store	store extra data for linesearch based minimization on a LIFO stack
min_pushstore	push the minimization LIFO stack one element down
min_popstore	pop the minimization LIFO stack one element up
min_clearstore	clear minimization LIFO stack
min_reset_ref	reset the reference state for the line search
min_step	reset or move forward on line search minimization
min_dof	report number of degrees of freedom *added* by this fix in minimization
max_alpha	report maximum allowed step size during linesearch minimization
pack_forward_comm	pack a buffer to communicate a per-atom quantity
unpack_forward_comm	unpack a buffer to communicate a per-atom quantity
pack_reverse_comm_size	return the dynamic size of the reverse communication buffer
pack_reverse_comm	pack a buffer to reverse communicate a per-atom quantity
unpack_reverse_comm	unpack a buffer to reverse communicate a per-atom quantity
dof	report number of degrees of freedom *removed* by this fix during MD
compute_scalar	return a global scalar property that the fix computes
compute_vector	return a component of a vector property that the fix computes
compute_array	return a component of an array property that the fix computes
get_thermo_colname	return custom thermo column label for a vector or array component
deform	called when the box size is changed
reset_target	called when a change of the target temperature is requested during a run
reset_dt	called when a change of the time step is requested during a run
modify_param	called when a fix_modify request is executed
memory_usage	report memory used by fix
image	pass lists of graphics objects to *dump image fix*

Typically, only a small fraction of these methods are defined for a particular fix. The `setmask()` method is mandatory, as it determines *when* the fix will be invoked during *the evolution of a timestep*. Fixes that perform time integration (*nve*, *nvt*, *npt*) implement `initial_integrate()` and `final_integrate()` to perform velocity Verlet time stepping updates. Fixes that apply forces implement `post_force()`, i.e. after the forces on atoms have been computed and

collected to the local atoms.

Fixes that perform diagnostics typically implement `end_of_step()`. For such a fix, one of your fix arguments must set the variable "nevery" which is used to determine when to call the fix and you **must** set this variable in the constructor of your fix. By convention, this is the first argument the fix defines (after the fix-ID, group-ID, and fix style).

If the fix needs to store information for each atom that persists from timestep to timestep, it can manage that memory and migrate the info with the atoms as they move from processors to processor by implementing the `grow_arrays()`, `copy_arrays()`, `pack_exchange()`, and `unpack_exchange()` methods. Similarly, the `pack_restart()` and `unpack_restart()` methods can be implemented to store information about the fix in binary restart files. If you wish an integrator or force constraint fix to work with rRESPA (see the *run_style* command), the `initial_integrate_respa()`, `post_force_respa()`, and `final_integrate_respa()` methods can be implemented. The `compute_scalar()` and `compute_vector()` methods enable a fix to contribute values to thermodynamic output, as printed quantities and/or to be summed to the potential energy of the system. The corresponding flags (`scalar_flag`, `vector_flag`, etc.) must be set in the constructor to tell LAMMPS which of these methods are implemented.

3.10 Input script command style

New commands can be added to LAMMPS input scripts by adding new classes that are derived from the Command class and thus must have a "command" method. For example, the *create_atoms*, *read_data*, *velocity*, and *run* commands are all implemented in this fashion. When such a command is encountered in the LAMMPS input script, LAMMPS simply creates a class instance with the corresponding name, invokes the "command" method of the class, and passes it the arguments from the input script. The command method can perform whatever operations it wishes on LAMMPS data structures. After the command method returns the class instance is deleted.

There is a detailed discussion of *how to write new command styles* in LAMMPS.

The method that your new Command class *must* define is as follows:

command	operations performed by the new command

Of course, the new class can define other methods and variables as needed.

3.11 Dump styles

Classes that dump per-atom info to files are derived from the Dump class. To dump new quantities or in a new format, a new derived dump class can be added, but it is typically simpler to modify the DumpCustom class contained in the `dump_custom.cpp` file.

`src/dump_atom.cpp` is a simple example of a derived dump class.

Here is a brief description of methods you define in your new derived class. See `src/dump.h` for details.

Required	"pure" methods that *must* be overridden
init_style	initialize style-specific state before a run
write_header	write the header section of a snapshot of atoms
pack	pack a proc's output data into a buffer
write_data	write a proc's data to a file

Optional	methods that have a default or empty implementation
count	count the number of lines a processor will output
openfile	open the output file (override for custom I/O)
convert_string	convert atom data to a string buffer
write_footer	write a footer after each snapshot
pack_forward_comm	pack a buffer for forward ghost communication
unpack_forward_comm	unpack a forward communication buffer
pack_reverse_comm	pack a buffer for reverse ghost communication
unpack_reverse_comm	unpack a reverse communication buffer
modify_param	called when dump_modify is executed (optional)
extract	provide access to internal data (optional)

See the *dump* command and its *custom* style for a list of keywords for atom information that can already be dumped by DumpCustom. It includes options to dump per-atom info from Compute classes, so adding a new derived Compute class is one way to calculate new quantities to dump.

Note that new keywords for atom properties are not typically added to the *dump custom* command. Instead they are added to the *compute property/atom* command.

3.12 Kspace styles

Classes that compute long-range Coulombic interactions via K-space representations (Ewald, PPPM) are derived from the KSpace class. New styles can be created to add new K-space options to LAMMPS.

`src/ewald.cpp` is an example of computing K-space interactions.

Here is a brief description of methods you define in your new derived class. See `src/kspace.h` for details.

Required	"pure" methods that *must* be overridden in a derived class
init	initialize the calculation before a run
setup	computation before the first timestep of a run
compute	every-timestep computation

Optional	methods that have a default or empty implementation
settings	process the arguments to the kspace_style command
compute_group_group	compute energy/force between two groups of atoms
qsum_qsq	compute total charge and charge-squared sum
reset_grid	called when the FFT grid size changes
pack_forward_grid	pack FFT grid data into a buffer for forward communication
unpack_forward_grid	unpack FFT grid data from a forward communication buffer
pack_reverse_grid	pack FFT grid data into a buffer for reverse communication
unpack_reverse_grid	unpack FFT grid data from a reverse communication buffer
timing	report timing information (used by kspace_modify)
timing_1d	report 1d FFT timing
timing_3d	report 3d FFT timing
modify_param	handle arguments from the kspace_modify command
memory_usage	tally of memory usage

Here is a list of flags or settings that should be set in the constructor of the derived class when they differ from the default setting.

Name of flag	Description	default
ewaldflag	1 if this is an Ewald solver	0
pppmflag	1 if this is a PPPM solver	0
msmflag	1 if this is an MSM solver	0
dispersionflag	1 if this is a LJ/dispersion solver	0
tip4pflag	1 if this is a TIP4P solver	0
dipoleflag	1 if this is a dipole solver	0
spinflag	1 if this is a spin solver	0
triclinic_support	1 if the style supports triclinic boxes	1
group_group_enable	1 if compute_group_group() is implemented	0
centroidstressflag	CENTROID_SAME/CENTROID_AVAIL/CENTROID_NOTAVAIL	NOTAV.

The pair-style flags `ewaldflag`, `pppmflag`, `msmflag`, `dispersionflag`, `tip4pflag`, `dipoleflag`, and `spinflag` must match the corresponding flags set in the pair style that is used together with the kspace style. The default value of `centroidstressflag` is `CENTROID_NOTAVAIL` for kspace styles, as the centroid stress for long-range interactions is generally not equal to the two-body virial.

3.13 Minimization styles

Classes that perform energy minimization derived from the Min class. New styles can be created to add new minimization algorithms to LAMMPS.

`src/min_cg.cpp` is an example of conjugate gradient minimization.

Here is a brief description of methods you define in your new derived class. See `src/min.h` for details.

Required	"pure" methods that *must* be overridden
setup_style	initialize minimizer-specific data structures
reset_vectors	connect internal xvec/fvec pointers to atom coordinates
iterate	perform the minimization iterations; returns stop-code

Optional	methods that have a default or base-class implementation
init	initialize the minimization before a run
setup	called before minimization starts
setup_minimal	minimal setup variant used for restarts
init_style	check style-specific conditions at init time
run	called by LAMMPS to drive the full minimization
force_clear	clear forces; override for GPU/Kokkos variants
energy_force	evaluate energy and forces; override for Kokkos
fnorm_sqr	return the squared force norm; override for spin styles
fnorm_inf	return the inf-norm of forces; override for spin styles
fnorm_max	return the max force norm; override for spin styles
modify_param	handle arguments from the min_modify command
memory_usage	tally of memory usage

The `iterate()` method must return one of the following integer stop-condition codes defined as an enum in `src/min.h`: `MAXITER`, `MAXEVAL`, `ETOL`, `FTOL`, `DOWNHILL`, `ZEROALPHA`, `ZEROFORCE`, `ZEROQUAD`, `TRSMALL`, `INTERROR`, `TIMEOUT`, or `MAXVDOTF`.

The line-search style used by the minimizer is controlled by the `linestyle` member, which takes values from the enum `{ BACKTRACK, QUADRATIC, FORCEZERO, SPIN_CUBIC, SPIN_NONE }`.

3.14 Region styles

Classes that define geometric regions are derived from the Region class. Regions are used elsewhere in LAMMPS to group atoms, delete atoms to create a void, insert atoms in a specified region, etc. New styles can be created to add new region shapes to LAMMPS.

The files `region_sphere.cpp` and `region_block.cpp` and their corresponding headers are representative examples of region style implementations.

Here is a brief description of methods you define in your new derived class. See `src/region.h` for details.

Required	"pure" methods that *must* be overridden in a derived class
inside	determine whether a point is in the region
surface_interior	determine if a point is within a cutoff distance inside of surface
surface_exterior	determine if a point is within a cutoff distance outside of surface

Optional	methods that have a default or empty implementation
shape_update	change region shape if set by time-dependent variable
bbox_update	update the bounding box when the shape is variable
init	check style-specific conditions before a run
set_velocity	compute the velocity of a moving region surface
set_velocity_shape	shape-specific part of set_velocity
velocity_contact_shape	return velocity at a contact point for the specific shape
write_restart	write region state to a restart file
restart	read region state from a restart file
length_restart_string	return the size of the restart data
reset_vel	reset velocity when the region is reset

3.15 Body styles

Classes that define body particles are derived from the Body class. Body particles can represent complex entities, such as surface meshes of discrete points, collections of sub-particles, deformable objects, etc.

See the *Howto body* page for an overview of using body particles and the various body styles LAMMPS supports. New styles can be created to add new kinds of body particles to LAMMPS.

Body_nparticle.cpp is an example of a body particle that is treated as a rigid body containing N sub-particles.

Here is a brief description of methods you define in your new derived class. See `src/body.h` for details.

Required	"pure" methods that *must* be overridden
data_body	process a line from the Bodies section of a data file
pack_data_body	pack body data into a buffer for writing to a data file
write_data_body	write body data to a data file
noutrow	number of sub-particles output is generated for
noutcol	number of values per-sub-particle output is generated for
output	output values for the Mth sub-particle
image	provide geometry for dump image rendering

Optional	methods that have a default or empty implementation
pack_comm_body	body attributes to communicate every timestep
unpack_comm_body	unpacking of those attributes
pack_border_body	body attributes to communicate when reneighboring is done
unpack_border_body	unpacking of those attributes
radius_body	return effective radius for use by granular pair styles

3.16 Granular Sub-Model styles

In granular models, particles are spheres with a finite radius and rotational degrees of freedom as further described in the *Howto granular page*. Interactions between pair of particles or particles and walls may therefore depend on many different modes of motion as described in *pair granular* and *fix wall/gran*. In both cases, the exchange of forces, torques, and heat flow between two types of bodies is defined using a GranularModel class. The GranularModel class organizes the details of an interaction using a series of granular sub-models each of which describe a particular interaction mode (e.g. normal forces or rolling friction). From a parent GranSubMod class, several types of sub-model classes are derived:

- GranSubModNormal: normal force sub-model
- GranSubModDamping: normal damping sub-model
- GranSubModTangential: tangential forces and sliding friction sub-model
- GranSubModRolling: rolling friction sub-model
- GranSubModTwisting: twisting friction sub-model
- GranSubModHeat: heat conduction sub-model

For each type of sub-model, more classes are further derived, each describing a specific implementation. For instance, from the GranSubModNormal class the GranSubModNormalHooke, GranSubModNormalHertz, and GranSubModNormalJKR classes are derived which calculate Hookean, Hertzian, or JKR normal forces, respectively. This modular structure simplifies the addition of new granular contact models as one only needs to create a new GranSubMod class without having to modify the more complex PairGranular, FixGranWall, and GranularModel classes. Most GranSubMod methods are also already defined by the parent classes so new contact models typically only require edits to a few relevant methods (e.g. methods that define coefficients and calculate forces).

Each GranSubMod class has a pointer to both the LAMMPS class and the GranularModel class which owns it, `lmp` and `gm`, respectively. The GranularModel class includes several public variables that describe the geometry/dynamics of the contact such as

`xi` and `xj`	Positions of the two contacting bodies
`vi` and `vj`	Velocities of the two contacting bodies
`omegai` and `omegaj`	Angular velocities of the two contacting bodies
`dx` and `nx`	The displacement and normalized displacement vectors
`r`, `rsq`, and `rinv`	The distance, distance squared, and inverse distance
`radsum`	The sum of particle radii
`vr`, `vn`, and `vt`	The relative velocity vector and its normal and tangential components
`wr`	The relative rotational velocity

These quantities, among others, are calculated in the `GranularModel->check_contact()` and `GranularModel->calculate_forces()` methods which can be referred to for more details.

To create a new GranSubMod class, it is recommended that one first looks at similar GranSubMod classes. All GranSubMod classes share several general methods which may need to be defined

`mix_coeff()`	Optional method to define how coefficients are mixed for different atom types. By default, coefficients are mixed using a geometric mean.
`coeffs_to_local()`	Parses coefficients to define local variables. Run once at model construction.
`init()`	Optional method to define local variables after other GranSubMod types were created. For instance, this method may be used by a tangential model that derives parameters from the normal model.

The Normal, Damping, Tangential, Twisting, and Rolling sub-models also have a `calculate_forces()` method which calculate the respective forces/torques. Correspondingly, the Heat sub-model has a `calculate_heat()` method. Lastly, the Normal sub-model has a few extra optional methods:

`touch()`	Tests whether particles are in contact. By default, when particles overlap.
`pulloff_distance()`	Returns the distance at which particles stop interacting. By default, when particles no longer overlap.
`calculate_radius()`	Returns the radius of the contact. By default, the radius of the geometric cross section.
`set_fncrit()`	Defines the critical force to break the contact used by some tangential, rolling, and twisting sub-models. By default, the current total normal force including damping.

As an example, say one wanted to create a new normal force option that consisted of a Hookean force with a piecewise stiffness. This could be done by adding a new set of files `gran_sub_mod_custom.h`:

```
#ifndef GRAN_SUB_MOD_CUSTOM_H
#define GRAN_SUB_MOD_CUSTOM_H

#include "gran_sub_mod.h"
#include "gran_sub_mod_normal.h"

namespace LAMMPS_NS {
namespace Granular_NS {
  class GranSubModNormalHookePiecewise : public GranSubModNormal {
   public:
    GranSubModNormalHookePiecewise(class GranularModel *, class LAMMPS *);
    void coeffs_to_local() override;
    double calculate_forces() override;
   protected:
    double k1, k2, delta_switch;
  };
}    // namespace Granular_NS
}    // namespace LAMMPS_NS

#endif /*GRAN_SUB_MOD_CUSTOM_H */
```

and `gran_sub_mod_custom.cpp`

```
#include "gran_sub_mod_custom.h"
#include "gran_sub_mod_normal.h"
#include "granular_model.h"

using namespace LAMMPS_NS;
using namespace Granular_NS;
```

(continues on next page)

(continued from previous page)

```
GranSubModNormalHookePiecewise::GranSubModNormalHookePiecewise(GranularModel *gm, LAMMPS␣
↪*lmp) :
    GranSubModNormal(gm, lmp)
{
  num_coeffs = 4;
}

/* ---------------------------------------------------------------------- */

void GranSubModNormalHookePiecewise::coeffs_to_local()
{
  k1 = coeffs[0];
  k2 = coeffs[1];
  damp = coeffs[2];
  delta_switch = coeffs[3];
}

/* ---------------------------------------------------------------------- */

double GranSubModNormalHookePiecewise::calculate_forces()
{
  double Fne;
  if (gm->delta >= delta_switch) {
    Fne = k1 * delta_switch + k2 * (gm->delta - delta_switch);
  } else {
    Fne = k1 * gm->delta;
  }
  return Fne;
}
```

Finally, the new sub-model has to be registered so that it can be selected by keyword from the input script. Unlike the name-keyed styles (pair, fix, compute, ...), granular sub-models cannot be loaded as plugins, so they are registered through a checked-in table in the file `src/GRANULAR/gran_sub_mod_register.cpp` rather than through an auto-generated style header. Add an `#include` for the new header and one row to the `gran_sub_mod_table[]` array in that file:

```
// in the 1st customization section
#include "gran_sub_mod_custom.h"

// in the 2nd customization section, among the normal models
{ "hooke/piecewise", &creator<GranSubModNormalHookePiecewise>, NORMAL },
```

The keyword (here `hooke/piecewise`) is what selects the sub-model in the *pair_style granular* and *fix wall/gran* commands. The same keyword may be reused for different sub-model types; the type column (the last entry) selects the correct one.

3.17 Thermodynamic output options

The `Thermo` class computes and prints thermodynamic information to the screen and log file; see the files `thermo.cpp` and `thermo.h`.

There are four styles defined in `thermo.cpp`: "one", "multi", "yaml", and "custom". The "custom" style allows the user to explicitly list keywords for individual quantities to print when thermodynamic output is generated. The others

have a fixed list of keywords. See the *thermo_style* command for a list of available quantities. The formatting of the "custom" style defaults to the "one" style, but can be adapted using *thermo_modify line*.

The thermo styles (one, multi, etc) are defined by lists of keywords with associated formats for integer and floating point numbers and identified by an enumerator constant. Adding a new style thus mostly requires defining a new list of keywords and the associated formats and then inserting the required output processing where the enumerators are identified. Search for the word "CUSTOMIZATION" with references to "thermo style" in the `thermo.cpp` file to see the locations where code will need to be added. The member function `Thermo::header()` prints output at the very beginning of a thermodynamic output block and can be used to print column headers or other front matter. The member function `Thermo::footer()` prints output at the end of a thermodynamic output block. The formatting of the output is done by assembling a "line" (which may span multiple lines if the style inserts newline characters ("n" as in the "multi" style).

New thermodynamic keywords can also be added to `thermo.cpp` to compute new quantities for output. Search for the word "CUSTOMIZATION" with references to "keyword" in `thermo.cpp` to see the several locations where code will need to be added. Effectively, you need to define a member function that computes the property, add an if statement in `Thermo::parse_fields()` where the corresponding header string for the keyword and the function pointer is registered by calling the `Thermo::addfield()` method, and add an if statement in `Thermo::evaluate_keyword()` which is called from the `Variable` class when a thermo keyword is encountered.

Note

The third argument to `Thermo::addfield()` is a flag indicating whether the function for the keyword computes a floating point (FLOAT), regular integer (INT), or big integer (BIGINT) value. This information is used for formatting the thermodynamic output. Inside the function the result must then be stored either in the `dvalue`, `ivalue` or `bivalue` member variable, respectively.

Since the *thermo_style custom* command allows to use output of quantities calculated by *fixes*, *computes*, and *variables*, it may often be simpler to compute what you wish via one of those constructs, rather than by adding a new keyword to the thermo_style command.

3.18 Variable options

The `Variable` class computes and stores *variable* information in LAMMPS; see the file `variable.cpp`. The value associated with a variable can be periodically printed to the screen via the *print*, *fix print*, or *thermo_style custom* commands. Variables of style "equal" can compute complex equations that involve the following types of arguments:

```
thermo keywords = ke, vol, atoms, ...
other variables = v_a, v_myvar, ...
math functions = div(x,y), mult(x,y), add(x,y), ...
group functions = mass(group), xcm(group,x), ...
atom values = x[123], y[3], vx[34], ...
compute values = c_mytemp[0], c_thermo_press[3], ...
```

Adding keywords for the *thermo_style custom* command (which can then be accessed by variables) is discussed in the *Modify thermo* documentation.

Adding a new math function of one or two arguments can be done by editing one section of the `Variable::evaluate()` method. Search for the word "customize" to find the appropriate location.

Adding a new group function can be done by editing one section of the `Variable::evaluate()` method. Search for the word "customize" to find the appropriate location. You may need to add a new method to the Group class as well (see the `group.cpp` file).

Accessing a new atom-based vector can be done by editing one section of the Variable::evaluate() method. Search for the word "customize" to find the appropriate location.

Adding new *compute styles* (whose calculated values can then be accessed by variables) is discussed in the *Modify compute* documentation.

CHAPTER

FOUR

INFORMATION FOR DEVELOPERS

This section describes the internal structure and basic algorithms of the LAMMPS code. This is a work in progress and additional information will be added incrementally depending on availability of time and requests from the LAMMPS user community.

A discussion of software engineering methods applied to LAMMPS over time and a general outline of the design and maintenance approach by the LAMMPS developers can be found in the paper LAMMPS: A Case Study For Applying Modern Software Engineering to an Established Research Software Package, in the USRSE'25 conference proceedings.

On using AI coding agents

Recently AI coding agents have seen massive improvements and thus have become quite popular and viable in assisting with the development of new code or with adding features to existing code. The LAMMPS developers have made some experiments and tried to assess the how effective and reliable the results are. Below are some of our observations and suggestions. Since this is a rapidly evolving field, we will revise our position and the information here as needed.

A significant part of LAMMPS was written by taking some existing classes that perform similar calculations or operations and then replacing the functionality. That kind of task is well suited for a coding agent, but there are often little details that require some manual adjustments and thus careful checking of the resulting code is recommended. Similarly, porting styles to the KOKKOS or OPENMP package can often be delegated, provided suitable template examples exist and the coding agent is asked to look at those. Github Copilot and Claude code can also run LAMMPS unit tests and may even add unit tests for new styles if a suitable template already exists. Asking a coding agent to create new functionality for which there is no similar code in either the LAMMPS sources or some other MD package repository or standalone code has a much lower chance of success.

In general, it is best to be explicit and verbose when assigning tasks to coding agents. It can also helpful to ask the agent to break up complex tasks and create a detailed multi-step plan. Avoid asking a coding agent to do too much at once. For example, we have found that porting groups of about 5 styles each to the KOKKOS or OPENMP package is reasonably efficient, without running into session timeouts or the coding agent losing focus. When a session is finished, asking the agent to summarize what it learned and including that context in the next session can also improve efficiency.

Another task that can often be passed successfully to a coding agent is the creation of suitable documentation. However, the results have a tendency to be overly verbose, redundant and explicit about implementation details that are irrelevant for the usage of a new feature. So manual editing to tighten it up is strongly recommended.

Finally, coding agents are quite good at reviewing existing code. The LAMMPS developers use GitHub Copilot regularly to review submitted pull requests and over time the rate of incorrect advice has become rather low. When using an AI coding agent to create code, it is generally recommended to use a different model for the code review than what was used to write the code. Also, except for trivial tasks, it is usually required to use a so-called "frontier model" to obtain reliable and properly tested code.

To assist coding agents in their tasks, and particularly to provide instructions that GitHub Copilot and Claude Code will automatically read, we have created files in `.github` and `.claude` that provide suitable instructions and are structured to that by default only a minimum amount of text is parsed (and thus tokens consumed) and additional instructions are processed on demand.

When contributing code to LAMMPS that was at least partially created by a coding agent, please provide information in the pull request description to the extent of AI usage and which model or models were used. While we do not object to use AI coding tools (we use them ourselves), our requirements for accepting such code are higher (also for our own code) and we will be much more likely reject a contribution, since it can usually be re-create (with corrections) rather easily. Our own experience is that for challenging tasks it may take starting over from scratch several times until the result is acceptable.

More practical suggestions are collected on the *Working with AI coding agents* page.

4.1 Source files

The source files of the LAMMPS code are found in two directories of the distribution: `src` and `lib`. Most of the code is written in C++ but there are small a number of files in several other languages like C, Fortran, Shell script, or Python.

The core of the code is located in the `src` folder and its subdirectories. A sizable number of these files are in the `src` directory itself, but there are plenty of *packages*, which can be included or excluded when LAMMPS is built. See the *Include packages in build* section of the manual for more information about that part of the build process. LAMMPS currently supports building with *conventional makefiles* and through *CMake*. Those procedures differ in how packages are enabled or disabled for inclusion into a LAMMPS binary, so they cannot be mixed. The source files for each package are in all-uppercase subdirectories of the `src` folder, for example `src/MOLECULE` or `src/EXTRA-MOLECULE`. The `src/STUBS` subdirectory is not a package but contains a dummy MPI library, that is used when building a serial version of the code. The `src/MAKE` directory and its subdirectories contain makefiles with settings and flags for a variety of configuration and machines for the build process with traditional makefiles.

The `lib` directory contains the source code for several supporting libraries or files with configuration settings to use globally installed libraries, that are required by some optional packages. They may include python scripts that can transparently download additional source code on request. Each subdirectory, like `lib/colvars` or `lib/gpu`, contains the source files, some of which are in different languages such as Fortran or CUDA. These libraries included in the LAMMPS build, if the corresponding package is installed.

LAMMPS C++ source files almost always come in pairs, such as `src/run.cpp` (implementation file) and `src/run.h` (header file). Each pair of files defines a C++ class, for example the `LAMMPS_NS::Run` class, which contains the code invoked by the *run* command in a LAMMPS input script. As this example illustrates, source file and class names often have a one-to-one correspondence with a command used in a LAMMPS input script. Some source files and classes do not have a corresponding input script command, for example `src/force.cpp` and the `LAMMPS_NS::Force` class. They are discussed in the next section.

The names of all source files are in lower case and may use the underscore character '_' to separate words. Apart from bundled, externally maintained libraries, which may have different conventions, all C and C++ header files have a `.h` extension, all C++ files have a `.cpp` extension, and C files a `.c` extension. A few C++ classes and utility functions are implemented with only a `.h` file. Examples are the Pointers and Commands classes or the MathVec functions.

4.2 Class topology

Though LAMMPS has a lot of source files and classes, its class topology is not very deep, which can be seen from the *LAMMPS class topology* figure. In that figure, each name refers to a class and has a pair of associated source files in the `src` folder, for example the class `LAMMPS_NS::Memory` corresponds to the files `memory.cpp` and `memory.h`, or the class `LAMMPS_NS::AtomVec` corresponds to the files `atom_vec.cpp` and `atom_vec.h`. Full lines in the figure represent compositing: that is, the class at the base of the arrow holds a pointer to an instance of the class at the tip.

Dashed lines instead represent inheritance: the class at the tip of the arrow is derived from the class at the base. Classes with a red boundary are not instantiated directly, but they represent the base classes for "styles". Those "styles" make up the bulk of the LAMMPS code and only a few representative examples are included in the figure, so it remains readable.

The *LAMMPS_NS::LAMMPS* class is the topmost class and represents what is generally referred to as an "instance of LAMMPS". It is a composite holding pointers to instances of other core classes providing the core functionality of the MD engine in LAMMPS and through them abstractions of the required operations. The constructor of the LAMMPS class will instantiate those instances, process the command-line flags, initialize MPI (if not already done) and set up file pointers for input and output. The destructor will shut everything down and free all associated memory. Thus code for the standalone LAMMPS executable in `main.cpp` simply initializes MPI, instantiates a single instance of LAMMPS while passing it the command-line flags and input script. It deletes the LAMMPS instance after the method reading the input returns and shuts down the MPI environment before it exits the executable.

The *LAMMPS_NS::Pointers* class is not shown in the *LAMMPS class topology* figure for clarity. It holds references to many of the members of the *LAMMPS_NS::LAMMPS*, so that all classes derived from *LAMMPS_NS::Pointers* have direct access to those references. From the class topology all classes with blue boundary are referenced in the Pointers class and all classes in the second and third columns, that are not listed as derived classes, are instead derived from *LAMMPS_NS::Pointers*. To initialize the pointer references in Pointers, a pointer to the LAMMPS class instance needs to be passed to the constructor. All constructors for classes derived from it, must do so and thus pass that pointer to the constructor for *LAMMPS_NS::Pointers*. The default constructor for *LAMMPS_NS::Pointers* is disabled to enforce this.

Since all storage is supposed to be encapsulated (there are a few exceptions), the LAMMPS class can also be instantiated multiple times by a calling code. Outside the aforementioned exceptions, those LAMMPS instances can be used alternately. As of the time of this writing (early 2023) LAMMPS is not yet sufficiently thread-safe for concurrent execution. When running in parallel with MPI, care has to be taken, that suitable copies of communicators are used to not create conflicts between different instances.

The LAMMPS class currently holds instances of 19 classes representing the core functionality. There are a handful of virtual parent classes in LAMMPS that define what LAMMPS calls `styles`. These are shaded red in the *LAMMPS class topology* figure. Each of these are parents of a number of child classes that implement the interface defined by the parent class. There are two main categories of these `styles`: some may only have one instance active at a time (e.g. atom, pair, bond, angle, dihedral, improper, kspace, comm) and there is a dedicated pointer variable for each of them in the corresponding composite class. Setups that require a mix of different such styles have to use a *hybrid* class instance that acts as a proxy, and manages and forwards calls to the corresponding sub-style class instances for the designated subset of atoms or data. The composite class may also have lists of class instances, e.g. `Modify` handles lists of compute and fix styles, while `Output` handles a list of dump class instances.

The exception to this scheme are the `command` style classes. These implement specific commands that can be invoked before, after, or in between runs. For these an instance of the class is created, its command() method called and then, after completion, the class instance deleted. Examples for this are the create_box, create_atoms, minimize, run, set, or velocity command styles.

For all those `styles`, certain naming conventions are employed: for the fix nve command the class is called FixNVE and the source files are `fix_nve.h` and `fix_nve.cpp`. Similarly, for fix ave/time we have FixAveTime and `fix_ave_time.h` and `fix_ave_time.cpp`. Style names are lower case and without spaces or special characters. A suffix or words are appended with a forward slash '/' which denotes a variant of the corresponding class without the suffix. To connect the style name and the class name, LAMMPS uses macros like: `AtomStyle()`, `PairStyle()`, `BondStyle()`, `RegionStyle()`, and so on in the corresponding header file. During configuration or compilation, files with the pattern `style_<name>.h` are created that consist of a list of include statements including all headers of all styles of a given type that are currently enabled (or "installed").

More details on individual classes in the *LAMMPS class topology* are as follows:

- The Memory class handles allocation of all large vectors and arrays.
- The Error class prints all (terminal) error and warning messages.

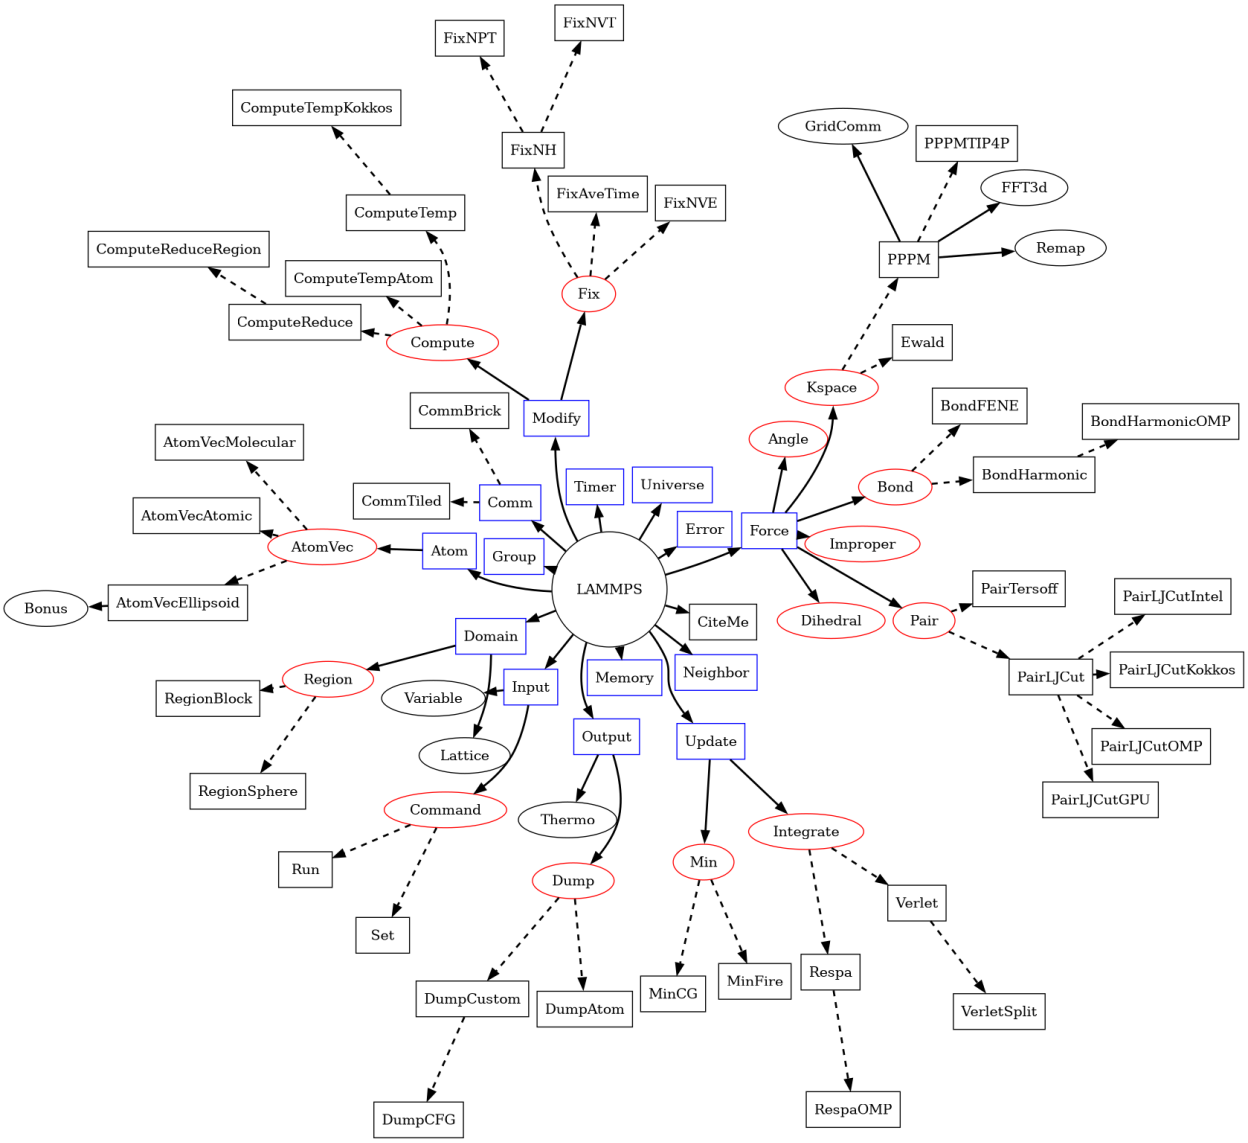


Fig. 1: LAMMPS class topology

This figure shows relations of base classes of the LAMMPS simulation package. Full lines indicate that a class holds an instance of the class it is pointing to; dashed lines point to derived classes that are given as examples of what classes may be instantiated during a LAMMPS run based on the input commands and accessed through the API define by their respective base classes. At the core is the *LAMMPS* class, which holds pointers to class instances with specific purposes. Those may hold instances of other classes, sometimes directly, or only temporarily, sometimes as derived classes or derived classes of derived classes, which may also hold instances of other classes.

- The Universe class sets up one or more partitions of processors so that one or multiple simulations can be run, on the processors allocated for a run, e.g. by the mpirun command.
- The Input class reads and processes input (strings and files), stores variables, and invokes *commands*.
- Command style classes are derived from the Command class. They provide input script commands that perform one-time operations before/after/between simulations or which invoke a simulation. They are usually instantiated from within the Input class, its `command` method invoked, and then immediately destructed.
- The Finish class is instantiated to print statistics to the screen after a simulation is performed, by commands like run and minimize.
- The Special class walks the bond topology of a molecular system to find first, second, third neighbors of each atom. It is invoked by several commands, like *read_data*, *read_restart*, or *replicate*.
- The Atom class stores per-atom properties associated with atom styles. More precisely, they are allocated and managed by a class derived from the AtomVec class, and the Atom class simply stores pointers to them. The classes derived from AtomVec represent the different atom styles, and they are instantiated through the *atom_style* command.
- The Update class holds instances of an integrator and a minimizer class. The Integrate class is a parent style for the Verlet and r-RESPA time integrators, as defined by the *run_style* command. The Min class is a parent style for various energy minimizers.
- The Neighbor class builds and stores neighbor lists. The NeighList class stores a single list (for all atoms). A NeighRequest class instance is created by pair, fix, or compute styles when they need a particular kind of neighbor list and use the NeighRequest properties to select the neighbor list settings for the given request. There can be multiple instances of the NeighRequest class. The Neighbor class will try to optimize how the requests are processed. Depending on the NeighRequest properties, neighbor lists are constructed from scratch, aliased, or constructed by post-processing an existing list into sub-lists.
- The Comm class performs inter-processor communication, typically of ghost atom information. This usually involves MPI message exchanges with 6 neighboring processors in the 3d logical grid of processors mapped to the simulation box. There are two *communication styles*, enabling different ways to perform the domain decomposition.
- The Irregular class is used, when atoms may migrate to arbitrary processors.
- The Domain class stores the simulation box geometry, as well as geometric Regions and any user definition of a Lattice. The latter are defined by the *region* and *lattice* commands in an input script.
- The Force class computes various forces between atoms. The Pair parent class is for non-bonded or pairwise forces, which in LAMMPS also includes many-body forces such as the Tersoff 3-body potential if those are computed by walking pairwise neighbor lists. The Bond, Angle, Dihedral, Improper parent classes are styles for bonded interactions within a static molecular topology. The KSpace parent class is for computing long-range Coulombic interactions. One of its child classes, PPPM, uses the FFT3D and Remap classes to redistribute and communicate grid-based information across the parallel processors.
- The Modify class stores lists of class instances derived from the *Fix* and *Compute* base classes.
- The Group class manipulates groups that atoms are assigned to via the *group* command. It also has functions to compute various attributes of groups of atoms.
- The Output class is used to generate 3 kinds of output from a LAMMPS simulation: thermodynamic information printed to the screen and log file, dump file snapshots, and restart files. These correspond to the *Thermo*, *Dump*, and *WriteRestart* classes respectively. The Dump class is a base class, with several derived classes implementing various dump style variants.
- The Timer class logs timing information, output at the end of a run.

4.3 Code design

This section explains some code design choices in LAMMPS with the goal of helping developers write new code similar to the existing code. Please see the section on *Requirements for contributed code* for more specific recommendations and guidelines. While that section is organized more in the form of a checklist for code contributors, the focus here is on overall code design strategy, choices made between possible alternatives, and discussing some relevant C++ programming language constructs.

Historically, the basic design philosophy of the LAMMPS C++ code was a "C with classes" style. The motivation was to make it easy to modify LAMMPS for people without significant training in C++ programming. Data structures and code constructs were used that resemble the previous implementation(s) in Fortran. A contributing factor to this choice was that at the time, C++ compilers were often not mature and some advanced features contained bugs or did not function as the standard required. There were also disagreements between compiler vendors as to how to interpret the C++ standard documents.

However, C++ compilers and the C++ programming language have advanced significantly. In 2020, the LAMMPS developers decided to require the C++11 standard as the minimum C++ language standard for LAMMPS. Since then, we have begun to replace C-style constructs with equivalent C++ functionality. This was taken either from the C++ standard library or implemented as custom classes or functions. The goal is to improve readability of the code and to increase code reuse through abstraction of commonly used functionality. In summer 2025, after the 22 July 2025 stable release, the minimum required C++ language standard was raised to C++17.

Note

Please note that as of summer 2025 there is still a sizable chunk of legacy code in LAMMPS that has not yet been refactored to reflect these style conventions in full. LAMMPS has a large code base and many contributors. There is also a hierarchy of precedence in which the code is adapted. Highest priority has been the code in the `src` folder, followed by code in packages in order of their popularity and complexity (simpler code gets adapted sooner), followed by code in the `lib` folder. Source code that is downloaded from external packages or libraries during compilation is not subject to the conventions discussed here.

4.3.1 Object-oriented code

LAMMPS is designed to be an object-oriented code. Each simulation is represented by an instance of the LAMMPS class. When running in parallel, each MPI process creates such an instance. This can be seen in the `main.cpp` file where the core steps of running a LAMMPS simulation are the following 3 lines of code:

```
LAMMPS *lammps = new LAMMPS(argc, argv, lammps_comm);
lammps->input->file();
delete lammps;
```

The first line creates a LAMMPS class instance and passes the command line arguments and the global communicator to its constructor. The second line triggers the LAMMPS instance to process the input (either from standard input or a provided input file) until the simulation ends. The third line deletes the LAMMPS instance. The remainder of the main.cpp file has code for error handling, MPI configuration, and other special features.

The basic LAMMPS class hierarchy which is created by the LAMMPS class constructor is shown in *LAMMPS class topology*. When input commands are processed, additional class instances are created, or deleted, or replaced. Likewise, specific member functions of specific classes are called to trigger actions such as creating atoms, computing forces, computing properties, time-propagating the system, or writing output.

Compositing and Inheritance

LAMMPS makes extensive use of the object-oriented programming (OOP) principles of *compositing* and *inheritance*. Classes like the `LAMMPS` class are a **composite** containing pointers to instances of other classes like `Atom`, `Comm`, `Force`, `Neighbor`, `Modify`, and so on. Each of these classes implements certain functionality by storing and manipulating data related to the simulation and providing member functions that trigger certain actions. Some of those classes like `Force` are themselves composites, containing instances of classes describing different force interactions. Similarly, the `Modify` class contains a list of `Fix` and `Compute` classes. If the input commands that correspond to these classes include the word *style*, then LAMMPS stores only a single instance of that class. E.g. *atom_style*, *comm_style*, *pair_style*, *bond_style*. If the input command does **not** include the word *style*, then there may be many instances of that class defined, for example *region*, *fix*, *compute*, *dump*.

Inheritance enables creation of *derived* classes that can share common functionality in their base class while providing a consistent interface. The derived classes replace (dummy or pure) functions in the base class. The higher level classes can then call those methods of the instantiated classes without having to know which specific derived class variant was instantiated. In LAMMPS these derived classes are often referred to as "styles", e.g. pair styles, fix styles, atom styles and so on.

This is the origin of the flexibility of LAMMPS. For example, pair styles implement a variety of different non-bonded interatomic potentials functions. All details for the implementation of a potential are stored and executed in a single class.

As mentioned above, there can be multiple instances of classes derived from the `Fix` or `Compute` base classes. They represent a different facet of LAMMPS' flexibility, as they provide methods which can be called at different points within a timestep, as explained in the *How a timestep works* doc page. This allows the input script to tailor how a specific simulation is run, what diagnostic computations are performed, and how the output of those computations is further processed or output.

Additional code sharing is possible by creating derived classes from the derived classes (e.g., to implement an accelerated version of a pair style) where only a subset of the derived class methods are replaced with accelerated versions.

Polymorphism

Polymorphism and dynamic dispatch are another OOP feature that play an important role in how LAMMPS selects what code to execute. In a nutshell, this is a mechanism where the decision of which member function to call from a class is determined at runtime and not when the code is compiled. To enable it, the function has to be declared as `virtual` and all corresponding functions in derived classes should use the `override` property. Below is a brief example.

```
class Base {
public:
 virtual ~Base() = default;
 void call();
 void normal();
 virtual void poly();
};

void Base::call() {
 normal();
 poly();
}

class Derived : public Base {
public:
 ~Derived() override = default;
 void normal();
```

(continues on next page)

(continued from previous page)

```
 void poly() override;
};

// [....]

Base *base1 = new Base();
Base *base2 = new Derived();

base1->call();
base2->call();
```

The difference in behavior of the `normal()` and the `poly()` member functions is which of the two member functions is called when executing *base1->call()* versus *base2->call()*. Without polymorphism, a function within the base class can only call member functions within the same scope: that is, `Base::call()` will always call `Base::normal()`. But for the *base2->call()* case, the call of the virtual member function will be dispatched to `Derived::poly()` instead. This mechanism results in calling functions that are within the scope of the class that was used to *create* the instance, even if they are assigned to a pointer for their base class. This is the desired behavior, and this way LAMMPS can even use styles that are loaded at runtime from a shared object file with the *plugin command*.

A special case of virtual functions are so-called pure functions. These are virtual functions that are initialized to 0 in the class declaration (see example below).

```
class Base {
public:
 virtual void pure() = 0;
};
```

This has the effect that an instance of the base class cannot be created and that derived classes **must** implement these functions. Many of the functions listed with the various class styles in the section *Modifying & extending LAMMPS* are pure functions. The motivation for this is to define the interface or API of the functions, but defer their implementation to the derived classes.

However, there are downsides to this. For example, calls to virtual functions from within a constructor, will *not* be in the scope of the derived class, and thus it is good practice to either avoid calling them or to provide an explicit scope such as `Base::poly()` or `Derived::poly()`. Furthermore, any destructors in classes containing virtual functions should be declared virtual too, so they will be processed in the expected order before types are removed from dynamic dispatch.

Important Notes

In order to be able to detect incompatibilities at compile time and to avoid unexpected behavior, it is crucial that all member functions that are intended to replace a virtual or pure function use the `override` property keyword. For the same reason, the use of overloads or default arguments for virtual functions should be avoided, as they lead to confusion over which function is supposed to override which, and which arguments need to be declared.

Style Factories

In order to create class instances for different styles, LAMMPS often uses a programming pattern called *Factory*. Those are functions that create an instance of a specific derived class, say `PairLJCut` and return a pointer to the type of the common base class of that style, `Pair` in this case. To associate the factory function with the style keyword, a process-global registry (the `CreatorRegistry` class template declared in `creator_registry.h`) is used that stores the factory function pointers indexed by their keyword (for example "lj/cut" for `PairLJCut` and "morse"

for PairMorse). A couple of typedefs help keep the code readable, and a template function is used to implement the actual factory functions for the individual classes.

During compilation, the build system parses the PairStyle() marker lines in the header files of all "installed" pair styles (those starting with pair_) and generates the file style_pair.cpp. That file #includes those headers and defines a register_pair_styles() function which adds one factory function per style to the registry returned by the Force::pair_styles() accessor. As with all style categories, the PAIR_CLASS macro is never actually defined during compilation; the #ifdef PAIR_CLASS block in each header is only a marker for the build system's parser. Below is an example of the relevant declarations and the generated code:

```
// from force.h
using PairCreator = Pair *(*)(LAMMPS *);
static CreatorRegistry<PairCreator> &pair_styles();

// from the generated file style_pair.cpp
template <typename T> static Pair *creator(LAMMPS *lmp)
{
  return new T(lmp);
}

void register_pair_styles()
{
  // [...] one add_builtin() call per installed pair style
  Force::pair_styles().add_builtin("lj/cut", &creator<PairLJCut>);
}

// from pair_lj_cut.h

#ifdef PAIR_CLASS
PairStyle(lj/cut,PairLJCut);
#else
// [...]
```

All per-category register_*_styles() functions are called once per process from register_builtin_styles() (guarded by std::call_once) when the first LAMMPS instance is created. Because the registry is process-global, the built-in styles are registered only once and remain available after a *clear* command and across multiple concurrent LAMMPS instances in the same process; this is also what allows *plugins* to persist (see *Writing plugins*). The same mechanism is used for the other style categories that are created from a user-facing keyword and managed by Modify (fixes, computes), Update (integrators, minimizers), Domain (regions), Output (dumps), Input (commands), and Atom (atom styles). A few internal style categories that are *not* selected by a user-facing keyword — the neighbor list nbin/npair/nstencil/ntopo classes in neighbor.cpp and the granular sub-models — still use the older approach that #includes a generated style_*.h file while the corresponding XXX_CLASS macro is defined.

4.3.2 I/O and output formatting

C-style stdio versus C++ style iostreams

LAMMPS uses the stdio library of the standard C library for reading from and writing to files and console instead of C++ iostreams. This is mainly motivated by better performance, better control over formatting, and less effort to achieve specific formatting.

Since mixing "stdio" and "iostreams" can lead to unexpected behavior, use of the latter is strongly discouraged. Output to the screen should *not* use the predefined stdout FILE pointer, but rather the screen and logfile FILE pointers managed by the LAMMPS class. Furthermore, output should generally only be done by MPI rank 0 (comm->me == 0). Output that is sent to both screen and logfile should use the *utils::logmesg() convenience function*.

We strongly discourage the use of stringstreams because the bundled {fmt} library or the C++ format library (for C++20 and later) and the customized tokenizer classes provide the same functionality in a cleaner way with better performance. This also helps maintain a consistent programming syntax with code from many different contributors.

Formatting with the {fmt} library and std::format

The LAMMPS source code currently includes a slightly modified copy of the {fmt} library, which is preferred over formatting with the "printf()" family of functions. When compiling for C++20 and later we switch to using the C++ format library. The namespace prefix currently remains `fmt::` through a small wrapper. In the future, this will be switched to `std::` when LAMMPS requires the C++20 standard as the minimum C++ standard. Thus only functionality compatible with the C++ format library for C++20 is accepted. Using `std::format` requires a fully C++20 compatible compiler (e.g. GCC 13 and later, Clang 14 and later, or MSVC 16.10 and later) and we use the __cpp_lib_format feature test macro to confirm the availability of `std::format`.

The primary reason for this choice is that it allows a typesafe default format for any type of supported data. This is particularly useful for formatting integers of a given size (32-bit or 64-bit) which may require different format strings depending on compile time settings or compilers/operating systems. Furthermore, {fmt} gives better performance, has more functionality, a familiar formatting syntax that has similarities to `format()` in Python, and provides a facility that can be used to integrate format strings and a variable number of arguments into custom functions in a much simpler way than the varargs mechanism of the C library.

Formatted strings are frequently created by calling the `fmt::format()` function, which will return a string as a `std::string` class instance. In contrast to the `%` placeholder in `printf()`, the {fmt} library uses `{}` to embed format descriptors. In the simplest case, no additional characters are needed, as {fmt} will choose the default format based on the data type of the argument. Otherwise, the *`utils::print()`* function may be used instead of `printf()` or `fprintf()`. The equivalent std::print() function will become available in C++ 23. In addition, several LAMMPS output functions, that originally accepted a single string as argument have been overloaded to accept a format string with optional arguments as well (e.g., `Error::all()`, `Error::one()`, *`utils::logmesg()`*).

Summary of the {fmt} format and std::format syntax

The syntax of the format string is "{[<argument id>][:<format spec>]}", where either the argument id or the format spec (separated by a colon ':') is optional. The argument id is usually a number starting from 0 that is the index to the arguments following the format string. By default, these are assigned in order (i.e. 0, 1, 2, 3, 4 etc.). The most common case for using argument id would be to use the same argument in multiple places in the format string without having to provide it as an argument multiple times. The argument id is rarely used in the LAMMPS source code.

More common is the use of a format specifier, which starts with a colon. This may optionally be followed by a fill character (default is ' '). If provided, the fill character **must** be followed by an alignment character ('<', '^', '>' for left, centered, or right alignment (default)). The alignment character may be used without a fill character. The next important format parameter would be the minimum width, which may be followed by a dot '.' and a precision for floating point numbers. The final character in the format string would be an indicator for the "presentation", i.e. 'd' for decimal presentation of integers, 'x' for hexadecimal, 'o' for octal, 'c' for character etc. This mostly follows the "printf()" scheme, but without requiring an additional length parameter to distinguish between different integer widths. The {fmt} library will detect those and adapt the formatting accordingly. For floating point numbers there are correspondingly, 'g' for generic presentation, 'e' for exponential presentation, and 'f' for fixed point presentation.

The format string "{:8}" would thus represent *any* type argument and be replaced by at least 8 characters; "{:<8}" would do this as left aligned, "{:^8}" as centered, "{:>8}" as right aligned. If a specific presentation is selected, the argument type must be compatible or else the {fmt} formatting code will throw an exception. Some format string examples are given below:

```
auto mesg = fmt::format("  CPU time: {:4d}:{:02d}:{:02d}\n", cpuh, cpum, cpus);
mesg = fmt::format("{:<8s}| {:<10.5g} | {:<10.5g} | {:<10.5g} |{:6.1f} |{:6.2f}\n",
                   label, time_min, time, time_max, time_sq, tmp);
utils::logmesg(lmp,"{:>6} = max # of 1-2 neighbors\n",maxall);
```

(continues on next page)

(continued from previous page)

```
utils::logmesg(lmp,"Lattice spacing in x,y,z = {:.8} {:.8} {:.8}\n",
               xlattice,ylattice,zlattice);
```

which will create the following output lines:

```
CPU time:    0:02:16
Pair    | 2.0133     | 2.0133     | 2.0133     |   0.0 | 84.21
     4 = max # of 1-2 neighbors
Lattice spacing in x,y,z = 1.6795962 1.6795962 1.6795962
```

Finally, a special feature of the {fmt} library is that format parameters like the width or the precision may be also provided as arguments. In that case a nested format is used where a pair of curly braces (with an optional argument id) "{}" are used instead of the value, for example "{:{}d}" will consume two integer arguments, the first will be the value shown and the second the minimum width.

For more details and examples, please consult the {fmt} syntax documentation website or the corresponding C++ syntax reference. Since we plan to eventually transition from {fmt} to using `std::format()` of the C++ standard library, it is advisable to avoid using any extensions beyond what the C++20 standard offers.

4.3.3 JSON format input and output

Since LAMMPS version 12 June 2025, the LAMMPS source code includes a copy of the header-only JSON C++ library from https://json.nlohmann.me/. Same as with the {fmt} library described above some modification to the namespace has been made to avoid collisions with other uses of the same library, which may use a different, incompatible version. To have a uniform interface with other parts of LAMMPS, you should be using `#include "json.h"` or `#include "json_fwd.h"` (in header files). See the implementation of the *molecule command* for an example of using this library.

4.3.4 Memory management

Dynamical allocation of small data and objects can be done with the C++ commands "new" and "delete/delete[]". Large data should use the member functions of the `Memory` class, most commonly, `Memory::create()`, `Memory::grow()`, and `Memory::destroy()`, which provide variants for vectors, 2d arrays, 3d arrays, etc. These can also be used for small data.

The use of `malloc()`, `calloc()`, `realloc()` and `free()` directly is strongly discouraged. To simplify adapting legacy code into the LAMMPS code base the member functions `Memory::smalloc()`, `Memory::srealloc()`, and `Memory::sfree()` are available, which perform additional error checks for safety.

Use of these custom memory allocation functions is motivated by the following considerations:

- Memory allocation failures on *any* MPI rank during a parallel run will trigger an immediate abort of the entire parallel calculation.
- A failing "new" will trigger an exception, which is also captured by LAMMPS and triggers a global abort.
- Allocation of multidimensional arrays will be done in a C compatible fashion, but such that the storage of the actual data is stored in one large contiguous block. Thus, when MPI communication is needed, the data can be communicated directly (similar to Fortran arrays).
- The "destroy()" and "sfree()" functions may safely be called on NULL pointers.
- The "destroy()" functions will nullify the pointer variables, thus making "use after free" errors easy to detect.
- It is possible to use a larger than default memory alignment (not on all operating systems, since the allocated storage pointers must be compatible with `free()` for technical reasons).

In the practical implementation of code this means, that any pointer variables, that are class members should be initialized to a `nullptr` value in their respective constructors. That way, it is safe to call `Memory::destroy()` or `delete[]` on them before *any* allocation outside the constructor. This helps prevent memory leaks.

4.4 Parallel algorithms

LAMMPS is designed to enable running simulations in parallel using the MPI parallel communication standard with distributed data via domain decomposition. The parallelization aims to be efficient, and resulting in good strong scaling (= good speedup for the same system) and good weak scaling (= the computational cost of enlarging the system is proportional to the system size). Additional parallelization using GPUs or OpenMP can also be applied within the subdomain assigned to an MPI process. For clarity, most of the following illustrations show the 2d simulation case. The underlying algorithms in those cases, however, apply to both 2d and 3d cases equally well.

Note

The text and most of the figures in this chapter were adapted for the manual from the section on parallel algorithms in the *new LAMMPS paper*.

4.4.1 Partitioning

The underlying spatial decomposition strategy used by LAMMPS for distributed-memory parallelism is set with the *comm_style command* and can be either "brick" (a regular grid) or "tiled".

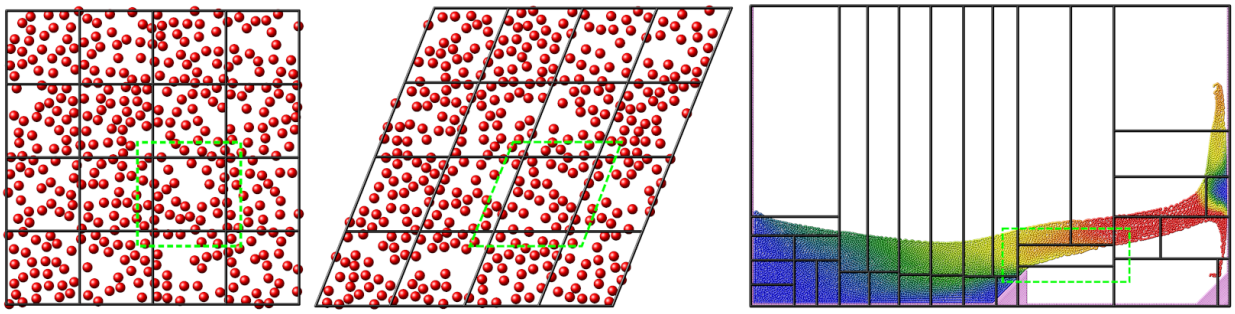

Fig. 2: Domain decomposition schemes

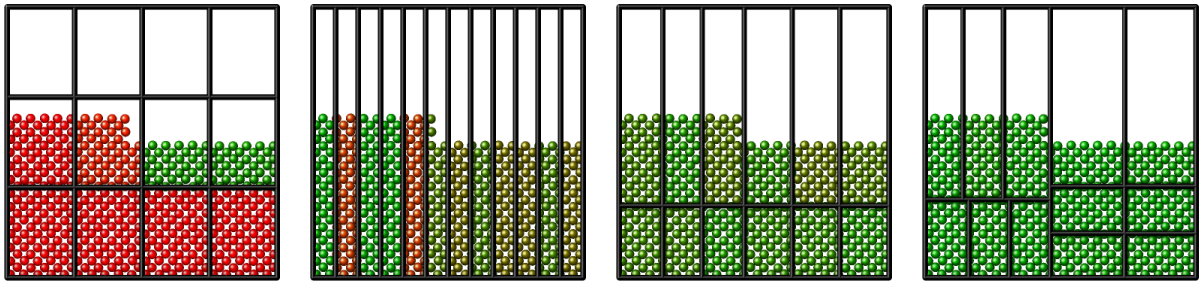

This figure shows the different kinds of domain decomposition used for MPI parallelization: "brick" on the left with an orthogonal (left) and a triclinic (middle) simulation domain, and a "tiled" decomposition (right). The black lines show the division into subdomains, and the contained atoms are "owned" by the corresponding MPI process. The green dashed lines indicate how subdomains are extended with "ghost" atoms up to the communication cutoff distance.

The LAMMPS simulation box is a 3d or 2d volume, which can be of orthogonal or triclinic shape, as illustrated in the *Domain decomposition schemes* figure for the 2d case. Orthogonal means the box edges are aligned with the x, y, z Cartesian axes, and the box faces are thus all rectangular. Triclinic allows for a more general parallelepiped shape in which edges are aligned with three arbitrary vectors and the box faces are parallelograms. In each dimension, box faces can be periodic, or non-periodic with fixed or shrink-wrapped boundaries. In the fixed case, atoms which move outside the face are deleted; shrink-wrapped means the position of the box face adjusts continuously to enclose all the atoms.

For distributed-memory MPI parallelism, the simulation box is spatially decomposed (partitioned) into non-overlapping subdomains which fill the box. The default partitioning, "brick", is most suitable when atom density is roughly uniform, as shown in the left-side images of the *Domain decomposition schemes* figure. The subdomains comprise a regular grid, and all subdomains are identical in size and shape. Both the orthogonal and triclinic boxes can deform continuously during a simulation, e.g. to compress a solid or shear a liquid, in which case the processor subdomains likewise deform.

For models with non-uniform density, the number of particles per processor can be load-imbalanced with the default partitioning. This reduces parallel efficiency, as the overall simulation rate is limited by the slowest processor, i.e. the one with the largest computational load. For such models, LAMMPS supports multiple strategies to reduce the load imbalance:

- The processor grid decomposition is by default based on the simulation cell volume and tries to optimize the volume to surface ratio for the subdomains. This can be changed with the *processors command*.
- The parallel planes defining the size of the subdomains can be shifted with the *balance command*. Which can be done in addition to choosing a more optimal processor grid.
- The recursive bisectioning algorithm in combination with the "tiled" communication style can produce a partitioning with equal numbers of particles in each subdomain.

The pictures above demonstrate different decompositions for a 2d system with 12 MPI ranks. The atom colors indicate the load imbalance of each subdomain, with green being optimal and red the least optimal.

Due to the vacuum in the system, the default decomposition is unbalanced, with several MPI ranks without atoms (left). By forcing a 1x12x1 processor grid, every MPI rank does computations now, but the number of atoms per subdomain is still uneven, and the thin slice shape increases the amount of communication between subdomains (center left). With a 2x6x1 processor grid and shifting the subdomain divisions, the load imbalance is further reduced and the amount of communication required between subdomains is less (center right). And using the recursive bisectioning leads to further improved decomposition (right).

4.4.2 Communication

Following the selected partitioning scheme, all per-atom data is distributed across the MPI processes, which allows LAMMPS to handle very large systems provided it uses a correspondingly large number of MPI processes. To be able to compute the short-range interactions, MPI processes need not only access to the data of atoms they "own" but also information about atoms from neighboring subdomains, in LAMMPS referred to as "ghost" atoms. These are copies of atoms storing required per-atom data for up to the communication cutoff distance. The green dashed-line boxes in the *Domain decomposition schemes* figure illustrate the extended ghost-atom subdomain for one processor.

This approach is also used to implement periodic boundary conditions: atoms that lie within the cutoff distance across a periodic boundary are also stored as ghost atoms and taken from the periodic replication of the subdomain, which may be the same subdomain, e.g. if running in serial. As a consequence of this, force computation in LAMMPS is not subject to minimum image conventions and thus cutoffs may be larger than half the simulation domain.

Efficient communication patterns are needed to update the "ghost" atom data, since that needs to be done at every MD time step or minimization step. The diagrams of the *ghost atom communication* figure illustrate how ghost atom communication is performed in two stages for a 2d simulation (three in 3d) for both a regular and irregular partitioning of the simulation box. For the regular case (left) atoms are exchanged first in the x-direction, then in y, with four neighbors in the grid of processor subdomains.

In the x stage, processor ranks 1 and 2 send owned atoms in their red-shaded regions to rank 0 (and vice versa). Then in the y stage, ranks 3 and 4 send atoms in their blue-shaded regions to rank 0, which includes ghost atoms they received in the x stage. Rank 0 thus acquires all its ghost atoms; atoms in the solid blue corner regions are communicated twice before rank 0 receives them.

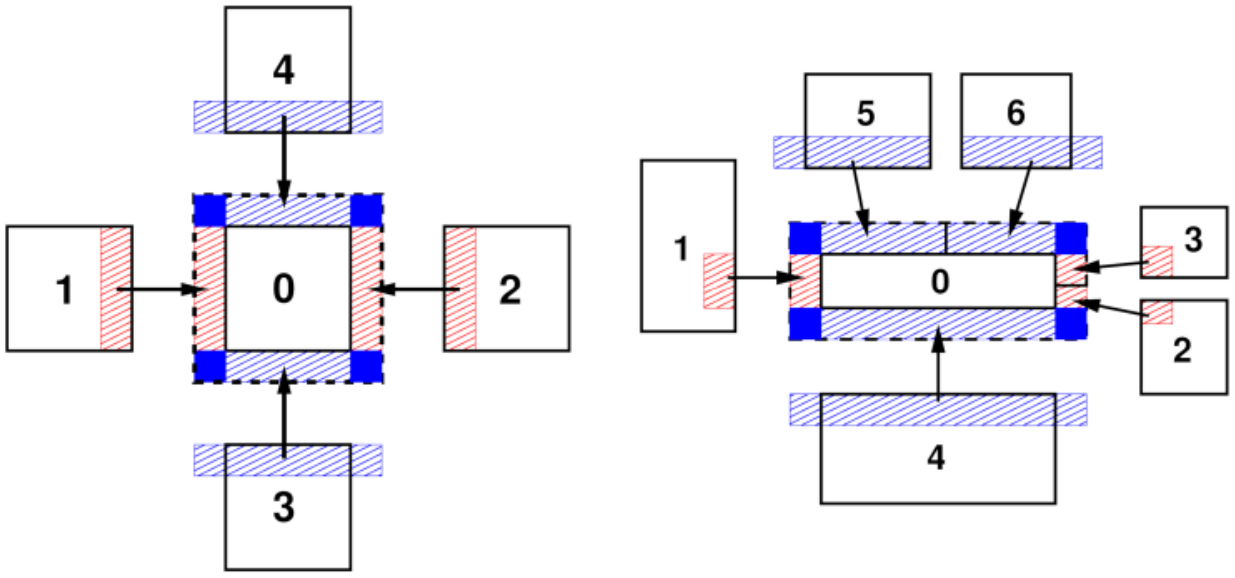

Fig. 3: ghost atom communication

This figure shows the ghost atom communication patterns between subdomains for "brick" (left) and "tiled" communication styles for 2d simulations. The numbers indicate MPI process ranks. Here the subdomains are drawn spatially separated for clarity. The dashed-line box is the extended subdomain of processor 0 which includes its ghost atoms. The red- and blue-shaded boxes are the regions of communicated ghost atoms.

For the irregular case (right) the two stages are similar, but a processor can have more than one neighbor in each direction. In the *x* stage, MPI ranks 1,2,3 send owned atoms in their red-shaded regions to rank 0 (and vice versa). These include only atoms between the lower and upper *y*-boundary of rank 0's subdomain. In the *y* stage, ranks 4,5,6 send atoms in their blue-shaded regions to rank 0. This may include ghost atoms they received in the *x* stage, but only if they are needed by rank 0 to fill its extended ghost atom regions in the +/-*y* directions (blue rectangles). Thus, in this case, ranks 5 and 6 do not include ghost atoms they received from each other (in the *x* stage) in the atoms they send to rank 0. The key point is that while the pattern of communication is more complex in the irregular partitioning case, it can still proceed in two stages (three in 3d) via atom exchanges with only neighboring processors.

When attributes of owned atoms are sent to neighboring processors to become attributes of their ghost atoms, LAMMPS calls this a "forward" communication. On timesteps when atoms migrate to new owning processors and neighbor lists are rebuilt, each processor creates a list of its owned atoms which are ghost atoms in each of its neighbor processors. These lists are used to pack per-atom coordinates (for example) into message buffers in subsequent steps until the next reneighboring.

A "reverse" communication is when computed ghost atom attributes are sent back to the processor who owns the atom. This is used (for example) to sum partial forces on ghost atoms to the complete force on owned atoms. The order of the two stages described in the *ghost atom communication* figure is inverted, and the same lists of atoms are used to pack and unpack message buffers with per-atom forces. When a received buffer is unpacked, the ghost forces are summed to owned atom forces. As in forward communication, forces on atoms in the four blue corners of the diagrams are sent, received, and summed twice (once at each stage) before owning processors have the full force.

These two operations are used in many places within LAMMPS aside from exchange of coordinates and forces, for example by manybody potentials to share intermediate per-atom values, or by rigid-body integrators to enable each atom in a body to access body properties. Here are additional details about how these communication operations are performed in LAMMPS:

- When exchanging data with different processors, forward and reverse communication is done using `MPI_Send()` and `MPI_IRecv()` calls. If a processor is "exchanging" atoms with itself, only the pack and unpack operations are performed, e.g. to create ghost atoms across periodic boundaries when running on a single processor.

- For forward communication of owned atom coordinates, periodic box lengths are added and subtracted when the receiving processor is across a periodic boundary from the sender. There is then no need to apply a minimum image convention when calculating distances between atom pairs when building neighbor lists or computing forces.
- The cutoff distance for exchanging ghost atoms is typically equal to the neighbor cutoff. But it can also set to a larger value if needed, e.g. half the diameter of a rigid body composed of multiple atoms or over 3x the length of a stretched bond for dihedral interactions. It can also exceed the periodic box size. For the regular communication pattern (left), if the cutoff distance extends beyond a neighbor processor's subdomain, then multiple exchanges are performed in the same direction. Each exchange is with the same neighbor processor, but buffers are packed/unpacked using a different list of atoms. For forward communication, in the first exchange, a processor sends only owned atoms. In subsequent exchanges, it sends ghost atoms received in previous exchanges. For the irregular pattern (right) overlaps of a processor's extended ghost-atom subdomain with all other processors in each dimension are detected.

4.4.3 Neighbor lists

To compute forces efficiently, each processor creates a Verlet-style neighbor list which enumerates all pairs of atoms *i,j* (*i* = owned, *j* = owned or ghost) with separation less than the applicable neighbor list cutoff distance. In LAMMPS, the neighbor lists are stored in a multiple-page data structure; each page is a contiguous chunk of memory which stores vectors of neighbor atoms *j* for many *i* atoms. This allows pages to be incrementally allocated or deallocated in blocks as needed. Neighbor lists typically consume the most memory of any data structure in LAMMPS. The neighbor list is rebuilt (from scratch) once every few timesteps, then used repeatedly each step for force or other computations. The neighbor cutoff distance is $R_n = R_f + \Delta_s$, where R_f is the (largest) force cutoff defined by the interatomic potential for computing short-range pairwise or manybody forces and Δ_s is a "skin" distance that allows the list to be used for multiple steps assuming that atoms do not move very far between consecutive time steps. Typically, the code triggers reneighboring when any atom has moved half the skin distance since the last reneighboring; this and other options of the neighbor list rebuild can be adjusted with the *neigh_modify* command.

On steps when reneighboring is performed, atoms which have moved outside their owning processor's subdomain are first migrated to new processors via communication. Periodic boundary conditions are also (only) enforced on these steps to ensure each atom is re-assigned to the correct processor. After migration, the atoms owned by each processor are stored in a contiguous vector. Periodically, each processor spatially sorts owned atoms within its vector to reorder it for improved cache efficiency in force computations and neighbor list building. For that, atoms are spatially binned and then reordered so that atoms in the same bin are adjacent in the vector. Atom sorting can be disabled or its settings modified with the *atom_modify* command.

To build a local neighbor list in linear time, the simulation domain is overlaid (conceptually) with a regular 3d (or 2d) grid of neighbor bins, as shown in the *neighbor list stencils* figure for 2d models and a single MPI processor's subdomain. Each processor stores a set of neighbor bins which overlap its subdomain, extended by the neighbor cutoff distance R_n. As illustrated, the bins need not align with processor boundaries; an integer number in each dimension is fit to the size of the entire simulation box.

Most often, LAMMPS builds what is called a "half" neighbor list where each *i,j* neighbor pair is stored only once, with either atom *i* or *j* as the central atom. The build can be done efficiently by using a pre-computed "stencil" of bins around a central origin bin which contains the atom whose neighbors are being searched for. A stencil is simply a list of integer offsets in *x,y,z* of nearby bins surrounding the origin bin which are close enough to contain any neighbor atom *j* within a distance R_n from any atom *i* in the origin bin. Note that for a half neighbor list, the stencil can be asymmetric, since each atom only need store half its nearby neighbors.

These stencils are illustrated in the figure for a half list and a bin size of $\frac{1}{2}R_n$. There are 13 red+blue stencil bins in 2d (for the orthogonal case, 15 for triclinic). In 3d there would be 63, 13 in the plane of bins that contain the origin bin and 25 in each of the two planes above it in the *z* direction (75 for triclinic). The triclinic stencil has extra bins because the bins tile the bounding box of the entire triclinic domain, and thus are not periodic with respect to the simulation box itself. The stencil and logic for determining which *i,j* pairs to include in the neighbor list are altered slightly to account for this.

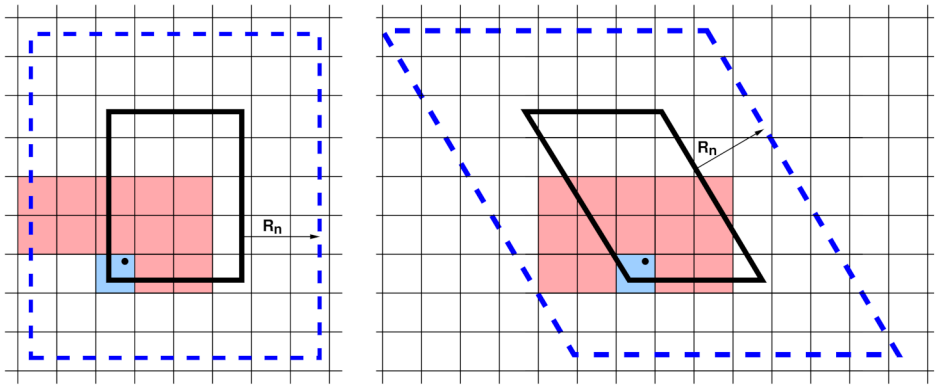

Fig. 4: neighbor list stencils

A 2d simulation subdomain (thick black line) and the corresponding ghost atom cutoff region (dashed blue line) for both orthogonal (left) and triclinic (right) domains. A regular grid of neighbor bins (thin lines) overlays the entire simulation domain and need not align with subdomain boundaries; only the portion overlapping the augmented subdomain is shown. In the triclinic case, it overlaps the bounding box of the tilted rectangle. The blue- and red-shaded bins represent a stencil of bins searched to find neighbors of a particular atom (black dot).

To build a neighbor list, a processor first loops over its "owned" plus "ghost" atoms and assigns each to a neighbor bin. This uses an integer vector to create a linked list of atom indices within each bin. It then performs a triply-nested loop over its owned atoms i, the stencil of bins surrounding atom i's bin, and the j atoms in each stencil bin (including ghost atoms). If the distance $r_{ij} < R_n$, then atom j is added to the vector of atom i's neighbors.

Here are additional details about neighbor list build options LAMMPS supports:

- The choice of bin size is an option; a size half of R_n has been found to be optimal for many typical cases. Smaller bins incur additional overhead to loop over; larger bins require more distance calculations. Note that for smaller bin sizes, the 2d stencil in the figure would be of a more semicircular shape (hemispherical in 3d), with bins near the corners of the square eliminated due to their distance from the origin bin.
- Depending on the interatomic potential(s) and other commands used in an input script, multiple neighbor lists and stencils with different attributes may be needed. This includes lists with different cutoff distances, e.g. for force computation versus occasional diagnostic computations such as a radial distribution function, or for the r-RESPA time integrator which can partition pairwise forces by distance into subsets computed at different time intervals. It includes "full" lists (as opposed to half lists) where each i,j pair appears twice, stored once with i and j, and which use a larger symmetric stencil. It also includes lists with partial enumeration of ghost atom neighbors. The full and ghost-atom lists are used by various manybody interatomic potentials. Lists may also use different criteria for inclusion of a pairwise interaction. Typically, this simply depends only on the distance between two atoms and the cutoff distance. But for finite-size coarse-grained particles with individual diameters (e.g. polydisperse granular particles), it can also depend on the diameters of the two particles.
- When using *pair style hybrid* multiple sub-lists of the master neighbor list for the full system need to be generated, one for each sub-style, which contains only the i,j pairs needed to compute interactions between subsets of atoms for the corresponding potential. This means, not all i or j atoms owned by a processor are included in a particular sub-list.
- Some models use different cutoff lengths for pairwise interactions between different kinds of particles, which are stored in a single neighbor list. One example is a solvated colloidal system with large colloidal particles where colloid/colloid, colloid/solvent, and solvent/solvent interaction cutoffs can be dramatically different. Another is a model of polydisperse finite-size granular particles; pairs of particles interact only when they are in contact with each other. Mixtures with particle size ratios as high as 10-100x may be used to model realistic systems. Efficient neighbor list building algorithms for these kinds of systems are available in LAMMPS. They include a method which uses different stencils for different cutoff lengths and trims the stencil to only include bins that straddle the cutoff sphere surface. More recently a method which uses both multiple stencils and multiple bin sizes was devel-

oped; it builds neighbor lists efficiently for systems with particles of any size ratio, though other considerations (timestep size, force computations) may limit the ability to model systems with huge polydispersity.

- For small and sparse systems and as a fallback method, LAMMPS also supports neighbor list construction without binning by using a full $O(N^2)$ loop over all *i,j* atom pairs in a subdomain when using the *neighbor nsq* command.
- Dependent on the "pair" setting of the *newton* command, the "half" neighbor lists may contain **all** pairs of atoms where atom *j* is a ghost atom (i.e. when the newton pair setting is *off*). For the newton pair *on* setting the atom *j* is only added to the list if its *z* coordinate is larger, or if equal the *y* coordinate is larger, and that is equal, too, the *x* coordinate is larger. For homogeneously dense systems, that will result in picking neighbors from a same size sector in always the same direction relative to the "owned" atom, and thus it should lead to similar length neighbor lists and reduce the chance of a load imbalance.

4.4.4 Long-range interactions

For charged systems, LAMMPS can compute long-range Coulombic interactions via the FFT-based particle-particle/particle-mesh (PPPM) method implemented in *kspace style pppm and its variants*. For that Coulombic interactions are partitioned into short- and long-range components. The short-ranged portion is computed in real space as a loop over pairs of charges within a cutoff distance, using neighbor lists. The long-range portion is computed in reciprocal space using a kspace style. For the PPPM implementation the simulation cell is overlaid with a regular FFT grid in 3d. It proceeds in several stages:

a) each atom's point charge is interpolated to nearby FFT grid points,

b) a forward 3d FFT is performed,

c) a convolution operation is performed in reciprocal space,

d) one or more inverse 3d FFTs are performed, and

e) electric field values from grid points near each atom are interpolated to compute its forces.

For any of the spatial-decomposition partitioning schemes each processor owns the brick-shaped portion of FFT grid points contained within its subdomain. The two interpolation operations use a stencil of grid points surrounding each atom. To accommodate the stencil size, each processor also stores a few layers of ghost grid points surrounding its brick. Forward and reverse communication of grid point values is performed similar to the corresponding *atom data communication*. In this case, electric field values on owned grid points are sent to neighboring processors to become ghost point values. Likewise charge values on ghost points are sent and summed to values on owned points.

For triclinic simulation boxes, the FFT grid planes are parallel to the box faces, but the mapping of charge and electric field values to/from grid points is done in reduced coordinates where the tilted box is conceptually a unit cube, so that the stencil and FFT operations are unchanged. However the FFT grid size required for a given accuracy is larger for triclinic domains than it is for orthogonal boxes.

Parallel 3d FFTs require substantial communication relative to their computational cost. A 3d FFT is implemented by a series of 1d FFTs along the *x*-, *y*-, and *z*-direction of the FFT grid. Thus, the FFT grid cannot be decomposed like atoms into 3 dimensions for parallel processing of the FFTs but only in 1 (as planes) or 2 (as pencils) dimensions and in between the steps the grid needs to be transposed to have the FFT grid portion "owned" by each MPI process complete in the direction of the 1d FFTs it has to perform. LAMMPS uses the pencil-decomposition algorithm as shown in the *Parallel FFT in PPPM* figure.

Initially (far left), each processor owns a brick of same-color grid cells (actually grid points) contained within in its subdomain. A brick-to-pencil communication operation converts this layout to 1d pencils in the *x*-dimension (center left). Again, cells of the same color are owned by the same processor. Each processor can then compute a 1d FFT on each pencil of data it wholly owns using a call to the configured FFT library. A pencil-to-pencil communication then converts this layout to pencils in the *y* dimension (center right) which effectively transposes the *x* and *y* dimensions of the grid, followed by 1d FFTs in *y*. A final transpose of pencils from *y* to *z* (far right) followed by 1d FFTs in *z* completes the forward FFT. The data is left in a *z*-pencil layout for the convolution operation. One or more inverse FFTs then perform the sequence of 1d FFTs and communication steps in reverse order; the final layout of resulting grid values is the same as the initial brick layout.

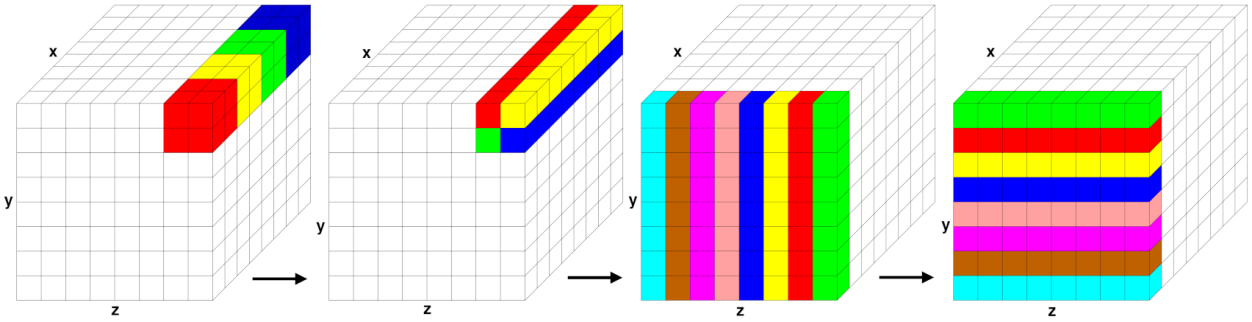

Fig. 5: Parallel FFT in PPPM

Stages of a parallel FFT for a simulation domain overlaid with an 8x8x8 3d FFT grid, partitioned across 64 processors. Within each of the 4 diagrams, grid cells of the same color are owned by a single processor; for simplicity, only cells owned by 4 or 8 of the 64 processors are colored. The two images on the left illustrate brick-to-pencil communication. The two images on the right illustrate pencil-to-pencil communication, which in this case transposes the y and z dimensions of the grid.

Each communication operation within the FFT (brick-to-pencil or pencil-to-pencil or pencil-to-brick) converts one tiling of the 3d grid to another, where a tiling in this context means an assignment of a small brick-shaped subset of grid points to each processor, the union of which comprise the entire grid. The parallel fftMPI library written for LAMMPS allows arbitrary definitions of the tiling so that an irregular partitioning of the simulation domain can use it directly. Transforming data from one tiling to another is implemented in *fftMPI* using point-to-point communication, where each processor sends data to a few other processors, since each tile in the initial tiling overlaps with a handful of tiles in the final tiling.

The transformations could also be done using collective communication across all P processors with a single call to `MPI_Alltoall()`, but this is typically much slower. However, for the specialized brick and pencil tiling illustrated in *Parallel FFT in PPPM* figure, collective communication across the entire MPI communicator is not required. In the example, an 8^3 grid with 512 grid cells is partitioned across 64 processors; each processor owns a 2x2x2 3d brick of grid cells. The initial brick-to-pencil communication (upper left to upper right) only requires collective communication within subgroups of 4 processors, as illustrated by the 4 colors. More generally, a brick-to-pencil communication can be performed by partitioning P processors into $P^{\frac{2}{3}}$ subgroups of $P^{\frac{1}{3}}$ processors each. Each subgroup performs collective communication only within its subgroup. Similarly, pencil-to-pencil communication can be performed by partitioning P processors into $P^{\frac{1}{2}}$ subgroups of $P^{\frac{1}{2}}$ processors each. This is illustrated in the figure for the $y \Rightarrow z$ communication (center). An eight-processor subgroup owns the front yz plane of data and performs collective communication within the subgroup to transpose from a y-pencil to z-pencil layout.

LAMMPS invokes point-to-point communication by default, but also provides the option of partitioned collective communication when using a *kspace_modify collective yes* command to switch to that mode. In the latter case, the code detects the size of the disjoint subgroups and partitions the single P-size communicator into multiple smaller communicators, each of which invokes collective communication. Testing on a large IBM Blue Gene/Q machine at Argonne National Labs showed a significant improvement in FFT performance for large processor counts; partitioned collective communication was faster than point-to-point communication or global collective communication involving all P processors.

Here are some additional details about FFTs for long-range and related grid/particle operations that LAMMPS supports:

- The fftMPI library allows each grid dimension to be a multiple of small prime factors (2,3,5), and allows any number of processors to perform the FFT. The resulting brick and pencil decompositions are thus not always as well-aligned, but the size of subgroups of processors for the two modes of communication (brick/pencil and pencil/pencil) still scale as $O(P^{\frac{1}{3}})$ and $O(P^{\frac{1}{2}})$.
- For efficiency in performing 1d FFTs, the grid transpose operations illustrated in Figure *Parallel FFT in PPPM* also involve reordering the 3d data so that a different dimension is contiguous in memory. This reordering can

be done during the packing or unpacking of buffers for MPI communication.

- For large systems and particularly many MPI processes, the dominant cost for parallel FFTs is often the communication, not the computation of 1d FFTs, even though the latter scales as $N \log(N)$ in the number of grid points N per grid direction. This is due to the fact that only a 2d decomposition into pencils is possible while atom data (and their corresponding short-range force and energy computations) can be decomposed efficiently in 3d.

  Reducing the number of MPI processes involved in the MPI communication will reduce this kind of overhead. By using a *hybrid MPI + OpenMP parallelization* it is still possible to use all processes for parallel computation. It will use OpenMP parallelization inside the MPI domains. While that may have a lower parallel efficiency for some part of the computation, that can be less than the communication overhead in the 3d FFTs.

  As an alternative, it is also possible to start a *multi-partition* calculation and then use the *verlet/split integrator* to perform the PPPM computation on a dedicated, separate partition of MPI processes. This uses an integer "1:p" mapping of p subdomains of the atom decomposition to one subdomain of the FFT grid decomposition and where pairwise non-bonded and bonded forces and energies are computed on the larger partition and the PPPM kspace computation concurrently on the smaller partition.

- LAMMPS also implements PPPM-based solvers for other long-range interactions, dipole and dispersion (Lennard-Jones), which can be used in conjunction with long-range Coulombics for point charges.

- LAMMPS implements a `GridComm` class which overlays the simulation domain with a regular grid, partitions it across processors in a manner consistent with processor subdomains, and provides methods for forward and reverse communication of owned and ghost grid point values. It is used for PPPM as an FFT grid (as outlined above) and also for the MSM algorithm, which uses a cascade of grid sizes from fine to coarse to compute long-range Coulombic forces. The GridComm class is also useful for models where continuum fields interact with particles. For example, the two-temperature model (TTM) defines heat transfer between atoms (particles) and electrons (continuum gas) where spatial variations in the electron temperature are computed by finite differences of a discretized heat equation on a regular grid. The *fix ttm/grid* command uses the `GridComm` class internally to perform its grid operations on a distributed grid instead of the original *fix ttm* which uses a replicated grid.

4.4.5 OpenMP Parallelism

The styles in the INTEL, KOKKOS, and OPENMP packages offer to use OpenMP thread parallelism to predominantly distribute loops over local data and thus follow an orthogonal parallelization strategy to the decomposition into spatial domains used by the *MPI partitioning*. For clarity, this section discusses only the implementation in the OPENMP package, as it is the simplest. The INTEL and KOKKOS packages offer additional options and are significantly more complex since they support more features like vectorization, accelerator support and a choice of using double, single, and mixed precision floating-point math.

A practical discussion of the actual implementation with source code examples can be found in the manual section on *writing styles for the OPENMP package*.

Rationale for OpenMP Integration

While LAMMPS is already well-parallelized using MPI-based domain decomposition, OpenMP provides additional benefits, particularly on modern multi-core hardware and at high node counts:

- **Efficient Resource Utilization**: On multi-core machines, MPI tasks can be communication-bandwidth limited because all MPI communication has to share the same network link for communication between nodes. Running fewer MPI tasks and using OpenMP threads can improve performance by reducing communication overhead and memory contention. However, the in-node memory bandwidth demands for multi-threading are higher, since domain decomposition promotes CPU cache locality, while the multi-thread implementation uses replicated per-thread storage to avoid data races. This has the additional overhead or requiring a reduction, which is most efficient for small numbers of threads.

- **PPPM Scaling**: Long-range electrostatics solvers like PPPM have scaling limitations with MPI communication at high node counts because the 3d-FFTs require all-to-all communications and with smaller domains the ratio

of computation versus communication become less favorable. Using OpenMP threads can allow running these solvers on a subset of MPI tasks, improving overall scaling.

- **Parallelization Granularity**: OpenMP allows parallelization over particles/neighbors within a node, providing a finer grain of parallelism than domain decomposition alone.
- **Load Balancing Considerations**: The domain decomposition based MPI parallelization implicitly assumes that the simulated system is homogeneous and thus roughly the same amount of work needs to be done by each MPI rank. However, for inhomogeneous systems, this is not always the case and the available load-balancing options have limitations, too. By shifting the parallelization to OpenMP, the subdomains per MPI rank become larger and load balancing is usually more effective then.
- **Capability Computing**: Hybrid MPI+OpenMP is often essential for achieving optimal performance on large HPC clusters or supercomputers.

Design of the OPENMP Package

One of the key decisions when implementing the OPENMP package was to keep the changes to the source code small, so that it would be easier to maintain the code and keep it in sync with the non-threaded standard implementation. This is achieved by:

- **Inheritance**: Making the OPENMP version a derived class from the regular version (e.g. `PairLJCutOMP` from `PairLJCut`) and only overriding methods that are multi-threaded or need to be modified (similar to what was done before in the OPT package).
- **Minimal Modification**: Keeping the structure in the modified code very similar so that side-by-side comparisons are still useful.
- **Helper Classes**: Offloading multi-thread support functions into three separate classes:
  - `ThrOMP`: Provides multi-thread aware functionality like "_thr" variants of tally functions via multiple inheritance.
  - `ThrData`: Manages per-thread data structures to avoid "false sharing" slowdowns.
  - `FixOMP`: Manages the global multi-thread state and settings activated by the *package omp* command.

Avoiding data races

A key problem when implementing thread parallelism in an MD code is to avoid data races when updating accumulated per-atom properties like forces, energies, stresses, and torques. When interactions are computed, they always involve multiple atoms and thus there are race conditions when multiple threads want to update per-atom data of the same atoms.

Without a significant rewrite of the code, there are three main approaches to avoid data races.

- Use locks or **atomic operations** to guarantee that only one thread at a time updates per-thread data. This is most commonly used when the access conflicts are rare.
- Compute per-atom properties **multiple times** for all threads that "own" one or more atoms of a tuple and store only the data for those "owned" atom. This is most effective for a large number of threads and thus commonly used with GPU acceleration.
- Have **per-thread copies** of the per-atom data and update them independently and use a reduction to combine the per-thread data into the regular per-atom storage. This requires additional steps to set up, manage, clear, and combine the collected data.

The OPENMP package uses **replicated per-thread data structures** because this approach:

- retains the performance for the single-thread case unlike the other options,
- keeps the code maintainable and similar to the non-threaded version,

- and is most efficient for a small number of threads (2-8), which is a common use case, since OpenMP is typically the secondary parallelization option after MPI.

Loop scheduling

Multi-thread parallelization is applied by distributing (outer) loops statically across threads. Typically, this is the loop over local atoms *i* when processing *i,j* pairs of atoms from a neighbor list or the list of bonds, angles, dihedrals, or impropers. Since neighbor lists typically result in a similar number of neighbors per atom (for homogeneous systems), significant load imbalances across threads are uncommon.

Neighbor list parallelization

In addition to force computations, neighbor list generation is parallelized. Each thread operates on a different chunk of "owned" atoms and manages its own set of neighbor "pages" using an instance of the `MyPage` page allocator.

4.5 Accessing per-atom data

This page discusses how per-atom data is managed in LAMMPS, how it can be accessed, what communication patterns apply, and some of the utility functions that exist for a variety of purposes.

4.5.1 Owned and ghost atoms

As described on the *parallel partitioning algorithms* page, LAMMPS uses a domain decomposition of the simulation domain, either in a *brick* or *tiled* manner. Each MPI process *owns* exactly one subdomain and the atoms within it. To compute forces for tuples of atoms that are spread across sub-domain boundaries, also a "halo" of *ghost* atoms are maintained within the communication cutoff distance of its subdomain.

The total number of atoms is stored in *Atom::natoms* (within any typical class this can be referred to at *atom->natoms*). The number of *owned* (or "local" atoms) are stored in *Atom::nlocal*; the number of *ghost* atoms is stored in *Atom::nghost*. The sum of *Atom::nlocal* over all MPI processes should be *Atom::natoms*. This is by default regularly checked by the Thermo class, and if the sum does not match, LAMMPS stops with a "lost atoms" error. For convenience also the property *Atom::nmax* is available, this is the maximum of *Atom::nlocal* + *Atom::nghost* across all MPI processes.

Per-atom properties are either managed by the atom style, individual classes, or as custom arrays by the individual classes. If only access to *owned* atoms is needed, they are usually allocated to be of size *Atom::nlocal*, otherwise of size *Atom::nmax*. Please note that not all per-atom properties are available or updated on *ghost* atoms. For example, per-atom velocities are only updated with *comm_modify vel yes*.

4.5.2 Atom indexing

When referring to individual atoms, they may be indexed by their local *index*, their index in their *Atom::x* array. This is densely populated containing first all *owned* atoms (index < *Atom::nlocal*) and then all *ghost* atoms. The order of atoms in these arrays can change due to atoms migrating between between subdomains, atoms being added or deleted, or atoms being sorted for better cache efficiency. Atoms are globally uniquely identified by their *atom ID*. There may be multiple atoms with the same atom ID present, but only one of them may be an *owned* atom.

To find the local *index* of an atom, when the *atom ID* is known, the *Atom::map()* function may be used. It will return the local atom index or -1. If the returned value is between 0 (inclusive) and *Atom::nlocal* (exclusive) it is an *owned* or "local" atom; for larger values the atom is present as a ghost atom; for a value of -1, the atom is not present on the current subdomain at all.

If multiple atoms with the same tag exist in the same subdomain, they can be found via the *Atom::sametag* array. It points to the next atom index with the same tag or -1 if there are no more atoms with the same tag. The list will be exhaustive when starting with an index of an *owned* atom, since the atom IDs are unique, so there can only be one such atom. Example code to count atoms with same atom ID in a subdomain:

```
for (int i = 0; i < atom->nlocal; ++i) {
  int count = 0;
  while (sametag[i] >= 0) {
    i = sametag[i];
    ++count;
  }
  printf("Atom ID: %ld is present %d times\n", atom->tag[i], count);
}
```

4.5.3 Atom class versus AtomVec classes

The *Atom* class contains all kinds of flags and counters about atoms in the system and that includes pointers to **all** per-atom properties available for atoms. However, only a subset of these pointers are non-NULL and which those are depends on the atom style. For each atom style there is a corresponding *AtomVecXXX* class derived from the *AtomVec* base class, where the XXX indicates the atom style. This *AtomVecXXX* class will update the counters and per-atom pointers if atoms are added or removed to the system or migrate between subdomains.

4.6 Communication patterns

This page describes various inter-processor communication operations provided by LAMMPS, mostly in the core *Comm* class. These are operations for common tasks implemented using MPI library calls. They are used by other classes to perform communication of different kinds. These operations are useful to know about when writing new code for LAMMPS that needs to communicate data between processors.

4.6.1 Owned and ghost atoms

As described on the *parallel partitioning algorithms* page, LAMMPS spatially decomposes the simulation domain, either in a *brick* or *tiled* manner. Each processor (MPI task) owns atoms within its subdomain and additionally stores ghost atoms within a cutoff distance of its subdomain.

Forward and reverse communication

As described on the *parallel communication algorithms* page, the most common communication operations are first, *forward communication* which sends owned atom information from each processor to nearby processors to store with their ghost atoms. The need to do this communication arises when data from the owned atoms is updated (e.g. their positions) and this updated information needs to be **copied** to the corresponding ghost atoms.

And second, *reverse communication*, which sends ghost atom information from each processor to the owning processor to **accumulate** (sum) the values with the corresponding owned atoms. The need for this arises when data is computed and also stored with ghost atoms (e.g. forces when using a "half" neighbor list) and thus those terms need to be added to their corresponding atoms on the process where they are "owned" atoms. Please note, that with the *newton off* setting this does not happen and the neighbor lists are constructed so that these interactions are computed on both MPI processes containing one of the atoms and only the data pertaining to the local atom is stored.

The time-integration classes in LAMMPS invoke these operations each timestep via the *forward_comm()* and *reverse_comm()* methods in the *Comm* class. Which per-atom data is communicated depends on the currently used *atom style* and whether *comm_modify vel* setting is "no" (default) or "yes".

Similarly, *Pair* style classes can invoke the *forward_comm(this)* and *reverse_comm(this)* methods in the *Comm* class to perform the same operations on per-atom data that is generated and stored within the pair style class. Note that this function requires passing the `this` pointer as the first argument to enable the *Comm* class to call the "pack" and "unpack" functions discussed below. An example of the use of these functions are many-body pair styles like the embedded-atom method (EAM) which compute intermediate values in the first part of the compute() function that need to be stored by both owned and ghost atoms for the second part of the force computation. The *Comm* class methods perform the MPI

communication for buffers of per-atom data. They "call back" to the *Pair* class, so it can *pack* or *unpack* the buffer with data the *Pair* class owns. There are 4 such methods that the *Pair* class must define, assuming it uses both forward and reverse communication:

- pack_forward_comm()
- unpack_forward_comm()
- pack_reverse_comm()
- unpack_reverse_comm()

The arguments to these methods include the buffer and a list of atoms to pack or unpack. The *Pair* class also must set the *comm_forward* and *comm_reverse* variables, which store the number of values stored in the communication buffers for each operation. This means, if desired, it can choose to store multiple per-atom values in the buffer, and they will be communicated together to minimize communication overhead. The communication buffers are defined vectors containing `double` values. To correctly store integers that may be 64-bit (bigint, tagint, imageint) in the buffer, you need to use the *ubuf union* construct.

The *Fix*, *Bond*, *Compute*, and *Dump* classes can also invoke the same kind of forward and reverse communication operations using the same *Comm* class methods. Likewise, the same pack/unpack methods and comm_forward/comm_reverse variables must be defined by the calling *Fix*, *Bond*, *Compute*, or *Dump* class.

For all of these classes, there is an optional second argument to the *forward_comm()* and *reverse_comm()* call which can be used when the class performs multiple modes of communication, with different numbers of values per atom. The class should set the *comm_forward* and *comm_reverse* variables to the maximum value, but can invoke the communication for a particular mode with a smaller value. For this to work, the *pack_forward_comm()*, etc. methods typically use a class member variable to choose which values to pack/unpack into/from the buffer.

Finally, for reverse communications in *Fix* classes there is also the *reverse_comm_variable()* method that allows the communication to have a different amount of data per-atom. It invokes these corresponding callback methods:

- pack_reverse_comm_size()
- unpack_reverse_comm_size()

which have extra arguments to specify the amount of data stored in the buffer for each atom.

4.6.2 Higher level communication

There are also several higher-level communication operations provided in LAMMPS which work for either *brick* or *tiled* decompositions. They may be useful for a new class to invoke if it requires more sophisticated communication than the *forward* and *reverse* methods provide. The 3 communication operations described here are

- ring
- irregular
- rendezvous

You can invoke these *grep* command in the LAMMPS src directory, to see a list of classes that invoke the 3 operations.

- `grep "\->ring" *.cpp */*.cpp`
- `grep "irregular\->" *.cpp`
- `grep "\->rendezvous" *.cpp */*.cpp`

Ring operation

The *ring* operation is invoked via the *ring()* method in the *Comm* class.

Each processor first creates a buffer with a list of values, typically associated with a subset of the atoms it owns. Now think of the *P* processors as connected to each other in a *ring*. Each processor *M* sends data to the next *M+1* processor. It receives data from the preceding *M-1* processor. The ring is periodic so that the last processor sends to the first processor, and the first processor receives from the last processor.

Invoking the *ring()* method passes each processor's buffer in *P* steps around the ring. At each step a *callback* method, provided as an argument to ring(), in the caller is invoked. This allows each processor to examine the data buffer provided by every other processor. It may extract values needed by its atoms from the buffers, or it may alter placeholder values in the buffer. In the latter case, when the *ring* operation is complete, each processor can examine its original buffer to extract modified values.

Note that the *ring* operation is similar to an MPI_Alltoall() operation, where every processor effectively sends and receives data to every other processor. The difference is that the *ring* operation does it one step at a time, so the total volume of data does not need to be stored by every processor. However, the *ring* operation is also less efficient than MPI_Alltoall() because of the *P* stages required. So it is typically only suitable for small data buffers and occasional operations that are not time-critical.

Irregular operation

The *irregular* operation is provided by the *Irregular* class. What LAMMPS terms irregular communication is when each processor knows what data it needs to send to what processor, but does not know what processors are sending it data. An example is when load-balancing is performed and each processor needs to send some of its atoms to new processors.

The *Irregular* class provides 5 high-level methods useful in this context:

- create_data()
- exchange_data()
- create_atom()
- exchange_atom()
- migrate_atoms()

For the *create_data()* method, each processor specifies a list of *N* datums to send, each to a specified processor. Internally, the method creates efficient data structures for performing the communication. The *exchange_data()* method triggers the communication to be performed. Each processor provides the vector of *N* datums to send, and the size of each datum. All datums must be the same size.

The *create_atom()* and *exchange_atom()* methods are similar, except that the size of each datum can be different. Typically, this is used to communicate atoms, each with a variable amount of per-atom data, to other processors.

The *migrate_atoms()* method is a convenience wrapper on the *create_atom()* and *exchange_atom()* methods to simplify communication of all the per-atom data associated with an atom so that the atom can effectively migrate to a new owning processor. It is similar to the *exchange()* method in the *Comm* class invoked when atoms move to neighboring processors (in the regular or tiled decomposition) during timestepping, except that it allows atoms to have moved arbitrarily long distances and still be properly communicated to a new owning processor.

Rendezvous operation

Finally, the *rendezvous* operation is invoked via the *rendezvous()* method in the *Comm* class. Depending on how much communication is needed and how many processors a LAMMPS simulation is running on, it can be a much more efficient choice than the *ring()* method. It uses the *irregular* operation internally once or twice to do its communication. The rendezvous algorithm is described in detail in *(Plimpton)*, including some LAMMPS use cases.

For the *rendezvous()* method, each processor specifies a list of *N* datums to send and which processor to send each of them to. Internally, this communication is performed as an irregular operation. The received datums are returned to the caller via invocation of *callback* function, provided as an argument to *rendezvous()*. The caller can then process the received datums and (optionally) assemble a new list of datums to communicate to a new list of specific processors. When the callback function exits, the *rendezvous()* method performs a second irregular communication on the new list of datums.

Examples in LAMMPS of use of the *rendezvous* operation are the *fix rigid/small* and *fix shake* commands (for one-time identification of the rigid body atom clusters) and the identification of special_bond 1-2, 1-3 and 1-4 neighbors within molecules. See the *special_bonds* command for context.

(Plimpton) Plimpton and Knight, JPDC, 147, 184-195 (2021).

4.7 How a timestep works

The first and most fundamental operation within LAMMPS to understand is how a timestep is structured. Timestepping is performed by calling methods of the Integrate class instance within the Update class. Since Integrate is a base class, it will point to an instance of a derived class corresponding to what is selected by the *run_style* input script command.

In this section, the timestep implemented by the Verlet class is described. A similar timestep protocol is implemented by the Respa class, for the r-RESPA hierarchical timestepping method.

The Min base class performs energy minimization, so does not perform a literal timestep. But it has logic similar to what is described here, to compute forces and invoke fixes at each iteration of a minimization. Differences between time integration and minimization are highlighted at the end of this section.

The Verlet class is encoded in the `src/verlet.cpp` and `verlet.h` files. It implements the velocity-Verlet timestepping algorithm. The workhorse method is `Verlet::run()`, but first we highlight several other methods in the class.

- The `init()` method is called at the beginning of each dynamics run. It simply sets some internal flags, based on user settings in other parts of the code.
- The `setup()` or `setup_minimal()` methods are also called before each run. The velocity-Verlet method requires current forces be calculated before the first timestep, so these routines compute forces due to all atomic interactions, using the same logic that appears in the timestepping described next. A few fixes are also invoked, using the mechanism described in the next section. Various counters are also initialized before the run begins. The `setup_minimal()` method is a variant that has a flag for performing less setup. This is used when runs are continued and information from the previous run is still valid. For example, if repeated short LAMMPS runs are being invoked, interleaved by other commands, via the *pre no* and *every* options of the run command, the `setup_minimal()` method is used.
- The `force_clear()` method initializes force and other arrays to zero before each timestep, so that forces (torques, etc) can be accumulated.

Now for the `Verlet::run()` method. Its basic structure in hi-level pseudocode is shown below. In the actual code in `src/verlet.cpp` some of these operations are conditionally invoked.

```
loop over N timesteps:
  if timeout condition: break
  ev_set()

  fix->initial_integrate()
  fix->post_integrate()

  nflag = neighbor->decide()
  if nflag:
```

(continues on next page)

(continued from previous page)

```
    fix->pre_exchange()
    domain->pbc()
    domain->reset_box()
    comm->setup()
    neighbor->setup_bins()
    comm->exchange()
    comm->borders()
    fix->pre_neighbor()
    neighbor->build()
    fix->post_neighbor()
  else:
    comm->forward_comm()

  force_clear()
  fix->pre_force()

  pair->compute()
  bond->compute()
  angle->compute()
  dihedral->compute()
  improper->compute()
  kspace->compute()

  fix->pre_reverse()
  comm->reverse_comm()

  fix->post_force()
  fix->final_integrate()
  fix->end_of_step()

  if any output on this step:
    output->write()

# after loop
fix->post_run()
```

The `ev_set()` method (in the parent Integrate class), sets two flags (*eflag* and *vflag*) for energy and virial computation. Each flag encodes whether global and/or per-atom energy and virial should be calculated on this timestep, because some fix or variable or output will need it. These flags are passed to the various methods that compute particle interactions, so that they either compute and tally the corresponding data or can skip the extra calculations if the energy and virial are not needed. See the comments for the `Integrate::ev_set()` method, which document the flag values.

At various points of the timestep, fixes are invoked, e.g. `fix->initial_integrate()`. In the code, this is actually done via the Modify class, which stores all the Fix objects and lists of which should be invoked at what point in the timestep. Fixes are the LAMMPS mechanism for tailoring the operations of a timestep for a particular simulation. As described elsewhere, each fix has one or more methods, each of which is invoked at a specific stage of the timestep, as show in the timestep pseudocode. All the active fixes defined in an input script, that are flagged to have an `initial_integrate()` method, are invoked at the beginning of each timestep. Examples are *fix nve* or *fix nvt or fix npt* which perform the start-of-timestep velocity-Verlet integration operations to update velocities by a half-step, and coordinates by a full step. The `post_integrate()` method is next for operations that need to happen immediately after those updates. Only a few fixes use this, e.g. to reflect particles off box boundaries in the *FixWallReflect class*.

The `decide()` method in the Neighbor class determines whether neighbor lists need to be rebuilt on the current timestep (conditions can be changed using the *neigh_modify every/delay/check* command). If not, coordinates of ghost atoms

are acquired by each processor via the `forward_comm()` method of the Comm class. If neighbor lists need to be built, several operations within the inner if clause of the pseudocode are first invoked. The `pre_exchange()` method of any defined fixes is invoked first. Typically, this inserts or deletes particles from the system.

Periodic boundary conditions are then applied by the Domain class via its `pbc()` method to remap particles that have moved outside the simulation box back into the box. Note that this is not done every timestep, but only when neighbor lists are rebuilt. This is so that each processor's subdomain will have consistent (nearby) atom coordinates for its owned and ghost atoms. It is also why dumped atom coordinates may be slightly outside the simulation box if not dumped on a step where the neighbor lists are rebuilt.

The box boundaries are then reset (if needed) via the `reset_box()` method of the Domain class, e.g. if box boundaries are shrink-wrapped to current particle coordinates. A change in the box size or shape requires internal information for communicating ghost atoms (Comm class) and neighbor list bins (Neighbor class) to be updated. The `setup()` method of the Comm class and `setup_bins()` method of the Neighbor class perform the update.

The code is now ready to migrate atoms that have left a processor's geometric subdomain to new processors. The `exchange()` method of the Comm class performs this operation. The `borders()` method of the Comm class then identifies ghost atoms surrounding each processor's subdomain and communicates ghost atom information to neighboring processors. It does this by looping over all the atoms owned by a processor to make lists of those to send to each neighbor processor. On subsequent timesteps, the lists are used by the `Comm::forward_comm()` method.

Fixes with a `pre_neighbor()` method are then called. These typically re-build some data structure stored by the fix that depends on the current atoms owned by each processor.

Now that each processor has a current list of its owned and ghost atoms, LAMMPS is ready to rebuild neighbor lists via the `build()` method of the Neighbor class. This is typically done by binning all owned and ghost atoms, and scanning a stencil of bins around each owned atom's bin to make a Verlet list of neighboring atoms within the force cutoff plus neighbor skin distance.

In the next portion of the timestep, all interaction forces between particles are computed, after zeroing the per-atom force vector via the `force_clear()` method. If the newton flag is set to *on* by the newton command, forces are added to both owned and ghost atoms, otherwise only to owned (aka local) atoms.

Pairwise forces are calculated first, which enables the global virial (if requested) to be calculated cheaply (at O(N) cost instead of O(N**2) at the end of the `Pair::compute()` method), by a dot product of atom coordinates and forces. By including owned and ghost atoms in the dot product, the effect of periodic boundary conditions is correctly accounted for. Molecular topology interactions (bonds, angles, dihedrals, impropers) are calculated next (if supported by the current atom style). The final contribution is from long-range Coulombic interactions, invoked by the KSpace class.

The `pre_reverse()` method in fixes is used for operations that have to be done *before* the upcoming reverse communication (e.g. to perform additional data transfers or reductions for data computed during the force computation and stored with ghost atoms).

If the newton flag is on, forces on ghost atoms are communicated and summed back to their corresponding owned atoms. The `reverse_comm()` method of the Comm class performs this operation, which is essentially the inverse operation of sending copies of owned atom coordinates to other processor's ghost atoms.

At this point in the timestep, the total force on each (local) atom is known. Additional force constraints (external forces, SHAKE, etc) are applied by Fixes that have a `post_force()` method. The second half of the velocity-Verlet integration, `final_integrate()` is then performed (another half-step update of the velocities) via fixes like nve, nvt, npt.

At the end of the timestep, fixes that contain an `end_of_step()` method are invoked. These typically perform a diagnostic calculation, e.g. the ave/time and ave/chunk fixes. The final operation of the timestep is to perform any requested output, via the `write()` method of the Output class. There are 3 kinds of LAMMPS output: thermodynamic output to the screen and log file, snapshots of atom data to a dump file, and restart files. See the *thermo_style*, *dump*, and *restart* commands for more details.

The flow of control during energy minimization iterations is similar to that of a molecular dynamics timestep. Forces are computed, neighbor lists are built as needed, atoms migrate to new processors, and atom coordinates and forces

are communicated to neighboring processors. The only difference is what Fix class operations are invoked when. Only a subset of LAMMPS fixes are useful during energy minimization, as explained in their individual doc pages. The relevant Fix class methods are `min_pre_exchange()`, `min_pre_force()`, and `min_post_force()`. Each fix is invoked at the appropriate place within the minimization iteration. For example, the `min_post_force()` method is analogous to the `post_force()` method for dynamics; it is used to alter or constrain forces on each atom, which affects the minimization procedure.

After all iterations are completed, there is a `cleanup` step which calls the `post_run()` method of fixes to perform operations only required at the end of a calculation (like freeing temporary storage or creating final outputs).

4.8 Writing new styles

The *Modifying & extending LAMMPS* section of the manual gives an overview of how LAMMPS can be extended by writing new classes that derive from existing parent classes in LAMMPS. Here, some specific coding details are provided for writing code for LAMMPS.

4.8.1 Writing new pair styles

Pair styles are at the core of most simulations with LAMMPS, since they are used to compute the forces (plus energy and virial contributions, if needed) on atoms for pairs or small clusters of atoms within a given cutoff. This is often the dominant computation in LAMMPS, and sometimes even the only one. Pair styles can be grouped into multiple categories:

1. simple pairwise additive interactions of point particles (e.g. *Lennard-Jones*, *Morse*, *Buckingham*)
2. pairwise additive interactions of point particles with added *Coulomb* interactions or *only* the Coulomb interactions
3. manybody interactions of point particles (e.g. *EAM*, *Tersoff*)
4. complex interactions that include additional per-atom properties (e.g. Discrete Element Models (DEM), Peridynamics, Ellipsoids)
5. special purpose pair styles that may not even compute forces like *pair_style zero* and *pair_style tracker*, or are a wrapper for multiple kinds of interactions like *pair_style hybrid*, *pair_style list*, and *pair_style kim*

In the text below, we will discuss aspects of implementing pair styles in LAMMPS by looking at representative case studies. The design of LAMMPS allows developers to focus on the essentials, which is to compute the forces (and energies or virial contributions), enter and manage the global settings as well as the potential parameters, and the pair style specific parts of reading and writing restart and data files. Most of the complex tasks like management of the atom positions, domain decomposition and boundaries, or neighbor list creation are handled transparently by other parts of the LAMMPS code.

As shown on the page for *writing or extending pair styles*, in order to implement a new pair style, a new class must be written that is either directly or indirectly derived from the `Pair` class. If that class is directly derived from `Pair`, there are three methods that *must* be re-implemented, since they are "pure" in the base class: `Pair::compute()`, `Pair::settings()`, `Pair::coeff()`. In addition, a custom constructor is needed. All other methods are optional and have default implementations in the base class (most of which do nothing), but they may need to be overridden depending on the requirements of the model.

We are looking at the following cases:

- *Case 1: a pairwise additive model*
- *Case 2: a many-body potential*
- *Case 3: a potential requiring communication*
- *Case 4: potentials without a compute() function*

4.8.2 Package and build system considerations

In general, new pair styles should be added to the *EXTRA-PAIR package* unless they are an accelerated pair style and then they should be added to the corresponding accelerator package (*GPU*, *INTEL*, *KOKKOS*, *OPENMP*, *OPT*). If you feel that your contribution should be added to a different package, please consult with the LAMMPS developers first.

The contributed code needs to support the *traditional GNU make build process* **and** the *CMake build process*. For the GNU make process and if the package has an `Install.sh` file, most likely that file needs to be updated to correctly copy the sources when installing the package and properly delete them when uninstalling. This is particularly important when added a new pair style that is a derived class from an existing pair style in a package, so that its installation depends on the the installation status of the package of the derived class. For the CMake process, it is sometimes necessary to make changes to the package specific CMake scripting in `cmake/Modules/Packages`.

4.8.3 Case 1: a pairwise additive model

In this section, we will describe the procedure of adding a simple pair style to LAMMPS: an empirical model that can be used to model liquid mercury. The pair style shall be called *born/gauss* and the complete implementation can be found in the files `src/EXTRA-PAIR/pair_born_gauss.cpp` and `src/EXTRA-PAIR/pair_born_gauss.h` of the LAMMPS source code.

Model and general considerations

The functional form of the model according to *(Bomont)* consists of a repulsive Born-Mayer exponential term and a temperature dependent, attractive Gaussian term.

$$E = A_0 \exp\left(-\alpha r\right) - A_1 \exp\left[-\beta\left(r - r_0\right)^2\right]$$

For the application to mercury, the following parameters are listed:

- $A_0 = 8.2464 \times 10^{13}$ eV
- $\alpha = 12.48$ Å^{-1}
- $\beta = 0.44$ Å^{-2}
- $r_0 = 3.56$ Å
- A_1 is temperature dependent and can be determined from $A_1 = a_0 + a_1 T + a_2 T^2$ with:
  - $a_0 = 1.97475 \times 10^{-2}$ eV
  - $a_1 = 8.40841 \times 10^{-5}$ eV/K
  - $a_2 = -2.58717 \times 10^{-8}$ eV/K^{-2}

With the optional cutoff, this means we have a total of 5 or 6 parameters for each pair of atom types. Additionally, we need to input a default cutoff value as a global setting.

Because of the combination of Born-Mayer with a Gaussian, the pair style shall be named "born/gauss" and thus the class name would be `PairBornGauss` and the source files `pair_born_gauss.h` and `pair_born_gauss.cpp`. Since this is a rather uncommon potential, it shall be added to the *EXTRA-PAIR* package.

Header file

The first segment of any LAMMPS source should be the copyright and license statement. Note the marker in the first line to indicate to editors like emacs that this file is a C++ source, even though the .h extension suggests a C source (this is a convention inherited from the very beginning of the C++ version of LAMMPS).

```
/* -*- c++ -*- ----------------------------------------------------------
   LAMMPS - Large-scale Atomic/Molecular Massively Parallel Simulator
   https://www.lammps.org/, Sandia National Laboratories
   LAMMPS development team: developers@lammps.org

   Copyright (2003) Sandia Corporation.  Under the terms of Contract
   DE-AC04-94AL85000 with Sandia Corporation, the U.S. Government retains
   certain rights in this software.  This software is distributed under
   the GNU General Public License.

   See the README file in the top-level LAMMPS directory.
------------------------------------------------------------------------- */
```

Every pair style must be registered in LAMMPS by including the following lines of code in the second part of the header after the copyright message and before the include guards for the class definition:

```
#ifdef PAIR_CLASS
// clang-format off
PairStyle(born/gauss,PairBornGauss);
// clang-format on
#else

/* the definition of the PairBornGauss class (see below) is inserted here */

#endif
```

This block between `#ifdef PAIR_CLASS` and `#else` registers the pair style with LAMMPS. During compilation, the build system parses the `PairStyle(born/gauss,PairBornGauss)` marker and generates a file `style_pair.cpp` that `#includes` the header files of all "installed" pair styles and registers a "factory function" for each of them — a small function that creates an instance of the class and returns a pointer to it. These factory functions are kept in a process-global registry that connects the pair style name, "born/gauss", to the class `PairBornGauss` and enables the *pair_style command* to create the pair style instance. The `PAIR_CLASS` macro is never actually defined during compilation; the `#ifdef PAIR_CLASS` block only serves as a marker for the build system's parser, so the header always provides the class definition from its `#else` branch.

The list of header files to include is automatically updated by the build system if there are new files, so the presence of the new header file in the `src/EXTRA-PAIR` folder and the enabling of the EXTRA-PAIR package will trigger LAMMPS to include the new pair style when it is (re-)compiled. The "// clang-format" format comments are needed so that running *clang-format* on the file will not insert unwanted blanks between "born", "/", and "gauss" which would break the `PairStyle` macro.

The third part of the header file is the actual class definition of the `PairBornGauss` class. This has the prototypes for all member functions that will be implemented by this pair style. This includes *a few required and a number of optional functions*. All functions that were labeled in the base class as "virtual" must be given the "override" property, as it is done in the code shown below.

The "override" property helps to detect unexpected mismatches because compilation will stop with an error in case the signature of a function is changed in the base class without also changing it in all derived classes. For example, if this change added an optional argument with a default value, then all existing source code *calling* the function would not need changes and still compile, but the function in the derived class would no longer override the one in the base class due to the different number of arguments and the behavior of the pair style is thus changed in an unintended way. Using the "override" keyword prevents such issues.

```
#ifndef LMP_PAIR_BORN_GAUSS_H
#define LMP_PAIR_BORN_GAUSS_H
```

(continues on next page)

(continued from previous page)

```
#include "pair.h"

namespace LAMMPS_NS {

class PairBornGauss : public Pair {
 public:
  PairBornGauss(class LAMMPS *);
  ~PairBornGauss() override;

  void compute(int, int) override;
  void settings(int, char **) override;
  void coeff(int, char **) override;
  double init_one(int, int) override;

  void write_restart(FILE *) override;
  void read_restart(FILE *) override;
  void write_restart_settings(FILE *) override;
  void read_restart_settings(FILE *) override;
  void write_data(FILE *) override;
  void write_data_all(FILE *) override;

  double single(int, int, int, int, double, double, double, double &) override;
  void *extract(const char *, int &) override;
```

Also, variables and arrays for storing global settings and potential parameters are defined. Since these are internal to the class, they are placed after a "protected:" label.

```
 protected:
  double cut_global;
  double **cut;
  double **biga0, **alpha, **biga1, **beta, **r0;
  double **a0, **a1, **a2;
  double **offset;

  virtual void allocate();
};
}    // namespace LAMMPS_NS
#endif
```

Implementation file

We move on to the implementation of the `PairBornGauss` class in the `pair_born_gauss.cpp` file. This file also starts with a LAMMPS copyright and license header. Below that notice is typically the space where comments may be added with additional information about this specific file, the author(s), affiliation(s), and email address(es). This way the contributing author(s) can be easily contacted, when there are questions about the implementation later. Since the file(s) may be around for a long time, it is beneficial to use some kind of "permanent" email address, if possible.

```
/* ----------------------------------------------------------------------

------------------------------------------------------------------------- */

// Contributing author: Axel Kohlmeyer, Temple University, akohlmey@gmail.com

#include "pair_born_gauss.h"

#include "atom.h"
#include "comm.h"
#include "error.h"
#include "fix.h"
#include "force.h"
#include "memory.h"
#include "neigh_list.h"

#include <cmath>
#include <cstring>

using namespace LAMMPS_NS;
```

The second section of the implementation file has various include statements. The include file for the class header has to come first, then a block of LAMMPS classes (sorted alphabetically) followed by a block of system headers and others, if needed. Note the standardized C++ notation for headers of C-library functions (`cmath` instead of `math.h`). The final statement of this segment imports the `LAMMPS_NS::` namespace globally for this file. This way, all LAMMPS specific functions and classes do not have to be prefixed with `LAMMPS_NS::`.

Constructor and destructor (required)

The first two functions in the implementation source file are typically the constructor and the destructor.

Pair styles are different from most classes in LAMMPS that define a "style", as their constructor only uses the LAMMPS class instance pointer as an argument, but **not** the arguments of the *pair_style command*. Instead, those arguments are processed in the `Pair::settings()` function (or rather the version in the derived class). The constructor is the place where global defaults are set and specifically flags are set indicating which optional features of a pair style are available.

```
/* ---------------------------------------------------------------------- */

PairBornGauss::PairBornGauss(LAMMPS *lmp) : Pair(lmp)
{
  writedata = 1;
}
```

The *writedata = 1;* statement indicates that the pair style is capable of writing the current pair coefficient parameters to data files. That is, the class implements specific versions for `Pair::data()` and `Pair::data_all()`. Other statements that could be added here would be *single_enable = 1;* or *respa_enable = 0;* to indicate that the `Pair::single()` function is present and the `Pair::compute_(inner|middle|outer)` functions are not, but those are also the default settings and already set in the base class.

In the destructor, we need to delete all memory that was allocated by the pair style, usually to hold force field parameters that were entered with the *pair_coeff command*. Most of those array pointers will need to be declared in the derived class header, but some (e.g. setflag, cutsq) are already declared in the base class.

```
PairBornGauss::~PairBornGauss()
{
  if (allocated) {
    memory->destroy(setflag);
    memory->destroy(cutsq);
    memory->destroy(cut);
    memory->destroy(biga0);
    memory->destroy(alpha);
    memory->destroy(biga1);
    memory->destroy(beta);
    memory->destroy(r0);
    memory->destroy(offset);
  }
}
```

Settings and coefficients (required)

To enter the global pair style settings and the pair style parameters, the functions `Pair::settings()` and `Pair::coeff()` need to be re-implemented. The arguments to the `settings()` function are the arguments given to the *pair_style command*. Normally, those would already be processed as part of the constructor, but moving this to a separate function allows users to change global settings like the default cutoff without having to reissue all pair_coeff commands or re-read the `Pair Coeffs` sections from the data file. In the `settings()` function, also the arrays for storing parameters, to define cutoffs, track which pairs of parameters have been explicitly set and allocated and, if needed, initialized. In this case, the memory allocation and initialization are moved to a function `allocate()`.

```
/* ----------------------------------------------------------------------
   allocate all arrays
------------------------------------------------------------------------- */

void PairBornGauss::allocate()
{
  allocated = 1;
  int np1 = atom->ntypes + 1;

  memory->create(setflag, np1, np1, "pair:setflag");
  for (int i = 1; i < np1; i++)
    for (int j = i; j < np1; j++) setflag[i][j] = 0;

  memory->create(cutsq, np1, np1, "pair:cutsq");
  memory->create(cut, np1, np1, "pair:cut");
  memory->create(biga0, np1, np1, "pair:biga0");
  memory->create(alpha, np1, np1, "pair:alpha");
  memory->create(biga1, np1, np1, "pair:biga1");
  memory->create(beta, np1, np1, "pair:beta");
  memory->create(r0, np1, np1, "pair:r0");
  memory->create(offset, np1, np1, "pair:offset");
}

/* ----------------------------------------------------------------------
```

(continues on next page)

(continued from previous page)

```
   global settings
------------------------------------------------------------------------- */

void PairBornGauss::settings(int narg, char **arg)
{
  if (narg != 1) error->all(FLERR, "Pair style born/gauss must have exactly one argument
↪");
  cut_global = utils::numeric(FLERR, arg[0], false, lmp);

  // reset per-type pair cutoffs that have been explicitly set previously

  if (allocated) {
    for (int i = 1; i <= atom->ntypes; i++)
      for (int j = i; j <= atom->ntypes; j++)
        if (setflag[i][j]) cut[i][j] = cut_global;
  }
}
```

The arguments to the `coeff()` function are the arguments to the *pair_coeff command*. The function is also called when processing the `Pair Coeffs` or `PairIJ Coeffs` sections of data files. In the case of the `Pair Coeffs` section, there is only one atom type per line and thus the first argument is duplicated. Since the atom type arguments of the *pair_coeff command* may be a range (e.g. *3 for atom types 1, 2, and 3), the corresponding arguments are passed to the *utils::bounds()* function which will then return the low and high end of the range. Note that the `setflag` array is set to 1 for all pairs of atom types processed by this call. This information is later used in the `init_one()` function to determine if any coefficients are missing and, if supported by the potential, generate those missing coefficients from the selected mixing rule.

```
/* ----------------------------------------------------------------------
   set coeffs for one or more type pairs
------------------------------------------------------------------------- */

void PairBornGauss::coeff(int narg, char **arg)
{
  if (narg < 7 || narg > 8) error->all(FLERR, "Incorrect args for pair coefficients");
  if (!allocated) allocate();

  int ilo, ihi, jlo, jhi;
  utils::bounds(FLERR, arg[0], 1, atom->ntypes, ilo, ihi, error);
  utils::bounds(FLERR, arg[1], 1, atom->ntypes, jlo, jhi, error);

  double biga0_one = utils::numeric(FLERR, arg[2], false, lmp);
  double alpha_one = utils::numeric(FLERR, arg[3], false, lmp);
  double biga1_one = utils::numeric(FLERR, arg[4], false, lmp);
  double beta_one = utils::numeric(FLERR, arg[5], false, lmp);
  double r0_one = utils::numeric(FLERR, arg[6], false, lmp);
  double cut_one = cut_global;
  if (narg == 10) cut_one = utils::numeric(FLERR, arg[7], false, lmp);

  int count = 0;
  for (int i = ilo; i <= ihi; i++) {
    for (int j = MAX(jlo, i); j <= jhi; j++) {
      biga0[i][j] = biga0_one;
```

(continues on next page)

(continued from previous page)

```
      alpha[i][j] = alpha_one;
      biga1[i][j] = biga1_one;
      beta[i][j] = beta_one;
      r0[i][j] = r0_one;
      cut[i][j] = cut_one;
      setflag[i][j] = 1;
      count++;
    }
  }

  if (count == 0) error->all(FLERR, "Incorrect args for pair coefficients");
}
```

Initialization

The `init_one()` function is called during the *"init" phase* of a simulation. This is where potential parameters are checked for completeness, derived parameters computed (e.g. the "offset" of the potential energy at the cutoff distance for use with the *pair_modify shift yes* command). If a pair style supports generating "mixed" parameters (i.e. where both atoms of a pair have a different atom type) using a "mixing rule" from the parameters of the type with itself, this is the place to compute and store those mixed values. The *born/gauss* pair style does not support mixing, so we only check for completeness. Another purpose of the `init_one()` function is to symmetrize the potential parameter arrays. The return value of the function is the cutoff for the given pair of atom types. This information is used by the neighbor list code to determine the largest cutoff and then build the neighbor lists accordingly.

```
/* ----------------------------------------------------------------------
   init for one type pair i,j and corresponding j,i
------------------------------------------------------------------------- */

double PairBornGauss::init_one(int i, int j)
{
  if (setflag[i][j] == 0) error->all(FLERR, "All pair coeffs are not set");

  if (offset_flag) {
    double dr = cut[i][j] - r0[i][j];
    offset[i][j] =
        biga0[i][j] * exp(-alpha[i][j] * cut[i][j]) - biga1[i][j] * exp(-beta[i][j] * dr␣
↪* dr);
  } else
    offset[i][j] = 0.0;

  biga0[j][i] = biga0[i][j];
  alpha[j][i] = alpha[i][j];
  biga1[j][i] = biga1[i][j];
  beta[j][i] = beta[i][j];
  r0[j][i] = r0[i][j];
  offset[j][i] = offset[i][j];

  return cut[i][j];
}
```

Computing forces from the neighbor list (required)

The `compute()` function is the "workhorse" of a pair style. This is where we have the nested loops over all pairs of particles from the neighbor list to compute forces and - if needed - energies and virials.

The first part is to define some variables for later use and store cached copies of data or pointers that we need to access frequently. Also, this is a good place to call `Pair::ev_init()`, which initializes several flags derived from the *eflag* and *vflag* parameters signaling whether the energy and virial need to be tallied and whether only globally or also per-atom.

```
/* ---------------------------------------------------------------------- */

void PairBornGauss::compute(int eflag, int vflag)
{
  int i, j, ii, jj, inum, jnum, itype, jtype;
  double xtmp, ytmp, ztmp, delx, dely, delz, evdwl, fpair;
  double rsq, r, dr, aexp, bexp, factor_lj;
  int *ilist, *jlist, *numneigh, **firstneigh;

  evdwl = 0.0;
  ev_init(eflag, vflag);

  double **x = atom->x;
  double **f = atom->f;
  int *type = atom->type;
  int nlocal = atom->nlocal;
  double *special_lj = force->special_lj;
  int newton_pair = force->newton_pair;

  inum = list->inum;
  ilist = list->ilist;
  numneigh = list->numneigh;
  firstneigh = list->firstneigh;
```

The outer loop (index *i*) is over local atoms of our sub-domain. Typically, the value of *inum* (the number of neighbor lists) is the same as the number of local atoms (= atoms *owned* by this sub-domain). But when the pair style is used as a sub-style of a *hybrid pair style* or neighbor list entries are removed with *neigh_modify exclude*, this number may be smaller. The array `list->ilist` has the (local) indices of the atoms for which neighbor lists have been created. Then `list->numneigh` is an *inum* sized array with the number of entries of each list of neighbors, and `list->firstneigh` is a list of pointers to those lists.

For efficiency reasons, cached copies of some properties of the outer loop atoms are also initialized.

```
// loop over neighbors of my atoms

for (ii = 0; ii < inum; ii++) {
  i = ilist[ii];
  xtmp = x[i][0];
  ytmp = x[i][1];
  ztmp = x[i][2];
  itype = type[i];
  jlist = firstneigh[i];
  jnum = numneigh[i];
```

The inner loop (index *j*) processes the neighbor lists. The neighbor list code encodes extra information using the upper 3 bits. The 2 highest bits encode whether a pair is a regular pair of neighbor (= 0) or a pair of 1-2 (= 1), 1-3 (= 2),

or 1-4 (= 3) *"special" neighbor*. The next highest bit encodes whether the pair stores data in a `fix neigh/history` instance (an undocumented internal fix style). The `sbmask()` inline function extracts those bits and converts them into a number. This number is used to look up the corresponding scaling factor for the non-bonded interaction from the `force->special_lj` array and stores it in the *factor_lj* variable. Due to the additional bits, the value of *j* would be out of range when accessing data from per-atom arrays, so we apply the NEIGHMASK constant with a bit-wise and operation to mask them out. This step *must* be done, even if a pair style does not use special bond scaling of forces and energies to avoid segmentation faults.

With the corrected *j* index, it is now possible to compute the distance of the pair. For efficiency reasons, the square root is only taken *after* the check for the cutoff (which has been stored as squared cutoff by the `Pair` base class). For some pair styles, like the 12-6 Lennard-Jones potential, computing the square root can be avoided entirely.

```
for (jj = 0; jj < jnum; jj++) {
  j = jlist[jj];
  factor_lj = special_lj[sbmask(j)];
  j &= NEIGHMASK;

  delx = xtmp - x[j][0];
  dely = ytmp - x[j][1];
  delz = ztmp - x[j][2];
  rsq = delx * delx + dely * dely + delz * delz;
  jtype = type[j];
```

The following block of code is the actual application of the model potential to compute the force. Note, that *fpair* is the pair-wise force divided by the distance, as this simplifies the projection of the x-, y-, and z-components of the force vector by simply multiplying with the respective distances in those directions.

```
if (rsq < cutsq[itype][jtype]) {
  r = sqrt(rsq);
  dr = r - r0[itype][jtype];
  aexp = biga0[itype][jtype] * exp(-alpha[itype][jtype] * r);
  bexp = biga1[itype][jtype] * exp(-beta[itype][jtype] * dr * dr);
  fpair = alpha[itype][jtype] * aexp;
  fpair -= 2.0 * beta[itype][jtype] * dr * bexp;
  fpair *= factor_lj / r;
```

In the next block, the force is added to the per-atom force arrays. This pair style uses a "half" neighbor list (each pair is listed only once) so we take advantage of the fact that $\vec{F}_{ij} = -\vec{F}_{ji}$, i.e. apply Newton's third law. The force is *always* stored when the atom is a "local" atom. Index *i* atoms are always "local" (i.e. *i* < nlocal); index *j* atoms may be "ghost" atoms (*j* >= nlocal).

Depending on the settings used with the *newton command*, those pairs are only listed once globally (newton_pair == 1), then forces must be stored even with ghost atoms and after all forces are computed a "reverse communication" is performed to add those ghost atom forces to their corresponding local atoms. If the setting is disabled, then the extra communication is skipped, since for pairs straddling sub-domain boundaries, the forces are computed twice and only stored with the local atoms in the domain that *owns* it.

```
f[i][0] += delx * fpair;
f[i][1] += dely * fpair;
f[i][2] += delz * fpair;
if (newton_pair || j < nlocal) {
  f[j][0] -= delx * fpair;
  f[j][1] -= dely * fpair;
  f[j][2] -= delz * fpair;
}
```

The `ev_tally()` function tallies global or per-atom energy and virial. For typical MD simulations, the potential energy is merely a diagnostic and only needed on output. Similarly, the pressure may only be computed for (infrequent) thermodynamic output. For all timesteps where this information is not needed either, *eflag* or *evflag* are zero and the computation and call to the tally function skipped. Note that evdwl is initialized to zero at the beginning of the function, so that it still is valid to access it, even if the energy is not computed (e.g. when only the virial is needed).

```
      if (eflag) evdwl = factor_lj * (aexp - bexp - offset[itype][jtype]);
      if (evflag) ev_tally(i, j, nlocal, newton_pair, evdwl, 0.0, fpair, delx, dely,␣
↪delz);
    }
  }
}
```

If only the global virial is needed and no energy, then calls to `ev_tally()` can be avoided altogether, and the global virial can be computed more efficiently from the dot product of the total per-atom force vector and the position vector of the corresponding atom, $\vec{F} \cdot \vec{r}$. This has to be done *after* all pair-wise forces are computed and *before* the reverse communication to collect data from ghost atoms, since the position has to be the position that was used to compute the force, i.e. *not* the "local" position if that ghost atom is a periodic copy.

```
  if (vflag_fdotr) virial_fdotr_compute();
}
```

Computing force and energy for a single pair

Certain features in LAMMPS only require computing interactions between individual pairs of atoms and the (optional) `single()` function is needed to support those features (e.g. for tabulation of force and energy with *pair_write*). This is a repetition of the force kernel in the `compute()` function, but only for a single pair of atoms, where the (squared) distance is provided as a parameter (so it may not even be an existing distance between two specific atoms). The energy is returned as the return value of the function and the force as the *fforce* reference. Note, that this is, similar to how *fpair* is used in the `compute()` function, the magnitude of the force along the vector between the two atoms *divided* by the distance.

The `single()` function is optional, but it is expected to be implemented for any true pair-wise additive potential. Many-body potentials and special case potentials do not implement it. In a few special cases (EAM, long-range Coulomb), the `single()` function implements the pairwise additive part of the complete force interaction and depends on either pre-computed properties (derivative of embedding term for EAM) or post-computed non-pair-wise force contributions (KSpace style in case of long-range Coulomb).

The member variable *single_enable* should be set to 0 in the constructor, if it is not implemented (its default value is 1).

```
/* ---------------------------------------------------------------------- */

double PairBornGauss::single(int /*i*/, int /*j*/, int itype, int jtype, double rsq,
                             double /*factor_coul*/, double factor_lj, double &fforce)
{
  double r, dr, aexp, bexp;

  r = sqrt(rsq);
  dr = r - r0[itype][jtype];
  aexp = biga0[itype][jtype] * exp(-alpha[itype][jtype] * r);
  bexp = biga1[itype][jtype] * exp(-beta[itype][jtype] * dr * dr);

  fforce = factor_lj * (alpha[itype][jtype] * aexp - 2.0 * dr * beta[itype][jtype] *␣
↪bexp) / r;
```

(continues on next page)

(continued from previous page)

```
  return factor_lj * (aexp - bexp - offset[itype][jtype]);
}
```

Reading and writing of restart files

Support for writing and reading binary restart files is provided by the following four functions. Writing is only done by MPI processor rank 0. The output of global (not related to atom types) settings is usually delegated to the `write_restart_settings()` function. This restart facility is commonly only used, if there are small number of per-type parameters. For potentials that use per-element parameters or tabulated data and read these from files, those parameters and the name of the potential file are not written to restart files and the *pair_coeff command* has to re-issued when restarting. For pair styles like "born/gauss" that do support writing to restart files, this is not required.

Implementing the functions to read and write binary restart files is optional. The member variable *restartinfo* should be set to 0 in the constructor, if they are not implemented (its default value is 1).

```
/* ----------------------------------------------------------------------
   proc 0 writes to restart file
------------------------------------------------------------------------- */

void PairBornGauss::write_restart(FILE *fp)
{
  write_restart_settings(fp);

  int i, j;
  for (i = 1; i <= atom->ntypes; i++) {
    for (j = i; j <= atom->ntypes; j++) {
      fwrite(&setflag[i][j], sizeof(int), 1, fp);
      if (setflag[i][j]) {
        fwrite(&biga0[i][j], sizeof(double), 1, fp);
        fwrite(&alpha[i][j], sizeof(double), 1, fp);
        fwrite(&biga1[i][j], sizeof(double), 1, fp);
        fwrite(&beta[i][j], sizeof(double), 1, fp);
        fwrite(&r0[i][j], sizeof(double), 1, fp);
        fwrite(&cut[i][j], sizeof(double), 1, fp);
      }
    }
  }
}

/* ----------------------------------------------------------------------
   proc 0 writes to restart file
------------------------------------------------------------------------- */

void PairBornGauss::write_restart_settings(FILE *fp)
{
  fwrite(&cut_global, sizeof(double), 1, fp);
  fwrite(&offset_flag, sizeof(int), 1, fp);
  fwrite(&mix_flag, sizeof(int), 1, fp);
}
```

Similarly, on reading, only MPI processor rank 0 has opened the restart file and will read the data. The data is then distributed across all parallel processes using calls to `MPI_Bcast()`. Before reading atom type specific data, the corresponding storage needs to be allocated. Order and number or storage size of items read must be exactly the same

as when writing, or else the data will be read incorrectly.

Reading uses the *utils::sfread* utility function to detect read errors and short reads, so that LAMMPS can abort if that happens, e.g. when the restart file is corrupted.

```
/* ----------------------------------------------------------------------
   proc 0 reads from restart file, bcasts
------------------------------------------------------------------------- */

void PairBornGauss::read_restart(FILE *fp)
{
  read_restart_settings(fp);

  allocate();

  int i, j;
  int me = comm->me;
  for (i = 1; i <= atom->ntypes; i++) {
    for (j = i; j <= atom->ntypes; j++) {
      if (me == 0) utils::sfread(FLERR, &setflag[i][j], sizeof(int), 1, fp, nullptr,␣
↪error);
      MPI_Bcast(&setflag[i][j], 1, MPI_INT, 0, world);
      if (setflag[i][j]) {
        if (me == 0) {
          utils::sfread(FLERR, &biga0[i][j], sizeof(double), 1, fp, nullptr, error);
          utils::sfread(FLERR, &alpha[i][j], sizeof(double), 1, fp, nullptr, error);
          utils::sfread(FLERR, &biga1[i][j], sizeof(double), 1, fp, nullptr, error);
          utils::sfread(FLERR, &beta[i][j], sizeof(double), 1, fp, nullptr, error);
          utils::sfread(FLERR, &r0[i][j], sizeof(double), 1, fp, nullptr, error);
          utils::sfread(FLERR, &cut[i][j], sizeof(double), 1, fp, nullptr, error);
        }
        MPI_Bcast(&biga0[i][j], 1, MPI_DOUBLE, 0, world);
        MPI_Bcast(&alpha[i][j], 1, MPI_DOUBLE, 0, world);
        MPI_Bcast(&biga1[i][j], 1, MPI_DOUBLE, 0, world);
        MPI_Bcast(&beta[i][j], 1, MPI_DOUBLE, 0, world);
        MPI_Bcast(&r0[i][j], 1, MPI_DOUBLE, 0, world);
        MPI_Bcast(&cut[i][j], 1, MPI_DOUBLE, 0, world);
      }
    }
  }
}

/* ----------------------------------------------------------------------
   proc 0 reads from restart file, bcasts
------------------------------------------------------------------------- */

void PairBornGauss::read_restart_settings(FILE *fp)
{
  if (comm->me == 0) {
    utils::sfread(FLERR, &cut_global, sizeof(double), 1, fp, nullptr, error);
    utils::sfread(FLERR, &offset_flag, sizeof(int), 1, fp, nullptr, error);
    utils::sfread(FLERR, &mix_flag, sizeof(int), 1, fp, nullptr, error);
  }
  MPI_Bcast(&cut_global, 1, MPI_DOUBLE, 0, world);
```

(continues on next page)

(continued from previous page)

```
  MPI_Bcast(&offset_flag, 1, MPI_INT, 0, world);
  MPI_Bcast(&mix_flag, 1, MPI_INT, 0, world);
}
```

Writing coefficients to data files

The `write_data()` and `write_data_all()` functions are optional and write out the current state of the *pair_coeff settings* as "Pair Coeffs" or "PairIJ Coeffs" sections to a data file when using the *write_data command*. The `write_data()` only writes out the diagonal elements of the pair coefficient matrix, as that is required for the format of the "Pair Coeffs" section. It is called when the "pair" option of the *write_data command* is "ii" (the default). This is suitable for force fields where *all* off-diagonal terms of the pair coefficient matrix are generated from mixing. If explicit settings for off-diagonal elements were made, LAMMPS will print a warning, as those would be lost. To avoid this, the "pair ij" option of *write_data* can be used which will trigger calling the `write_data_all()` function instead, which will write out all settings of the pair coefficient matrix (regardless of whether they were originally created from mixing or not).

These data file output functions are only useful for true pair-wise additive potentials, where the potential parameters can be entered through *multiple pair_coeff commands*. Pair styles that require a single "pair_coeff * *" command are not compatible with reading their parameters from data files. For pair styles like *born/gauss* that do support writing to data files, the potential parameters will be read from the data file, if present, and *pair_coeff commands* may not be needed.

The member variable `writedata` should be set to 1 in the constructor, if these functions are implemented (the default value is 0).

```
/* ----------------------------------------------------------------------
   proc 0 writes to data file
------------------------------------------------------------------------- */

void PairBornGauss::write_data(FILE *fp)
{
  for (int i = 1; i <= atom->ntypes; i++)
    fprintf(fp, "%d %g %g %g %g %g\n", i, biga0[i][i], alpha[i][i], biga1[i][i],␣
↪beta[i][i],
            r0[i][i]);
}

/* ----------------------------------------------------------------------
   proc 0 writes all pairs to data file
------------------------------------------------------------------------- */

void PairBornGauss::write_data_all(FILE *fp)
{
  for (int i = 1; i <= atom->ntypes; i++)
    for (int j = i; j <= atom->ntypes; j++)
      fprintf(fp, "%d %d %g %g %g %g %g %g\n", i, j, biga0[i][j], alpha[i][j],␣
↪biga1[i][j],
              beta[i][j], r0[i][j], cut[i][j]);
}
```

Give access to internal data

The purpose of the `extract()` function is to facilitate access to internal data of the pair style by other parts of LAMMPS. One possible application is to use *fix adapt* to gradually change potential parameters during a run. Here, we implement access to the pair coefficient matrix parameters.

```
/* ---------------------------------------------------------------------- */

void *PairBornGauss::extract(const char *str, int &dim)
{
  dim = 2;
  if (strcmp(str, "biga0") == 0) return (void *) biga0;
  if (strcmp(str, "biga1") == 0) return (void *) biga1;
  if (strcmp(str, "r0") == 0) return (void *) r0;
  return nullptr;
}
```

Since the mercury potential, for which we have implemented the born/gauss pair style, has a temperature dependent parameter "biga1", we can automatically adapt the potential based on the Taylor-MacLaurin expansion for "biga1" when performing a simulation with a temperature ramp. LAMMPS commands for that application are given below:

```
variable tlo  index 300.0
variable thi  index 600.0
variable temp equal ramp(v_tlo,v_thi)
variable biga1 equal (-2.58717e-8*v_temp+8.40841e-5)*v_temp+1.97475e-2

fix             1 all nvt temp ${tlo} ${thi} 0.1
fix             2 all adapt 1 pair born/gauss biga1 * * v_biga1
```

4.8.4 Case 2: a many-body potential

Since there is a detailed description of the purpose and general layout of a pair style in the previous case, we will focus on where the implementation of a typical many-body potential *differs* from a pair-wise additive potential. We will use the implementation of the Tersoff potential as *pair_style tersoff* as an example. The complete implementation can be found in the files `src/MANYBODY/pair_tersoff.cpp` and `src/MANYBODY/pair_tersoff.h` of the LAMMPS source code.

Constructor

In the constructor, several *pair style flags* must be set differently for many-body potentials:

- the potential is not pair-wise additive, so the `single()` function cannot be used. This is indicated by setting the *single_enable* member variable to 0 (default value is 1)
- many-body potentials are usually not written to *binary restart files*. This is indicated by setting the member variable *restartinfo* to 0 (default is 1)
- many-body potentials typically read *all* parameters from a file which stores parameters indexed with a string (e.g. the element). For this, only a single *pair_coeff* * * command is allowed. This requirement is set and checked for, when the member variable *one_coeff* is set to 1 (default value is 0)
- many-body potentials can produce incorrect results if pairs of atoms are excluded from the neighbor list, e.g. explicitly by *neigh_modify exclude* or implicitly through defining bonds, angles, etc. and having a *special_bonds setting* that is not "special_bonds lj/coul 1.0 1.0 1.0". LAMMPS will check for this and print a suitable warning, when the member variable *manybody_flag* is set to 1 (default value is 0).

```
PairTersoff::PairTersoff(LAMMPS *lmp) : Pair(lmp)
{
  single_enable = 0;
  restartinfo = 0;
  one_coeff = 1;
  manybody_flag = 1;
```

Neighbor list request

For computing the three-body interactions of the Tersoff potential a "full" neighbor list (both atoms of a pair are listed in each other's neighbor list) is required. By default a "half" neighbor list is requested (each pair is listed only once). The request is made in the `init_style()` function. A more in-depth discussion of neighbor lists in LAMMPS and how to request them is in *this section of the documentation*

Also, additional conditions must be met for some global settings which are checked in the `init_style()` function.

```
/* ----------------------------------------------------------------------
   init specific to this pair style
------------------------------------------------------------------------- */

void PairTersoff::init_style()
{
  if (atom->tag_enable == 0)
    error->all(FLERR,"Pair style Tersoff requires atom IDs");
  if (force->newton_pair == 0)
    error->all(FLERR,"Pair style Tersoff requires newton pair on");

  // need a full neighbor list

  neighbor->add_request(this,NeighConst::REQ_FULL);
}
```

Computing forces from the neighbor list

Computing forces for a many-body potential is usually more complex than for a pair-wise additive potential and there are multiple components. For Tersoff, there is a pair-wise additive two-body term (two nested loops over indices i and j) and a three-body term (three nested loops over indices i, j, and k). Since the neighbor list has all neighbors up to the maximum cutoff (for the two-body term), but the three-body interactions have a significantly shorter cutoff, a "short neighbor list" is also constructed at the same time while computing the two-body term and looping over the neighbor list for the first time.

```
if (rsq < cutshortsq) {
  neighshort[numshort++] = j;
  if (numshort >= maxshort) {
    maxshort += maxshort/2;
    memory->grow(neighshort,maxshort,"pair:neighshort");
  }
}
```

For the two-body term, only a half neighbor list would be needed, even though we have requested a full list (for the three-body loops). Rather than computing all interactions twice, we skip over half of the entries. This is done in a slightly complex way to make certain the same choice is made across all subdomains and so that there is no load imbalance introduced.

```
jtag = tag[j];
if (itag > jtag) {
  if ((itag+jtag) % 2 == 0) continue;
} else if (itag < jtag) {
  if ((itag+jtag) % 2 == 1) continue;
} else {
  if (x[j][2] < x[i][2]) continue;
  if (x[j][2] == ztmp && x[j][1] < ytmp) continue;
  if (x[j][2] == ztmp && x[j][1] == ytmp && x[j][0] < xtmp) continue;
}
```

For the three-body term, there is one additional nested loop and it uses the "short" neighbor list, accumulated previously.

```
// three-body interactions
// skip immediately if I-J is not within cutoff
double fjxtmp,fjytmp,fjztmp;

for (jj = 0; jj < numshort; jj++) {
  j = neighshort[jj];
  jtype = map[type[j]];

  [...]

  for (kk = 0; kk < numshort; kk++) {
    if (jj == kk) continue;
    k = neighshort[kk];
    ktype = map[type[k]];

    [...]
  }
[...]
```

Reading potential parameters

For the Tersoff potential, the parameters are listed in a file and associated with triples of elements. Because we have set the `one_coeff` flag to 1 in the constructor, there may only be a single *pair_coeff* * * line in the input for this pair style, and as a consequence the `coeff()` function will only be called once. Thus, the `coeff()` function has to do three tasks, each of which is delegated to a function in the `PairTersoff` class:

1. map elements to atom types. Those follow the potential file name in the command arguments and are processed by the `map_element2type()` function.
2. read and parse the potential parameter file in the `read_file()` function.
3. Build data structures where the original and derived parameters are indexed by all possible triples of atom types and thus can be looked up quickly in the loops for the force computation

```
void PairTersoff::coeff(int narg, char **arg)
{
  if (!allocated) allocate();

  map_element2type(narg-3,arg+3);

  // read potential file and initialize potential parameters
```

(continues on next page)

(continued from previous page)

```
  read_file(arg[2]);
  setup_params();
}
```

4.8.5 Case 3: a potential requiring communication

For some models, the interactions between atoms depends on properties of their environment which have to be computed *before* the the forces can be computed. Since LAMMPS is designed to run in parallel using a *domain decomposition strategy*, not all information of the atoms may be directly available and thus communication steps may be need to collect data from ghost atoms of neighboring subdomains or send data to ghost atoms for application during the pairwise computation.

Specifically, two communication patterns are needed: a "reverse communication" and a "forward communication". The reverse communication collects data added to "ghost" atoms from neighboring sub-domains and sums it to their corresponding "local" atoms. This communication is only required and thus executed when the `Force::newton_pair` setting is 1 (i.e. *newton on*, the default). The forward communication is used to copy computed per-atom data from "local" atoms to their corresponding "ghost" atoms in neighboring sub-domains.

For this we will look at how the embedding term of the *embedded atom potential EAM* is implemented in LAMMPS. The complete implementation of this pair style can be found in the files `src/MANYBODY/pair_eam.cpp` and `src/MANYBODY/pair_eam.h` of the LAMMPS source code.

Allocating additional per-atom storage

First suitable (local) per-atom arrays (*rho*, *fp*, *numforce*) are allocated. These have to be large enough to include ghost atoms, are not used outside the `compute()` function and are re-initialized to zero once per timestep.

```
if (atom->nmax > nmax) {
  memory->destroy(rho);
  memory->destroy(fp);
  memory->destroy(numforce);
  nmax = atom->nmax;
  memory->create(rho,nmax,"pair:rho");
  memory->create(fp,nmax,"pair:fp");
  memory->create(numforce,nmax,"pair:numforce");
}
```

Reverse communication

Then a first loop over all pairs (i and j) is performed, where data is stored in the *rho* array representing the electron density at the site of i contributed from all neighbors j. Since the EAM pair style uses a half neighbor list (for efficiency reasons), a reverse communication is needed to collect the contributions to *rho* from ghost atoms (only if *newton on* is set for pair styles).

```
if (newton_pair) comm->reverse_comm(this);
```

To support the reverse communication, two functions must be defined: `pack_reverse_comm()` that copies relevant data into a buffer for ghost atoms and `unpack_reverse_comm()` that takes the collected data and adds it to the *rho* array for the corresponding local atoms that match the ghost atoms. In order to allocate sufficiently sized buffers, a flag must be set in the pair style constructor. Since in this case a single double precision number is communicated per atom, the *comm_reverse* member variable is set to 1 (default is 0 = no reverse communication).

```
int PairEAM::pack_reverse_comm(int n, int first, double *buf)
{
  int i,m,last;

  m = 0;
  last = first + n;
  for (i = first; i < last; i++) buf[m++] = rho[i];
  return m;
}

void PairEAM::unpack_reverse_comm(int n, int *list, double *buf)
{
  int i,j,m;

  m = 0;
  for (i = 0; i < n; i++) {
    j = list[i];
    rho[j] += buf[m++];
  }
}
```

Forward communication

From the density array *rho*, the derivative of the embedding energy *fp* is computed. The computation is only done for "local" atoms, but for the force computation, that property also is needed on ghost atoms. For that a forward communication is needed.

```
comm->forward_comm(this);
```

Similar to the reverse communication, this requires implementing a `pack_forward_comm()` and an `unpack_forward_comm()` function. Since there is one double precision number per atom that needs to be communicated, we must set the *comm_forward* member variable to 1 (default is 0 = no forward communication).

```
int PairEAM::pack_forward_comm(int n, int *list, double *buf, int pbc_flag, int *pbc)
{
  int i,j,m;

  m = 0;
  for (i = 0; i < n; i++) {
    j = list[i];
    buf[m++] = fp[j];
  }
  return m;
}

void PairEAM::unpack_forward_comm(int n, int first, double *buf)
{
  int i,m,last;

  m = 0;
  last = first + n;
  for (i = first; i < last; i++) fp[i] = buf[m++];
}
```

4.8.6 Case 4: potentials without a compute() function

A small number of pair style classes do not implement a `compute()` function, but instead use that of a different pair style.

Embedded atom variants "eam/fs" and "eam/alloy"

The pair styles *eam/fs and eam/alloy* share the same model and potential function as the *eam pair style*. They differ in the format of the potential files. Pair style *eam* supports only potential files for single elements. For multi-element systems, the mixed terms are computed from mixed parameters. The *eam/fs* and *eam/alloy* pair styles, however, **require** the use of a single potential file for all elements where the mixed element potential is included in the tabulation. That enables more accurate models for alloys, since the mixed terms can be adjusted for a better representation of material properties compared to terms created from mixing of per-element terms in the `PairEAM` class.

We take a closer at the *eam/alloy* pair style. The complete implementation is in the files `src/MANYBODY/pair_eam_alloy.cpp` and `src/MANYBODY/pair_eam_alloy.h`.

The `PairEAMAlloy` class is derived from `PairEAM` and not `Pair` and overrides only a small number of functions:

```
class PairEAMAlloy : virtual public PairEAM {
 public:
  PairEAMAlloy(class LAMMPS *);
  void coeff(int, char **) override;

 protected:
  void read_file(char *) override;
  void file2array() override;
};
```

All other functionality is inherited from the base classes. In the constructor we set the `one_coeff` flag and the `many_body` flag to 1 to indicate the different behavior.

```
PairEAMAlloy::PairEAMAlloy(LAMMPS *lmp) : PairEAM(lmp)
{
  one_coeff = 1;
  manybody_flag = 1;
}
```

The `coeff()` function (not shown here) implements the different behavior when processing the *pair_coeff command*. The `read_file()` and `file2array()` replace the corresponding `PairEAM` class functions to accommodate the different data and file format.

AIREBO and AIREBO-M potentials

The AIREBO-M potential differs from the better known AIREBO potential in that it use a Morse potential instead of a Lennard-Jones potential for non-bonded interactions. Since this difference is very minimal compared to the entire potential, both potentials are implemented in the `PairAIREBO` class and which non-bonded potential is used is determined by the value of the `morseflag` flag, which would be set to either 0 or 1.

```
class PairAIREBOMorse : public PairAIREBO {
 public:
  PairAIREBOMorse(class LAMMPS *);
  void settings(int, char **) override;
};
```

The `morseflag` variable defaults to 0 and is set to 1 in the `PairAIREBOMorse::settings()` function which is called by the *pair_style* command. This function delegates all command argument processing and setting of other parameters

to the `PairAIREBO::settings()` function of the base class.

```
void PairAIREBOMorse::settings(int narg, char **arg)
{
  PairAIREBO::settings(narg, arg);

  morseflag = 1;
}
```

The complete implementation is in the files `src/MANYBODY/pair_airebo.cpp`, `src/MANYBODY/pair_airebo.h`, `src/MANYBODY/pair_airebo_morse.cpp`, `src/MANYBODY/pair_airebo_morse.h`.

4.8.7 Writing new bond, angle, dihedral, and improper styles

Bond, angle, dihedral, and improper styles are used to compute bonded interactions between groups of two, three, or four atoms whose topology is described in a data file or set by other commands. They are derived from the `Bond`, `Angle`, `Dihedral`, and `Improper` base classes, respectively. As shown on the corresponding pages *Bond, angle, dihedral, improper styles*, the classes that compute these molecular interactions share a common design.

In general, new styles for bonded interactions should be added to the *EXTRA-MOLECULE package*. If you feel that your contribution should be added to a different package (e.g. the *MOLECULE package*), please consult with the *LAMMPS developers* first.

Before implementing an accelerated style the corresponding plain CPU version should be implemented and properly tested. The accelerated version should then be derived from the plain CPU version so that only the code relevant for acceleration is re-implemented. Those should then be added to the corresponding accelerator package (*KOKKOS*, *OPENMP*, *INTEL*).

The contributed code needs to support the *traditional GNU make build process* **and** the *CMake build process*. This is usually automatic unless the new style uses some external library, which is uncommon for bonded interactions.

It is highly recommended also to include one or more example input decks and *force-style unit tests*. The tests will be particularly useful to test consistency between the `compute()` and `single()` methods, plain and accelerated versions, and to test correct restarting and writing and reading of data files.

4.8.8 Case 1: Implementing a bond style

In this section we describe the procedure of implementing a new bond style. As a concrete example we use the harmonic bond style *bond_style harmonic*, the simplest non-trivial bond style. The implementation can be found in the files `src/MOLECULE/bond_harmonic.cpp` and `src/MOLECULE/bond_harmonic.h` of the LAMMPS source code. It implements the potential:

$$E = K(r - r_0)^2$$

with the spring constant K and the equilibrium distance r_0 as per-type coefficients.

Header file

The header file `bond_harmonic.h` starts with the standard LAMMPS copyright and license block (see, for example, the discussion in *Writing a new pair style* for details).

After the copyright block, every bond style must be registered in LAMMPS by including the following lines before the include guards:

```
#ifdef BOND_CLASS
// clang-format off
BondStyle(harmonic,BondHarmonic);
// clang-format on
#else
```

This block between `#ifdef BOND_CLASS` and `#else` registers the bond style with LAMMPS. During compilation, the build system parses the `BondStyle(harmonic,BondHarmonic)` marker and generates a file `style_bond.cpp` that `#includes` the header files of all installed bond styles and registers a factory function for each of them. These factory functions are kept in a process-global registry that connects the bond style name, "harmonic", with the class `BondHarmonic`. The `BOND_CLASS` macro is never actually defined during compilation; the `#ifdef BOND_CLASS` block only serves as a marker for the build system's parser, so the header always provides the class definition from its `#else` branch. The `// clang-format` comments prevent `clang-format` from reformatting the macro argument in a way that would break it.

Analogously, an angle style would use `#ifdef ANGLE_CLASS` and `AngleStyle(name,class)`, a dihedral style would use `#ifdef DIHEDRAL_CLASS` and `DihedralStyle(name,class)`, and an improper style would use `#ifdef IMPROPER_CLASS` and `ImproperStyle(name,class)`.

The class definition itself follows after the include guard:

```
#ifndef LMP_BOND_HARMONIC_H
#define LMP_BOND_HARMONIC_H

#include "bond.h"

namespace LAMMPS_NS {

class BondHarmonic : public Bond {
 public:
  BondHarmonic(class LAMMPS *);
  ~BondHarmonic() override;
  void compute(int, int) override;
  void coeff(int, char **) override;
  double equilibrium_distance(int) override;
  void write_restart(FILE *) override;
  void read_restart(FILE *) override;
  void write_data(FILE *) override;
  double single(int, double, int, int, double &) override;
  void born_matrix(int, double, int, int, double &, double &) override;
  void *extract(const char *, int &) override;

 protected:
  double *k, *r0;

  virtual void allocate();
};

}    // namespace LAMMPS_NS
#endif
#endif
```

The class is derived from `Bond` and overrides all *pure* virtual methods as require by the C++ standard (`compute()`, `coeff()`, `equilibrium_distance()`, `write_restart()`, `read_restart()`, and `single()`) and several optional ones. All overriding methods use the `override` keyword to allow the compiler to detect mismatches. The per-type co-

efficient arrays `k` and `r0` are declared as protected member variables. The `allocate()` method is declared as `virtual` so that derived classes can override it if needed.

> **Note**
>
> Ideally, there should be no additional `#include` statements outside of `#include "bond.h"`. Where possible, forward declarations should be used and the proper include statements only added to the implementation file (discussed below). Exceptions are headers for C++ container classes. Please see *Requirements for contributions to LAMMPS* and *LAMMPS programming style* for more information and this and related issues.

Implementation file

The implementation file `bond_harmonic.cpp` starts with the same copyright block and includes, followed by `using namespace LAMMPS_NS;`.

Constructor and destructor

The constructor is minimal; it only calls the base class constructor and sets the `born_matrix_enable` flag to enable the optional `born_matrix()` method:

```
BondHarmonic::BondHarmonic(LAMMPS *_lmp) : Bond(_lmp), k(nullptr), r0(nullptr)
{
  born_matrix_enable = 1;
}
```

It is recommended to always initialize all pointers to `nullptr` in the initializer list so that they can be safely deleted in the destructor.

The destructor frees the per-type coefficient arrays, but only if `allocated` is true and `copymode` is false. The `copymode` flag is set by Kokkos-accelerated styles that copy the base class rather than owning the storage:

```
BondHarmonic::~BondHarmonic()
{
  if (allocated && !copymode) {
    memory->destroy(setflag);
    memory->destroy(k);
    memory->destroy(r0);
  }
}
```

The allocate() method

The `allocate()` helper allocates all per-type arrays. Types are one-indexed, so arrays of size `nbondtypes + 1` are created. The `setflag` array, which tracks whether coefficients have been set for each type, is also allocated here and initialized to zero:

```
void BondHarmonic::allocate()
{
  allocated = 1;
  const int np1 = atom->nbondtypes + 1;

  memory->create(k, np1, "bond:k");
  memory->create(r0, np1, "bond:r0");
```

(continues on next page)

(continued from previous page)

```
  memory->create(setflag, np1, "bond:setflag");
  for (int i = 1; i < np1; i++) setflag[i] = 0;
}
```

The `setflag` array is declared in the `Bond` base class. It is used by `Bond::init()` to check that coefficients have been set for all bond types.

The coeff() method (required)

The `coeff()` method processes the arguments of the *bond_coeff* command. The first argument is always the type range (e.g. `1*3`, handled by `utils::bounds()`); subsequent arguments are the potential coefficients.

```
void BondHarmonic::coeff(int narg, char **arg)
{
  if (narg != 3) error->all(FLERR, "Incorrect args for bond coefficients" +␣
↪utils::errorurl(21));
  if (!allocated) allocate();

  int ilo, ihi;
  utils::bounds(FLERR, arg[0], 1, atom->nbondtypes, ilo, ihi, error);

  double k_one = utils::numeric(FLERR, arg[1], false, lmp);
  double r0_one = utils::numeric(FLERR, arg[2], false, lmp);

  int count = 0;
  for (int i = ilo; i <= ihi; i++) {
    k[i] = k_one;
    r0[i] = r0_one;
    setflag[i] = 1;
    count++;
  }

  if (count == 0) error->all(FLERR, "Incorrect args for bond coefficients" +␣
↪utils::errorurl(21));
}
```

The `utils::bounds()` function converts the type string into integer lower and upper bounds `ilo` and `ihi`. After setting the coefficients for each type in the range, `setflag[i]` is set to 1. The final check guards against a range that matches no types.

The compute() method (required)

The `compute()` method iterates over all bonds in the local bond list (`neighbor->bondlist`) and accumulates forces and energies. The two arguments `eflag` and `vflag` control whether energies and virial contributions are computed. The actual energy and virial accumulation is handled by calling `ev_tally()` at the end of each iteration step.

```
void BondHarmonic::compute(int eflag, int vflag)
{
  int i1, i2, n, type;
  double delx, dely, delz, ebond, fbond;
  double rsq, r, dr, rk;
```

(continues on next page)

(continued from previous page)

```
  ebond = 0.0;
  ev_init(eflag, vflag);

  double **x = atom->x;
  double **f = atom->f;
  int **bondlist = neighbor->bondlist;
  int nbondlist = neighbor->nbondlist;
  int nlocal = atom->nlocal;
  int newton_bond = force->newton_bond;

  for (n = 0; n < nbondlist; n++) {
    i1 = bondlist[n][0];
    i2 = bondlist[n][1];
    type = bondlist[n][2];

    delx = x[i1][0] - x[i2][0];
    dely = x[i1][1] - x[i2][1];
    delz = x[i1][2] - x[i2][2];

    rsq = delx * delx + dely * dely + delz * delz;
    r = sqrt(rsq);
    dr = r - r0[type];
    rk = k[type] * dr;

    // force & energy

    if (r > 0.0)
      fbond = -2.0 * rk / r;
    else
      fbond = 0.0;

    if (eflag) ebond = rk * dr;

    // apply force to each of 2 atoms

    if (newton_bond || i1 < nlocal) {
      f[i1][0] += delx * fbond;
      f[i1][1] += dely * fbond;
      f[i1][2] += delz * fbond;
    }

    if (newton_bond || i2 < nlocal) {
      f[i2][0] -= delx * fbond;
      f[i2][1] -= dely * fbond;
      f[i2][2] -= delz * fbond;
    }

    if (evflag) ev_tally(i1, i2, nlocal, newton_bond, ebond, fbond, delx, dely, delz);
  }
}
```

Before the loop, `ev_init(eflag, vflag)` initializes the energy and virial accumulators and sets several flags (in-

cluding `evflag`) that control which quantities are computed. The force scalar `fbond` is defined such that the force on atom `i1` is `fbond * (x[i1] - x[i2])` and the force on atom `i2` is `-fbond * (x[i1] - x[i2])`. This sign convention matches the force as the negative gradient of the energy.

The Newton's third law check (`newton_bond || i < nlocal`) is important for correctness in parallel runs: when `newton_bond` is on, forces are computed for both atoms even when they are on different MPI ranks, relying on a subsequent reverse communication to add up the contributions; when `newton_bond` is off, only forces on local atoms (`i < nlocal`) are accumulated.

The equilibrium_distance() method (required for bond styles)

The `equilibrium_distance()` method returns the equilibrium bond length for the given type. This is used, for instance, by the *fix shake* and *fix rattle* commands:

```
double BondHarmonic::equilibrium_distance(int i)
{
  return r0[i];
}
```

The single() method (required for bond styles)

The `single()` method computes the force divided by r and the potential energy for a single pair of atoms. It is called by *compute bond/local* and related commands:

```
double BondHarmonic::single(int type, double rsq, int /*i*/, int /*j*/, double &fforce)
{
  double r = sqrt(rsq);
  double dr = r - r0[type];
  double rk = k[type] * dr;
  fforce = 0;
  if (r > 0.0) fforce = -2.0 * rk / r;
  return rk * dr;
}
```

The return value is the potential energy. `fforce` is set to `-dE/dr / r` (i.e. the force divided by the interatomic distance) so that it can be easily converted into the x-, y-, and z-direction force components by multiplying with Δx, Δy, and Δz, respectively.

Restart and data file methods (required)

The `write_restart()` method is called by proc 0 to write the per-type coefficients to the binary restart file. The matching `read_restart()` method is called when reading a restart file; it allocates storage, reads coefficients on proc 0, and broadcasts them to all ranks.

```
void BondHarmonic::write_restart(FILE *fp)
{
  fwrite(&k[1], sizeof(double), atom->nbondtypes, fp);
  fwrite(&r0[1], sizeof(double), atom->nbondtypes, fp);
}

void BondHarmonic::read_restart(FILE *fp)
{
  allocate();
```

(continues on next page)

(continued from previous page)

```
  if (comm->me == 0) {
    utils::sfread(FLERR, &k[1], sizeof(double), atom->nbondtypes, fp, nullptr, error);
    utils::sfread(FLERR, &r0[1], sizeof(double), atom->nbondtypes, fp, nullptr, error);
  }
  MPI_Bcast(&k[1], atom->nbondtypes, MPI_DOUBLE, 0, world);
  MPI_Bcast(&r0[1], atom->nbondtypes, MPI_DOUBLE, 0, world);

  for (int i = 1; i <= atom->nbondtypes; i++) setflag[i] = 1;
}

void BondHarmonic::write_data(FILE *fp)
{
  for (int i = 1; i <= atom->nbondtypes; i++) fprintf(fp, "%d %g %g\n", i, k[i], r0[i]);
}
```

Note that index 0 of each array is unused (types are one-indexed), so `&k[1]` is the start of the actual data. Using `utils::sfread()` (instead of `fread()`) provides error checking.

4.8.9 Case 2: Implementing an angle style

Angle styles are similar to bond styles but involve three atoms. The implementation follows the same pattern as for bond styles, so for details not mentioned here, you can refer to the corresponding section documenting the implementation of bond styles. As an example we use *angle_style harmonic* which implements the potential:

$$E = K(\theta - \theta_0)^2$$

with spring constant K and equilibrium angle θ_0.

The header file uses `#ifdef ANGLE_CLASS` and `AngleStyle(name,class)` for the registration block, and the class is derived from `Angle`:

```
#ifdef ANGLE_CLASS
// clang-format off
AngleStyle(harmonic,AngleHarmonic);
// clang-format on
#else

#ifndef LMP_ANGLE_HARMONIC_H
#define LMP_ANGLE_HARMONIC_H

#include "angle.h"

namespace LAMMPS_NS {

class AngleHarmonic : public Angle {
 public:
  AngleHarmonic(class LAMMPS *);
  ~AngleHarmonic() override;
  void compute(int, int) override;
  void coeff(int, char **) override;
  double equilibrium_angle(int) override;
```

(continues on next page)

(continued from previous page)

```
  void write_restart(FILE *) override;
  void read_restart(FILE *) override;
  void write_data(FILE *) override;
  double single(int, int, int, int) override;
  void *extract(const char *, int &) override;

 protected:
  double *k, *theta0;

  virtual void allocate();
};

}    // namespace LAMMPS_NS
#endif
#endif
```

Key differences from a bond style:

- The registration macro is `AngleStyle` and the include guard `#ifdef ANGLE_CLASS`.
- The base class is `Angle` (`#include "angle.h"`).
- The `equilibrium_distance()` method is replaced by `equilibrium_angle()` (used by *fix shake*).
- The `single()` method signature takes four atom indices instead of a distance squared plus two atom indices.
- The `compute()` loop iterates over `neighbor->anglelist` and `neighbor->nanglelist` involving three-atom groups.
- The types array is `atom->nangletypes`.

The `compute()` method for angle styles uses three atom indices (`i1`, `i2`, `i3`) from `neighbor->anglelist[n][0..3]`, where the type is at index 3. The equilibrium angle `theta0` is stored in radians (converted from degrees in `coeff()`).

4.8.10 Case 3: Implementing a dihedral style

Dihedral styles compute interactions among four atoms forming a torsion angle. Harmonic dihedrals implement the potential:

$$E = K\left[1 + d\cos(n\phi)\right]$$

where K is the force constant, d is the sign (+1 or -1), and n is the multiplicity (periodicity). The implementation can be found in `src/MOLECULE/dihedral_harmonic.cpp` and `src/MOLECULE/dihedral_harmonic.h`.

The header file uses `#ifdef DIHEDRAL_CLASS` and `DihedralStyle(name,class)`, and the class is derived from `Dihedral`:

```
#ifdef DIHEDRAL_CLASS
// clang-format off
DihedralStyle(harmonic,DihedralHarmonic);
// clang-format on
#else

#ifndef LMP_DIHEDRAL_HARMONIC_H
```

(continues on next page)

(continued from previous page)

```
#define LMP_DIHEDRAL_HARMONIC_H

#include "dihedral.h"

namespace LAMMPS_NS {

class DihedralHarmonic : public Dihedral {
 public:
  DihedralHarmonic(class LAMMPS *);
  ~DihedralHarmonic() override;
  void compute(int, int) override;
  void coeff(int, char **) override;
  void write_restart(FILE *) override;
  void read_restart(FILE *) override;
  void write_data(FILE *) override;

 protected:
  double *k, *cos_shift, *sin_shift;
  int *sign, *multiplicity;

  virtual void allocate();
};

}    // namespace LAMMPS_NS
#endif
#endif
```

Key differences from bond and angle styles:

- The base class is `Dihedral` (`#include "dihedral.h"`).
- There is no `equilibrium_distance()` or `equilibrium_angle()` method; dihedral styles have no analogue required by other LAMMPS subsystems.
- There is no `single()` method in the base class for dihedrals.
- The `compute()` loop uses four atom indices from `neighbor->dihedrallist[n][0..4]` (type at index 4).
- The types array is `atom->ndihedraltypes`.
- The `writedata` flag must be set to 1 in the constructor if `write_data()` is implemented (the default is 0 for dihedral styles).

In the constructor, the `writedata` flag is set:

```
DihedralHarmonic::DihedralHarmonic(LAMMPS *_lmp) :
    Dihedral(_lmp), k(nullptr), cos_shift(nullptr), sin_shift(nullptr), sign(nullptr),
    multiplicity(nullptr)
{
  writedata = 1;
}
```

4.8.11 Case 4: Implementing an improper style

Improper styles compute interactions involving four atoms where the geometry represents an out-of-plane deformation rather than a conventional torsion. Harmonic impropers implement:

$$E = K(\chi - \chi_0)^2$$

where K is the force constant and χ_0 is the equilibrium improper angle.

The header file uses `#ifdef IMPROPER_CLASS` and `ImproperStyle(name,class)`, and the class is derived from `Improper`:

```
#ifdef IMPROPER_CLASS
// clang-format off
ImproperStyle(harmonic,ImproperHarmonic);
// clang-format on
#else

#ifndef LMP_IMPROPER_HARMONIC_H
#define LMP_IMPROPER_HARMONIC_H

#include "improper.h"

namespace LAMMPS_NS {

class ImproperHarmonic : public Improper {
 public:
  ImproperHarmonic(class LAMMPS *);
  ~ImproperHarmonic() override;
  void compute(int, int) override;
  void coeff(int, char **) override;
  void write_restart(FILE *) override;
  void read_restart(FILE *) override;
  void write_data(FILE *) override;
  void *extract(const char *, int &) override;

 protected:
  double *k, *chi;

  virtual void allocate();
};

}    // namespace LAMMPS_NS
#endif
#endif
```

Key differences from dihedral styles:

- The base class is `Improper` (`#include "improper.h"`).
- The `compute()` loop uses four atom indices from `neighbor->improperlist[n][0..4]` (type at index 4).
- The types array is `atom->nimpropertypes`.
- A `symmatoms` array in the base class can be used to record which atom in the quadruplet is the central atom of symmetry. In `ImproperHarmonic`, `symmatoms[0] = 1` indicates that the first atom in the quadruplet is the atom of symmetry.

Constructor setup:

```
ImproperHarmonic::ImproperHarmonic(LAMMPS *_lmp) : Improper(_lmp), k(nullptr),␣
↪chi(nullptr)
{
  writedata = 1;
  // the first atom in the quadruplet is the atom of symmetry
  symmatoms[0] = 1;
}
```

4.8.12 Writing a new fix style

Writing fix styles is a flexible way of extending LAMMPS. Users can implement many things using fixes. Some fix styles are only used internally to support compute styles or pair styles:

- change particles attributes (positions, velocities, forces, etc.). Examples: `FixNVE`, `FixFreeze`.
- read or write data. Example: `FixRestart`.
- adding or modifying properties due to geometry. Example: `FixWall`.
- interacting with other subsystems or external code: Examples: `FixTTM`, `FixExternal`, `FixMDI`
- saving information for analysis or future use (previous positions, for instance). Examples: `FixAveTime`, `FixStoreState`.

All fixes are derived from the `Fix` base class and must have a constructor with the signature: `FixPrintVel(class LAMMPS *, int, char **)`.

Every fix must be registered in LAMMPS by writing the following lines of code in the header before include guards:

```
#ifdef FIX_CLASS
// clang-format off
FixStyle(print/vel,FixPrintVel);
// clang-format on
#else
/* the definition of the FixPrintVel class comes here */
...
#endif
```

Where `print/vel` is the style name of your fix in the input script and `FixPrintVel` is the name of the class. The header file would be called `fix_print_vel.h` and the implementation file `fix_print_vel.cpp`. These conventions allow LAMMPS to automatically integrate it into the executable when compiling and associate your new fix class with the designated keyword when it parses the input script.

Let's write a simple fix which will print the average velocity at the end of each timestep. First of all, implement a constructor:

```
FixPrintVel::FixPrintVel(LAMMPS *lmp, int narg, char **arg)
: Fix(lmp, narg, arg)
{
  if (narg < 4) utils::missing_cmd_args(FLERR, "fix print/vel", error);

  nevery = utils::inumeric(FLERR,arg[3],false,lmp);
  if (nevery <= 0)
    error->all(FLERR,"Illegal fix print/vel nevery value: {}", nevery);
}
```

In the constructor you should parse the fix arguments which are specified in the script. All fixes have pretty much the same syntax: `fix <fix-ID> <fix group> <fix name> <fix arguments ...>`. The first 3 parameters are parsed by Fix base class constructor, while `<fix arguments>` should be parsed by you. In our case, we need to specify how often we want to print an average velocity. For instance, once in 50 timesteps: `fix 1 print/vel 50`. There is a special variable in the Fix class called `nevery` which specifies how often the method `end_of_step()` is called. Thus all we need to do is just set it up.

The next method we need to implement is `setmask()`:

```
int FixPrintVel::setmask()
{
  int mask = 0;
  mask |= FixConst::END_OF_STEP;
  return mask;
}
```

Here the we specify which methods of the fix should be called during *execution of a timestep*. The constant `END_OF_STEP` corresponds to the `end_of_step()` method.

```
void FixPrintVel::end_of_step()
{
  // for add3, scale3
  using namespace MathExtra;

  double** v = atom->v;
  int nlocal = atom->nlocal;
  double localAvgVel[4]; // 4th element for particles count
  memset(localAvgVel, 0, 4 * sizeof(double));
  for (int particleInd = 0; particleInd < nlocal; ++particleInd) {
    add3(localAvgVel, v[particleInd], localAvgVel);
  }
  localAvgVel[3] = nlocal;
  double globalAvgVel[4];
  memset(globalAvgVel, 0, 4 * sizeof(double));
  MPI_Allreduce(localAvgVel, globalAvgVel, 4, MPI_DOUBLE, MPI_SUM, world);
  scale3(1.0 / globalAvgVel[3], globalAvgVel);
  if ((comm->me == 0) && screen) {
    utils::print(screen, "{}, {}, {}\n",
                 globalAvgVel[0], globalAvgVel[1], globalAvgVel[2]);
  }
}
```

In the code above, we use MathExtra routines defined in `math_extra.h`. There are bunch of math functions to work with arrays of doubles as with math vectors. It is also important to note that LAMMPS code should always assume to be run in parallel and that atom data is thus distributed across the MPI ranks. Thus you can only process data from local atoms directly and need to use MPI library calls to combine or exchange data. For serial execution, LAMMPS comes bundled with the MPI STUBS library that contains the MPI library function calls in dummy versions that only work for a single MPI rank.

In this code we use an instance of Atom class. This object is stored in the Pointers class (see `pointers.h`) which is the base class of the Fix base class. This object contains references to various class instances (the original instances are created and held by the LAMMPS class) with all global information about the simulation system. Data from the Pointers class is available to all classes inherited from it using protected inheritance. Hence when you write you own class, which is going to use LAMMPS data, don't forget to inherit from Pointers or pass a Pointer to it to all functions that need access. When writing fixes we inherit from class Fix which is inherited from Pointers so there is no need to

inherit from it directly.

The code above computes average velocity for all particles in the simulation. Yet you have one unused parameter in fix call from the script: `group_name`. This parameter specifies the group of atoms used in the fix. So we should compute the average for all particles in the simulation only if `group_name == "all"`, but it can be any group. The group membership information of an atom is contained in the *mask* property of an atom and the bit corresponding to a given group is stored in the groupbit variable which is defined in Fix base class:

```
for (int i = 0; i < nlocal; ++i) {
  if (atom->mask[i] & groupbit) {
  // Do all job here
  }
}
```

Class Atom encapsulates atoms positions, velocities, forces, etc. Users can access them using the particle index. Note, that particle indexes are usually changed every few timesteps because of neighbor list rebuilds and spatial sorting (to improve cache efficiency).

Let us consider another Fix example: We want to have a fix which stores atoms position from the previous time step in your fix. The local atoms indexes may not be valid on the next iteration. In order to handle this situation there are several methods which should be implemented:

- `double memory_usage()`: return how much memory the fix uses (optional)
- `void grow_arrays(int)`: do reallocation of the per-particle arrays in your fix
- `void copy_arrays(int i, int j, int delflag)`: copy i-th per-particle information to j-th particle position. Used when atom sorting is performed. if delflag is set and atom j owns a body, move the body information to atom i.
- `void set_arrays(int i)`: sets i-th particle related information to zero

Note, that if your class implements these methods, it must add calls of add_callback and delete_callback to the constructor and destructor. Since we want to store positions of atoms from the previous timestep, we need to add `double** xold` to the header file. Than add allocation code to the constructor:

```
FixSavePos::FixSavePos(LAMMPS *lmp, int narg, char **arg), xold(nullptr)
{
//...
  memory->create(xold, atom->nmax, 3, "FixSavePos:x");
  atom->add_callback(0);
}

FixSavePos::~FixSavePos() {
  atom->delete_callback(id, 0);
  memory->destroy(xold);
}
```

Implement the aforementioned methods:

```
double FixSavePos::memory_usage()
{
  int nmax = atom->nmax;
  double bytes = 0.0;
  bytes += nmax * 3 * sizeof(double);
  return bytes;
}
```

(continues on next page)

(continued from previous page)

```
void FixSavePos::grow_arrays(int nmax)
{
  memory->grow(xold, nmax, 3, "FixSavePos:xold");
}

void FixSavePos::copy_arrays(int i, int j, int delflag)
{
  memcpy(xold[j], xold[i], sizeof(double) * 3);
}

void FixSavePos::set_arrays(int i)
{
  memset(xold[i], 0, sizeof(double) * 3);
}

int FixSavePos::pack_exchange(int i, double *buf)
{
  int m = 0;
  buf[m++] = xold[i][0];
  buf[m++] = xold[i][1];
  buf[m++] = xold[i][2];

  return m;
}

int FixSavePos::unpack_exchange(int nlocal, double *buf)
{
  int m = 0;
  xold[nlocal][0] = buf[m++];
  xold[nlocal][1] = buf[m++];
  xold[nlocal][2] = buf[m++];

  return m;
}
```

Now, a little bit about memory allocation. We use the Memory class which is just a bunch of template functions for allocating 1D and 2D arrays. So you need to add include `memory.h` to have access to them.

Finally, if you need to write/read some global information used in your fix to the restart file, you might do it by setting the flag `restart_global = 1` in the constructor and implementing methods `void write_restart(FILE *fp)` and `void restart(char *buf)`. If, in addition, you want to write the per-atom property to restart files then these additional settings and functions are needed:

- a fix flag indicating this needs to be set `restart_peratom = 1;`
- `atom->add_callback()` and `atom->delete_callback()` must be called a second time with the final argument set to 1 instead of 0 (indicating restart processing instead of per-atom data memory management).
- the functions `void pack_restart(int i, double *buf)` and `void unpack_restart(int nlocal, int nth)` need to be implemented

4.8.13 Writing new compute styles

Compute styles are used to calculate global or per-atom scalar, vector, or array quantities or local or per-chunk or grid based properties from the current state of the simulation. Examples include temperatures, pressures, kinetic energies, and user-defined quantities. All compute styles are derived from the `Compute` base class, which is defined in `src/compute.h`. An overview of the available methods and flags is given on the page for *modifying or extending compute styles*.

Computes are executed *on demand* and thus require a "consumer" like *fix ave/time*, *compute reduce*, or a *custom thermo style* or *custom dump style*. This is different from *Writing a new fix style* which are executed at *pre-determined steps during a run* and either at every steps or with a set frequency. Some compute instances are also created and used internally, e.g. for *thermo output*. It should be noted that some computes do not actually perform computations (e.g. computes for potential energy or virial) but rather suitable flags are set and then the corresponding data is collected by the force computation as needed and then the compute merely makes that pre-collected data available. Such computes may not be executed between runs but only during a run (or minimization).

In general, new compute styles should be added to the *EXTRA-COMPUTE package*. It is usually not necessary to create accelerated compute styles except for the *KOKKOS* package where there is a significant benefit to avoid time consuming data transfers between GPU and host. If you feel that your contribution should be added to a different package, please consult with the *LAMMPS developers* first. The contributed code needs to support the *traditional GNU make build process* **and** the *CMake build process*.

4.8.14 Case 1: A global scalar compute

In this section we describe how to implement a compute that produces a single global scalar value. As a concrete example we use *compute temp*, which computes the kinetic temperature of a group of atoms. The full implementation can be found in `src/compute_temp.cpp` and `src/compute_temp.h`.

Header file

Every compute style must be registered in LAMMPS by including the following lines after the copyright block and before the include guards for the class definition:

```
#ifdef COMPUTE_CLASS
// clang-format off
ComputeStyle(temp,ComputeTemp);
// clang-format on
#else
```

The block between `#ifdef COMPUTE_CLASS` and `#else` registers the compute style with LAMMPS. During compilation, the build system parses the `ComputeStyle(temp,ComputeTemp)` marker and generates a file `style_compute.cpp` that `#includes` the header files of all installed compute styles and registers a factory function for each of them. These factory functions are kept in a process-global registry that connects the style name `temp` with the class name `ComputeTemp`. The `COMPUTE_CLASS` macro is never actually defined during compilation; the `#ifdef COMPUTE_CLASS` block only serves as a marker for the build system's parser, so the header always provides the class definition from its `#else` branch. The `// clang-format` comments prevent the `clang-format` tool from incorrectly inserting spaces inside the macro arguments.

The class definition:

```
#ifndef LMP_COMPUTE_TEMP_H
#define LMP_COMPUTE_TEMP_H

#include "compute.h"
```

(continues on next page)

(continued from previous page)

```
namespace LAMMPS_NS {

class ComputeTemp : public Compute {
 public:
  ComputeTemp(class LAMMPS *, int, char **);
  ~ComputeTemp() override;
  void init() override {}
  void setup() override;
  double compute_scalar() override;
  void compute_vector() override;

 protected:
  double tfactor;

  virtual void dof_compute();
};

}    // namespace LAMMPS_NS
#endif
#endif
```

The class derives from `Compute` and overrides the pure virtual method `init()` (here with an empty inline body since there is no initialization needed for this example) as well as several optional methods. All overriding methods carry the `override` keyword.

Implementation file

Constructor

The constructor calls the base class constructor and sets the flags that tell LAMMPS what kind of output this compute produces:

```
ComputeTemp::ComputeTemp(LAMMPS *lmp, int narg, char **arg) : Compute(lmp, narg, arg)
{
  if (narg != 3) error->all(FLERR, "Illegal compute temp command");

  scalar_flag = vector_flag = 1;
  size_vector = 6;
  extscalar = 0;
  extvector = 1;
  tempflag = 1;

  vector = new double[size_vector];
}
```

The flags have the following meanings:

- `scalar_flag = 1`: this compute provides a global scalar via `compute_scalar()`.
- `vector_flag = 1`: this compute also provides a global vector via `compute_vector()`.
- `size_vector = 6`: the vector has 6 components (the six components of the kinetic energy tensor).
- `extscalar = 0`: the scalar is *intensive* (does not scale with the number of atoms since temperature is an inten-

sive property).

- `extvector = 1`: each vector component is *extensive* (since kinetic energy scales with the number of atoms).
- `tempflag = 1`: marks this compute as providing a temperature, which is used by thermostat fixes to find a compatible temperature compute.

The `vector` array is allocated in the constructor; the base class `Compute` provides a pointer `vector` that derived classes should point to their allocated storage.

The destructor frees the `vector` array if `copymode` is false. The `copymode` flag is set to `0` by default and set to `1` by the `ComputeTempKokkos` class. This class is derived from `ComputeTemp` and replaces the storage assigned to `vector` with a Kokkos specific storage object to facilitate convenient data transfer between host and accelerator devices:

```
ComputeTemp::~ComputeTemp()
{
  if (!copymode) delete[] vector;
}
```

The init() method (required)

The `init()` method must be overridden in every compute style; it is pure virtual in the base class. It is called once before each run or minimization to perform one-time initialization (e.g., checking that all required fixes or computes exist, requesting neighbor lists, etc.). Here, `init()` has nothing to do and is given an empty body inline in the header.

The setup() method (optional)

The optional `setup()` method is called at the start of each run, after `init()`. For `ComputeTemp`, it computes the number of degrees of freedom:

```
void ComputeTemp::setup()
{
  dynamic = 0;
  if (dynamic_user || group->dynamic[igroup]) dynamic = 1;
  dof_compute();
}
```

The `dynamic` flag controls whether the number of degrees of freedom is re-computed every timestep (needed when atoms enter or leave the group or the simulation).

The compute_scalar() method (optional)

The `compute_scalar()` method computes the temperature and returns it as a double:

```
double ComputeTemp::compute_scalar()
{
  invoked_scalar = update->ntimestep;

  double **v = atom->v;
  double *mass = atom->mass;
  double *rmass = atom->rmass;
  int *type = atom->type;
  int *mask = atom->mask;
  int nlocal = atom->nlocal;
```

(continues on next page)

(continued from previous page)

```
  double t = 0.0;

  if (rmass) {
    for (int i = 0; i < nlocal; i++)
      if (mask[i] & groupbit)
        t += (v[i][0] * v[i][0] + v[i][1] * v[i][1] + v[i][2] * v[i][2]) * rmass[i];
  } else {
    for (int i = 0; i < nlocal; i++)
      if (mask[i] & groupbit)
        t += (v[i][0] * v[i][0] + v[i][1] * v[i][1] + v[i][2] * v[i][2]) * mass[type[i]];
  }

  MPI_Allreduce(&t, &scalar, 1, MPI_DOUBLE, MPI_SUM, world);
  if (dynamic) dof_compute();
  if (dof < 0.0 && natoms_temp > 0.0)
    error->all(FLERR, "Temperature compute degrees of freedom < 0");
  scalar *= tfactor;
  return scalar;
}
```

There are several important points:

- `invoked_scalar` is set to the current timestep number to allow other computes and fixes to check whether the result is fresh and avoid redundant re-computation.
- The group membership is checked via `mask[i] & groupbit`. The `groupbit` variable is defined in the base class `Compute` and corresponds to the group specified in the compute command.
- Atom data may be distributed across MPI ranks. Only *local* atoms (`i < atom->nlocal`) are iterated. `MPI_Allreduce` is used to sum the result across all ranks.
- The result is stored in `scalar` (declared in the base class) and also returned.
- The branch on `rmass` handles the case where atoms have individual masses (e.g. for granular simulations) versus per-type masses.

The compute_vector() method (optional)

The `compute_vector()` method computes the kinetic energy tensor and stores it in the pre-allocated `vector` array:

```
void ComputeTemp::compute_vector()
{
  invoked_vector = update->ntimestep;

  double **v = atom->v;
  double *mass = atom->mass;
  double *rmass = atom->rmass;
  int *type = atom->type;
  int *mask = atom->mask;
  int nlocal = atom->nlocal;

  double massone, t[6];
  for (int i = 0; i < 6; i++) t[i] = 0.0;

  for (int i = 0; i < nlocal; i++)
```

(continues on next page)

(continued from previous page)

```
    if (mask[i] & groupbit) {
      if (rmass)
        massone = rmass[i];
      else
        massone = mass[type[i]];
      t[0] += massone * v[i][0] * v[i][0];
      t[1] += massone * v[i][1] * v[i][1];
      t[2] += massone * v[i][2] * v[i][2];
      t[3] += massone * v[i][0] * v[i][1];
      t[4] += massone * v[i][0] * v[i][2];
      t[5] += massone * v[i][1] * v[i][2];
    }

  MPI_Allreduce(t, vector, 6, MPI_DOUBLE, MPI_SUM, world);
  for (int i = 0; i < 6; i++) vector[i] *= force->mvv2e;
}
```

The result must be stored in the `vector` array (declared in the base class) and `invoked_vector` must be set to mark the result as fresh.

4.8.15 Case 2: A per-atom compute

In this section we describe a compute that produces a per-atom quantity. As an example we use *compute ke/atom*, which computes the kinetic energy of each atom. The full implementation can be found in `src/compute_ke_atom.cpp` and `src/compute_ke_atom.h`.

Header file

The registration block uses `ComputeStyle(ke/atom,ComputeKEAtom)`. The class definition:

```
class ComputeKEAtom : public Compute {
 public:
  ComputeKEAtom(class LAMMPS *, int, char **);
  ~ComputeKEAtom() override;
  void init() override;
  void compute_peratom() override;
  double memory_usage() override;

 private:
  int nmax;
  double *ke;
};
```

The compute overrides `init()`, `compute_peratom()`, and `memory_usage()`. The per-atom data array `ke` and its current allocated size `nmax` are private members.

Constructor

```
ComputeKEAtom::ComputeKEAtom(LAMMPS *lmp, int narg, char **arg) :
    Compute(lmp, narg, arg), ke(nullptr)
{
```

(continues on next page)

(continued from previous page)

```
  if (narg != 3) error->all(FLERR, "Illegal compute ke/atom command");

  peratom_flag = 1;
  size_peratom_cols = 0;

  nmax = 0;
}
```

The flags have the following meanings:

- `peratom_flag = 1`: marks this compute as providing per-atom data via `compute_peratom()`.
- `size_peratom_cols = 0`: the per-atom data is a vector (one value per atom); set to a non-zero value for arrays with multiple values per atom.

The destructor must free `ke`:

```
ComputeKEAtom::~ComputeKEAtom()
{
  memory->destroy(ke);
}
```

The init() method (required)

```
void ComputeKEAtom::init()
{
  if (modify->get_compute_by_style(style).size() > 1)
    if (comm->me == 0) error->warning(FLERR, "More than one compute {}", style);
}
```

This `init()` implementation emits a warning if more than one compute of this style exists, since having duplicates wastes computation. Most compute styles implement at least a minimal `init()` that checks for required fixes or computes and requests neighbor lists when needed.

The compute_peratom() method (optional)

```
void ComputeKEAtom::compute_peratom()
{
  invoked_peratom = update->ntimestep;

  // grow ke array if necessary

  if (atom->nmax > nmax) {
    memory->destroy(ke);
    nmax = atom->nmax;
    memory->create(ke, nmax, "ke/atom:ke");
    vector_atom = ke;
  }

  // compute kinetic energy for each atom in group

  double mvv2e = force->mvv2e;
  double **v = atom->v;
```

(continues on next page)

(continued from previous page)

```
  double *mass = atom->mass;
  double *rmass = atom->rmass;
  int *mask = atom->mask;
  int *type = atom->type;
  int nlocal = atom->nlocal;

  if (rmass)
    for (int i = 0; i < nlocal; i++) {
      if (mask[i] & groupbit) {
        ke[i] = 0.5 * mvv2e * rmass[i] *
            (v[i][0] * v[i][0] + v[i][1] * v[i][1] + v[i][2] * v[i][2]);
      } else
        ke[i] = 0.0;
    }
  else
    for (int i = 0; i < nlocal; i++) {
      if (mask[i] & groupbit) {
        ke[i] = 0.5 * mvv2e * mass[type[i]] *
            (v[i][0] * v[i][0] + v[i][1] * v[i][1] + v[i][2] * v[i][2]);
      } else
        ke[i] = 0.0;
    }
}
```

There are several important points:

- `invoked_peratom` is set to the current timestep to mark the result as fresh.
- The `ke` array is grown if the number of owned+ghost atoms (`atom->nmax`) has increased since the last allocation. The base class pointer `vector_atom` must be updated whenever `ke` is reallocated. Setting `vector_atom = ke` after each reallocation ensures that callers always see the current storage.
- Atoms not in the group have their per-atom value set to 0.0.
- Only *local* atoms (`i < nlocal`) are processed; ghost atoms are not included.

The memory_usage() method (optional)

The `memory_usage()` method returns an estimate of the memory usage in bytes. This is used by the *info command* and for diagnostic output:

```
double ComputeKEAtom::memory_usage()
{
  double bytes = (double) nmax * sizeof(double);
  return bytes;
}
```

4.8.16 Notes on flags and output types

The `Compute` base class provides several flags and member variables that control how the compute's output is used elsewhere in LAMMPS. The most important ones for new compute styles are summarized below.

Flag	Meaning
scalar_flag	1 if compute_scalar() is implemented
vector_flag	1 if compute_vector() is implemented
array_flag	1 if compute_array() is implemented
peratom_flag	1 if compute_peratom() is implemented
local_flag	1 if compute_local() is implemented
size_vector	length of the global vector
size_array_rows	number of rows of the global array
size_array_cols	number of columns of the global array
size_peratom_cols	number of columns in the per-atom array (0=vector)
extscalar	0 if scalar is intensive, 1 if extensive
extvector	0 if each vector component is intensive, 1 extensive
extarray	0 if each array column is intensive, 1 extensive
tempflag	1 if compute produces a temperature
pressflag	1 if compute produces a pressure
vector	pointer to the global vector output array
array	pointer to the global 2D array output
vector_atom	pointer to the per-atom vector output array
array_atom	pointer to the per-atom 2D array output

For the output arrays (vector, array, vector_atom, array_atom), the derived class is responsible for allocating storage and pointing the base class pointer to it. The scalar variable is declared in the base class and need not be separately allocated.

The invoked_scalar, invoked_vector, invoked_array, and invoked_peratom variables should be set to update->ntimestep at the start of the corresponding compute method to allow other routines to detect whether the output is current.

4.8.17 Writing a new command style

Command styles allow to do system manipulations or interfaces to the operating system.

In the text below, we will discuss the implementation of one example. As shown on the page for *writing or extending command styles*, in order to implement a new command style, a new class must be written that is either directly or indirectly derived from the Command class. There is just one method that must be implemented: Command::command(). In addition, a custom constructor is needed to get access to the members of the LAMMPS class like the Error class to print out error messages. The Command::command() method processes the arguments passed to the command in the input and executes it. Any other methods would be for the convenience of implementation of the new command.

In general, new command styles should be added to the *EXTRA-COMMAND package*. If you feel that your contribution should be added to a different package, please consult with the *LAMMPS developers* first. The contributed code needs to support the *traditional GNU make build process* **and** the *CMake build process*.

4.8.18 Case 1: Implementing the geturl command

In this section, we will describe the procedure of adding a simple command style to LAMMPS: the *geturl command* that allows to download files directly without having to rely on an external program like "wget" or "curl". The complete implementation can be found in the files src/EXTRA-COMMAND/geturl.cpp and src/EXTRA-COMMAND/geturl.h of the LAMMPS source code.

Interfacing the *libcurl* library

Rather than implementing the various protocols for downloading files, we rely on an external library: libcurl library. This requires that the library and its headers are installed. For the traditional GNU make build system, this simply requires edits to the machine makefile to add compilation flags like for other libraries. For the CMake based build system, we need to add some lines to the file `cmake/Modules/Packages/EXTRA-COMMAND.cmake`:

```
find_package(CURL QUIET COMPONENTS HTTP HTTPS)
option(WITH_CURL "Enable libcurl support" ${CURL_FOUND})
if(WITH_CURL)
  find_package(CURL REQUIRED COMPONENTS HTTP HTTPS)
  target_compile_definitions(lammps PRIVATE -DLAMMPS_CURL)
  target_link_libraries(lammps PRIVATE CURL::libcurl)
endif()
```

The first `find_package()` command uses a built-in CMake module to find an existing *libcurl* installation with development headers and support for using the HTTP and HTTPS protocols. The "QUIET" flag ensures that there is no screen output and no error if the search fails. The status of the search is recorded in the "${CURL_FOUND}" variable. That variable sets the default of the WITH_CURL option, which toggles whether support for *libcurl* is included or not.

The second `find_package()` uses the "REQUIRED" flag to produce an error if the WITH_CURL option was set to `True`, but no suitable *libcurl* implementation with development support was found. This construct is used so that the CMake script code inside the `if(WITH_CURL)` and `endif()` block can be expanded later to download and compile *libcurl* as part of the LAMMPS build process, if it is not found locally. The `target_compile_definitions()` function added the define `-DLAMMPS_CURL` to the compilation flags when compiling objects for the LAMMPS library. This allows to always compile the *geturl command*, but use pre-processing to compile in the interface to *libcurl* only when it is present and usable and otherwise stop with an error message about the unavailability of *libcurl* to execute the functionality of the command.

Header file

The first segment of any LAMMPS source should be the copyright and license statement. Note the marker in the first line to indicate to editors like emacs that this file is a C++ source, even though the .h extension suggests a C source (this is a convention inherited from the very beginning of the C++ version of LAMMPS).

```
/* -*- c++ -*- ----------------------------------------------------------
   LAMMPS - Large-scale Atomic/Molecular Massively Parallel Simulator
   https://www.lammps.org/, Sandia National Laboratories
   LAMMPS development team: developers@lammps.org

   Copyright (2003) Sandia Corporation.  Under the terms of Contract
   DE-AC04-94AL85000 with Sandia Corporation, the U.S. Government retains
   certain rights in this software.  This software is distributed under
   the GNU General Public License.

   See the README file in the top-level LAMMPS directory.
------------------------------------------------------------------------- */
```

Every command style must be registered in LAMMPS by including the following lines of code in the second part of the header after the copyright message and before the include guards for the class definition:

```
#ifdef COMMAND_CLASS
// clang-format off
CommandStyle(geturl,GetURL);
```

(continues on next page)

(continued from previous page)

```
// clang-format on
#else
```

This block between `#ifdef COMMAND_CLASS` and `#else` registers the command style with LAMMPS. During compilation, the build system parses the `CommandStyle(geturl,GetURL)` marker and generates a file `style_command.cpp` that `#includes` the header files of all "installed" command styles and registers a "factory function" for each of them — a small function that creates an instance of the `Command` class so its `command()` method can be called. These factory functions are kept in a process-global registry that connects the command name `geturl` with the class `GetURL` and enables the `Input` class to execute the command. The `COMMAND_CLASS` macro is never actually defined during compilation; the `#ifdef COMMAND_CLASS` block only serves as a marker for the build system's parser, so the header always provides the class definition from its `#else` branch.

The list of command style files is automatically updated by the build system if there are new files, so the presence of the new header file in the `src/EXTRA-COMMAND` folder and the enabling of the EXTRA-COMMAND package will trigger LAMMPS to include the new command style when it is (re-)compiled. The "// clang-format" format comments are needed so that running *clang-format* on the file will not insert unwanted blanks which would break the `CommandStyle` macro.

The third part of the header file is the actual class definition of the `GetURL` class. This has the custom constructor and the `command()` method implemented by this command style. For the constructor there is nothing to do but to pass the `lmp` pointer to the base class. Since the `command()` method is labeled "virtual" in the base class, it must be given the "override" property.

```
#ifndef LMP_GETURL_H
#define LMP_GETURL_H

#include "command.h"

namespace LAMMPS_NS {

class GetURL : public Command {
 public:
  GetURL(class LAMMPS *lmp) : Command(lmp) {};
  void command(int, char **) override;
};
}    // namespace LAMMPS_NS
#endif
#endif
```

The "override" property helps to detect unexpected mismatches because compilation will stop with an error in case the signature of a function is changed in the base class without also changing it in all derived classes.

Implementation file

We move on to the implementation of the `GetURL` class in the `geturl.cpp` file. This file also starts with a LAMMPS copyright and license header. Below that notice is typically the space where comments may be added with additional information about this specific file, the author(s), affiliation(s), and email address(es). This way the contributing author(s) can be easily contacted, when there are questions about the implementation later. Since the file(s) may be around for a long time, it is beneficial to use some kind of "permanent" email address, if possible.

```
/* ----------------------------------------------------------------------

   https://www.lammps.org/, Sandia National Laboratories
   LAMMPS development team: developers@lammps.org
```

(continues on next page)

(continued from previous page)

```
   Copyright (2003) Sandia Corporation.  Under the terms of Contract
   DE-AC04-94AL85000 with Sandia Corporation, the U.S. Government retains
   certain rights in this software.  This software is distributed under
   the GNU General Public License.

   See the README file in the top-level LAMMPS directory.
------------------------------------------------------------------------- */

/* ----------------------------------------------------------------------
   Contributing authors:  Axel Kohlmeyer (Temple U),
------------------------------------------------------------------------- */

#include "geturl.h"

#include "comm.h"
#include "error.h"

#if defined(LAMMPS_CURL)
#include <curl/curl.h>
#endif

using namespace LAMMPS_NS;
```

The second section of the implementation file has various include statements. The include file for the class header has to come first, then a couple of LAMMPS classes (sorted alphabetically) followed by the header for the *libcurl* interface. This is wrapped into an `#ifdef` block so that LAMMPS will compile this file without error when the *libcurl* header is not available and thus the define not set. The final statement of this segment imports the `LAMMPS_NS::` namespace globally for this file. This way, all LAMMPS specific functions and classes do not have to be prefixed with `LAMMPS_NS::`.

The command() function (required)

Since the required custom constructor is trivial and implemented in the header, there is only one function that must be implemented for a command style and that is the `command()` function.

```
void GetURL::command(int narg, char **arg)
{
#if !defined(LAMMPS_CURL)
  error->all(FLERR, "LAMMPS has not been compiled with libcurl support");
#else
  if (narg < 1) utils::missing_cmd_args(FLERR, "geturl", error);
  int verify = 1;
  int overwrite = 1;
  int verbose = 0;
```

This first part also has the `#ifdef` block depending on the LAMMPS_CURL define. This way the command will simply print an error, if *libcurl* is not available but will not fail to compile. Furthermore, it sets the defaults for the following optional arguments.

```
// process arguments

std::string url = arg[0];
```

(continues on next page)

(continued from previous page)

```
// sanity check

if ((url.find(':') == std::string::npos) || (url.find('/') == std::string::npos))
  error->all(FLERR, "URL '{}' is not a supported URL", url);

std::string output = url.substr(url.find_last_of('/') + 1);
if (output.empty()) error->all(FLERR, "URL '{}' must end in a file string", url);
```

This block stores the positional, i.e. non-optional argument of the URL to be downloaded and adds a couple of sanity checks on the string to make sure it is a valid URL. Also it derives the default name of the output file from the URL.

```
int iarg = 1;
while (iarg < narg) {
  if (strcmp(arg[iarg], "output") == 0) {
    if (iarg + 2 > narg) utils::missing_cmd_args(FLERR, "geturl output", error);
    output = arg[iarg + 1];
    ++iarg;
  } else if (strcmp(arg[iarg], "overwrite") == 0) {
    if (iarg + 2 > narg) utils::missing_cmd_args(FLERR, "geturl overwrite", error);
    overwrite = utils::logical(FLERR, arg[iarg + 1], false, lmp);
    ++iarg;
  } else if (strcmp(arg[iarg], "verify") == 0) {
    if (iarg + 2 > narg) utils::missing_cmd_args(FLERR, "geturl verify", error);
    verify = utils::logical(FLERR, arg[iarg + 1], false, lmp);
    ++iarg;
  } else if (strcmp(arg[iarg], "verbose") == 0) {
    if (iarg + 2 > narg) utils::missing_cmd_args(FLERR, "geturl verbose", error);
    verbose = utils::logical(FLERR, arg[iarg + 1], false, lmp);
    ++iarg;
  } else {
    error->all(FLERR, "Unknown geturl keyword: {}", arg[iarg]);
  }
  ++iarg;
}
```

This block parses the optional arguments following the URL and stops with an error if there are arguments missing or an unknown argument is encountered.

```
// only download files from rank 0

if (comm->me != 0) return;

if (!overwrite && platform::file_is_readable(output)) return;

// open output file for writing

FILE *out = fopen(output.c_str(), "wb");
if (!out)
  error->all(FLERR, "Cannot open output file {} for writing: {}", output,␣
 ↪utils::getsyserror());
```

Here all MPI ranks other than 0 will return, so that the URL download will only happen from a single MPI rank. For

that rank the output file is opened for writing using the C library function `fopen()`.

```
// initialize curl and perform download

CURL *curl;
curl_global_init(CURL_GLOBAL_DEFAULT);
curl = curl_easy_init();
if (curl) {
  (void) curl_easy_setopt(curl, CURLOPT_URL, url.c_str());
  (void) curl_easy_setopt(curl, CURLOPT_WRITEDATA, (void *) out);
  (void) curl_easy_setopt(curl, CURLOPT_FILETIME, 1L);
  (void) curl_easy_setopt(curl, CURLOPT_FAILONERROR, 1L);
  if (verbose && screen) {
    (void) curl_easy_setopt(curl, CURLOPT_VERBOSE, 1L);
    (void) curl_easy_setopt(curl, CURLOPT_STDERR, (void *) screen);
  }
  if (!verify) {
    (void) curl_easy_setopt(curl, CURLOPT_SSL_VERIFYPEER, 0L);
    (void) curl_easy_setopt(curl, CURLOPT_SSL_VERIFYHOST, 0L);
  }
  auto res = curl_easy_perform(curl);
  if (res != CURLE_OK) {
    long response = 0L;
    curl_easy_getinfo(curl, CURLINFO_RESPONSE_CODE, &response);
    error->one(FLERR, "Download of {} failed with: {} {}", output, curl_easy_
↪strerror(res),
               response);
  }
  curl_easy_cleanup(curl);
```

This block now implements the actual URL download with the selected options via the "easy" interface of *libcurl*. For the details of what these function calls do, please have a look at the *libcurl documentation.

```
  }
  curl_global_cleanup();
  fclose(out);
#endif
}
```

Finally, the previously opened file is closed and the command is complete.

4.8.19 Creating styles for the OPENMP package

The OPENMP package in LAMMPS provides an accelerated execution of many LAMMPS styles with multi-threading using OpenMP pragmas. Adding support for a new style to the OPENMP package involves creating a derived class that overrides the standard serial method.

For a high-level discussion on the rationale and parallelization strategy of the OpenMP package, see *OpenMP Parallelism*.

In the text below, we will describe important steps of the procedure of adding multi-thread style to the OPENMP package by looking at a few selected example sections of source files in the OPENMP package.

Package and build system considerations

The OPENMP package is one of the accelerator packages. New styles should be added to the *src/OPENMP* directory. The contributed code needs to support both the CMake build process and (if applicable) the traditional GNU make process.

Case study: a pairwise additive model

For many pair styles, adding OpenMP support involves creating a derived class that inherits from the serial pair style class. Let's look at the *pair_lj_cut* style and its OpenMP-accelerated variant.

Header file

The header file for an OPENMP-enabled pair style (e.g., *pair_lj_cut_omp.h*) typically derives from the original style class (e.g., *PairLJCut*).

```
#ifndef LMP_PAIR_LJ_CUT_OMP_H
#define LMP_PAIR_LJ_CUT_OMP_H

#include "pair_lj_cut.h"
#include "thr_omp.h"

namespace LAMMPS_NS {

class PairLJCutOMP : public PairLJCut, public ThrOMP {
 public:
  PairLJCutOMP(class LAMMPS *);
  virtual ~PairLJCutOMP() {}

  void compute(int, int) override;
  double memory_usage() override;

 private:
  template <int EVFLAG, int EFLAG, int NEWTON_PAIR>
  void eval(int ifrom, int ito, ThrData *const thr);
};
}
```

The class inherits from *PairLJCut* (the base serial style) and *ThrOMP*, a utility class that manages the OpenMP-specific data, such as thread-local force and energy accumulation arrays.

Constructor and methods

The constructor for an OMP style typically just calls the base class constructor and initializes the *ThrOMP* base:

```
PairLJCutOMP::PairLJCutOMP(LAMMPS *lmp) :
  PairLJCut(lmp), ThrOMP(lmp, THR_PAIR)
{
  respa_enable = 0;
}
```

- The *THR_PAIR* argument tells the *ThrOMP* base class that this is a pair-style acceleration, which influences how data is allocated and managed.
- Setting *respa_enable = 0* is common for OMP accelerated styles as RESPA acceleration often requires separate implementation logic.

Why only few methods?

You may notice that only a few methods are overridden. Most methods (e.g., *coeff()*, *init_one()*, *write_restart()*) are inherited directly from *PairLJCut*. This is possible because:

- The serial class already handles the data structures and input parsing.
- The *compute()* method is the part that consumes most of the CPU time and is called in every step during a run.
- *single()* is not overridden because it cannot be efficiently parallelized with OpenMP. It represents just one iteration of the inner loop of the main loop constructs of the *compute()* function.

Utility Functions for Threading

The *ThrOMP* class and related LAMMPS infrastructure provide several key methods to manage parallel execution:

- *loop_setup_thr(int nlocal)*: This method calculates the range of atoms (or neighbors) each thread should process based on the number of threads and the total count. It ensures an even workload distribution across threads.
- *FixOMP::get_thr(int tid)*: This method retrieves the *ThrData* object for a specific thread ID (*tid*). *ThrData* maintains thread-private buffers for forces and energies, avoiding race conditions during the force computation.
- *reduce_thr(ThrData* thr, int eflag, int vflag)*: After the parallel region, this method is used to perform the reduction of per-thread force, energy, and virial contributions into the global arrays (e.g., *atom->f*).

ev_setup_thr() and *ev_tally_thr()*

These methods replace their non-OpenMP counterparts (*ev_setup()* and *ev_tally()*) to support thread-local data:

- *ev_setup_thr(eflag, vflag, thr)*: Unlike *ev_setup()*, which initializes global energy/virial flags, *ev_setup_thr()* initializes the thread-specific *ThrData* structures to track energy and virial contributions independently per thread.
- *ev_tally_thr(i, j, nlocal, newton, evdwl, ecoul, fpair, delx, dely, delz, thr)*: Instead of updating global force/energy arrays directly, *ev_tally_thr()* updates the per-thread tally arrays stored within the provided *ThrData* object (*thr*). This allows multiple threads to record force/energy contributions simultaneously without locking or memory contention.

Performance Optimization with Templates and *_noalias*

The template-based approach in *eval<EVFLAG, EFLAG, NEWTON_PAIR>()* is a powerful optimization technique:

- **Branch Elimination**: By passing state as template parameters, the compiler can generate specialized machine code for each combination of flags (e.g., *NEWTON_PAIR=1*, *EFLAG=0*). This removes conditional branches (*if* statements) from the inner loop, which is critical for performance because CPU branch predictors often struggle with these toggles in tight loops.
- **`_noalias`**: The *_noalias* keyword (or compiler hint) tells the compiler that pointers (e.g., force arrays) do not point to the same memory addresses as other pointers used in the same context. This enables the compiler to aggressively optimize load/store operations and loop unrolling, as it no longer needs to ensure memory consistency across potential pointer aliasing.

Porting complex many-body styles (e.g., PairSWOMP, PairTersoffOMP)

Many-body pair styles like Stillinger-Weber (*PairSW*) or Tersoff (*PairTersoff*) differ significantly from pairwise additive potentials. In pairwise additive potentials (like LJ), the force on atom *i* depends only on its neighbors *j*. Many-body styles, however, compute forces based on three-body (or higher-order) terms, meaning the force on atom *i* depends on the environment of atom *j* as well.

Differences from Pairwise Additive Potentials

1. **Neighbor List Requirements**: Pairwise additive potentials typically require a "half" neighbor list. Many-body potentials, however, usually require a "full" neighbor list to iterate over all neighbors of both atoms *i* and *j* when calculating the three-body interaction *i*-*j*-*k*.
2. **Computational Structure**: Instead of a simple nested loop, many-body potentials involve complex kernels that iterate over neighbors of neighbors. This significantly increases the complexity of the parallel execution and data locality requirements.
3. **Communication**: Due to the three-body nature, the potential needs access to the positions of all atoms within the cutoff of *j*, even if *j* is a ghost atom. This increases the amount of ghost-atom data that must be kept synchronized.

Case Study: PairEAMOMP

Many-body pair styles like EAM are more complex because they require multiple passes (e.g., one pass to accumulate density, one to compute forces). In *PairEAMOMP*, this is handled by having the *compute()* function orchestrate multiple parallel loops, each calling its own *eval()* variant:

```
// First loop: accumulate density
#pragma omp parallel
{
  eval_rho<...>(...);
}

// Communication step:
comm->forward_comm(this);

// Second loop: compute forces
#pragma omp parallel
{
  eval_force<...>(...);
}
```

Case Study: PairSWOMP and PairTersoffOMP

In *PairSWOMP* and *PairTersoffOMP*, the acceleration is handled by parallelizing the nested loops while maintaining thread-safety.

- **Data Locality**: Because these styles require a full neighbor list, the *PairTersoffOMP::compute()* function must carefully partition the neighbor list among threads, ensuring that every thread processes a unique set of interactions without redundant calculations.
- **Tallying**: Just as in pairwise styles, *ev_tally_thr()* is used to accumulate energy/virial. However, since the many-body calculation is more involved, the tallying is often called multiple times or with different arguments to properly decompose the contributions of the 2-body and 3-body terms.
- **Kernel Specialization**: Similar to the pairwise case, the *eval()* kernels for many-body styles are heavily templated to handle various scenarios (e.g., different Newton's third law configurations).

When porting these styles, the primary challenge is to ensure that the many-body logic remains correct within a multi-threaded environment. Developers must carefully synchronize data access, especially for shared neighbor list information and thread-local atom data, by utilizing the *ThrData* structure.

Accelerating bonded force styles

Accelerating bonded force styles follows the same philosophy as pair styles. A *BondLJCutOMP* class would inherit from *BondLJCut* and *ThrOMP*. The same principle applies to angle, dihedral, and improper styles. The *compute()* function again loops over the bonds using OpenMP pragmas, using the same thread-local tallying mechanisms as pair styles.

```
void BondLJCutOMP::compute(int eflag, int vflag)
{
  // ...
  #pragma omp parallel
  {
     // loop over bond list in chunks
     // use ev_tally_thr for tallies
  }
  // ...
}
```

The reduction logic and templated kernels remain nearly identical to those used in pair styles, making it relatively straightforward to port any bonded interaction style to OpenMP.

Implementation file

The core of the OPENMP implementation resides in the *.cpp* file (e.g., *pair_lj_cut_omp.cpp*).

The *compute()* function is overridden to trigger the parallel execution and handle thread synchronization:

```
void PairLJCutOMP::compute(int eflag, int vflag)
{
  // ... (initialization of evflag, vflag, etc.)

  const int nthreads = comm->nthreads;
  const int inum = list->inum;

  #if defined(_OPENMP)
  #pragma omp parallel default(none) shared(eflag,vflag)
  #endif
  {
    // ... (setup thread-local data)

    if (newton_pair) eval<1,1,1>(...);
    else eval<1,1,0>(...);
  }
  // ... (reduce per-thread forces/energies/virials)
}
```

1. The *compute()* function initializes the OpenMP parallel region using *#pragma omp parallel*.
2. The *eval()* method (a template function) encapsulates the actual force-calculation loop. It uses template parameters (*EVFLAG*, *EFLAG*, *NEWTON_PAIR*) to optimize the loop based on whether energy/virial calculations are enabled and if Newton's third law is used, avoiding runtime conditionals inside the hot loop.
3. The *eval()* method uses *ThrData* to accumulate force and energy contributions safely within each thread.
4. After the parallel loop, the results from each thread's local buffers are reduced into the main force arrays, handling thread-safety during the reduction process.

By templating the *eval()* method, we can compile multiple variants of the kernel at build time, significantly improving performance by removing branches inside the main force loop.

Refer to existing files in *src/OPENMP/* for comprehensive implementation details and complex scenarios involving many-body interactions or communication.

4.8.20 Writing or updating documentation

Every contribution that adds a new style or command, or that changes the behavior or the arguments of an existing one, **must** come with matching documentation. This is a *strict requirement* for inclusion into the LAMMPS distribution. The documentation sources are written in reStructuredText (files with a `.rst` suffix in the `doc/src/` folder) and translated to HTML and PDF with Sphinx. All text must be written in American English and the `.rst` files may only contain 7-bit ASCII characters, so they can be cleanly converted to PDF via PDFLaTeX. Special characters and formulas can be included as embedded math typeset in a LaTeX subset.

This page complements the previous sections on *writing new styles*: where those describe the *C++ code* of a style, this one describes the *documentation* that has to accompany it. We use the *pair_style born/gauss* page (file `doc/src/pair_born_gauss.rst`) and the *fix nve* page (file `doc/src/fix_nve.rst`) as running examples, since both follow the established conventions closely and are short enough to quote in full.

A documentation page is not complete by itself: a new style also has to be registered in the corresponding command tables and overview lists, and the build and consistency checks described at the *bottom of this page* must pass without errors or warnings.

4.8.21 Anatomy of a style documentation page

A typical per-style documentation page is built from a fixed sequence of elements. The order and the exact wording of the section headers matter, because several of them are verified by automated checks and because common include files (like `accel_styles.rst`) are shared across all pages. The most reliable way to create a new page is to copy the page of a similar, existing style and adapt it.

Index entries

The very first lines of a documentation page are the Sphinx index directives. There must be one `.. index::` entry for **every** style that is documented on the page, *including every accelerated variant* (`/gpu`, `/intel`, `/kk`, `/omp`, `/opt`).

```
.. index:: pair_style born/gauss
.. index:: pair_style born/gauss/kk
.. index:: pair_style born/gauss/omp
```

A single documentation file may describe several closely related styles (for example `doc/src/pair_born.rst` documents `born`, `born/coul/long`, `born/coul/msm`, and `born/coul/wolf`). In that case each of those styles, and each of their accelerated variants, needs its own `.. index::` line. The completeness of these index entries is verified by `make style_check` (see *below*), which parses the `...Style(name,class)` macros from the C++ headers and reports any style or accelerated variant whose index entry is missing.

Title and command heading

The page title is the name of the command followed by the word "command", underlined with a row of = characters that must be at least as long as the title text.

```
pair_style born/gauss command
=============================
```

When a page documents multiple styles, it is customary to list the primary style in the title (or to use a more generic title), and to make sure each documented style has an index entry and is reachable through the command tables.

In reStructuredText a heading is indicated by underlining it with characters and the the level of a heading is set by kind of character used. The underline must be **at least as long** as the heading text; a shorter underline will trigger an error message, and the convention is to match the length exactly. LAMMPS uses a fixed set of characters for the heading levels so that pages nest consistently. This matters in particular for the combined PDF/LaTeX manual, where all pages are concatenated into a single document and therefore have to share one global hierarchy. From the outermost to the innermost level the characters are:

- `======` – the title of an individual page
- `------` – a section
- `^^^^^^` – a subsection
- `"""""""` – a subsubsection

A per-style reference page needs only two of these levels: `======` for the page title (the line ending in "command") and `"""""""` for each of the standard section headers (Syntax, Examples, Description, ...). Pages with a deeper structure – such as Howto or Programmer Guide pages, and this developer page – additionally use `------` and `^^^^^^` for the intermediate levels.

The page title and the section headers show up as collapsible, expandable entries in the navigation sidebar of the HTML manual (the theme is configured with a navigation depth of three levels) and in the table of contents of the PDF manual.

Accelerator Variants line

If, and only if, one or more accelerated variants of the style exist, an "Accelerator Variants:" line follows the title. It lists the full names of the accelerated styles in italics.

```
Accelerator Variants: *born/gauss/kk*, *born/gauss/omp*
```

This line and the `.. index::` entries for the accelerated variants must be kept consistent with each other and with the actual accelerated styles present in the source tree. Further down the page, the shared file `accel_styles.rst` is included (see *below*); `make style_check` enforces that a page which lists accelerated index entries also includes `accel_styles.rst` and, conversely, that a page without accelerated styles does not.

Syntax, Examples, and Description

The body of the page begins with a "Syntax" section. It shows the command in a `LAMMPS` code block and then explains each argument with a bullet list.

```
Syntax
"""""""

.. code-block:: LAMMPS

   pair_style born/gauss cutoff

* born/gauss = name of the pair style
* cutoff = global cutoff (distance units)
```

The "Examples" section gives one or more short, realistic command sequences, again in a `LAMMPS` code block.

```
Examples
""""""""

.. code-block:: LAMMPS
```

(continues on next page)

(continued from previous page)

```
   pair_style born/gauss 10.0
   pair_coeff 1 1 8.2464e13 12.48 0.042644277 0.44 3.56
```

The "Description" section is the main explanatory text. It describes the model or behavior, typically including the functional form as a `.. math::` block and a list of the coefficients with their units.

```
Description
"""""""""""

.. versionadded:: 4Jul2026

Pair style *born/gauss* computes pairwise interactions ...

.. math::

   E = A_0 \exp \left( -\alpha r \right) - A_1 \exp\left[ -\beta \left(r - r_0 \right)^2␣
↪\right]
```

Version markers

New publicly visible commands or newly added keywords must be marked with `.. versionadded:: TBD`; behavior that changed for an existing command uses `.. versionchanged:: TBD`. The literal text `TBD` is replaced automatically with the upcoming version date at release time. These directives are standalone markers: any explanatory text follows as an ordinary, *unindented* paragraph below the directive, **not** as the indented body of the directive. Version markers do not apply to internal (uppercase) style names.

Accelerator styles include

For any page that has accelerated variants, a standard block describing how to use accelerated styles is pulled in from the shared file `accel_styles.rst`, set off by horizontal rules:

```
----------

.. include:: accel_styles.rst

----------
```

Using the shared include keeps the description of the accelerator suffixes uniform across all pages, so this text should never be written out by hand.

Category-specific information sections

After the description, most styles have one or more information sections whose header and content are largely standardized per style category. Copy the wording from a closely related style and adjust it for the behavior of your style. Common examples are:

- For **pair styles**: a section titled "Mixing, shift, table, tail correction, restart, rRESPA info" describing whether the style supports *pair_modify* mixing, the shift, table, and tail options, whether it writes to *binary restart files*, and which *run_style respa* keywords it supports.
- For **fix styles**: a section titled "Restart, fix_modify, output, run start/stop, minimize info" describing what (if anything) the fix writes to restart files, which *fix_modify* options it honors, what global or per-atom quantities it makes available to *output commands*, and whether it is invoked during *energy minimization*.

- For **compute styles**: an "Output info" section describing the shape and meaning of the computed scalar, vector, or array and its units.

These sections should be present even when the answer is "none" or "not supported"; the *fix nve* page is a good template for the minimal case.

Restrictions, related commands, and defaults

Three short sections close out the page.

The "Restrictions" section documents any conditions that must be met for the style to be usable. The most common one is a **package requirement**: the style is only available when LAMMPS was built with a particular package, with a pointer to the *Build package* page.

```
Restrictions
""""""""""""

This pair style is only enabled if LAMMPS was built with the EXTRA-PAIR
package.  See the :doc:`Build package <Build_package>` page for more
info.
```

Restrictions are *not* limited to package membership, however. Many styles impose additional conditions; copy the exact wording from the page of a similar style. The most common categories are:

- **Package requirement:** only enabled when built with a given package (almost all styles outside the core); always link to *Build package*.
- **Newton setting:** the style requires the *newton* setting to be "on" (common for many-body and communication-heavy pair styles) or, more rarely, "off".
- **Command ordering:** the command must appear before or after another command – for example before the simulation box is defined by *create_box* or *read_data*, after a prerequisite fix, or before any *pair_coeff* commands.
- **Atom style requirement:** the style needs an *atom style* that stores particular per-atom data (e.g. charge, finite size/radius, torque and angular momentum, density or temperature, or support for bonds and angles).
- **Dependency on another command:** the style only works in conjunction with a specific fix, pair style, bond style, or *kspace_style*.
- **Uniqueness or mutual exclusivity:** only a single instance of the style may be defined, or certain keyword combinations cannot be used together.
- **Geometry and dimensionality:** the style only works for 2d or only for 3d systems, or only for orthogonal (not triclinic) simulation boxes.
- **Integrator and parallel constraints:** the style is incompatible with *run_style respa*, is not invoked during *energy minimization*, or has limitations under MPI domain decomposition.

If there are no restrictions at all, the section contains only the single word `none`.

The "Related commands" section is a comma-separated list of links (`:doc:` roles) to closely related commands. The "Default" section describes the default settings of any optional keywords, or the single word `none` if there are none.

Typical section order

Putting it together, the canonical order of a per-style page is:

1. `.. index::` entries (one per documented style and accelerated variant)
2. title with the `command` suffix
3. "Accelerator Variants:" line (only if accelerated styles exist)

4. Syntax
5. Examples
6. Description (with a `versionadded`/`versionchanged` marker if applicable)
7. `.. include:: accel_styles.rst` block (only if accelerated styles exist)
8. category-specific info section(s) (Mixing... / Restart... / Output info / ...)
9. Restrictions
10. Related commands
11. Default
12. literature citations (if any)

Literature citations

If the page cites publications, the citations are placed at the very bottom of the file behind a horizontal rule, each with a unique anchor label and a bold key.

```
----------

.. _Bomont:

**(Bomont)** Bomont, Bretonnet, J. Chem. Phys. 124, 054504 (2006)
```

The in-text reference then uses `:ref:`(Bomont) <Bomont>``. Citation anchor labels must be **unique across all `.rst` files**, so a distinctive label (often including a number or the style name) is needed; `make anchor_check` reports duplicate labels. See the bottom of `doc/fix_nh.rst` for more elaborate examples of citation formatting.

4.8.22 Integrating a new style into the command lists

Creating the per-style page is not enough: a new style must also be added to the compact command table and to the alphabetical overview list for its category, or the documentation will build with warnings and `make style_check` will fail. For a pair style, two files need an entry:

- `Commands_pair.rst` contains a multi-column table. Add the style in alphabetical order; the accelerator suffix letters are appended in parentheses (`g` = GPU, `i` = INTEL, `k` = KOKKOS, `o` = OPENMP, `t` = OPT) and the link target is the documentation file:

  ```
  * :doc:`born/gauss (ko) <pair_born_gauss>`
  ```

- `pair_style.rst` contains the alphabetical overview list with a short, one-line description after the link:

  ```
  * :doc:`born/gauss <pair_born_gauss>` - Born-Mayer / Gaussian potential
  ```

The other style categories follow the same pattern with different files. `make style_check` (via `utils/check-styles.py`) checks exactly these files for completeness:

Category	Compact table file	Overview list file
pair	Commands_pair.rst	pair_style.rst
bond	Commands_bond.rst	bond_style.rst
angle	Commands_bond.rst	angle_style.rst
dihedral	Commands_bond.rst	dihedral_style.rst
improper	Commands_bond.rst	improper_style.rst
compute	Commands_compute.rst	compute.rst
fix	Commands_fix.rst	fix.rst
kspace	Commands_kspace.rst	(none)
dump	Commands_dump.rst	(none)
command	Commands_all.rst	(none)

The suffix letters in the compact table must be listed in the canonical order `g i k o t`, with no separators (for example `ko`, never `ok` or `o,k`).

4.8.23 Documenting an accelerated variant of an existing style

When a new accelerated variant (e.g. a `/kk` or `/omp` version) is added for a style that already exists and is already documented, several small edits are required rather than a new page:

1. Add a `.. index::` line for the new accelerated style near the top of the existing page.
2. Add or extend the "Accelerator Variants:" line below the title so it lists the new variant.
3. Make sure the page includes the shared `accel_styles.rst` block; if the style previously had no accelerated variants, add that include (with surrounding horizontal rules).
4. Add the corresponding suffix **letter** to the style's entry in the compact command table (`Commands_pair.rst`, `Commands_fix.rst`, ...), keeping the canonical `g i k o t` letter order.

The overview list file (`pair_style.rst`, `fix.rst`, ...) does not encode the suffix letters and therefore does not need to change for a new accelerated variant.

4.8.24 Adding and referencing example inputs

For most new features it is preferred (see *the examples requirement*) to add a small, fast example input under the `examples` or `examples/PACKAGES` directory. The documentation page should point the reader to it. Two conventions are in common use; both are acceptable:

- mention the directory inside the "Description" or "Examples" section, for instance a line like `Example input scripts available: examples/PACKAGES/<foo>` for a new command called <foo>;
- reference specific input files by their path in the relevant discussion.

4.8.25 Other documentation that may need updating

Depending on the nature of the contribution, additional documentation may have to be created or updated:

- **New package:** add a description to `Packages_details.rst` and an entry to the package list, and, if the package needs special build steps, add the corresponding build instructions.
- **Complex features:** if a feature needs more background or a multi-command workflow to be used correctly, contribute a *Howto document* and add it to the toctree in `Howto.rst`.
- **Library or API changes:** additions or changes to the C++ library interface or the Fortran module require doxygen comments in the source and matching updates to the "Programmer Guide" section of the manual.

- **Error explanations:** errors with multiple possible causes can be given a detailed explanation on the `Error_details` page with an error code anchor, referenced from the code via *`utils::errorurl()`* (see the *error message requirements*).
- **Figures and PDFs:** inline figures live in `doc/JPG` and supplementary PDF files in `doc/PDF`; see existing pages for how to embed them.

4.8.26 Building and checking the documentation

Before submitting, build and proofread the documentation from within the `doc` directory:

```
make html          # build the HTML manual; there should be no warnings
make spelling      # run the spell checker
make anchor_check  # check for duplicate anchors and labels
make style_check   # check completeness of style tables and index entries
make check         # run all consistency checks at once
```

The `make check` target bundles `anchor_check`, `style_check`, `package_check`, `char_check`, and `role_check`. The `char_check` target rejects any non-ASCII character in the `.rst` files, and the `role_check` target catches malformed roles and directives (for example a `:doc:` or `:ref:` role not immediately followed by a backtick, a `text <target>` hyperlink missing its role, or a directive written with a single colon instead of `::`). Carefully read and proofread the generated HTML page before opening the pull request.

If the spell checker reports a false positive (such as an author surname or an established acronym), add it to `doc/utils/sphinx-config/false_positives.txt`.

4.9 Notes for developers and code maintainers

This section documents how some of the code functionality within LAMMPS works at a conceptual level. Comments on code in source files typically document what a variable stores, what a small section of code does, or what a function does and its input/outputs. The topics on this page are intended to document code functionality at a higher level.

Available notes

- *Reading and parsing of text and text files*
- *Requesting and accessing neighbor lists*
- *Errors, warnings, and informational messages*
- *Choosing between a custom atom style, fix property/atom, and fix STORE/ATOM*
- *Fix contributions to instantaneous energy, virial, and cumulative energy*
- *KSpace PPPM FFT grids*

4.9.1 Reading and parsing of text and text files

Classes in LAMMPS frequently need to read in additional data from a file, e.g. potential parameters from a potential file for manybody potentials. LAMMPS provides several custom classes and convenience functions to simplify the process. They offer the following benefits:

- better code reuse and fewer lines of code needed to implement reading and parsing data from a file
- better detection of format errors, incompatible data, and better error messages

- exit with an error message instead of silently converting only part of the text to a number or returning a 0 on unrecognized text and thus reading incorrect values
- re-entrant code through avoiding global static variables (as used by `strtok()`)
- transparent support for translating unsupported UTF-8 characters to their ASCII equivalents (the text-to-value conversion functions **only** accept ASCII characters)

In most cases (e.g. potential files) the same data is needed on all MPI ranks. Then it is best to do the reading and parsing only on MPI rank 0, and communicate the data later with one or more `MPI_Bcast()` calls. For reading generic text and potential parameter files the custom classes *TextFileReader* and *PotentialFileReader* are available. They allow reading the file as individual lines for which they can return a tokenizer class (see below) for parsing the line. Or they can return blocks of numbers as a vector directly. The documentation on *File reader classes* contains an example for a typical case.

When reading per-atom data, the data on each line of the file usually needs to include an atom ID so it can be associated with a particular atom. In that case the data can be read in multi-line chunks and broadcast to all MPI ranks with *utils::read_lines_from_file()*. Those chunks are then split into lines, parsed, and applied only to atoms the MPI rank "owns".

For splitting a string (incrementally) into words and optionally converting those to numbers, the *Tokenizer* and *ValueTokenizer* can be used. Those provide a superset of the functionality of `strtok()` from the C-library and the latter also includes conversion to different types. Any errors while processing the string in those classes will result in an exception, which can be caught and the error processed as needed. Unlike the C-library functions `atoi()`, `atof()`, `strtol()`, or `strtod()` the conversion will check if the converted text is a valid integer or floating point number and will not silently return an unexpected or incorrect value. For example, `atoi()` will return 12 when converting "12.5", while the ValueTokenizer class will throw an *InvalidIntegerException* if *ValueTokenizer::next_int()* is called on the same string.

4.9.2 Requesting and accessing neighbor lists

LAMMPS uses Verlet-style neighbor lists to avoid having to loop over *all* pairs of *all* atoms when computing pairwise properties with a cutoff (e.g. pairwise forces or radial distribution functions). There are three main algorithms that can be selected by the *neighbor command*: *bin* (the default, uses binning to achieve linear scaling with system size), *nsq* (without binning, quadratic scaling), *multi* (with binning, optimized for varying cutoffs or polydisperse granular particles). In addition to how the neighbor lists are constructed a number of different variants of neighbor lists need to be created (e.g. "full" or "half") for different purposes and styles and those may be required in every time step ("perpetual") or on some steps ("occasional").

The neighbor list creation is managed by the `Neighbor` class. Individual classes can obtain a neighbor list by creating an instance of a `NeighRequest` class which is stored in a list inside the `Neighbor` class. The `Neighbor` class will then analyze the various requests and apply optimizations where neighbor lists that have the same settings will be created only once and then copied, or a list may be constructed by processing a neighbor list from a different request that is a superset of the requested list. The neighbor list build is then *processed in parallel*.

The most commonly required neighbor list is a so-called "half" neighbor list, where each pair of atoms is listed only once (except when the *newton command setting* for pair is off; in that case pairs straddling subdomains or periodic boundaries will be listed twice). Thus these are the default settings when a neighbor list request is created in:

```
void Pair::init_style()
{
  neighbor->add_request(this);
}

void Pair::init_list(int /*id*/, NeighList *ptr)
{
```

(continues on next page)

(continued from previous page)

```
  list = ptr;
}
```

The `this` pointer argument is required so the neighbor list code can access the requesting class instance to store the assembled neighbor list with that instance by calling its `init_list()` member function. The optional second argument (omitted here) contains a bitmask of flags that determines the kind of neighbor list requested. The default value used here asks for a perpetual "half" neighbor list.

Non-default values of the second argument need to be used to adjust a neighbor list request to the specific needs of a style. The *tersoff* pair style, for example, needs a "full" neighbor list:

```
void PairTersoff::init_style()
{
  // [...]
  neighbor->add_request(this, NeighConst::REQ_FULL);
}
```

When a pair style supports r-RESPA time integration with different cutoff regions, the request flag may depend on the corresponding r-RESPA settings. Here is an example from pair style lj/cut:

```
void PairLJCut::init_style()
{
  int list_style = NeighConst::REQ_DEFAULT;

  if (update->whichflag == 1 && utils::strmatch(update->integrate_style, "^respa")) {
    auto respa = (Respa *) update->integrate;
    if (respa->level_inner >= 0) list_style = NeighConst::REQ_RESPA_INOUT;
    if (respa->level_middle >= 0) list_style = NeighConst::REQ_RESPA_ALL;
  }
  neighbor->add_request(this, list_style);
  // [...]
}
```

Granular pair styles need neighbor lists based on particle sizes and not cutoff and also may need to store data across timesteps ("history"). For example with:

```
if (use_history) neighbor->add_request(this, NeighConst::REQ_SIZE | NeighConst::REQ_
↪HISTORY);
else neighbor->add_request(this, NeighConst::REQ_SIZE);
```

In case a class would need to make multiple neighbor list requests with different settings, each request can set an id which is then used in the corresponding `init_list()` function to assign it to the suitable pointer variable. This is done for example by the *pair style meam*:

```
void PairMEAM::init_style()
{
// [...]
  neighbor->add_request(this, NeighConst::REQ_FULL)->set_id(1);
  neighbor->add_request(this)->set_id(2);
}
void PairMEAM::init_list(int id, NeighList *ptr)
{
  if (id == 1) listfull = ptr;
```

(continues on next page)

(continued from previous page)

```
  else if (id == 2) listhalf = ptr;
}
```

Fixes may require a neighbor list that is only build occasionally (or just once) and this can also be indicated by a flag. As an example here is the request from the `FixPeriNeigh` class which is created internally by *Peridynamics pair styles*:

```
neighbor->add_request(this, NeighConst::REQ_FULL | NeighConst::REQ_OCCASIONAL);
```

It is also possible to request a neighbor list that uses a different cutoff than what is usually inferred from the pair style settings (largest cutoff of all pair styles plus neighbor list skin). Since the default neighbor list is built with a cutoff *per pair of atom types*, such a request must also state how its cutoff is to be interpreted, by calling exactly one of:

Function	Interpretation of the requested cutoff
`set_cutoff_max(cutoff`	the maximum across atom types, individual type pairs may use a shorter cutoff. This is the typical case for pair styles.
`set_cutoff_fixed(cuto`	applies uniformly to every pair of atom types. This is the typical case for a fix or compute analyzing a fixed range, e.g. an RDF.

Using `set_cutoff_max()` where a uniform cutoff is meant will silently truncate the list for those type pairs that use a shorter pair style cutoff.

The following is used in the *compute rdf* command implementation, where the requested cutoff applies to all atom types:

```
if (cutflag)
  neighbor->add_request(this, NeighConst::REQ_OCCASIONAL)->set_cutoff_fixed(mycutneigh);
else
  neighbor->add_request(this, NeighConst::REQ_OCCASIONAL);
```

The neighbor list request function has a slightly different set of arguments when created by a command style. In this case the neighbor list is *always* an occasional neighbor list, so that flag is not needed. However for printing the neighbor list summary the name of the requesting command should be set. Below is the request from the *delete atoms* command:

```
neighbor->add_request(this, "delete_atoms", NeighConst::REQ_FULL);
```

4.9.3 Errors, warnings, and informational messages

LAMMPS has specialized functionality to handle errors (which should terminate LAMMPS), warning messages (which should indicate possible problems *without* terminating LAMMPS), and informational text for messages about the progress and chosen settings. We *strongly* encourage using these facilities and to *stay away* from using `printf()` or `fprintf()` or `std::cout` or `std::cerr` and calling `MPI_Abort()` or `exit()` directly. Warnings and informational messages should be printed only on MPI rank 0 to avoid flooding the output when running in parallel with many MPI processes.

Errors

When LAMMPS encounters an error, for example a syntax error in the input, then a suitable error message should be printed giving a brief, one line remark about the reason and then call either `Error::all()` or `Error::one()`. `Error::all()` must be called when the failing code path is executed by *all* MPI processes and the error condition will appear for *all* MPI processes the same. If desired, each MPI process may set a flag to either 0 or 1 and then MPI_Allreduce() searching for the maximum can be used to determine if there was an error on *any* of the MPI processes and make this information available to *all*. `Error::one()` in contrast needs to be called when only one or a few MPI processes execute the code path or can have the error condition. `Error::all()` is generally the preferred option.

Calling these functions does not abort LAMMPS directly, but rather throws either a `LAMMPSException` (from `Error::all()`) or a `LAMMPSAbortException` (from `Error::one()`). These exceptions are caught by the LAMMPS `main()` program and then handled accordingly. The reason for this approach is to support applications, especially graphical applications like *LAMMPS-GUI*, that are linked to the LAMMPS library and have a mechanism to avoid that an error in LAMMPS terminates the application. By catching the exceptions, the application can delete the failing LAMMPS class instance and create a new one to try again. In a similar fashion, the *LAMMPS Python module* checks for this and then re-throws a corresponding Python exception, which in turn can be caught by the calling Python code.

There are multiple "signatures" that can be called:

- `Error::all(FLERR, "Error message")`: this will abort LAMMPS with the error message "Error message", followed by the last line of input that was read and processed before the error condition happened.
- `Error::all(FLERR, Error::NOLASTLINE, "Error message")`: this is the same as before but without the last line of input. This is preferred for errors that would happen *during* a *run* or *minimization*, since the last line would be showing the "run" or "minimize" command yet those are unrelated to the command *causing* the error.
- `Error::all(FLERR, idx, "Error message")`: this is for argument parsing where "idx" is the index (starting at 0) of the argument for a LAMMPS command that is causing the failure (use `Error::COMMAND` for the command itself). For index 0, i.e. the first command argument, you need to use the constant `Error::ARGZERO` to work around the inability of some compilers to disambiguate between a NULL pointer and an integer constant 0, even with an added type cast. The output may also include the last input line *before* and *after* substituting variables, if they differ. A textual indicator is pointing to the specific word that failed. Using the constant `Error::NOPOINTER` in place of the *idx* argument will suppress the marker and then the behavior is like the *idx* argument is not provided.

FLERR is a macro containing the filename and line where the Error class is called and that information is appended to the error message. This allows to quickly find the relevant source code causing the error. For all three signatures, the single string "Error message" may be replaced with a format string using '{}' placeholders and followed by a variable number of arguments, one for each placeholder. This format string and the arguments are then handed for formatting to the {fmt} library (which is bundled with LAMMPS) or the C++ format library (for C++20 and later) and thus allow processing similar to the "format()" functionality in Python.

Note

Commands that accept wildcard arguments, for example *fix ave/time*, use *`utils::expand_args()`* to convert the wildcards into a list of explicit arguments. This function accepts a pointer address as an optional argument, which will be set to a map to the original arguments from the expanded argument indices. Please see the corresponding source code for details on how to apply this map in error messages.

For complex errors, that can have multiple causes and which cannot be explained in a single line, you can append to the error message, the string created by *`utils::errorurl()`*, which then provides a URL pointing to a paragraph of the *Errors and warnings details* that corresponds to the number provided. Example:

```
error->all(FLERR, "Unknown identifier in data file: {}{}", keyword, utils::errorurl(1));
```

This will output something like this:

```
ERROR: Unknown identifier in data file: Massess
For more information see https://docs.lammps.org/err0001 (src/read_data.cpp:1482)
Last input line: read_data       data.peptide
```

Where the URL points to the first paragraph with explanations on the *Errors and warnings details* page in the manual.

Warnings

To print warnings, the `Errors::warning()` function should be used. It also requires the FLERR macros as first argument to easily identify the location of the warning in the source code. Same as with the error functions above, the function has two variants: one just taking a single string as final argument and a second that uses the {fmt} library to make it similar to, say, `fprintf()`. One motivation to use this function is that it will output warnings with always the same capitalization of the leading "WARNING" string. A second is that it has a built in rate limiter. After a given number (by default 100), that can be set via the *thermo_modify command* no more warnings are printed. Also, warnings are written consistently to both screen and logfile or not, depending on the settings for *screen* or *logfile* output.

Note

Unlike `Error::all()`, the warning function will produce output on *every* MPI process, so it typically would be prefixed with an if statement testing for `comm->me == 0`, i.e. limiting output to MPI rank 0.

Informational messages

Finally, for informational message LAMMPS has the *utils::logmesg() convenience function*. It also uses the {fmt} library to support using a format string followed by a matching number of arguments. It will output the resulting formatted text to both, the screen and the logfile and will honor the corresponding settings about whether this output is active and to which file it should be send. Same as for `Error::warning()`, it would produce output for every MPI process and thus should usually be called only on MPI rank 0 to avoid flooding the output when running with many parallel processes.

4.9.4 Choosing between a custom atom style, fix property/atom, and fix STORE/ATOM

There are multiple ways to manage per-atom data within LAMMPS. Often the per-atom storage is only used locally and managed by the class that uses it. If the data has to persist between multiple time steps and migrate with atoms when they move from sub-domain to sub-domain or across periodic boundaries, then using a custom atom style, or *fix property/atom*, or the internal fix STORE/ATOM are possible options.

- Using the atom style is usually the most programming effort and mostly needed when the per-atom data is an integral part of the model like a per-atom charge or diameter and thus should be part of the Atoms section of a *data file*.
- Fix property/atom is useful if the data is optional or should be entered by the user, or accessed as a (named) custom property. In this case the fix should be entered as part of the input (and not internally) which allows to enter and store its content with data files.
- Fix STORE/ATOM should be used when the data should be accessed internally only and thus the fix can be created internally.

4.9.5 Fix contributions to instantaneous energy, virial, and cumulative energy

Fixes can calculate contributions to the instantaneous energy and/or virial of the system, both in a global and peratom sense. Fixes that perform thermostatting or barostatting can calculate the cumulative energy they add to or subtract from the system, which is accessed by the *ecouple* and *econserve* thermodynamic keywords. This subsection explains how both work and what flags to set in a new fix to enable this functionality.

Let's start with thermostatting and barostatting fixes. Examples are the *fix langevin* and *fix npt* commands. Here is what the fix needs to do:

- Set the variable *ecouple_flag* = 1 in the constructor. Also set *scalar_flag* = 1, *extscalar* = 1, and *global_freq* to a timestep increment which matches how often the fix is invoked.
- Implement a compute_scalar() method that returns the cumulative energy added or subtracted by the fix, e.g. by rescaling the velocity of atoms. The sign convention is that subtracted energy is positive, added energy is negative. This must be the total energy added to the entire system, i.e. an "extensive" quantity, not a per-atom

energy. Cumulative means the summed energy since the fix was instantiated, even across multiple runs. This is because the energy is used by the *econserve* thermodynamic keyword to check that the fix is conserving the total energy of the system, i.e. potential energy + kinetic energy + coupling energy = a constant.

And here is how the code operates:

- The Modify class makes a list of all fixes that set *ecouple_flag* = 1.
- The *thermo_style custom* command defines *ecouple* and *econserve* keywords.
- These keywords sum the energy contributions from all the *ecouple_flag* = 1 fixes by invoking the *energy_couple()* method in the Modify class, which calls the *compute_scalar()* method of each fix in the list.

Next, here is how a fix contributes to the instantaneous energy and virial of the system. First, it sets any or all of these flags to a value of 1 in their constructor:

- *energy_global_flag* to contribute to global energy, example: *fix indent*
- *energy_peratom_flag* to contribute to peratom energy, *fix cmap*
- *virial_global_flag* to contribute to global virial, example: *fix wall*
- *virial_peratom_flag* to contribute to peratom virial, example: *fix wall*

The fix must also do the following:

- For global energy, implement a compute_scalar() method that returns the energy added or subtracted on this timestep. Here the sign convention is that added energy is positive, subtracted energy is negative.
- For peratom energy, invoke the ev_init(eflag,vflag) function each time the fix is invoked, which initializes peratom energy storage. The value of eflag may need to be stored from an earlier call to the fix during the same timestep. See how the *fix cmap* command does this in src/MOLECULE/fix_cmap.cpp. When an energy for one or more atoms is calculated, invoke the ev_tally() function to tally the contribution to each atom. Both the ev_init() and ev_tally() methods are in the parent Fix class.
- For global and/or peratom virial, invoke the v_init(vflag) function each time the fix is invoked, which initializes virial storage. When forces on one or more atoms are calculated, invoke the v_tally() function to tally the contribution. Both the v_init() and v_tally() methods are in the parent Fix class. Note that there are several variants of v_tally(); choose the one appropriate to your fix.

Note

The ev_init() and ev_tally() methods also account for global and peratom virial contributions. Thus you do not need to invoke the v_init() and v_tally() methods if the fix also calculates peratom energies.

The fix must also specify whether (by default) to include or exclude these contributions to the global/peratom energy/virial of the system. For the fix to include the contributions, set either or both of these variables in the constructor:

- *thermo_energy* = 1, for global and peratom energy
- *thermo_virial* = 1, for global and peratom virial

Note that these variables are zeroed in fix.cpp. Thus if you don't set the variables, the contributions will be excluded (by default).

However, the user has ultimate control over whether to include or exclude the contributions of the fix via the *fix modify* command:

- fix modify *energy yes* to include global and peratom energy contributions
- fix modify *virial yes* to include global and peratom virial contributions

If the fix contributes to any of the global/peratom energy/virial values for the system, it should be explained on the fix doc page, along with the default values for the *energy yes/no* and *virial yes/no* settings of the *fix modify* command.

Finally, these 4 contributions are included in the output of 4 computes:

- global energy in *compute pe*
- peratom energy in *compute pe/atom*
- global virial in *compute pressure*
- peratom virial in *compute stress/atom*

These computes invoke a method of the Modify class to include contributions from fixes that have the corresponding flags set, e.g. *energy_peratom_flag* and *thermo_energy* for *compute pe/atom*.

Note that each compute has an optional keyword to either include or exclude all contributions from fixes. Also note that *compute pe* and *compute pressure* are what is used (by default) by *thermodynamic output* to calculate values for its *pe* and *press* keywords.

4.9.6 KSpace PPPM FFT grids

The various *KSpace PPPM* styles in LAMMPS use FFTs to solve Poisson's equation. This subsection describes:

- how FFT grids are defined
- how they are decomposed across processors
- how they are indexed by each processor
- how particle charge and electric field values are mapped to/from the grid

An FFT grid cell is a 3d volume; grid points are corners of a grid cell and the code stores values assigned to grid points in vectors or 3d arrays. A global 3d FFT grid has points indexed 0 to N-1 inclusive in each dimension.

Each processor owns two subsets of the grid, each subset is brick-shaped. Depending on how it is used, these subsets are allocated as a 1d vector or 3d array. Either way, the ordering of values within contiguous memory x fastest, then y, z slowest.

For the `3d decomposition` of the grid, the global grid is partitioned into bricks that correspond to the subdomains of the simulation box that each processor owns. Often, this is a regular 3d array (Px by Py by Pz) of bricks, where P = number of processors = Px * Py * Pz. More generally it can be a tiled decomposition, where each processor owns a brick and the union of all the bricks is the global grid. Tiled decompositions are produced by load balancing with the RCB algorithm; see the *balance rcb* command.

For the `FFT decomposition` of the grid, each processor owns a brick that spans the entire x dimension of the grid while the y and z dimensions are partitioned as a regular 2d array (P1 by P2), where P = P1 * P2.

The following indices store the inclusive bounds of the brick a processor owns, within the global grid:

```
nFOO_in = 3d decomposition brick
nFOO_fft = FFT decomposition brick
nFOO_out = 3d decomposition brick + ghost cells
```

where `FOO` corresponds to `xlo, xhi, ylo, yhi, zlo,` or `zhi`.

The `in` and `fft` indices are from 0 to N-1 inclusive in each dimension, where N is the grid size.

The `out` indices index an array which stores the `in` subset of the grid plus ghost cells that surround it. These indices can thus be < 0 or >= N.

The number of ghost cells a processor owns in each of the 6 directions is a function of:

```
neighbor skin distance (since atoms can move outside a proc subdomain)
qdist = offset or charge from atom due to TIP4P fictitious charge
order = mapping stencil size
shift = factor used when order is an even number (see below)
```

Here is an explanation of how the PPPM variables `order`, `nlower` / `nupper`, `shift`, and `OFFSET` work. They are the relevant variables that determine how atom charge is mapped to grid points and how field values are mapped from grid points to atoms:

```
order = # of nearby grid points in each dim that atom charge/field are mapped to/from
nlower,nupper = extent of stencil around the grid point an atom is assigned to
OFFSET = large integer added/subtracted when mapping to avoid int(-0.75) = 0 when -1 is␣
↪the desired result
```

The particle_map() method assigns each atom to a grid point.

If order is even, say 4:

```
atom is assigned to grid point to its left (in each dim)
shift = OFFSET
nlower = -1, nupper = 2, which are offsets from assigned grid point
window of mapping grid pts is thus 2 grid points to left of atom, 2 to right
```

If order is odd, say 5:

```
atom is assigned to left/right grid pt it is closest to (in each dim)
shift = OFFSET + 0.5
nlower = 2, nupper = 2
if point is in left half of cell, then window of affected grid pts is 3 grid points to␣
↪left of atom, 2 to right
if point is in right half of cell, then window of affected grid pts is 2 grid points to␣
↪left of atom, 3 to right
```

These settings apply to each dimension, so that if order = 5, an atom's charge is mapped to 125 grid points that surround the atom.

4.10 Notes for updating code written for older LAMMPS versions

This section documents how C++ source files that are available *outside of the LAMMPS source distribution* (e.g. in external USER packages or as source files provided as a supplement to a publication) that are written for an older version of LAMMPS and thus need to be updated to be compatible with the current version of LAMMPS. Due to the active development of LAMMPS it is likely to always be incomplete. Please contact developers@lammps.org in case you run across an issue that is not (yet) listed here. Please also review the latest information about the LAMMPS *programming style conventions*, especially if you are considering to submit the updated version for inclusion into the LAMMPS distribution.

Available topics in mostly chronological order are:

- *Setting flags in the constructor*
- *Rename of pack/unpack_comm() to pack/unpack_forward_comm()*
- *Use ev_init() to initialize variables derived from eflag and vflag*
- *Use utils::count_words() functions instead of atom->count_words()*
- *Use utils::numeric() functions instead of force->numeric()*

- *Use utils::open_potential() function to open potential files*
- *Use symbolic Atom and AtomVec constants instead of numerical values*
- *Simplify customized error messages*
- *Use of "override" instead of "virtual"*
- *Simplified and more compact neighbor list requests*
- *Split of fix STORE into fix STORE/GLOBAL and fix STORE/PERATOM*
- *Rename of fix STORE/PERATOM to fix STORE/ATOM and change of arguments*
- *Use Output::get_dump_by_id() instead of Output::find_dump()*
- *Refactored grid communication using Grid3d/Grid2d classes instead of GridComm*
- *FLERR as first argument to minimum image functions in Domain class*
- *Use utils::logmesg() instead of error->warning()*
- *Explicit interpretation for custom neighbor list cutoffs*

4.10.1 Setting flags in the constructor

As LAMMPS gains additional functionality, new flags may need to be set in the constructor or a class to signal compatibility with such features. Most of the time the defaults are chosen conservatively, but sometimes the conservative choice is the uncommon choice, and then those settings need to be made when updating code.

Pair styles:

- `manybody_flag`: set to 1 if your pair style is not pair-wise additive
- `restartinfo`: set to 0 if your pair style does not store data in restart files

4.10.2 Rename of pack/unpack_comm() to pack/unpack_forward_comm()

Changed in version 8Aug2014.

In this change set, the functions to pack/unpack data into communication buffers for *forward communications* were renamed from `pack_comm()` and `unpack_comm()` to `pack_forward_comm()` and `unpack_forward_comm()`, respectively. Also the meaning of the return value of these functions was changed: rather than returning the number of items per atom stored in the buffer, now the total number of items added (or unpacked) needs to be returned. Here is an example from the *PairEAM* class. Of course the member function declaration in corresponding header file needs to be updated accordingly.

Old:

```
int PairEAM::pack_comm(int n, int *list, double *buf, int pbc_flag, int *pbc)
{
  int m = 0;
  for (int i = 0; i < n; i++) {
    int j = list[i];
    buf[m++] = fp[j];
  }
  return 1;
}
```

New:

```
int PairEAM::pack_forward_comm(int n, int *list, double *buf, int pbc_flag, int *pbc)
{
  int m = 0;
  for (int i = 0; i < n; i++) {
    int j = list[i];
    buf[m++] = fp[j];
  }
  return m;
}
```

Note

Because the various "pack" and "unpack" functions are defined in the respective base classes as dummy functions doing nothing, and because of the the name mismatch the custom versions in the derived class will no longer be called, there will be no compilation error when this change is not applied. Only calculations will suddenly produce incorrect results because the required forward communication calls will cease to function correctly.

4.10.3 Use ev_init() to initialize variables derived from eflag and vflag

Changed in version 29Mar2019.

There are several variables that need to be initialized based on the values of the "eflag" and "vflag" variables and since sometimes there are new bits added and new variables need to be set to 1 or 0. To make this consistent across all styles, there is now an inline function `ev_init(eflag, vflag)` that makes those settings consistently and calls either `ev_setup()` or `ev_unset()`. Example from a pair style:

Old:

```
if (eflag || vflag) ev_setup(eflag, vflag);
else evflag = vflag_fdotr = eflag_global = eflag_atom = 0;
```

New:

```
ev_init(eflag, vflag);
```

Not applying this change will not cause a compilation error, but can lead to inconsistent behavior and incorrect tallying of energy or virial.

4.10.4 Use utils::count_words() functions instead of atom->count_words()

Changed in version 2Jun2020.

The "count_words()" functions for parsing text have been moved from the Atom class to the *utils namespace*. The "count_words()" function in "utils" uses the Tokenizer class internally to split a line into words and count them, thus it will not modify the argument string as the function in the Atoms class did and thus had a variant using a copy buffer. Unlike the old version, the new version does not remove comments. For that you can use the *`utils::trim_comment()` function* as shown in the example below.

Old:

```
nwords = atom->count_words(line);
int nwords = atom->count_words(buf);
```

New:

```
nwords = utils::count_words(line);
int nwords = utils::count_words(utils::trim_comment(buf));
```

See also

utils::count_words(), *utils::trim_comment()*

4.10.5 Use utils::numeric() functions instead of force->numeric()

Changed in version 18Sep2020.

The "numeric()" conversion functions (including "inumeric()", "bnumeric()", and "tnumeric()") have been moved from the Force class to the *utils namespace*. Also they take an additional argument that selects whether the `Error::all()` or `Error::one()` function should be called in case of an error. The former should be used when *all* MPI processes call the conversion function and the latter *must* be used when they are called from only one or a subset of the MPI processes.

Old:

```
val = force->numeric(FLERR, arg[1]);
num = force->inumeric(FLERR, arg[2]);
```

New:

```
val = utils::numeric(FLERR, true, arg[1], lmp);
num = utils::inumeric(FLERR, false, arg[2], lmp);
```

See also

utils::numeric(), *utils::inumeric()*, *utils::bnumeric()*, *utils::tnumeric()*

4.10.6 Use utils::open_potential() function to open potential files

Changed in version 18Sep2020.

The *utils::open_potential()* function must be used to replace calls to `force->open_potential()` and should be used to replace `fopen()` for opening potential files for reading. The custom function does three additional steps compared to `fopen()`: 1) it will try to parse the `UNITS:` and `DATE:` metadata and will stop with an error on a units mismatch and will print the date info, if present, in the log file; 2) for pair styles that support it, it will set up possible automatic unit conversions based on the embedded unit information and LAMMPS' current units setting; 3) it will not only try to open a potential file at the given path, but will also search in the folders listed in the `LAMMPS_POTENTIALS` environment variable. This allows potential files to reside in a common location instead of having to copy them around for simulations.

Old:

```
fp = force->open_potential(filename);
fp = fopen(filename, "r");
```

New:

```
fp = utils::open_potential(filename, lmp);
```

4.10.7 Use symbolic Atom and AtomVec constants instead of numerical values

Changed in version 18Sep2020.

Properties in LAMMPS that were represented by integer values (0, 1, 2, 3) to indicate settings in the `Atom` and `AtomVec` classes (or classes derived from it) (and its derived classes) have been converted to use scoped enumerators instead.

Symbolic Constant	Value	Symbolic Constant	Value	Symbolic Constant	Value
Atom::GROW	0	Atom::ATOMIC	0	Atom::MAP_NONE	0
Atom::RESTART	1	Atom::MOLECULAR	1	Atom::MAP_ARRAY	1
Atom::BORDER	2	Atom::TEMPLATE	2	Atom::MAP_HASH	2
AtomVec::PER_ATOM	0	AtomVec::PER_TYPE	1	Atom::MAP_YES	3

Old:

```
molecular = 0;
mass_type = 1;
if (atom->molecular == 2)
if (atom->map_style == 2)
atom->add_callback(0);
atom->delete_callback(id,1);
```

New:

```
molecular = Atom::ATOMIC;
mass_type = AtomVec::PER_TYPE;
if (atom->molecular == Atom::TEMPLATE)
if (atom->map_style == Atom::MAP_HASH)
atom->add_callback(Atom::GROW);
atom->delete_callback(id,Atom::RESTART);
```

4.10.8 Simplify customized error messages

Changed in version 14May2021.

Aided by features of the bundled {fmt} library, error messages now can have a variable number of arguments and the string will be interpreted as a {fmt} style format string so that error messages can be easily customized without having to use temporary buffers and `sprintf()`. Example:

Old:

```
if (fptr == NULL) {
  char str[128];
  sprintf(str,"Cannot open AEAM potential file %s",filename);
  error->one(FLERR,str);
}
```

New:

```
if (fptr == nullptr)
  error->one(FLERR, "Cannot open AEAM potential file {}: {}", filename,␣
 ↪utils::getsyserror());
```

4.10.9 Use of "override" instead of "virtual"

Changed in version 17Feb2022.

Since LAMMPS requires C++17, we switched to use the "override" keyword instead of "virtual" to indicate polymorphism in derived classes. This allows the C++ compiler to better detect inconsistencies when an override is intended or not. Please note that "override" has to be added to **all** polymorph functions in derived classes and "virtual" *only* to the function in the base class (or the destructor). Here is an example from the `FixWallReflect` class:

Old:

```
FixWallReflect(class LAMMPS *, int, char **);
virtual ~FixWallReflect();
int setmask();
void init();
void post_integrate();
```

New:

```
FixWallReflect(class LAMMPS *, int, char **);
~FixWallReflect() override;
int setmask() override;
void init() override;
void post_integrate() override;
```

This change set will neither cause a compilation failure, nor will it change functionality, but if you plan to submit the updated code for inclusion into the LAMMPS distribution, it will be requested for achieve a consistent *programming style*.

4.10.10 Simplified function names for forward and reverse communication

Changed in version 24Mar2022.

Rather than using the function name to distinguish between the different forward and reverse communication functions for styles, LAMMPS now uses the type of the "this" pointer argument.

Old:

```
comm->forward_comm_pair(this);
comm->forward_comm_fix(this);
comm->forward_comm_compute(this);
comm->forward_comm_dump(this);
comm->reverse_comm_pair(this);
comm->reverse_comm_fix(this);
comm->reverse_comm_compute(this);
comm->reverse_comm_dump(this);
```

New:

```
comm->forward_comm(this);
comm->reverse_comm(this);
```

This change is **required** or else the code will not compile.

4.10.11 Simplified and more compact neighbor list requests

Changed in version 24Mar2022.

This change set reduces the amount of code required to request a neighbor list. It enforces consistency and no longer requires to change internal data of the request. More information on neighbor list requests can be *found here*. Example from the `ComputeRDF` class:

Old:

```
int irequest = neighbor->request(this,instance_me);
neighbor->requests[irequest]->pair = 0;
neighbor->requests[irequest]->compute = 1;
neighbor->requests[irequest]->occasional = 1;
if (cutflag) {
  neighbor->requests[irequest]->cut = 1;
  neighbor->requests[irequest]->cutoff = mycutneigh;
}
```

New:

```
auto req = neighbor->add_request(this, NeighConst::REQ_OCCASIONAL);
if (cutflag) req->set_cutoff(mycutneigh);
```

Public access to the `NeighRequest` class data members has been removed so this update is **required** to avoid compilation failure.

4.10.12 Split of fix STORE into fix STORE/GLOBAL and fix STORE/PERATOM

Changed in version 15Sep2022.

This change splits the GLOBAL and PERATOM modes of fix STORE into two separate fixes STORE/GLOBAL and STORE/PERATOM. There was very little shared code between the two fix STORE modes and the two different code paths had to be prefixed with if statements. Furthermore, some flags were used differently in the two modes leading to confusion. Splitting the code into two fix styles, makes it more easily maintainable. Since these are internal fixes, there is no user visible change.

Old:

```
#include "fix_store.h"

FixStore *fix = dynamic_cast<FixStore *>(
   modify->add_fix(fmt::format("{} {} STORE peratom 1 13",id_pole,group->names[0]));

FixStore *fix = dynamic_cast<FixStore *>(modify->get_fix_by_id(id_pole));
```

New:

```
#include "fix_store_peratom.h"

FixStorePeratom *fix = dynamic_cast<FixStorePeratom *>(
   modify->add_fix(fmt::format("{} {} STORE/PERATOM 1 13",id_pole,group->names[0]));

FixStorePeratom *fix = dynamic_cast<FixStorePeratom *>(modify->get_fix_by_id(id_pole));
```

Old:

```
#include "fix_store.h"

FixStore *fix = dynamic_cast<FixStore *>(
   modify->add_fix(fmt::format("{} {} STORE global 1 1",id_fix,group->names[igroup]));

FixStore *fix = dynamic_cast<FixStore *>(modify->get_fix_by_id(id_fix));
```

New:

```
#include "fix_store_global.h"

FixStoreGlobal *fix = dynamic_cast<FixStoreGlobal *>(
   modify->add_fix(fmt::format("{} {} STORE/GLOBAL 1 1",id_fix,group->names[igroup]));

FixStoreGlobal *fix = dynamic_cast<FixStoreGlobal *>(modify->get_fix_by_id(id_fix));
```

This change is **required** or else the code will not compile.

4.10.13 Rename of fix STORE/PERATOM to fix STORE/ATOM and change of arguments

Changed in version 28Mar2023.

The available functionality of the internal fix to store per-atom properties was expanded to enable storing data with ghost atoms and to support binary restart files. With those changes, the fix was renamed to fix STORE/ATOM and the number and order of (required) arguments has changed.

Old syntax: `ID group-ID STORE/PERATOM rflag n1 n2 [n3]`

- *rflag* = 0/1, *no*/*yes* store per-atom values in restart file
- $n1 = 1, n2 = 1$, no $n3 \rightarrow$ per-atom vector, single value per atom
- $n1 = 1, n2 > 1$, no $n3 \rightarrow$ per-atom array, *n2* values per atom
- $n1 = 1, n2 > 0, n3 > 0 \rightarrow$ per-atom tensor, *n2* x *n3* values per atom

New syntax: `ID group-ID STORE/ATOM n1 n2 gflag rflag`

- $n1 = 1, n2 = 0 \rightarrow$ per-atom vector, single value per atom
- $n1 > 1, n2 = 0 \rightarrow$ per-atom array, *n1* values per atom
- $n1 > 0, n2 > 0 \rightarrow$ per-atom tensor, *n1* x *n2* values per atom
- *gflag* = 0/1, *no*/*yes* communicate per-atom values with ghost atoms
- *rflag* = 0/1, *no*/*yes* store per-atom values in restart file

Since this is an internal fix, there is no user visible change.

4.10.14 Use Output::get_dump_by_id() instead of Output::find_dump()

Changed in version 15Sep2022.

The accessor function to individual dump style instances has been changed from `Output::find_dump()` returning the index of the dump instance in the list of dumps to `Output::get_dump_by_id()` returning a pointer to the dump directly. Example:

Old:

```
int idump = output->find_dump(arg[iarg+1]);
if (idump < 0)
  error->all(FLERR,"Dump ID in hyper command does not exist");
memory->grow(dumplist,ndump+1,"hyper:dumplist");
dumplist[ndump++] = idump;

[...]

if (dumpflag)
  for (int idump = 0; idump < ndump; idump++)
    output->dump[dumplist[idump]]->write();
```

New:

```
auto idump = output->get_dump_by_id(arg[iarg+1]);
if (!idump) error->all(FLERR,"Dump ID {} in hyper command does not exist", arg[iarg+1]);
dumplist.emplace_back(idump);

[...]

if (dumpflag) for (auto idump : dumplist) idump->write();
```

This change is **required** or else the code will not compile.

4.10.15 Refactored grid communication using Grid3d/Grid2d classes instead of GridComm

Changed in version 22Dec2022.

The `GridComm` class was for creating and communicating distributed grids was replaced by the `Grid3d` class with added functionality. A `Grid2d` class was also added for additional flexibility.

The new functionality and commands using the two grid classes are discussed on the following documentation pages:

- *Using distributed grids*
- *Use of distributed grids within style classes*

If you have custom LAMMPS code, which uses the GridComm class, here are some notes on how to adapt it for using the Grid3d class.

(1) The constructor has changed to allow the `Grid3d` / `Grid2d` classes to partition the global grid across processors, both for owned and ghost grid cells. Previously any class which called `GridComm` performed the partitioning itself and that information was passed in the `GridComm::GridComm()` constructor. There are several "set" functions which can be called to alter how `Grid3d` / `Grid2d` perform the partitioning. They should be sufficient for most use cases of the grid classes.

(2) The partitioning is triggered by the `setup_grid()` method.

(3) The `setup()` method of the `GridComm` class has been replaced by the `setup_comm()` method in the new grid classes. The syntax for the `forward_comm()` and `reverse_comm()` methods is slightly altered as is the syntax of the associated pack/unpack callback methods. But the functionality of these operations is the same as before.

(4) The new `Grid3d` / `Grid2d` classes have additional functionality for dynamic load-balancing of grids and their associated data across processors. This did not exist in the `GridComm` class.

This and more is explained in detail on the *Use of distributed grids within style classes* page. The following LAMMPS source files can be used as illustrative examples for how the new grid classes are used by computes, fixes, and various KSpace solvers which use distributed FFT grids:

- src/fix_ave_grid.cpp
- src/compute_property_grid.cpp
- src/EXTRA-FIX/fix_ttm_grid.cpp
- src/KSPACE/pppm.cpp

This change is **required** or else the code will not compile.

4.10.16 FLERR as first argument to minimum image functions in Domain class

Changed in version 12Jun2025.

The `Domain::minimum_image()` and `Domain::minimum_image_big()` functions were changed to take the `FLERR` macros as first argument. This way the error message indicates *where* the function was called instead of pointing to the implementation of the function. Example:

Old:

```
double delx1 = x[i1][0] - x[i2][0];
double dely1 = x[i1][1] - x[i2][1];
double delz1 = x[i1][2] - x[i2][2];
domain->minimum_image(delx1, dely1, delz1);
double r1 = sqrt(delx1 * delx1 + dely1 * dely1 + delz1 * delz1);

double delx2 = x[i3][0] - x[i2][0];
double dely2 = x[i3][1] - x[i2][1];
double delz2 = x[i3][2] - x[i2][2];
domain->minimum_image_big(delx2, dely2, delz2);
double r2 = sqrt(delx2 * delx2 + dely2 * dely2 + delz2 * delz2);
```

New:

```
double delx1 = x[i1][0] - x[i2][0];
double dely1 = x[i1][1] - x[i2][1];
double delz1 = x[i1][2] - x[i2][2];
domain->minimum_image(FLERR, delx1, dely1, delz1);
double r1 = sqrt(delx1 * delx1 + dely1 * dely1 + delz1 * delz1);

double delx2 = x[i3][0] - x[i2][0];
double dely2 = x[i3][1] - x[i2][1];
double delz2 = x[i3][2] - x[i2][2];
domain->minimum_image_big(FLERR, delx2, dely2, delz2);
double r2 = sqrt(delx2 * delx2 + dely2 * dely2 + delz2 * delz2);
```

This change is **required** or else the code will not compile.

4.10.17 Use utils::logmesg() instead of error->warning()

Changed in version 22Jul2025.

The `Error::message()` method has been removed since its functionality has been superseded by the *`utils::logmesg()`* function.

Old:

```
 if (comm->me == 0) {
   error->message(FLERR, "INFO: About to read data file: {}", filename);
}
```

New:

```
if (comm->me == 0) utils::logmesg(lmp, "INFO: About to read data file: {}\n", filename);
```

This change is **required** or else the code will not compile.

4.10.18 Explicit interpretation for custom neighbor list cutoffs

The default neighbor list is built with a cutoff *per pair of atom types*, so a request for a custom cutoff is ambiguous on its own: the same number can mean "the largest cutoff used by any type pair" or "this cutoff for every type pair". Assuming the former where the latter was meant silently truncates the list for the type pairs that use a shorter pair style cutoff.

`NeighRequest::set_cutoff()` has therefore been replaced by two functions that each state the intended interpretation, and must be called instead:

- `set_cutoff_max(cutoff)` – the maximum across atom types, individual type pairs may use a shorter cutoff. This is the typical case for pair styles.
- `set_cutoff_fixed(cutoff)` – applies uniformly to every pair of atom types. This is the typical case for a fix or compute analyzing a fixed range, e.g. an RDF.

Old:

```
auto req = neighbor->add_request(this, NeighConst::REQ_OCCASIONAL);
if (cutflag) req->set_cutoff(mycutneigh);
```

New:

```
auto req = neighbor->add_request(this, NeighConst::REQ_OCCASIONAL);
if (cutflag) req->set_cutoff_fixed(mycutneigh);
```

This change is **required** or else the code will not compile.

4.11 Writing plugins

Plugins provide a mechanism to add functionality to a LAMMPS executable without recompiling LAMMPS. The functionality for this and the *plugin command* are implemented in the *PLUGIN package* which must be installed to use plugins.

Plugins use the operating system's capability to load dynamic shared object (DSO) files in a way similar shared libraries and then reference specific functions in those DSOs. Any DSO file with plugins has to include an initialization function with a specific name, "lammpsplugin_init", that has to follow specific rules described below. When loading the DSO with the "plugin" command, this function is looked up and called and will then register the contained plugin(s) with LAMMPS.

When the environment variable `LAMMPS_PLUGIN_PATH` is set, then LAMMPS will search the directory (or directories) listed in this path for files with names that end in `plugin.so` (e.g. `helloplugin.so`) and will try to load the contained plugins automatically at start-up. For plugins that are loaded this way, the behavior of LAMMPS should be identical to a binary where the corresponding code was compiled in statically as a package.

From the programmer perspective this can work because of the object oriented design of LAMMPS where all pair style commands are derived from the class Pair, all fix style commands from the class Fix and so on and usually only

functions present in those base classes are called directly. When a *pair_style command* command or *fix command* command is issued a new instance of such a derived class is created. This is done by a so-called factory function which is mapped to the style name. Thus when, for example, the LAMMPS processes the command `pair_style lj/cut 2.5`, LAMMPS will look up the factory function for creating the `PairLJCut` class and then execute it. The return value of that function is a `Pair *` pointer and the pointer will be assigned to the location for the currently active pair style.

A DSO file with a plugin thus has to implement such a factory function and register it with LAMMPS so that it gets added to the map of available styles of the given category. To register a plugin with LAMMPS an initialization function has to be present in the DSO file called `lammpsplugin_init` which is called with three `void *` arguments: a pointer to the current LAMMPS instance, a pointer to the opened DSO handle, and a pointer to the registration function. The registration function takes two arguments: a pointer to a `lammpsplugin_t` struct with information about the plugin and a pointer to the current LAMMPS instance. Please see below for an example of how the registration is done.

4.11.1 Members of `lammpsplugin_t`

Member	Description
version	LAMMPS Version string the plugin was compiled for
style	Style of the plugin (pair, bond, fix, command, etc.)
name	Name of the plugin style
info	String with information about the plugin
author	String with the name and email of the author
creator.v1	Pointer to factory function for pair, bond, angle, dihedral, improper, kspace, command, or minimize styles
creator.v2	Pointer to factory function for compute, fix, region, or run styles
handle	Pointer to the open DSO file handle

Only one of the two alternate creator entries can be used at a time and which of those is determined by the style of plugin. The "creator.v1" element is for factory functions of supported styles computing forces (i.e. pair, bond, angle, dihedral, or improper styles), command styles, or minimize styles and the function takes as single argument the pointer to the LAMMPS instance. The factory function is cast to the `lammpsplugin_factory1` type before assignment. The "creator.v2" element is for factory functions creating an instance of a fix, compute, region, or run style and takes three arguments: a pointer to the LAMMPS instance, an integer with the length of the argument list and a `char **` pointer to the list of arguments. The factory function pointer needs to be cast to the `lammpsplugin_factory2` type before assignment.

4.11.2 Pair style example

As an example, a hypothetical pair style plugin "morse2" implemented in a class `PairMorse2` in the files `pair_morse2.h` and `pair_morse2.cpp` with the factory function and initialization function would look like this:

```
#include "lammpsplugin.h"
#include "version.h"
#include "pair_morse2.h"

using namespace LAMMPS_NS;

static Pair *morse2creator(LAMMPS *lmp)
{
  return new PairMorse2(lmp);
}
```

(continues on next page)

(continued from previous page)

```
extern "C" void lammpsplugin_init(void *lmp, void *handle, void *regfunc)
{
  lammpsplugin_regfunc register_plugin = (lammpsplugin_regfunc) regfunc;
  lammpsplugin_t plugin;

  plugin.version = LAMMPS_VERSION;
  plugin.style   = "pair";
  plugin.name    = "morse2";
  plugin.info    = "Morse2 variant pair style v1.0";
  plugin.author  = "Axel Kohlmeyer (akohlmey@gmail.com)";
  plugin.creator.v1 = (lammpsplugin_factory1 *) &morse2creator;
  plugin.handle  = handle;
  (*register_plugin)(&plugin,lmp);
}
```

The factory function in this example is called `morse2creator()`. It receives a pointer to the LAMMPS class as only argument and thus has to be assigned to the *creator.v1* member of the plugin struct and cast to the `lammpsplugin_factory1` function pointer type. It returns a pointer to the allocated class instance derived from the `Pair` class. This function may be declared static to avoid clashes with other plugins. The name of the derived class, `PairMorse2`, however must be unique inside the entire LAMMPS executable.

4.11.3 Fix style example

If the factory function is for a fix or compute, which take three arguments (a pointer to the LAMMPS class, the number of arguments and the list of argument strings), then the pointer type is `lammpsplugin_factory2` and it must be assigned to the *creator.v2* member of the plugin struct. Below is an example for that:

```
#include "lammpsplugin.h"
#include "version.h"
#include "fix_nve2.h"

using namespace LAMMPS_NS;

static Fix *nve2creator(LAMMPS *lmp, int argc, char **argv)
{
  return new FixNVE2(lmp,argc,argv);
}

extern "C" void lammpsplugin_init(void *lmp, void *handle, void *regfunc)
{
  lammpsplugin_regfunc register_plugin = (lammpsplugin_regfunc) regfunc;
  lammpsplugin_t plugin;

  plugin.version = LAMMPS_VERSION;
  plugin.style   = "fix";
  plugin.name    = "nve2";
  plugin.info    = "NVE2 variant fix style v1.0";
  plugin.author  = "Axel Kohlmeyer (akohlmey@gmail.com)";
  plugin.creator.v2 = (lammpsplugin_factory2 *) &nve2creator;
  plugin.handle  = handle;
  (*register_plugin)(&plugin,lmp);
}
```

4.11.4 Command style example

Command styles also use the first variant of factory function as demonstrated in the following example, which also shows that the implementation of the plugin class may be within the same source file as the plugin interface code:

```
#include "lammpsplugin.h"

#include "comm.h"
#include "error.h"
#include "command.h"
#include "version.h"

#include <cstring>

namespace LAMMPS_NS {
  class Hello : public Command {
   public:
    Hello(class LAMMPS *lmp) : Command(lmp) {};
    void command(int, char **);
  };
}

using namespace LAMMPS_NS;

void Hello::command(int argc, char **argv)
{
   if (argc != 1) error->all(FLERR,"Illegal hello command");
   if (comm->me == 0)
     utils::logmesg(lmp,fmt::format("Hello, {}!\n",argv[0]));
}

static void hellocreator(LAMMPS *lmp)
{
  return new Hello(lmp);
}

extern "C" void lammpsplugin_init(void *lmp, void *handle, void *regfunc)
{
  lammpsplugin_t plugin;
  lammpsplugin_regfunc register_plugin = (lammpsplugin_regfunc) regfunc;

  plugin.version = LAMMPS_VERSION;
  plugin.style   = "command";
  plugin.name    = "hello";
  plugin.info    = "Hello world command v1.1";
  plugin.author  = "Axel Kohlmeyer (akohlmey@gmail.com)";
  plugin.creator.v1 = (lammpsplugin_factory1 *) &hellocreator;
  plugin.handle  = handle;
  (*register_plugin)(&plugin,lmp);
}
```

4.11.5 Additional Details

The initialization function **must** be called `lammpsplugin_init`, it **must** have C bindings and it takes three void pointers as arguments. The first is a pointer to the LAMMPS class that calls it and it needs to be passed to the registration function. The second argument is a pointer to the internal handle of the DSO file, this needs to be added to the plugin info struct, so that the DSO can be closed and unloaded when all its contained plugins are unloaded. The third argument is a function pointer to the registration function and needs to be stored in a variable of `lammpsplugin_regfunc` type and then called with a pointer to the `lammpsplugin_t` struct and the pointer to the LAMMPS instance as arguments to register a single plugin. There may be multiple calls to multiple plugins in the same initialization function.

To register a plugin a struct of the `lammpsplugin_t` needs to be filled with relevant info: current LAMMPS version string, kind of style, name of style, info string, author string, pointer to factory function, and the DSO handle. The registration function is called with a pointer to the address of this struct and the pointer of the LAMMPS class. The registration function will then add the factory function of the plugin style to the respective process-global style registry under the provided name. It will also make a copy of the struct in a global list of all loaded plugins and update the reference counter for loaded plugins from this specific DSO file.

The pair style itself (i.e. the PairMorse2 class in this example) can be written just like any other pair style that is included in LAMMPS. For a plugin, the use of the `PairStyle` macro in the section encapsulated by `#ifdef PAIR_CLASS` is not needed, since the mapping of the class name to the style name is done by the plugin registration function with the information from the `lammpsplugin_t` struct. It may be included in case the new code is intended to be later included in LAMMPS directly.

A plugin may be registered under an existing style name. In that case the plugin will override the existing code. This can be used to modify the behavior of existing styles or to debug new versions of them without having to re-compile or re-install all of LAMMPS.

Changed in version 12Jun2025.

When using the *clear* command, plugins are not unloaded.

Changed in version 2Sep2026.

Style factory functions are stored in a process-global registry instead of in per-instance style maps. As a result, a loaded plugin persists across the *clear* command, and a plugin loaded by any LAMMPS instance is immediately available to all other LAMMPS instances in the same process; no explicit restore step is needed (the *plugin restore* command is retained only for backward compatibility and does nothing). The *plugin load* command may be issued again, but already-loaded plugins are skipped; to replace a plugin it must first be explicitly unloaded with *plugin unload*. Plugins are removed only when they are explicitly unloaded or the LAMMPS library interface is "finalized". Concurrent plugin load and unload operations from multiple instances are serialized internally so that the shared plugin registry cannot be corrupted. The *info styles* command and the `-help` command-line output mark a style currently provided by a plugin with a trailing asterisk (*).

4.11.6 Compiling plugins

Plugins need to be compiled with the same compilers and libraries (e.g. MPI) and compilation settings (MPI on/off, OpenMP, integer sizes) as the LAMMPS executable and library. Otherwise the plugin will likely not load due to mismatches in the function signatures (LAMMPS is C++ so scope, type, and number of arguments are encoded into the symbol names and thus differences in them will lead to failed plugin load commands). Compilation of the plugin can be managed via both, CMake or traditional GNU makefiles. Some examples that can be used as a template are in the `examples/plugins` folder. The CMake script code has some small adjustments to allow building the plugins for running unit tests with them.

Another example that converts the KIM package into a plugin can be found in the `examples/kim/plugin` folder. No changes to the sources of the KIM package themselves are needed; only the plugin interface and loader code needs to be added. This example only supports building with CMake, but is probably a more typical example. To compile you need to run CMake with `-DLAMMPS_SOURCE_DIR=<path/to/lammps/src/folder>`. Other configuration setting are identical to those for compiling LAMMPS.

A second example for a plugin from a package is in the `examples/PACKAGES/pace/plugin` folder that will create a plugin from the ML-PACE package. In this case the bulk of the code is in a static external library that is being downloaded and compiled first and then combined with the pair style wrapper and the plugin loader. This example also contains a NSIS script that can be used to create an Installer package for Windows (the mutual licensing terms of the external library and LAMMPS conflict when distributing binaries, so the ML-PACE package cannot be linked statically, but the LAMMPS headers required to build the plugin are also available under a less restrictive license). This will automatically set the required environment variable and launching a (compatible) LAMMPS binary will load and register the plugin and the ML-PACE package can then be used as it was linked into LAMMPS.

You can find additional LAMMPS plugins in the LAMMPS plugins source code repository on GitHub

4.12 Adding tests for unit testing

- *Tests for utility functions*
  - *FFT Testing Infrastructure*
- *Tests for individual LAMMPS commands*
- *Tests for the C-style library interface*
- *Tests for the Python module and package*
- *Tests for the Fortran interface*
- *Tests for the C++-style library interface*
- *Tests for reading and writing file formats*
- *Tests for styles computing or modifying forces*
  - *Tests for minimizer styles*
  - *Tests for compute and fix output data*
- *Tests for granular (DEM) models*
  - *Adding a new reference (YAML) file*
  - *Adding a new test program*
  - *References*
- *Tests for dump image and GRAPHICS package rendering*
- *Writing tests that give the same results on all platforms*
- *Tests for programs in the tools folder*
- *Troubleshooting failed unit tests*

This section discusses adding or expanding tests for the unit test infrastructure included into the LAMMPS source code distribution. Unlike example inputs, unit tests focus on testing the "local" behavior of individual features, tend to run fast, and should be set up to cover as much of the added code as possible. When contributing code to the distribution, the LAMMPS developers will appreciate if additions to the integrated unit test facility are included.

Given the complex nature of MD simulations where many operations can only be performed when suitable "real" simulation environment has been set up, not all tests will be unit tests in the strict definition of the term. They are rather

executed on a more abstract level by issuing LAMMPS script commands and then inspecting the changes to the internal data. For some classes of tests, generic test programs have been written that can be applied to parts of LAMMPS that use the same interface (via polymorphism) and those are driven by input files, so tests can be added by simply adding more of those input files. Those tests should be seen more as a hybrid between unit and regression tests.

When adding tests it is recommended to also *enable support for code coverage reporting*, and study the coverage reports so that it is possible to monitor which parts of the code of a given file are executed during the tests and which tests would need to be added to increase the coverage.

The tests are grouped into categories and corresponding folders. The following sections describe how the tests are implemented and executed in those categories with increasing complexity of tests and implementation.

4.12.1 Tests for utility functions

These tests are driven by programs in the `unittest/utils` folder and most closely resemble conventional unit tests. There is one test program for each namespace or group of classes or file. The naming convention for the sources and executables is that they start with with `test_`. The following sources and groups of tests are currently available:

File name:	Test name:	Description:
`test_argutils.cpp`	ArgInfo	Tests for `ArgInfo` class used by LAMMPS
`test_fmtlib.cpp`	FmtLib	Tests for `{fmt}` or `std::format` functions used by LAMMPS
`test_math_eigen_impl.cpp`	MathEigen	Tests for `MathEigen::` classes and functions
`test_mempool.cpp`	MemPool	Tests for *`MyPage`* and *`MyPoolChunk`*
`test_tokenizer.cpp`	Tokenizer	Tests for *`Tokenizer`* and *`ValueTokenizer`*
`test_utils.cpp`	Utils	Tests for `utils::` *functions*
`test_fft3d.cpp`	FFT3D	Tests for standard FFT3d wrapper (KISS, FFTW3, MKL, NVPL)
`test_fft3d_kokkos.cpp`	FFT3DKokkos	Tests for KOKKOS FFT3d wrapper (CPU and GPU back ends)

To add tests either an existing source file needs to be modified or a new source file needs to be added to the distribution and enabled for testing. To add a new file suitable CMake script code needs to be added to the `CMakeLists.txt` file in the `unittest/utils` folder. Example:

```
add_executable(test_tokenizer test_tokenizer.cpp)
target_link_libraries(test_tokenizer PRIVATE lammps GTest::GMockMain GTest::GMock␣
↪GTest::GTest)
add_test(Tokenizer test_tokenizer)
```

This adds instructions to build the `test_tokenizer` executable from `test_tokenizer.cpp` and links it with the GoogleTest libraries and the LAMMPS library as well as it uses the `main()` function from the GoogleMock library of GoogleTest. The third line registers the executable as a test program to be run from `ctest` under the name `Tokenizer`.

The test executable itself will execute multiple individual tests through the GoogleTest framework. In this case each test consists of creating a tokenizer class instance with a given string and explicit or default separator choice, and then executing member functions of the class and comparing their results with expected values. A few examples:

```
TEST(Tokenizer, empty_string)
{
    Tokenizer t("", " ");
    ASSERT_EQ(t.count(), 0);
}
```

(continues on next page)

(continued from previous page)

```
TEST(Tokenizer, two_words)
{
    Tokenizer t("test word", " ");
    ASSERT_EQ(t.count(), 2);
}

TEST(Tokenizer, default_separators)
{
    Tokenizer t(" \r\n test \t word \f");
    ASSERT_THAT(t.next(), Eq("test"));
    ASSERT_THAT(t.next(), Eq("word"));
    ASSERT_EQ(t.count(), 2);
}
```

Each of these TEST functions will become an individual test run by the test program. When using the `ctest` command as a front end to run the tests, their output will be suppressed and only a summary printed, but adding the '-V' option will then produce output from the tests above like the following:

```
[...]
1: [ RUN      ] Tokenizer.empty_string
1: [       OK ] Tokenizer.empty_string (0 ms)
1: [ RUN      ] Tokenizer.two_words
1: [       OK ] Tokenizer.two_words (0 ms)
1: [ RUN      ] Tokenizer.default_separators
1: [       OK ] Tokenizer.default_separators (0 ms)
[...]
```

The MathEigen test collection has been adapted from a standalone test and does not use the GoogleTest framework and thus not representative. The other test sources, however, can serve as guiding examples for additional tests.

FFT Testing Infrastructure

Added in version 10Dec2025.

The FFT tests (`test_fft3d.cpp` and `test_fft3d_kokkos.cpp`) validate the LAMMPS FFT wrapper implementations for both standard (CPU) and KOKKOS (CPU/GPU) back ends. These tests require the KSPACE package and use specialized helper utilities to ensure FFT correctness across different library back ends (KISS FFT, FFTW3, MKL, NVPL, cuFFT, hipFFT, etc.).

Building and Running FFT Tests:

The FFT tests are automatically enabled when `ENABLE_TESTING=ON` and `PKG_KSPACE=ON` are set during CMake configuration. For KOKKOS FFT tests, `PKG_KOKKOS=ON` is also required.

Run only FFT tests using the `ctest` command of the CMake software:

```
ctest -R FFT3D          # Run all tests with FFT3D in their name
ctest -R FFT3D -V       # Same as above but with verbose output
ctest -L fft            # Run all tests labeled with 'fft'
```

Tests automatically skip configurations requiring libraries or back ends not available in the current build (e.g., FFTW3, MPI, CUDA).

FFT Test Helper Header:

The testing infrastructure uses `fft_test_helpers.h` which contains test data generators, validators, and utilities.

For runtime configuration detection, tests use the existing `Info` class API (`Info::has_package()`, `Info::has_accelerator_feature()`, etc.).

The `fft_test_helpers.h` header provides three main namespaces:

1. **FFTTestHelpers** - utility functions: `FFTBuffer` (RAII wrapper), `idx3d()` (index conversion), `scaled_tolerance()` (grid-size-dependent precision)
2. **FFTTestData** - test data generators: `DeltaFunctionGenerator`, `ConstantGenerator`, `SineWaveGenerator`, `GaussianGenerator`, `RandomComplexGenerator`, `MixedModesGenerator`
3. **FFTValidation** - validators: `RoundTripValidator`, `KnownAnswerValidator`, `ParsevalValidator`, `HermitianSymmetryValidator`, `LinearityValidator`

Example Test:

```
TEST_F(FFT3DTest, RoundTrip_32x32x32) {
    FFTBuffer original(32, 32, 32), fft_result(32, 32, 32), recovered(32, 32, 32);

    GaussianGenerator generator(2.0);
    generator.generate(original.data(), 32, 32, 32);

    fft->compute(original.data(), fft_result.data(), FFT3d::FORWARD);
    fft->compute(fft_result.data(), recovered.data(), FFT3d::BACKWARD);

    RoundTripValidator validator(original.data(), recovered.data(), 32, 32, 32,
                                 scaled_tolerance(ROUNDTRIP_TOLERANCE, 32, 32, 32));
    EXPECT_TRUE(validator.validate());
}
```

Precision and Tolerances:

FFT tests use precision-aware tolerances that automatically adjust based on floating-point precision (`-D FFT_SINGLE=ON` vs `-D FFT_SINGLE=off`), grid size, and accelerator back end. Base tolerances (`ROUNDTRIP_TOLERANCE`, `PARSEVAL_TOLERANCE`, etc.) are defined in `fft_test_helpers.h`. Use `scaled_tolerance()` to adjust for grid size effects.

4.12.2 Tests for individual LAMMPS commands

The tests `unittest/commands` are a bit more complex as they require to first create a *LAMMPS* class instance and then use the *C++ API* to pass individual commands to that LAMMPS instance. For that reason these tests use a GoogleTest "test fixture", i.e. a class derived from `testing::Test` that will create (and delete) the required LAMMPS class instance for each set of tests in a `TEST_F()` function. Please see the individual source files for different examples of setting up suitable test fixtures. Here is an example for implementing a test using a fixture by first checking the default value and then issuing LAMMPS commands and checking whether they have the desired effect:

```
TEST_F(SimpleCommandsTest, ResetTimestep)
{
    ASSERT_EQ(lmp->update->ntimestep, 0);

    BEGIN_HIDE_OUTPUT();
    command("reset_timestep 10");
    END_HIDE_OUTPUT();
    ASSERT_EQ(lmp->update->ntimestep, 10);

    BEGIN_HIDE_OUTPUT();
    command("reset_timestep 0");
```

(continues on next page)

(continued from previous page)

```
    END_HIDE_OUTPUT();
    ASSERT_EQ(lmp->update->ntimestep, 0);

    TEST_FAILURE(".*ERROR: Timestep must be >= 0.*", command("reset_timestep -10"););
    TEST_FAILURE(".*ERROR: Illegal reset_timestep .*", command("reset_timestep"););
    TEST_FAILURE(".*ERROR: Illegal reset_timestep .*", command("reset_timestep 10 10"););
    TEST_FAILURE(".*ERROR: Expected integer .*", command("reset_timestep xxx"););
}
```

Please note the use of the `BEGIN_HIDE_OUTPUT` and `END_HIDE_OUTPUT` functions that will capture output from running LAMMPS. This is normally discarded but by setting the verbose flag (via setting the `TEST_ARGS` environment variable, `TEST_ARGS=-v`) it can be printed and used to understand why tests fail unexpectedly.

The specifics of so-called "death tests", i.e. conditions where LAMMPS should fail and throw an exception, are implemented in the `TEST_FAILURE()` macro. These tests operate by capturing the screen output when executing the failing command and then comparing that with a provided regular expression string pattern. Example:

```
TEST_F(SimpleCommandsTest, UnknownCommand)
{
    TEST_FAILURE(".*ERROR: Unknown command.*", lmp->input->one("XXX one two"););
}
```

The following test programs are currently available:

File name:	Test name:	Description:
`test_simple_commands.cpp`	SimpleCommands	Tests for LAMMPS commands that do not require a box
`test_lattice_region.cpp`	LatticeRegion	Tests to validate the *lattice* and *region* commands
`test_groups.cpp`	GroupTest	Tests to validate the *group* command
`test_variables.cpp`	VariableTest	Tests to validate the *variable* command
`test_kim_commands.cpp`	KimCommands	Tests for several commands from the *KIM package*
`test_reset_atoms.cpp`	ResetAtoms	Tests to validate the *reset_atoms* sub-commands

4.12.3 Tests for the C-style library interface

Tests for validating the LAMMPS C-style library interface are in the `unittest/c-library` folder. They text either utility functions or LAMMPS commands, but use the functions implemented in `src/library.cpp` as much as possible. There may be some overlap with other tests as far as the LAMMPS functionality is concerned, but the focus is on testing the C-style library API. The tests are distributed over multiple test programs which try to match the grouping of the functions in the source code and *in the manual*.

This group of tests also includes tests invoking LAMMPS in parallel through the library interface, provided that LAMMPS was compiled with MPI support. These include tests where LAMMPS is run in multi-partition mode or only on a subset of the MPI world communicator. The CMake script code for adding this kind of test looks like this:

```
if (BUILD_MPI)
  add_executable(test_library_mpi test_library_mpi.cpp)
  target_link_libraries(test_library_mpi PRIVATE lammps GTest::GTest GTest::GMock)
  target_compile_definitions(test_library_mpi PRIVATE ${TEST_CONFIG_DEFS})
  add_mpi_test(NAME LibraryMPI NUM_PROCS 4 COMMAND $<TARGET_FILE:test_library_mpi>)
endif()
```

Note the custom function `add_mpi_test()` which adapts how `ctest` will execute the test so it is launched in parallel (with 4 MPI ranks).

4.12.4 Tests for the Python module and package

The `unittest/python` folder contains primarily tests for classes and functions in the LAMMPS python module but also for commands in the PYTHON package. These tests are only enabled, if the necessary prerequisites are detected or enabled during configuration and compilation of LAMMPS (shared library build enabled, Python interpreter found, Python development files found).

The Python tests are implemented using the `unittest` standard Python module and split into multiple files with similar categories as the tests for the C-style library interface.

4.12.5 Tests for the Fortran interface

Tests for using the Fortran module are in the `unittest/fortran` folder. Since they are also using the GoogleTest library, they require test wrappers written in C++ that will call fortran functions with a C function interface through ISO_C_BINDINGS which will in turn call the functions in the LAMMPS Fortran module.

4.12.6 Tests for the C++-style library interface

The tests in the `unittest/cplusplus` folder are somewhat similar to the tests for the C-style library interface, but do not need to test the convenience and utility functions that are only available through the C-style library interface. Instead they focus on the more generic features that are used in LAMMPS internally. This part of the unit tests is currently still mostly in the planning stage.

4.12.7 Tests for reading and writing file formats

The `unittest/formats` folder contains test programs for reading and writing files like data files, restart files, potential files or dump files. This covers simple things like the file i/o convenience functions in the `utils::` namespace to complex tests of atom styles where creating and deleting of atoms with different properties is tested in different ways and through script commands or reading and writing of data or restart files.

4.12.8 Tests for styles computing or modifying forces

These are tests common configurations for pair styles, bond styles, angle styles, kspace styles and certain fix styles. Those are tests driven by some test executables build from sources in the `unittest/force-styles` folder and use LAMMPS input template and data files as well as input files in YAML format from the `unittest/force-styles/tests` folder. The YAML file names have to follow some naming conventions so they get associated with the test programs and categorized and listed with canonical names in the list of tests as displayed by `ctest -N`. If you add a new YAML file, you need to re-run CMake to update the corresponding list of tests. The same folder also contains two more test programs built on the same YAML infrastructure: one for minimizer styles and one for the output data of computes and fixes; they are described in their own subsections at the end of this section.

A minimal YAML file for a (molecular) pair style test will looks something like the following (see `mol-pair-zero.yaml`):

```
---
lammps_version: 24 Aug 2020
date_generated: Tue Sep 15 09:44:21 202
epsilon: 1e-14
prerequisites: ! |
  atom full
  pair zero
pre_commands: ! ""
post_commands: ! ""
input_file: in.fourmol
pair_style: zero 8.0
```

(continues on next page)

(continued from previous page)

```
pair_coeff: ! |
  * *
extract: ! ""
natoms: 29
init_vdwl: 0
init_coul: 0

[...]
```

The following table describes the available keys and their purpose. The `Tester` column lists which test program(s) use each key. `all` means every force-style tester (`test_pair_style`, `test_bond_style`, `test_angle_style`, `test_dihedral_style`, `test_improper_style`, `test_fix_timestep`, and the `test_min_style` and `test_output_style` programs described in the subsections below), and `bonded interaction tests` means the `test_bond_style`, `test_angle_style`, `test_dihedral_style`, and `test_improper_style` testers. The `Required` column indicates whether a valid YAML file (for the listed tester) must contain the key (`yes`) or whether it may be omitted (`no`). The reference generator always writes the required keys; the optional keys are either metadata added by hand (`skip_tests`, `tags`) or reference data that is only emitted when the tested style actually provides it (e.g. `global_scalar` only for a fix with scalar output):

Key:	Tester:	Required:	Description:
lammps_version	all	yes	LAMMPS version used to last update the reference data
date_generated	all	yes	date when the file was last updated
epsilon	all	yes	base value for the relative precision required for tests to pass
skip_tests	all	no	request to skip the indicated test fixtures (see table below)
tags	all	no	used to classify tests and to adjust behavior of test fixtures (see table below)
prerequisites	all	yes	list of style kind / style name pairs required to run the test
pre_commands	all	yes	LAMMPS commands to be executed before the input template file is read
post_commands	all	yes	LAMMPS commands to be executed right before the actual tests
input_file	all	yes	LAMMPS input file template

continues on next page

Table 1 – continued from previous page

Key:	Tester:	Required:	Description:
input_coeffs	test_fix_timestep, test_min_style, test_output_style	yes	file with the force-field and group setup commands applied after the input template (optional for `test_output_style` when the input template is self-contained, e.g. the metal system template)
natoms	all	yes	number of atoms in the input file template
timestep	test_fix_timestep, test_min_style, test_output_style	no	timestep size for the test run, overriding the tester's default
pair_style	test_pair_style	yes	arguments to the pair_style command to be tested
pair_coeff	test_pair_style	yes	list of pair_coeff arguments to set parameters for the input template
init_vdwl	test_pair_style	yes	non-Coulomb pair energy after "run 0"
init_coul	test_pair_style	yes	Coulomb pair energy after "run 0"
run_vdwl	test_pair_style	yes	non-Coulomb pair energy after "run 4"
run_coul	test_pair_style	yes	Coulomb pair energy after "run 4"
bond_style	test_bond_style	yes	arguments to the bond_style command to be tested
bond_coeff	test_bond_style	yes	list of bond_coeff arguments to set parameters
angle_style	test_angle_style	yes	arguments to the angle_style command to be tested
angle_coeff	test_angle_style	yes	list of angle_coeff arguments to set parameters
dihedral_style	test_dihedral_style	yes	arguments to the dihedral_style command to be tested
dihedral_coeff	test_dihedral_style	yes	list of dihedral_coeff arguments to set parameters
improper_style	test_improper_style	yes	arguments to the improper_style command to be tested
improper_coeff	test_improper_style	yes	list of improper_coeff arguments to set parameters

continues on next page

Table 1 – continued from previous page

Key:	Tester:	Required:	Description:
init_energy	bonded interaction tests, test_min_style	yes	bonded interaction energy after "run 0"; for `test_min_style` the potential energy before the minimization
run_energy	bonded interaction tests, test_min_style	yes	bonded interaction energy after "run 4"; for `test_min_style` the potential energy after the minimization
equilibrium	test_bond_style	yes	equilibrium distance for each type
equilibrium	test_angle_style	yes	equilibrium angle for each type
extract	pair and bonded interaction tests	yes	list of keywords supported by the style's `extract()` method and their dimension
init_stress	pair and bonded interaction tests	yes	stress tensor after "run 0"
init_forces	pair and bonded interaction tests	yes	forces on atoms after "run 0"
run_stress	pair and bonded interaction tests, test_fix_timestep	no	stress tensor after the run (omitted by `test_fix_timestep` when the fix has no virial contribution)
run_forces	pair and bonded interaction tests	yes	forces on atoms after "run 4"
run_pos	test_fix_timestep	yes	per-atom positions after the run
run_vel	test_fix_timestep	yes	per-atom velocities after the run
run_torque	test_fix_timestep	no	per-atom torques after the run (only when the atom style stores torque)
global_scalar	test_fix_timestep, test_min_style, test_output_style	no	the global scalar output of the tested fix, if any; for `test_min_style` the total force norm after the minimization
global_vector	test_fix_timestep, test_min_style, test_output_style	no	the global vector output of the tested fix, if any; for `test_min_style` the box dimensions and tilt factors after the minimization
global_array	test_output_style	no	the global array output of the tested compute or fix, if any

continues on next page

Table 1 – continued from previous page

Key:	Tester:	Required:	Description:
peratom_data	test_output_style	no	the per-atom vector or array output of the tested compute or fix, if any
local_data	test_output_style	no	the local vector or array output of the tested compute or fix, if any

These reference files can be validated against the JSON schema file `tools/json/force-style-test-schema.json` with the `check-jsonschema` tool, which catches typos in keys, missing required keys, and values of the wrong type. For example, to validate all of them at once:

```
check-jsonschema --schemafile tools/json/force-style-test-schema.json \
    unittest/force-styles/tests/*.yaml
```

See the *JSON support files* section of the *Auxiliary tools* documentation for how to install `check-jsonschema`.

The test program will read all this data from the YAML file and then create a LAMMPS instance, apply the settings/commands from the YAML file as needed and then issue a "run 0" command, write out a restart file, a data file and a coeff file. The actual test will then compare computed energies, stresses, and forces with the reference data, issue a "run 4" command and compare to the second set of reference data. This will be run with both the newton_pair setting enabled and disabled and is expected to generate the same results (allowing for some numerical noise). Then it will restart from the previously generated restart and compare with the reference and also start from the data file. A final check will use multi-cutoff r-RESPA (if supported by the pair style) at a 1:1 split and compare to the Verlet results. These sets of tests are run with multiple test fixtures for accelerated styles: OPT, OPENMP and INTEL (the latter two with 4 OpenMP threads enabled), and three mutually exclusive KOKKOS fixtures selected by the active back end: the `kokkos_omp` fixture requires the KOKKOS package compiled with the OpenMP back end and uses 4 OpenMP threads, while the `kokkos_serial` fixture only runs when the Serial back end is the sole back end of the KOKKOS package (with any other back end enabled the host execution space would not be Serial, so this configuration must be tested with a separate build). Both of these host fixtures skip when a GPU back end (CUDA, HIP, SYCL) is enabled, since the KOKKOS package then must run on the GPU. The third fixture, `kokkos_gpu`, is the complement: it runs only when a GPU back end is enabled (using `-k on g 1`) and is skipped on host-only builds. Because enabling the KOKKOS package with a GPU back end aborts when no usable device is present, this fixture first probes for a compatible GPU at runtime with `Info::has_kokkos_gpu_device()` (the KOKKOS package analog of `Info::has_gpu_device()` for the GPU package) and skips transparently when none is available, so the test suite can be run unchanged on machines without a GPU. For these tests the relative error (epsilon) is lowered by a common factor due to the additional numerical noise, but the tests are still comparing to the same reference data.

The KOKKOS fixtures also support the KOKKOS package compiled for reduced precision with `-D KOKKOS_PREC=mixed` (compute in single precision, accumulate in double precision) or `-D KOKKOS_PREC=single`: the test tolerance is then relaxed by a large additional factor, similar to what is done for the mixed and single precision variants of the GPU package. Individual tests can be skipped for a given fixture by listing the fixture name in the `skip_tests:` field of the YAML file (e.g. `skip_tests: kokkos_omp kokkos_serial kokkos_gpu`). A skip entry may also be qualified by the KOKKOS precision, e.g. `kokkos_serial_single` or `kokkos_omp_mixed`, which skips the test only for that combination of fixture and precision. This is used for tests whose reference quantities cannot be meaningfully compared in reduced precision, for example global force totals that are the cancellation sum of large per-atom contributions in a charge-neutral system.

Note

CTest reports a test as *passed* when all of its GoogleTest cases were skipped, since skipping is not a failure. A test that skips because a prerequisite style is missing in the current build is expected, but a test that *always* skips (for

example because the prerequisites list names a style that does not exist) never compares anything and still shows up as passing. When adding or changing tests, run them with `ctest -V` at least once and confirm the output contains `[ OK ]` lines and not only `[ SKIPPED ]` lines; a grep for `SKIPPED` over the verbose output of the whole suite finds such cases in bulk. Malformed YAML files (e.g. a missing `input_coeffs` entry where the tester requires one) are reported as failures, not skips.

The test fixture names accepted by `skip_tests` (each fixture runs the corresponding variant or check and self-skips when its package or back end is not available) are listed below. Not every fixture exists for every style kind (e.g. `gpu`, `intel`, and `opt` are used by the pair-style tester, while `numdiff` is used by the bonded-style testers).

Fixture	Description
plain	the unmodified (base class) style, without a suffix
omp	the `/omp` variant from the OPENMP package (run with 4 threads)
intel	the `/intel` variant from the INTEL package
opt	the `/opt` variant from the OPT package
gpu	the `/gpu` variant from the GPU package
kokkos_serial	the `/kk` variant from the KOKKOS package with a Serial-only build
kokkos_omp	the `/kk` variant from the KOKKOS package with the OpenMP back end (run with 4 threads)
kokkos_gpu	the `/kk` variant from the KOKKOS package with a GPU back end
single	consistency check of the style's `single()` method against `compute()`
extract	check of the style's `extract()` keywords (base style)
extract_omp	check of the style's `extract()` keywords (`/omp` variant)
numdiff	check of the forces against a numerical derivative of the energy

The `kokkos_omp`, `kokkos_serial`, and `kokkos_gpu` entries may be qualified with `_single` or `_mixed` (e.g. `kokkos_gpu_single`), as noted above.

The `tags:` field of a YAML file lists keywords that classify a test or request special handling from the test fixtures. The fixtures query them with `TestConfig::has_tag()` so that style-specific behavior is selected by a descriptive tag instead of by hard-coded style names. The recognized tags are:

Tag	Purpose
gpu_	The GPU package variant of the style does not support mixed precision GPU mode; the `gpu` fixture skips the test when the GPU package was compiled for mixed precision.
gpu_	The GPU package variant of the style does not support single precision GPU mode (e.g. `born/coul/long/cs/gpu`); the `gpu` fixture skips the test when the GPU package was compiled for single precision.
single_t	The style cannot run correctly with more than one thread in the test (e.g. `dpd` uses multiple per-thread pRNGs; `snap` and `pace` due to their implementation), so the threaded fixtures (`omp`, `intel`, `kokkos_omp`) run it with a single thread.
no_re	The `fix_timestep` tester does not exercise this style under *run_style respa*: rigid fixes need additional work to test correctly with r-RESPA, `fix nve/limit` and `fix recenter` do not support it, stochastic integrators and barostats (`brownian`, `gjf`, `press/langevin`) draw their random numbers differently under r-RESPA, and velocity-dependent forcing fixes (`viscous`, `accelerate/cos`) and the isokinetic `nvk` integrator follow a different trajectory under r-RESPA - in all of these cases the verlet and r-RESPA runs cannot match.
no_re	The `fix_timestep` tester does not exercise a timestep change for this style. The fix rejects a timestep reset (its `Fix::reset_dt()` raises an error, e.g. *fix move*), which would otherwise abort the test.
no_re	The `fix_timestep` tester skips the restarted-run comparisons for this style. Part of the internal state of the fix (typically the pRNG state of a stochastic fix like *fix langevin*) is not stored in restart files, so a restarted run cannot reproduce the reference trajectory.
no_t_	The `fix_timestep` tester does not compare the extracted `t_target` property against the input variable for this style, because the fix computes its target temperature internally (e.g. the *fix nphug* hugoniostat).
ellipsoid	The test includes ellipsoids and thus requires *fix nve/asphere*.
spica	The test setup uses `pair_style lj/spica` instead of the default `pair_style zero` (required by the `spica` angle style).
slow	The test runs significantly longer than others and `ctest -LE slow` would skip it.
noWindows	Indicates that this test must be skipped on Windows; use `ctest -LE noWindows`
unstable	The test exhibits numerically unstable behavior on some platforms, e.g. ARM64; Until a proper correction is found, tests can be skipped with `ctest -LE unstable`. Please check the causes discussed in *Writing tests that give the same results on all platforms* before adding this tag.
generated	Automatically added whenever reference data is generated or regenerated; it marks data that has not been reviewed and validated yet. *Remove* after confirming the correctness of the updated YAML file.

Additional tests will check whether all listed extract keywords are supported and have the correct dimensionality and the final set of tests will set up a few pairs of atoms explicitly and in such a fashion that the forces on the atoms computed from `Pair::compute()` will match individually with the results from `Pair::single()`, if the pair style does support that functionality.

With this scheme a large fraction of the code of any tested pair style will be executed and consistent results are required for different settings and between different accelerated pair style variants and the base class, as well as for computing individual pairs through the `Pair::single()` method where supported.

The `test_pair_style` tester is used with 4 categories of test inputs:

pair styles compatible with molecular systems using bonded interactions and exclusions.
: For pair styles requiring a KSpace style the KSpace computations are disabled. The YAML files match the pattern `mol-pair-*.yaml` and the tests are correspondingly labeled with `MolPairStyle:*`

pair styles not compatible with the previous input template
: The YAML files match the pattern `atomic-pair-*.yaml` and the tests are correspondingly labeled with `AtomicPairStyle:*`

manybody pair styles

The YAML files match the pattern `manybody-pair-*.yaml` and the tests are correspondingly labeled with `ManybodyPairStyle:*`

kspace styles
The YAML files match the pattern `kspace-*.yaml` and the tests are correspondingly labeled with `KSpaceStyle:*`. In these cases a compatible pair style is defined, but the computation of the pair style contributions is disabled.

The `test_bond_style`, `test_angle_style`, `test_dihedral_style`, and `test_improper_style` tester programs are set up in a similar fashion and share support functions with the pair style tester. The final group of tests in this section is for fix styles that add/manipulate forces and velocities, e.g. for time integration, thermostats and more.

Adding a new test is easiest done by copying and modifying an existing YAML file for a style that is similar to one to be tested. The file name should follow the naming conventions described above and after copying the file, the first step is to replace the style names where needed. The coefficient values do not have to be meaningful, just in a reasonable range for the given system. It does not matter if some forces are large, for as long as they do not diverge.

The template input files define a large number of index variables at the top that can be modified inside the YAML file to control the behavior. For example, if a pair style requires a "newton on" setting, the following can be used in as the "pre_commands" section:

```
pre_commands: ! |
  variable newton_pair delete
  variable newton_pair index on
```

And for a pair style requiring a kspace solver the following would be used as the "post_commands" section:

```
post_commands: ! |
  pair_modify table 0
  kspace_style pppm/tip4p 1.0e-6
  kspace_modify gewald 0.3
  kspace_modify compute no
```

Note that this disables computing the kspace contribution, but still will run the setup. The "gewald" parameter should be set explicitly to speed up the run. For styles with long-range electrostatics, typically two tests are added one using the (slower) analytic approximation of the erfc() function and the other using the tabulated coulomb, to test both code paths. The reference results in the YAML files then should be compared manually, if they agree well enough within the limits of those two approximations.

The `test_pair_style` and equivalent programs have special command-line options to update the YAML files. Running a command like

```
test_pair_style mol-pair-lennard_mdf.yaml -g new.yaml
```

will read the settings from the `mol-pair-lennard_mdf.yaml` file and then compute the reference data and write a new file with to `new.yaml`. If this step fails, there are likely some (LAMMPS or YAML) syntax issues in the YAML file that need to be resolved and then one can compare the two files to see if the output is as expected.

It is also possible to do an update in place with:

```
test_pair_style mol-pair-lennard_mdf.yaml -u
```

And one can finally run the full set of tests with:

```
test_pair_style mol-pair-lennard_mdf.yaml
```

This will just print a summary of the groups of tests. When using the "-v" flag the test will also keep any LAMMPS output and when using the "-s" flag, there will be some statistics reported on the relative errors for the individual checks

which can help to figure out what would be a good choice of the epsilon parameter. It should be as small as possible to catch any unintended side effects from changes elsewhere, but large enough to accommodate the numerical noise due to the implementation of the potentials and differences in compilers.

Note

These kinds of tests can be very sensitive to compiler optimization and thus the expectation is that they pass with compiler optimization turned off. When compiler optimization is enabled, there may be some failures, but one has to carefully check whether those are acceptable due to the enhanced numerical noise from reordering floating-point math operations or due to the compiler mis-compiling the code. That is not always obvious.

Tests for minimizer styles

Added in version 2Sep2026.

The `test_min_style` program tests the *min_style* minimizers and *min_modify* settings. The YAML files match the pattern `min-*.yaml` and the tests are correspondingly labeled with `MinStyle:*`. Each YAML file sets up the molecular test system in the same way as the fix tests (`input_file` plus `input_coeffs`) and selects the minimizer in the `post_commands` block (`min_style`, `min_modify`, and optional fixes like *fix box/relax*). The driver then runs a minimization with a fixed iteration budget (`minimize 0.0 0.0 100 10000`); using a fixed number of iterations instead of a convergence tolerance keeps the reference data deterministic. The `timestep` key matters for the damped-dynamics minimizers (quickmin and fire).

The line search and step acceptance logic of the minimizers branches on floating-point comparisons, so differences in the last bits of the computed forces – for example from a different compiler or math library – can send the descent along a different but equally valid path. Only observables that are stable against such path changes are compared to the reference data: the potential energy before (`init_energy`) and after (`run_energy`) the minimization and the box dimensions and tilt factors (`global_vector`), all with the relative precision `epsilon`. In addition, the minimization must have lowered the potential energy and must have reduced the total force norm to no more than 10 times the recorded reference value (`global_scalar`). The exact force norm and the per-atom positions after a fixed number of iterations are *not* portable across platforms and are therefore not part of the reference data. Only the plain minimizer styles are exercised; accelerated variants are not covered. Reference files are created and updated with the same `-g` and `-u` command-line options as for the other testers.

Tests for compute and fix output data

Added in version 2Sep2026.

The `test_output_style` program tests the *output data* of computes and fixes: global scalars, global vectors, global arrays (including arrays with a variable number of rows, for example per-chunk data), per-atom vectors and arrays, and local vectors and arrays. The YAML files match the patterns `compute-*.yaml` and `fix-output-*.yaml` and the tests are labeled with `OutputStyle:*` using the full file base name (so `compute-msd.yaml` becomes `OutputStyle:compute-msd`).

The `post_commands` block must define the compute or fix to be tested with the ID `test`, plus any helper commands it needs (groups, chunk computes, or feeder computes and fixes). The driver adds a plain *fix nve* time integrator – unless the test itself defines a time-integrating fix, like *fix rigid/small* – so that history-dependent quantities (mean-squared displacement, velocity auto-correlation, time averages) report real data, and runs 10 MD steps with `thermo 5`, which matches the sampling windows of the `ave/*` reporting fixes. It then queries the output flags of the tested style (`scalar_flag`, `vector_flag`, `array_flag`, `peratom_flag`, `local_flag`) and compares every kind of output the style provides against the recorded reference blocks (`global_scalar`, `global_vector`, `global_array`, `peratom_data`, `local_data`). Output data is a deterministic function of the (short) trajectory, so the reference data is typically compared with a tight `epsilon` (1e-8).

Computes that require per-atom energy or virial data to be tallied during the force computation – for example *compute pe/atom*, *compute stress/atom*, and *compute heat/flux* – are not yet supported by this driver. Reference files are created

and updated with the same `-g` and `-u` command-line options as for the other testers.

4.12.9 Tests for granular (DEM) models

Added in version 2Sep2026.

The `unittest/granular` folder contains a YAML-driven test suite for discrete element method (DEM) / granular contact models, built in the same spirit as the force-style tests above but specialized for time-resolved trajectories of small, analytically tractable granular systems. These tests are only enabled if the *GRANULAR package* is enabled.

There are 15 test programs, `test_dem_01` through `test_dem_15`, covering particle-impact-level benchmarks: two-sphere and sphere-wall collisions, oblique and spinning-sphere impacts, rolling and slipping contact, cohesive pull-off, settling under fluid drag, exact ballistic integration and static multi-contact compression, region walls, superellipsoid contact, twisting friction, and granular heat conduction. These follow the software-agnostic DEM benchmark of *Mohajeri et al.* (rolling resistance and cohesion), the particle-impact benchmark of *Chung and Ooi* (normal, oblique, and spinning-sphere collisions), and the MFiX-DEM verification cases of *Garg et al.* (terminal velocity under drag). The test programs are:

Program	Scenario	Analytic model
`test_dem_`	two-sphere head-on normal collision	`collision_restitution`
`test_dem_`	two-sphere elastic Hertzian normal impact (peak force)	`hertz_normal_impact`
`test_dem_`	sphere-wall elastic Hertzian normal impact (peak force)	`hertz_normal_impact`
`test_dem_`	oblique impact on a wall (gross-sliding friction)	`oblique_impact`
`test_dem_`	sphere sliding then rolling without slipping	`slip_cessation`
`test_dem_`	spinning sphere impact (rebound with friction)	`spin_impact`
`test_dem_`	rolling-resistance decay	`rolling_decay`
`test_dem_`	cohesive DMT pull-off force	`pulloff_dmt`
`test_dem_`	terminal velocity under fluid drag	`terminal_velocity_linear`, `terminal_velocity_schiller_naumann`
`test_dem_`	exact integration and static contact (free fall, stacked compression)	`freefall`, `stack_energy`
`test_dem_`	contact with region walls (restitution)	`wall_restitution`
`test_dem_`	superellipsoid collision	`momentum_conservation`
`test_dem_`	spinning sphere damped by twisting friction	`twist_decay`, `twist_decay_marshall`
`test_dem_`	granular heat conduction in static contact	`heat_equilibration`
`test_dem_`	oblique impact of two spheres (gross sliding)	`oblique_impact_pair`

Every test program shares the same driver logic, implemented in `unittest/granular/test_dem_common.cpp` and compiled into the `granular_tests` support library; each `test_dem_0N.cpp` only contains the two GoogleTest fixtures (`newton_on` and `newton_off`). As with the force-style tests, the reference systems are defined by YAML files in the `unittest/granular/tests` folder and registered as CTest cases by their file name (`dem0N-*.yaml` becomes test `DEM0N:*`); adding or removing a YAML file requires re-running CMake. A given driver may cover several variants of one scenario – across contact models (`hooke`, `hooke/history`, `hertz`, `hertz/material`, `mindlin`, `mindlin/rescale`), dimensionality, or unit systems – since it simply runs every `dem0N-*.yaml` file that matches its number. Variants that exercise the classic granular styles (`gran/hooke`, `gran/hooke/history`, `gran/hertz/history` and the matching classic *fix wall/gran* models) carry a `legacy-` token in the file name and a `legacy` entry in the `tags` line, which also becomes a CTest label (so `ctest -L legacy` runs exactly those tests).

Unlike the force-style tests, the entire system is built *from the YAML file* rather than from a fixed input template. A YAML file provides an optional `variables` block (emitted as *index variables* so they can be substituted as `${name}`

anywhere in the command strings), `pre_commands` that create the geometry, `pair_style` / `pair_coeff` that select the contact model, and `post_commands` that add the integrator and any walls. The trajectory is then advanced in a sequence of `run_segments` and, after each segment, the per-atom positions, velocities, torques, and angular velocities are compared against the recorded reference. A minimal example (`dem03-hertz-wall-3d-si.yaml`) looks like:

```

analytic_tol: 0.01
analytic_segment: 1
# run_pos / run_vel / run_torque / run_omega blocks follow
```

The following table describes the available keys:

Key:	Description:
epsilon	relative precision required for the recorded (regression) reference data
prerequisites	list of style kind / style name pairs required to run the test
variables	name/value pairs exposed as `${name}` index variables for substitution
pre_commands	commands that build the geometry (units, box, atoms, `set`, timestep)
pair_style / pair_coeff	the particle-particle (or particle-wall) contact model
post_commands	fixes added after the geometry (integrator, walls)
run_segments	whitespace-separated list of run lengths; state is captured after each
run_pos, run_vel	reference positions and velocities, as `segment tag x y z` rows
run_torque, run_omega	reference torque / angular velocity (when applicable)
analytic_enable	`yes` to also assert a closed-form (analytic) model
analytic_model	which analytic model to evaluate (see below)
analytic_tol	relative tolerance for the analytic assertion (looser than `epsilon`)
analytic_segment	run segment at which the analytic model is checked (`-1` means the last)

The per-atom reference blocks use a `segment tag x y z` row format, so a single block holds the data for all run segments and the row order does not matter. Because granular/atomic systems do not build an atom map by default, the reference generator iterates over local atoms by tag rather than calling `Atom::map()`.

Each test runs as a pure regression check (the recorded data is reproduced to within `epsilon`) under both the `newton on` and `newton off` fixtures, which are expected to give identical results. In addition, every test opts in to an *analytic* check that compares a derived quantity against a closed-form solution implemented in `unittest/granular/test_analytic_models.cpp`. The analytic tolerance is deliberately loose, because the soft-sphere DEM result only approaches the idealized (hard-sphere or instantaneous-contact) solution. The models currently implemented are:

Model:	Checks:
collision_restitution	two-sphere momentum conservation and restitution $e = -(v_1' - v_2')/(v_1 - v_2)$
hertz_normal_impact	Hertzian peak energy balance $\frac{1}{2}\mu_{red}V_{rela}^2 = \frac{2}{5}P_{max}\alpha_{max}$
oblique_impact	gross-sliding rebound $v_x' = v_x - \mu(1+e)v_z$, $\omega_y = \frac{5}{2}\mu(1+e)v_z/r$
oblique_impact_pair	symmetric two-sphere gross-sliding impact: per sphere $v_n' = -ev_n$, $v_t' = v_t - \mu(1+e)v_n$, $\omega' = -\frac{5}{2}\mu(1+e)v_n/r$
slip_cessation	rolling-without-slipping limit $u = 5u_0/7$, $\omega = u/r$
spin_impact	gross-sliding rebound of a spinning sphere: $v_x' = \mu(1+e)v_n$, $\omega_y' = \omega_0 - \frac{5}{2}\mu(1+e)v_n/r$
rolling_decay	linear spin-down under rolling resistance: $\omega = \omega_0 - \frac{5\mu_r g}{2r}t$
pulloff_dmt	DMT pull-off force at contact $\|F\| = 4\pi\gamma R_{\text{eff}}$
energy_dissipation	total kinetic energy of a frictional impact must not increase (guards against the historic grazing-impact energy-injection bug of the classic tangential model)
spin_no_friction	counter-spinning spheres with zero contact slip keep their spin and gain no tangential velocity
terminal_velocity_linear	Stokes drag terminal velocity $v_{term} = mg/\gamma$
terminal_velocity_schiller_r	Schiller-Naumann terminal velocity from $mg = \frac{1}{2}C_d\rho_g\pi r^2 v^2$
freefall	ballistic motion before contact: $z = z_0 - gt^2/2$, $v_z = -gt$
stack_energy	conservation of total mechanical energy for an elastic two-particle stack
hertz_peak	per-quantity Hertzian peak values $\alpha_{max} = (5\mu_{red}V_{rela}^2/(4k))^{2/5}$ and $P_{max} = k\alpha_{max}^{3/2}$
slip_transient	sliding-phase laws $u = u_0 - \mu gt$, $\omega_y = \frac{5}{2}\mu gt/r$ (pins down the slip-cessation time)
incline_rolling	rolling without slipping down an incline: $v = \frac{5}{7}g(\sin\theta - \mu_r\cos\theta)t$; at rest for $\mu_r \geq \tan\theta$
wall_restitution	rebound $v' = -e\,v$ off walls without another closed form (e.g. region walls)
momentum_conservation	total linear and angular momentum conservation for particle types carrying angular momentum (superellipsoids)
pulloff_jkr	JKR tensile force at zero overlap $\|F\| = \frac{8}{3}\pi\gamma R_{\text{eff}} = \frac{8}{9}F_{pulloff}$
twist_decay	linear spin-down under Coulomb-capped sds twisting friction: $\omega_z = \omega_0 - \frac{5\mu_t g}{2r^2}t$
twist_decay_marshall	like twist_decay for the marshall model cap $\frac{2}{3}\mu_t aN$ with measured contact radius a
heat_equilibration	exponential temperature equilibration of two spheres in static contact; conductance $h\pi a^2$ (area) or $2ka$ (radius)

Adding a new reference (YAML) file

Copy an existing `dem0N-*.yaml` for a similar scenario, adjust the `variables`, `pre_commands`, `pair_style/pair_coeff` and `post_commands` for the new model, and give it a new name matching the `dem0N-*.yaml` pattern of the test program it belongs to. Leave out the reference data blocks initially, then (re)generate them in place with:

```
TEST_ARGS=-u ctest -R DEM0N:myvariant
```

or by running the driver directly (`test_dem_0N dem0N-myvariant.yaml -u`). Do **not** write the generated file to a sibling `dem0N-*.yaml` name (for example with the `-g newfile.yaml` option pointing into the `tests` folder), because the `CONFIGURE_DEPENDS` glob would then register it as an extra, stale test. After adding the file, re-run CMake so the new test is registered, then verify it with `ctest -V -R DEM0N:myvariant` (the `-s` option of the driver reports per-quantity error statistics, which helps when choosing `epsilon` and the analytic tolerance).

Adding a new test program

Create `test_dem_0N.cpp` as a thin copy of an existing one (only the GoogleTest suite name changes), add an `add_executable/register_dem_tests` pair to `unittest/granular/CMakeLists.txt`, and add the corresponding `dem0N-*.yaml` reference files. If the new scenario needs a closed-form check, add a named model to `test_analytic_models.cpp` that reads its parameters from the `variables` block (and reads masses, radii, etc. from the live LAMMPS instance to avoid depending on derived quantities) and assert it with `EXPECT_LE` on the relative error.

4.12.10 Tests for dump image and GRAPHICS package rendering

Added in version 2Sep2026.

The `unittest/graphics` folder contains a YAML-driven test suite for the image rendering of the *dump image* command and its *dump_modify* options: atom, bond, and body rendering, color maps, transparency, lighting, view and camera settings, and the drawing of simulation boxes, axes, and regions. These tests are only enabled if the *GRAPHICS package* is enabled.

The `test_dump_image` driver renders a scene described by a YAML file from the `unittest/graphics/tests` folder and compares sampled pixel data of the rendered image against reference data stored directly in the same YAML file, so no library of reference images is needed. The YAML files are registered as CTest cases by their file name (`name.yaml` becomes test `GRAPHICS:name`); adding or removing a YAML file requires re-running CMake. As in the granular tests, the entire scene is built from the YAML file: the `setup_commands` block contains the scene setup including the `dump image` and `dump_modify` commands under test, and the `run_commands` block triggers the render (usually just `run 0`; scenes with time-dependent features run multiple steps and the frame with the highest timestep number is compared).

Two complementary sets of reference data are recorded for every test:

- the mean red, green, and blue values of every pixel row and of every pixel column of the image (`row_means` and `col_means`). These projections cover every pixel of the image, so any localized or diffuse rendering change shows up in some row or column mean. They are compared with the absolute tolerance `epsilon_projection` (default 0.5 on the 0 to 255 color scale).
- the mean red, green, and blue values of small pixel blocks (default 3x3 pixels) on a uniform grid (default stride 16 pixels), stored as `sample_blocks` and compared with the tolerance `epsilon_blocks` (default 2.0). Their main purpose is to localize a detected failure to a position in the image.

The rendering code produces bit-identical images in serial across the compilers and optimization levels that were tested; the tolerances above leave headroom for differences between math libraries. The rendered image legitimately depends on the number of MPI ranks, however: pixels where multiple objects tie in depth composite differently, and the screen-space ambient occlusion (`ssao`) shading partitions its random number stream by rank. Every test therefore carries an `nprocs` key with the rank count its reference data was created with: tests with `nprocs: 1` run serially, tests with larger values are registered with the MPI launcher by CMake (and are skipped when LAMMPS was compiled without MPI) and exercise the parallel image compositing code. A minimal test file looks like this:

```
---
lammps_version: 4 Jul 2026
```

(continues on next page)

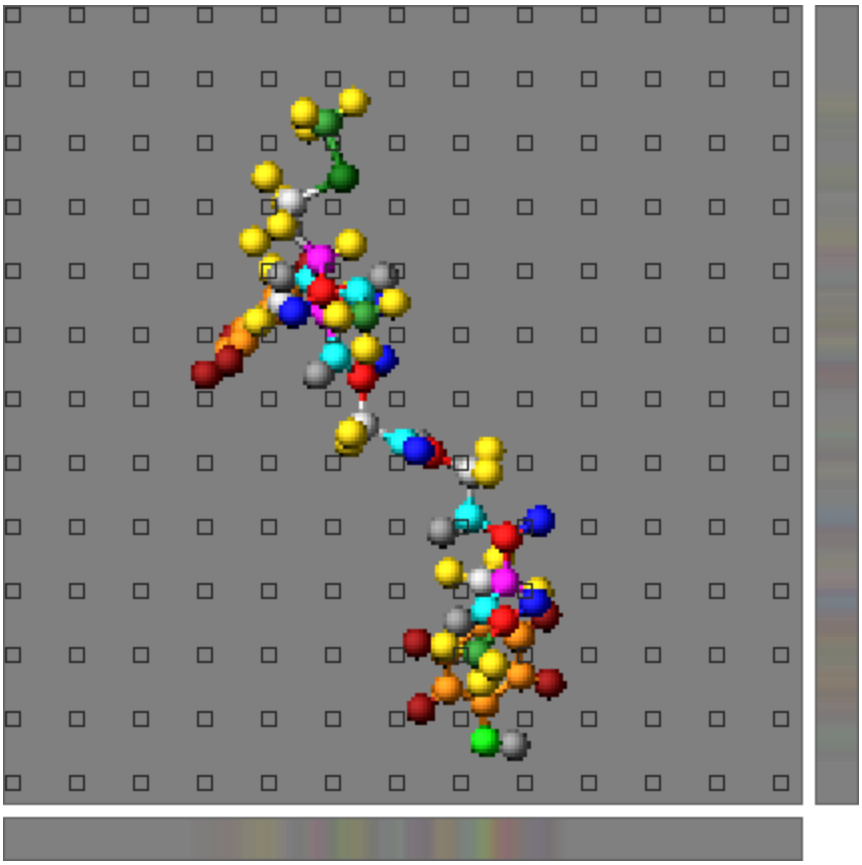

Fig. 6: The rendered image of the `GRAPHICS:dump-image-acolor-type` test (enlarged 2x) with the sampled 3x3 pixel blocks outlined in gray. The color strips on the right and below show the per-row and per-column mean RGB reference data: where the peptide crosses a row or column, its mean color shifts away from the background value.

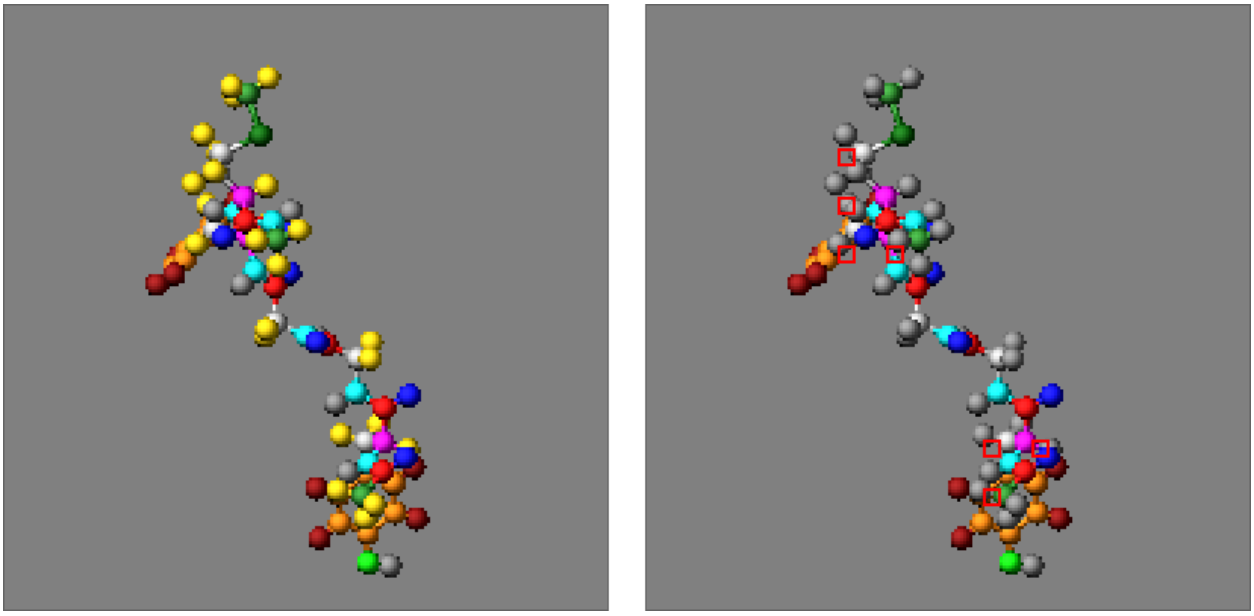

Fig. 7: How a rendering change is detected: the reference scene (left) and the same scene with one atom type recolored (right). The sample blocks whose mean color changed by more than `epsilon_blocks` are outlined in red and localize the change; the row and column mean projections (previous figure) detect it as well, in this example in 104 of the 200 rows and 69 of the 200 columns, including changed atoms that fall between the sampled blocks.

row_means: ...      # reference data written by the generator
col_means: ...
sample_blocks: ...
```

The image file name must be given as `${imagefile}`: the driver defines this variable with a name containing the

* placeholder required by `dump image` and, for the comparison, picks the written frame with the highest timestep number. The variable `${input_dir}` points to the `tests` folder, for scenes that read a data or molecule file. When a comparison fails, the test keeps the rendered image next to the test executable as `<name>.failed.ppm` for visual inspection.

To add a new test, copy an existing YAML file for a similar scene, adjust the commands, delete the reference data blocks (`row_means`, `col_means`, `sample_blocks`), and (re)generate them with the same `-u` (update in place) and `-g` (write new file) options as for the force-style testers, run from the build folder:

```
test_dump_image path/to/new-test.yaml -u              # serial reference
mpirun -np 4 test_dump_image path/to/test.yaml -u     # 4-rank reference
```

Keep the images small (about 200x200 pixels): each test then runs in well under a second and the reference data stays compact. Most importantly, verify that the option under test actually changes the rendered image, because `dump image` options can be silently ignored in some combinations. For example, `dump_modify acolor` has no effect when the dump colors atoms by element, `dump_modify btrans` has no effect when bonds are colored by atom (the two bond halves then follow the transparency of their atoms), and the `autobond` keyword draws nothing on a molecular system with default *special_bonds* settings because bonded pairs are excluded from the neighbor list it searches. Render the scene with and without the option under test and compare the two images before generating the reference data. More authoring notes of this kind are collected in `unittest/graphics/README.md`.

4.12.11 Writing tests that give the same results on all platforms

The unit tests are run for Linux on x86_64 and ARM64 CPUs, for macOS, and for Windows. Results on those platforms may differ in the last digits for several reasons:

- On ARM64 CPUs, compilers by default combine a multiplication and a following addition into a single "fused multiply-add" instruction, which rounds only once and thus can give a result that differs in the last bit.
- The `char` data type is unsigned on Linux for ARM64 but signed on x86_64 and macOS, which matters when code computes with the numerical values of characters.
- Different compilers and math libraries can produce slightly different results for functions like `sin()` or `exp()`.

Since most tests compare *relative* differences against the reference data, a reference value that should be zero but consists only of accumulated floating point rounding errors (magnitudes like 1e-16 to 1e-21) can produce relative errors of order one on a different platform, even though the physics is identical. Such tests should be designed so that those values are exactly zero, or so that they do not depend on the last bits of the input:

- In 2d tests, define *fix enforce2d after* all fixes that add forces or torques. Fixes are invoked in the order they are defined, so a fix that adds forces after fix enforce2d has zeroed the out-of-plane components can re-introduce rounding-error sized components that end up in the reference data.
- Do not start a test from a system at rest (e.g. a data file without a Velocities section and no *velocity* command). After a few steps its velocities and temperature are of the size of rounding errors and cannot be compared reliably.
- Use `velocity ... loop all` (the default) instead of `loop geom` in test inputs. With `loop geom` the random numbers are derived from the atom coordinates, so a coordinate that differs in its last bit (e.g. after *displace_atoms* with the *random* option) produces a different velocity for that atom, and through the removal of the net momentum, for all others as well.
- Avoid comparing quantities that are zero by symmetry but are computed from sums of non-zero terms, e.g. the smallest eigenvalue of the gyration tensor of a planar molecule.
- Iterative solvers that are converged to very tight tolerances (e.g. charge equilibration) amplify small differences; such tests need a correspondingly larger `epsilon`.

A cheap way to check a test for this kind of fragility is to change the initial coordinates or velocities of a few atoms in the last digit (in a local copy of the data or coefficient file) and to rerun the test program with the `-s` flag to print the error statistics: a robust test barely changes. The ARM64 behavior can also be reproduced on an x86_64 machine by

configuring a separate build with `-D CMAKE_CXX_FLAGS="-mfma -ffp-contract=fast"` (fused multiply-add) or `-D CMAKE_CXX_FLAGS=-funsigned-char` (unsigned `char`). The macOS tests also run on x86_64 CPUs, so failures only seen there are usually due to differences in the compiler or math library; a build with the Clang compiler on Linux can help to reproduce them.

Before a test is tagged `unstable`, please try to identify the cause with these methods; the platform differences above have exposed several real bugs (e.g. code that computed with `char` values or that relied on an expression being exactly zero, or a race condition between OpenMP threads that only showed up on ARM64 CPUs).

4.12.12 Tests for programs in the tools folder

The `unittest/tools` folder contains tests for programs in the `tools` folder. This currently only contains tests for the LAMMPS shell, which are implemented as a python scripts using the `unittest` Python module and launching the tool commands through the `subprocess` Python module.

4.12.13 Troubleshooting failed unit tests

There are by default no unit tests for newly added features (e.g. pair, fix, or compute styles) unless your pull request also includes tests for these added features. If you are modifying some existing LAMMPS features, you may see failures for existing tests, if your modifications have some unexpected side effects or your changes render the existing test invalid. If you are adding an accelerated version of an existing style, then only tests for INTEL, KOKKOS (with the OpenMP or Serial host back ends, depending on how the KOKKOS package was configured), OPENMP, and OPT will be run automatically. Tests for the GPU package are time consuming and thus are only run *after* a merge, or when a special label, `gpu_unit_tests` is added to the pull request. After the test has started, it is often best to remove the label since every PR activity will re-trigger the test (that is a limitation of triggering a test with a label). Support for unit tests using KOKKOS with GPU acceleration is currently not supported.

When you see a failed build on GitHub, click on `Details` to be taken to the corresponding LAMMPS Jenkins CI web page. Click on the "Exit" symbol near the `Logout` button on the top right of that page to go to the "classic view". In the classic view, there is a list of the individual runs that make up this test run (they are shown but cannot be inspected in the default view). You can click on any of those. Clicking on `Test Result` will display the list of failed tests. Click on the "Status" column to sort the tests based on their Failed or Passed status. Then click on the failed test to expand its output.

For example, the following output snippet shows the failed unit test

```
[ RUN      ] PairStyle.gpu
/home/builder/workspace/dev/pull_requests/ubuntu_gpu/unit_tests/cmake_gpu_opencl_mixed_
↪smallbig_clang_static/unittest/force-styles/test_main.cpp:63: Failure
Expected: (err) <= (epsilon)
Actual: 0.00018957912910606503 vs 0.0001
Google Test trace:
/home/builder/workspace/dev/pull_requests/ubuntu_gpu/unit_tests/cmake_gpu_opencl_mixed_
↪smallbig_clang_static/unittest/force-styles/test_main.cpp:56: EXPECT_FORCES: init_
↪forces (newton off)
/home/builder/workspace/dev/pull_requests/ubuntu_gpu/unit_tests/cmake_gpu_opencl_mixed_
↪smallbig_clang_static/unittest/force-styles/test_main.cpp:64: Failure
Expected: (err) <= (epsilon)
Actual: 0.00022892713393549854 vs 0.0001
```

The failed assertions provide line numbers in the test source (e.g. `test_main.cpp:56`), from which one can understand what specific assertion failed.

Note that the force style engine runs one of a small number of systems in a rather off-equilibrium configuration with a few atoms for a few steps, writes data and restart files, uses *the clear command* to reset LAMMPS, and then runs from those files with different settings (e.g. newton on/off) and integrators (e.g. verlet vs. respa). Beyond potential

issues/bugs in the source code, the mismatch between the expected and actual values could be that force arrays are not properly cleared between multiple run commands or that class members are not correctly initialized or written to or read from a data or restart file.

While the epsilon (relative precision) for a single, IEEE 754 compliant, double precision floating point operation is at about 2.2e-16, the achievable precision for the tests is lower due to most numbers being sums over intermediate results for which the non-associativity of floating point math leads to larger errors. As a rule of thumb, the test epsilon can often be in the range 5.0e-14 to 1.0e-13. But for "noisy" force kernels, e.g. those a larger amount of arithmetic operations involving *exp()*, *log()* or *sin()* functions, and also due to the effect of compiler optimization or differences between compilers or platforms, epsilon may need to be further relaxed, sometimes epsilon can be relaxed to 1.0e-12. If interpolation or lookup tables are used, epsilon may need to be set to 1.0e-10 or even higher. For tests of accelerated styles, the per-test epsilon is multiplied by empirical factors that take into account the differences in the order of floating point operations or that some or most intermediate operations may be done using approximations or with single precision floating point math. If a test fails only on some platforms, please first check the test input as described in *Writing tests that give the same results on all platforms* before relaxing epsilon.

To rerun a failed unit test individually, change to the `build` directory and run the test with verbose output. For example,

```
env TEST_ARGS=-v ctest -R ^MolPairStyle:lj_cut_coul_long -V
```

`ctest` with the `-V` flag also shows the exact command of the test. One can then use `gdb --args` to further debug and catch exceptions with the test command, for example,

```
gdb --args /path/to/lammps/build/test_pair_style /path/to/lammps/unittest/force-styles/
↪tests/mol-pair-lj_cut_coul_long.yaml
```

It is recommended to configure the build with `-D BUILD_SHARED_LIBS=on` and use a custom linker to shorten the build time during recompilation. Installing *ccache* in your development environment helps speed up recompilation by caching previous compilations and detecting when the same compilation is being done again. Please see *Development build options* for further details.

4.13 C++ base classes

LAMMPS is designed to be used as a C++ class library where one can set up and drive a simulation through creating a class instance and then calling some abstract operations or commands on that class or its member class instances. These are interfaced to the *C library API*, which providing an additional level of abstraction simplification for common operations. The C API is also the basis for calling LAMMPS from Python or Fortran.

When used from a C++ program, most of the symbols and functions in LAMMPS are wrapped into the `LAMMPS_NS` namespace so they will not collide with your own classes or other libraries. This, however, does not extend to the additional libraries bundled with LAMMPS in the lib folder and some of the low-level code of some packages.

Behind the scenes this is implemented through inheritance and polymorphism where base classes define the abstract interface and derived classes provide the specialized implementation for specific models or optimizations or ports to accelerator platforms. This document will provide an outline of the fundamental class hierarchy and some selected examples for derived classes of specific models.

Note

Please see the *note about thread-safety* in the library Howto doc page.

4.13.1 LAMMPS Class

The LAMMPS class is encapsulating an MD simulation state and thus it is the class that needs to be created when starting a new simulation system state. The LAMMPS executable essentially creates one instance of this class and passes the command-line flags and tells it to process the provided input (a file or `stdin`). It shuts the class down when control is returned to it and then exits. When using LAMMPS as a library from another code it is required to create an instance of this class, either directly from C++ with `new LAMMPS()` or through one of the library interface functions like *lammps_open()* of the C-library interface, or the *lammps.lammps* class constructor of the Python module, or the *lammps()* constructor of the Fortran module.

In order to avoid clashes of function names, all of the core code in LAMMPS is placed into the `LAMMPS_NS` namespace. Functions or variables outside of that namespace must be "static", i.e. visible only to the scope of the file/object they are defined in. Code in packages or the libraries in the `lib` folder may not adhere to this as some of them are adapted from legacy code or consist of external libraries with their own requirements and policies.

---

class **LAMMPS**

LAMMPS simulation instance.

The *LAMMPS* class contains pointers of all constituent class instances and global variables that are used by a *LAMMPS* simulation. Its contents represent the entire state of the simulation.

The *LAMMPS* class manages the components of an MD simulation by creating, deleting, and initializing instances of the classes it is composed of, processing command-line flags, and providing access to some global properties. The specifics of setting up and running a simulation are handled by the individual component class instances.

Public Functions

const char ***non_pair_suffix**() const

Return suffix for non-pair styles depending on pair_only_flag.

Returns
suffix or null pointer

const char ***match_style**(const char *style, const char *name)

Return name of package that a specific style belongs to.

This function checks the given name against all list of styles for all types of styles and if the name and the style match, it returns which package this style belongs to.

Parameters

- **style** – Type of style (e.g. atom, pair, fix, etc.)
- **name** – Name of style

Returns
Name of the package this style is part of

LAMMPS(argv &args, MPI_Comm)

Create a *LAMMPS* simulation instance

Parameters

- **args** – list of arguments
- **communicator** – MPI communicator used by this *LAMMPS* instance

LAMMPS(int, char**, MPI_Comm)

Create a *LAMMPS* simulation instance

The *LAMMPS* constructor starts up a simulation by allocating all fundamental classes in the necessary order, parses input switches and their arguments, initializes communicators, screen and logfile output FILE pointers.

Parameters

- **narg** – number of arguments
- **arg** – list of arguments
- **communicator** – MPI communicator used by this *LAMMPS* instance

~LAMMPS()

Shut down a *LAMMPS* simulation instance

The *LAMMPS* destructor shuts down the simulation by deleting top-level class instances, closing screen and log files for the global instance (aka "world") and files and MPI communicators in sub-partitions ("universes"). Then it deletes the fundamental class instances and copies of data inside the class.

Public Static Functions

static std::vector<char*> **argv_pointers**(argv &args)

Create vector of argv char pointers including terminating nullptr element

Parameters
args – list of arguments

Returns
vector of argument pointers

class **Pointers**

Base class for *LAMMPS* features.

The *Pointers* class contains references to many of the pointers and members of the *LAMMPS_NS::LAMMPS* class. Derived classes thus gain access to the constituent class instances in the *LAMMPS* composite class and thus to the core functionality of *LAMMPS*.

This kind of construct is needed, since the *LAMMPS* constructor should only be run once per *LAMMPS* instance and thus classes cannot be derived from *LAMMPS* itself. The *Pointers* class constructor instead only initializes C++ references to component pointer in the *LAMMPS* class.

Subclassed by *Atom*, *CiteMe*, *Input*, *LabelMap*, *PotentialFileReader*, *STLReader*

4.13.2 LAMMPS Atom and AtomVec Base Classes

class **Atom** : protected *Pointers*

Class to provide access to atom data.

The Atom class provides access to atom style related global settings and per-atom data that is stored with atoms and migrates with them from sub-domain to sub-domain as atoms move around. This includes topology data, which is stored with either one specific atom or all atoms involved depending on the settings of the *newton command*.

The actual per-atom data is allocated and managed by one of the various classes derived from the AtomVec class as determined by the *atom_style command*. The pointers in the Atom class are updated by the AtomVec class as needed.

Public Functions

Atom(class *LAMMPS**)

Atom class constructor

This resets and initializes all kinds of settings, parameters, and pointer variables for per-atom arrays. This also initializes the factory for creating instances of classes derived from the AtomVec base class, which correspond to the selected atom style.

Parameters
_lmp – pointer to the base *LAMMPS* class

int **find_custom**(const char*, int&, int&)

Find a custom per-atom property with given name.

This function returns the list index of a custom per-atom property with the name "name", also returning by reference its data type and number of values per atom.

Parameters

- **name** – Name of the property (w/o a "i_" or "d_" or "i2_" or "d2_" prefix)
- **&flag** – Returns data type of property: 0 for int, 1 for double
- **&cols** – Returns number of values: 0 for a single value, 1 or more for a vector of values

Returns
index of property in the respective list of properties

int **find_custom_ghost**(const char*, int&, int&, int&)

Find a custom per-atom property with given name and retrieve ghost property.

This function returns the list index of a custom per-atom property with the name "name", also returning by reference its data type, number of values per atom, and if it is communicated to ghost particles. Classes rarely need to check on ghost communication and so *find_custom* is typically preferred to this function. See *pair amoeba* for an example where checking ghost communication is necessary.

Parameters

- **name** – Name of the property (w/o a "i_" or "d_" or "i2_" or "d2_" prefix)
- **&flag** – Returns data type of property: 0 for int, 1 for double
- **&cols** – Returns number of values: 0 for a single value, 1 or more for a vector of values
- **&ghost** – Returns whether property is communicated to ghost atoms: 0 for no, 1 for yes

Returns
index of property in the respective list of properties

virtual int **add_custom**(const char*, int, int, int ghost = 0)

Add a custom per-atom property with the given name and type and size.

This function will add a custom per-atom property with one or more values with the name "name" to the list of custom properties. This function is called, e.g. from *fix property/atom*.

Parameters

- **name** – Name of the property (w/o a "i_" or "d_" or "i2_" or "d2_" prefix)
- **flag** – Data type of property: 0 for int, 1 for double
- **cols** – Number of values: 0 for a single value, 1 or more for a vector of values
- **ghost** – Whether property is communicated to ghost atoms: 0 for no, 1 for yes

Returns

index of property in the respective list of properties

virtual void **remove_custom**(int, int, int)

Remove a custom per-atom property of a given type and size.

This will remove a property that was requested, e.g. by the *fix property/atom* command. It frees the allocated memory and sets the pointer to `nullptr` for the entry in the list so it can be reused. The lists of these pointers are never compacted or shrunk, so that indices to name mappings remain valid.

Parameters

- **index** – Index of property in the respective list of properties
- **flag** – Data type of property: 0 for int, 1 for double
- **cols** – Number of values: 0 for a single value, 1 or more for a vector of values

virtual void ***extract**(const char*)

Provide access to internal data of the *Atom* class by keyword

This function is a way to access internal per-atom data. This data is distributed across MPI ranks and thus only the data for "local" atoms are expected to be available. Whether also data for "ghost" atoms is stored and up-to-date depends on various simulation settings.

This table lists a large part of the supported names, their data types, length of the data area, and a short description.

Name	Type	Items per atom	Description
mass	double	1	per-type mass. This array is **NOT** a per-atom array but of length `ntypes+1`, element 0 is ignored.
id	tagint	1	atom ID of the particles
type	int	1	atom type of the particles
mask	int	1	bitmask for mapping to groups. Individual bits are set to 0 or 1 for each group.
image	imageint	1	3 image flags encoded into a single integer. See *lammps_encode_image_flags()*.
x	double	3	x-, y-, and z-coordinate of the particles
v	double	3	x-, y-, and z-component of the velocity of the particles
f	double	3	x-, y-, and z-component of the force on the particles
molecule	int	1	molecule ID of the particles
q	double	1	charge of the particles
mu	double	3	dipole moment of the particles
omega	double	3	x-, y-, and z-component of rotational velocity of the particles
angmom	double	3	x-, y-, and z-component of angular momentum of the particles
torque	double	3	x-, y-, and z-component of the torque on the particles
radius	double	1	radius of the (extended) particles
rmass	double	1	per-atom mass of the particles. `nullptr` if per-type masses are used. See the *rmass_flag* setting.
ellipsoid	int	1	1 if the particle is an ellipsoidal particle, 0 if not
line	int	1	1 if the particle is a line particle, 0 if not
tri	int	1	1 if the particle is a triangulated particle, 0 if not
body	int	1	1 if the particle is a body particle, 0 if not
quat	double	4	four quaternion components of the particles
temperature	double	1	temperature of the particles
heatflow	double	1	heatflow of the particles
i_name	int	1	single integer value defined by fix property/atom vector name
d_name	double	1	single double value defined by fix property/atom vector name
i2_name	int	N	N integer values defined by fix property/atom array name
d2_name	double	N	N double values defined by fix property/atom array name

See also

lammps_extract_atom(), *lammps_extract_atom_datatype()*, *lammps_extract_atom_size()*

See also

extract_datatype, *extract_size*

Parameters
name – string with the keyword of the desired property. Typically the name of the pointer variable returned

Returns
pointer to the requested data cast to `void *` or `nullptr`

int **extract_datatype**(const char*)

Provide data type info about internal data of the *Atom* class

Added in version 18Sep2020.

See also

extract extract_size

Parameters
name – string with the keyword of the desired property.

Returns
data type constant for desired property or -1

int **extract_size**(const char*, int)

Provide vector or array size info of internal data of the *Atom* class

Added in version 19Nov2024.

See also

extract extract_datatype

Parameters

- **name** – string with the keyword of the desired property.
- **type** – either LMP_SIZE_ROWS or LMP_SIZE_COLS for per-atom array or ignored

Returns
size of the vector or size of the array for the requested dimension or -1

struct **PerAtom**

4.13.3 LAMMPS Input Base Class

class **Input** : protected *Pointers*

Class for processing commands and input files.

The Input class contains methods for reading, pre-processing and parsing LAMMPS commands and input files and will dispatch commands to the respective class instances or contain the code to execute the commands directly. It also contains the instance of the Variable class which performs computations and text substitutions.

Public Functions

Input(class *LAMMPS**, int, char**)

Input class constructor

This sets up the input processing, processes the *-var* and *-echo* command-line flags, holds the factory of commands and creates and initializes an instance of the Variable class.

To execute a command, a specific class instance, derived from `Command`, is created, then its `command()` member function executed, and finally the class instance is deleted.

Parameters

- **lmp** – pointer to the base *LAMMPS* class
- **argc** – number of entries in *argv*
- **argv** – argument vector

void **file**()

Process all input from the `FILE *` pointer *infile*

This will read lines from *infile*, parse and execute them until the end of the file is reached. The *infile* pointer will usually point to `stdin` or the input file given with the `-in` command-line flag.

void **file**(const char*)

Process all input from the file *filename*

This function opens the file at the path *filename*, puts the current file pointer stored in *infile* on a stack and instead assigns *infile* with the newly opened file pointer. Then it will call the *Input::file()* function to read, parse and execute the contents of that file. When the end of the file is reached, it is closed and the previous file pointer from the infile file pointer stack restored to *infile*.

Parameters

filename – name of file with *LAMMPS* commands

char ***one**(const std::string&)

Process a single command from a string in *single*

This function takes the text in *single*, makes a copy, parses that, executes the command and returns the name of the command (without the arguments). If there was no command in *single* it will return `nullptr`.

Parameters

single – string with *LAMMPS* command

Returns

string with name of the parsed command w/o arguments

4.13.4 Citation management for contributed features

LAMMPS provides a built-in mechanism to remind users to cite publications that describe the implementation of contributed features. This is implemented through the *CiteMe* class.

Overview

When users use specific features in LAMMPS, a citation reminder can be configured in the contributed source code to remind users which publications they should cite. Citations are output in three ways:

- To the screen (with configurable verbosity)
- To the log file (with configurable verbosity)
- To an optional BibTeX file for easy integration with bibliography managers

The system automatically deduplicates citations, so each publication is listed only once even if multiple features reference it or they are used multiple times.

Adding a citation reminder to contributed code

If you are contributing a new feature to LAMMPS you can add a reminder for citing a publication describing the implementation of that feature. This is a simple two-step process:

Step 1: Define the citation string

At the top of your implementation file (typically a `.cpp` file), define a static string containing the citation in BibTeX format. The string should start with a single line description including a DOI URL, followed by a complete BibTeX entry. Example:

```
static const char cite_my_feature[] =
  "my_feature command: https://doi.org/10.1234/example.doi\n\n"
  "@Article{AuthorYear,\n"
  " author = {First Author and Second Author},\n"
  " title = {Title of the Paper},\n"
  " journal = {Journal Name},\n"
  " year = 2024,\n"
  " volume = 100,\n"
  " pages = {1-10}\n"
  "}\n\n";
```

Step 2: Register the citation

In your style's constructor, add a call to register the citation. Always check that the `citeme` pointer instance in the LAMMPS is available before calling, since the pointer will be NULL when citation tracking is disabled via a command line option:

```
MyStyle::MyStyle(LAMMPS *lmp) : Parent(lmp)
{
  if (lmp->citeme) lmp->citeme->add(cite_my_feature);
  // ... rest of constructor code
}
```

Output:

The example from above will produce by default the following output:

```
CITE-CITE-CITE-CITE-CITE-CITE-CITE-CITE-CITE-CITE-CITE-CITE-CITE-CITE
```

(continues on next page)

(continued from previous page)

```
Your simulation uses code contributions which should be cited:

- my_feature command: https://doi.org/10.1234/example.doi

The file log.cite lists these citations in BibTeX format.

CITE-CITE-CITE-CITE-CITE-CITE-CITE-CITE-CITE-CITE-CITE-CITE-CITE
```

Implementation details

The *CiteMe* class uses hash-based deduplication to ensure each citation is shown only once, even if multiple features in a simulation reference the same publication. Only MPI rank 0 performs citation output to avoid flooding the output in parallel runs.

Citations added with *CiteMe::add()* are:

1. Written immediately to the BibTeX file (if enabled)
2. Buffered for screen and log file output
3. Flushed to screen and log file at appropriate times (typically at the end of the run or when LAMMPS has reached the end of the input file).

For the complete API documentation see the class reference below:

---

class **CiteMe** : protected *Pointers*

The *CiteMe* class provides a mechanism for *LAMMPS* to remind users to cite relevant publications when they use specific contributed features. This ensures proper attribution for the scientific work underlying *LAMMPS* implementations.

Public Functions

CiteMe(class *LAMMPS**, int, int, const char*)

Constructor for *CiteMe* class

Parameters

- **lmp** – Pointer to the main *LAMMPS* object
- **_screen** – Output mode for screen (VERBOSE or TERSE)
- **_logfile** – Output mode for log file (VERBOSE or TERSE)
- **_file** – Optional filename for BibTeX citation output file (can be NULL)

~CiteMe() override

Destructor flushes any remaining citations

void **add**(const std::string &reference)

Register a publication for citation output

Adds a citation to the set of publications to be cited. Each citation should contain a BibTeX entry and is output only once, even if add() is called multiple times with the same citation. The citation string should start with a brief description including a DOI, followed by a complete BibTeX entry.

This method should typically be called in the constructor of a style that implements a published method or algorithm.

Parameters
reference – String containing the citation in BibTeX format with DOI header

void **flush**()

Flush accumulated citation buffers to screen and log file

Outputs all pending citations to the screen and log file with appropriate formatting. Called automatically by the destructor when LAMMPS terminates or is reset by the *clear* command and at the end of a *run* or *minimize* command.

4.14 Platform abstraction functions

The `platform` sub-namespace inside the `LAMMPS_NS` namespace provides a collection of wrapper and convenience functions and utilities that perform common tasks for which platform specific code would be required or for which a more high-level abstraction would be convenient and reduce duplicated code. This reduces redundant implementations and encourages consistent behavior and thus has some overlap with the *"utils" sub-namespace*.

4.14.1 Time functions

double `LAMMPS_NS::platform::`**cputime**()

Return the consumed CPU time for the current process in seconds

This is a wrapper around the POSIX function getrusage() and its Windows equivalent. It is to be used in a similar fashion as MPI_Wtime(). Its resolution may be rather low so it can only be trusted when observing processes consuming CPU time of at least a few seconds.

Returns
used CPU time in seconds

double `LAMMPS_NS::platform::`**walltime**()

Return the wall clock state for the current process in seconds

This clock is counting continuous time and is initialized during load of the executable/library. Its absolute value must be considered arbitrary and thus elapsed wall times are measured in taking differences. It is therefore to be used in a similar fashion as MPI_Wtime() but has a different offset, usually leading to better resolution.

Returns
wall clock time in seconds

void `LAMMPS_NS::platform::`**usleep**(int usec)

Suspend execution for a microsecond interval

This emulates the usleep(3) BSD function call also mentioned in POSIX.1-2001. This is not a precise delay; it may be longer, but not shorter.

Parameters
usec – length of delay in microseconds

4.14.2 Platform information functions

std::string `LAMMPS_NS::platform::`**os_info**()

Return string with the operating system version and architecture info

Returns
string with info about the OS and the platform is is running on

std::string LAMMPS_NS::platform::**compiler_info**()

Return string with compiler version info

This function uses predefined compiler macros to identify Compilers and their version and configuration info.

Returns
string with the compiler information text

std::string LAMMPS_NS::platform::**cxx_standard**()

Return string with C++ standard version used to compile *LAMMPS*.

This function uses predefined compiler macros to identify the C++ standard version used to compile *LAMMPS* with.

Returns
string with the C++ standard version or "unknown"

std::string LAMMPS_NS::platform::**openmp_standard**()

Return string with OpenMP standard version info

This function uses predefined compiler macros to identify OpenMP support and the supported version of the standard.

Returns
string with the openmp information text

std::string LAMMPS_NS::platform::**mpi_vendor**()

Return string with MPI vendor info

This function uses predefined macros to identify the vendor of the MPI library used.

Returns
string with the MPI vendor information text

std::string LAMMPS_NS::platform::**mpi_info**(int &major, int &minor)

Return string with MPI version info

This function uses predefined macros and MPI function calls to identify the version of the MPI library used.

Parameters

- **major** – major version of the MPI standard (set on exit)
- **minor** – minor version of the MPI standard (set on exit)

Returns
string with the MPI version information text

std::string LAMMPS_NS::platform::**compress_info**()

Return string with list of available compression types and executables

This function tests which of the supported compression executables are available for reading or writing compressed files where supported.

Returns
string with list of available compression tools

4.14.3 File and path functions and global constants

Since we are requiring C++17 to compile LAMMPS, you can also make use of the functionality of the C++ filesystem library. The following functions are in part convenience functions or emulate the behavior of similar Python functions or Unix shell commands. Please note that the you need to use the `string()` member function of the std::filesystem::path class to get access to the path as a C++ string class instance.

constexpr char LAMMPS_NS::platform::**filepathsep**[] = "/"

Platform specific file path component separator

This is a string with the character that separates directories and filename in paths on a platform. If multiple are characters are provided, the first is the preferred one.

constexpr char LAMMPS_NS::platform::**pathvarsep** = ':'

Platform specific path environment variable component separator

This is the character that separates entries in "PATH"-style environment variables.

const char *LAMMPS_NS::platform::**guesspath**(FILE *fp, char *buf, int len)

Try to detect pathname from FILE pointer

Currently only supported on Linux, MacOS, and Windows. Otherwise will report "(unknown)".

On Linux the folder /proc/self/fd holds symbolic links to the actual pathnames associated with each open file descriptor of the current process. On MacOS the same kind of information can be obtained using `fcntl(fd, F_GETPATH,buf)`. On Windows we use `GetFinalPathNameByHandleA()` which is available with Windows Vista and later. If the buffer is too small (< 16 bytes) a null pointer is returned.

This function is used to provide a filename with error messages in functions where the filename is not passed as an argument, but the FILE * pointer.

Parameters

- **fp** – FILE pointer struct from STDIO library for which we want to detect the name
- **buf** – storage buffer for pathname. output will be truncated if not large enough
- **len** – size of storage buffer. output will be truncated to this length - 1

Returns

pointer to the storage buffer with path or a NULL pointer if buf is invalid or the buffer size is too small

std::string LAMMPS_NS::platform::**path_basename**(const std::string &path)

Strip off leading part of path, return just the filename

Parameters

path – file path

Returns

file name

std::string LAMMPS_NS::platform::**path_dirname**(const std::string &path)

Return the directory part of a path. Return "." if empty

Parameters

path – file path

Returns

directory name

std::string LAMMPS_NS::platform::**path_join**(const std::string &a, const std::string &b)

Join two pathname segments

This uses the forward slash '/' character unless *LAMMPS* is compiled for Windows where it uses the backward slash '\'

Parameters

- **a** – first path
- **b** – second path

Returns
combined path

bool LAMMPS_NS::platform::**file_is_readable**(const std::string &path)

Check if file exists and is readable

Parameters
path – file path

Returns
true if file exists and is readable

bool LAMMPS_NS::platform::**file_is_writable**(const std::string &path)

Check if file can be opened for writing

Parameters
path – file path

Returns
true if file can be opened for writing

std::string LAMMPS_NS::platform::**file_redirect**(const std::string &path)

Return target path if the file is a 'redirect file'

Git uses 'redirect files' instead of symbolic links on Windows since the Windows file system has no symbolic links. The redirect file is a text file with just one line: the symbolic link target path. This function opens the path parameter and reads a line. If that line is a readable file, it returns that path, otherwise the original path. The check is only performed when compiled for Windows. Otherwise the original path is always returned.

Parameters
path – file path to check

Returns
the redirected path or the original path

bool LAMMPS_NS::platform::**is_console**(FILE *fp)

Check if a file pointer may be connected to a console

Parameters
fp – file pointer

Returns
true if the file pointer is flagged as a TTY

int LAMMPS_NS::platform::**terminal_width**(FILE *fp)

Determine the width (number of columns) of the terminal connected to a file pointer

This queries the terminal connected to the given file pointer for its current width in characters. It returns 0 when the file pointer is not connected to a terminal (e.g. when output is redirected to a file or a pipe), so callers can fall back to a fixed default width for reproducible non-interactive output.

Parameters
fp – file pointer

Returns
number of terminal columns, or 0 if *fp* is not a terminal

double LAMMPS_NS::platform::**disk_free**(const std::string &path)

Return free disk space in bytes of file system pointed to by path

Returns -1.0 if the path is invalid or free space reporting not supported.

Parameters
path – file or folder path in file system

Returns

std::vector<std::string> LAMMPS_NS::platform::**list_directory**(const std::string &dir)

Get list of entries in a directory

This provides a list of strings of the entries in the directory without the leading path name while also skipping over ".." and ".".

Parameters
dir – path to directory

Returns
vector with strings of all directory entries

int LAMMPS_NS::platform::**chdir**(const std::string &path)

Change current directory

Parameters
path – new current working directory path

Returns
-1 if unsuccessful, otherwise >= 0

int LAMMPS_NS::platform::**mkdir**(const std::string &path)

Create a directory or directory path

Unlike the the `mkdir()` or `_mkdir()` functions of the C library, this function will also try to create non-existing sub-directories in case they don't exist, and thus it behaves like the `mkdir -p` command rather than plain `mkdir` or `md` in a Unix or Windows shell, respectively.

Parameters
path – directory path

Returns
-1 if unsuccessful, otherwise >= 0

int LAMMPS_NS::platform::**rmdir**(const std::string &path)

Delete a directory

Unlike the the `rmdir()` or `_rmdir()` functions of the C library, this function will check for the contents of the folder and recurse into any sub-folders, if necessary, and delete all contained folders and their contents before deleting the folder *path*.

Parameters
path – directory path

Returns
-1 if unsuccessful, otherwise >= 0

int LAMMPS_NS::platform::**unlink**(const std::string &path)

Delete a file

Parameters
path – path to file to be deleted

Returns
0 on success, -1 on error

4.14.4 Standard I/O function wrappers

constexpr bigint LAMMPS_NS::platform::**END_OF_FILE** = -1

constant to seek to the end of the file

bigint LAMMPS_NS::platform::**ftell**(FILE *fp)

Get current file position

Parameters
fp – FILE pointer of the given file

Returns
current FILE pointer position cast to a bigint

int LAMMPS_NS::platform::**fseek**(FILE *fp, bigint pos)

Set absolute file position

If the absolute position is END_OF_FILE, then position at the end of the file.

Parameters

- **fp** – FILE pointer of the given file
- **pos** – new position of the FILE pointer

Returns
0 if successful, otherwise -1

int LAMMPS_NS::platform::**ftruncate**(FILE *fp, bigint length)

Truncate file to a given length and re-position file pointer

Parameters

- **fp** – FILE pointer of the given file
- **length** – length to which the file is being truncated to

Returns
0 if successful, otherwise -1

FILE *LAMMPS_NS::platform::**popen**(const std::string &cmd, const std::string &mode)

Open a pipe to a command for reading or writing

Parameters

- **cmd** – command for the pipe
- **mode** – "r" for reading from *cmd* or "w" for writing to *cmd*

Returns
file pointer to the pipe if successful or null

int LAMMPS_NS::platform::**pclose**(FILE *fp)

Close a previously opened pipe

Parameters
fp – FILE pointer for the pipe

Returns
exit status of the pipe command or -1 in case of errors

4.14.5 Environment variable functions

int LAMMPS_NS::platform::**putenv**(const std::string &vardef)

Add variable to the environment

Parameters
vardef – variable name or variable definition (NAME=value)

Returns
-1 if failure otherwise 0

int LAMMPS_NS::platform::**unsetenv**(const std::string &variable)

Delete variable from the environment

Parameters
variable – variable name

Returns
-1 if failure otherwise 0

std::vector<std::string> LAMMPS_NS::platform::**list_pathenv**(const std::string &var)

Get list of entries in a path environment variable

This provides a list of strings of the entries in an environment variable that is containing a "path" like "PATH" or "LD_LIBRARY_PATH".

Parameters
var – name of the environment variable

Returns
vector with strings of all entries in that path variable

std::string LAMMPS_NS::platform::**find_exe_path**(const std::string &cmd)

Find pathname of an executable in the standard search path

This function will traverse the list of directories in the PATH environment variable and look for the executable *cmd*. If the file exists and is executable the full path is returned as string, otherwise an empty string is returned.

On Windows the *cmd* string must not include an extension as this function will automatically append the extensions ".exe", ".com" and ".bat" and look for those paths. On Windows also the current directory is checked (and first), but otherwise is not checked unless "." exists in the PATH environment variable.

Because of the nature of the check, this will not detect shell functions built-in command or aliases.

Parameters
cmd – name of command

Returns
vector with strings of all directory entries

4.14.6 Dynamically loaded object or library functions

void *LAMMPS_NS::platform::**dlopen**(const std::string &fname)

Open a shared object file or library

Parameters
fname – name or path of the shared object

Returns
handle to the shared object or null

int LAMMPS_NS::platform::**dlclose**(void *handle)

Close a shared object

This releases the object corresponding to the provided handle. Resolved symbols associated with this handle may not be used after this call

Parameters
handle – handle to an opened shared object

Returns
0 if successful, non-zero of not

void *LAMMPS_NS::platform::**dlsym**(void *handle, const std::string &symbol)

Resolve a symbol in shared object

Parameters

- **handle** – handle to an opened shared object
- **symbol** – name of the symbol to extract

Returns
pointer to the resolved symbol or null

std::string LAMMPS_NS::platform::**dlerror**()

Obtain error diagnostic info after dynamic linking function calls

Return a human-readable string describing the most recent error that occurred when using one of the functions for dynamic loading objects the last call to this function. If there was no error, the string is empty.

Returns
string with error message or empty

4.14.7 Compressed file I/O functions

bool LAMMPS_NS::platform::**has_compress_extension**(const std::string &file)

Check if a file name ends in a known extension for a compressed file format

Currently supported file extensions are: .gz, .bz2, .zst, .xz, .lzma, .lz4, .br, and .7z

Parameters
file – name of the file to check

Returns
true if the file has a known extension, otherwise false

FILE *LAMMPS_NS::platform::**compressed_read**(const std::string &file)

Open pipe to compressed text file for reading

Parameters
file – name of the file to open

Returns
FILE pointer to pipe using for reading the compressed file.

FILE *LAMMPS_NS::platform::**compressed_write**(const std::string &file)

Open pipe to compressed text file for writing

Parameters
file – name of the file to open

Returns
FILE pointer to pipe using for reading the compressed file.

4.15 Utility functions

The `utils` sub-namespace inside the `LAMMPS_NS` namespace provides a collection of convenience functions and utilities that perform common tasks that are required repeatedly throughout the LAMMPS code like reading or writing to files with error checking or translation of strings into specific types of numbers with checking for validity. This reduces redundant implementations and encourages consistent behavior and thus has some overlap with the *"platform" sub-namespace*.

- *I/O with status check and similar functions*
- *String to number conversions with validity check*
- *String processing*
- *Potential file functions*
- *Argument processing*
- *Convenience functions*
- *Customized standard functions*

4.15.1 I/O with status check and similar functions

The the first two functions are wrappers around the corresponding C library calls `fgets()` or `fread()`. They will check if there were errors on reading or an unexpected end-of-file state was reached. In that case, the functions will stop with an error message, indicating the name of the problematic file, if possible unless the *error* argument is a NULL pointer.

The *utils::fgets_trunc()* function will work similar for `fgets()` but it will read in a whole line (i.e. until the end of line or end of file), but store only as many characters as will fit into the buffer including a final newline character and the terminating NULL byte. If the line in the file is longer it will thus be truncated in the buffer. This function is used by *utils::read_lines_from_file()* to read individual lines but make certain they follow the size constraints.

The *utils::read_lines_from_file()* function will read the requested number of lines of a maximum length into a buffer and will return 0 if successful or 1 if not. It also guarantees that all lines are terminated with a newline character and the entire buffer with a NULL character.

---

void `LAMMPS_NS::utils::`**`sfgets`**(const char *srcname, int srcline, char *s, int size, FILE *fp, const char *filename, Error *error)

Safe wrapper around fgets() which aborts on errors or EOF and prints a suitable error message to help debugging.

Use nullptr as the error parameter to avoid the abort on EOF or error.

Parameters

- **`srcname`** – name of the calling source file (from FLERR macro)
- **`srcline`** – line in the calling source file (from FLERR macro)
- **`s`** – buffer for storing the result of fgets()
- **`size`** – size of buffer s (max number of bytes read by fgets())
- **`fp`** – file pointer used by fgets()

- **filename** – file name associated with fp (may be a null pointer; then *LAMMPS* will try to detect)
- **error** – pointer to Error class instance (for abort) or nullptr

void LAMMPS_NS::utils::**sfread**(const char *srcname, int srcline, void *s, size_t size, size_t num, FILE *fp, const char *filename, Error *error)

Safe wrapper around fread() which aborts on errors or EOF and prints a suitable error message to help debugging.

Use nullptr as the error parameter to avoid the abort on EOF or error.

Parameters

- **srcname** – name of the calling source file (from FLERR macro)
- **srcline** – line in the calling source file (from FLERR macro)
- **s** – buffer for storing the result of fread()
- **size** – size of data elements read by fread()
- **num** – number of data elements read by fread()
- **fp** – file pointer used by fread()
- **filename** – file name associated with fp (may be a null pointer; then *LAMMPS* will try to detect)
- **error** – pointer to Error class instance (for abort) or nullptr

char *LAMMPS_NS::utils::**fgets_trunc**(char *s, int size, FILE *fp)

Wrapper around fgets() which reads whole lines but truncates the data to the buffer size and ensures a newline char at the end.

This function is useful for reading line based text files with possible comments that should be parsed later. This applies to data files, potential files, atomfile variable files and so on. It is used instead of fgets() by utils::read_lines_from_file().

Parameters

- **s** – buffer for storing the result of fgets()
- **size** – size of buffer s (max number of bytes returned)
- **fp** – file pointer used by fgets()

int LAMMPS_NS::utils::**read_lines_from_file**(FILE *fp, int nlines, int nmax, char *buffer, int me, MPI_Comm comm)

Read N lines of text from file into buffer and broadcast them

This function uses repeated calls to fread() to fill a buffer with newline terminated text. If a line does not end in a newline (e.g. at the end of a file), it is added. The caller has to allocate an nlines by nmax sized buffer for storing the text data. Reading is done by MPI rank 0 of the given communicator only, and thus only MPI rank 0 needs to provide a valid file pointer.

Parameters

- **fp** – file pointer used by fread
- **nlines** – number of lines to be read
- **nmax** – maximum length of a single line
- **buffer** – buffer for storing the data.
- **me** – MPI rank of calling process in MPI communicator

- **comm** – MPI communicator for broadcast

Returns
1 if the read was short, 0 if read was successful

4.15.2 String to number conversions with validity check

These functions should be used to convert strings to numbers. They are are strongly preferred over C library calls like `atoi()` or `atof()` since they check if the **entire** string is a valid (floating-point or integer) number, and will error out instead of silently returning the result of a partial conversion or zero in cases where the string is not a valid number. This behavior improves detecting typos or issues when processing input files.

Similarly the *utils::logical()* function will convert a string into a boolean and will only accept certain words.

The *do_abort* flag should be set to `true` in case this function is called only on a single MPI rank, as that will then trigger the a call to `Error::one()` for errors instead of `Error::all()` and avoids a "hanging" calculation when run in parallel.

Please also see *utils::is_integer()* and *utils::is_double()* for testing strings for compliance without conversion.

---

double LAMMPS_NS::utils::**numeric**(const char *file, int line, const std::string &str, bool do_abort, *LAMMPS* *lmp)

Convert a string to a floating point number while checking if it is a valid floating point or integer number

Parameters

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – string to be converted to number
- **do_abort** – determines whether to call Error::one() or Error::all()
- **lmp** – pointer to top-level *LAMMPS* class instance

Returns
double precision floating point number

double LAMMPS_NS::utils::**numeric**(const char *file, int line, const char *str, bool do_abort, *LAMMPS* *lmp)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Parameters

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – string to be converted to number
- **do_abort** – determines whether to call Error::one() or Error::all()
- **lmp** – pointer to top-level *LAMMPS* class instance

Returns
double precision floating point number

int LAMMPS_NS::utils::**inumeric**(const char *file, int line, const std::string &str, bool do_abort, *LAMMPS* *lmp)

Convert a string to an integer number while checking if it is a valid integer number (regular int)

Parameters

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – string to be converted to number
- **do_abort** – determines whether to call Error::one() or Error::all()
- **lmp** – pointer to top-level *LAMMPS* class instance

Returns

integer number (regular int)

int LAMMPS_NS::utils::**inumeric**(const char *file, int line, const char *str, bool do_abort, *LAMMPS* *lmp)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Parameters

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – string to be converted to number
- **do_abort** – determines whether to call Error::one() or Error::all()
- **lmp** – pointer to top-level *LAMMPS* class instance

Returns

double precision floating point number

bigint LAMMPS_NS::utils::**bnumeric**(const char *file, int line, const std::string &str, bool do_abort, *LAMMPS* *lmp)

Convert a string to an integer number while checking if it is a valid integer number (bigint)

Parameters

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – string to be converted to number
- **do_abort** – determines whether to call Error::one() or Error::all()
- **lmp** – pointer to top-level *LAMMPS* class instance

Returns

integer number (bigint)

bigint LAMMPS_NS::utils::**bnumeric**(const char *file, int line, const char *str, bool do_abort, *LAMMPS* *lmp)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Parameters

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – string to be converted to number

- **do_abort** – determines whether to call Error::one() or Error::all()
- **lmp** – pointer to top-level *LAMMPS* class instance

Returns
double precision floating point number

tagint LAMMPS_NS::utils::**tnumeric**(const char *file, int line, const std::string &str, bool do_abort, *LAMMPS* *lmp)

Convert a string to an integer number while checking if it is a valid integer number (tagint)

Parameters

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – string to be converted to number
- **do_abort** – determines whether to call Error::one() or Error::all()
- **lmp** – pointer to top-level *LAMMPS* class instance

Returns
integer number (tagint)

tagint LAMMPS_NS::utils::**tnumeric**(const char *file, int line, const char *str, bool do_abort, *LAMMPS* *lmp)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Parameters

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – string to be converted to number
- **do_abort** – determines whether to call Error::one() or Error::all()
- **lmp** – pointer to top-level *LAMMPS* class instance

Returns
double precision floating point number

int LAMMPS_NS::utils::**logical**(const char *file, int line, const std::string &str, bool do_abort, *LAMMPS* *lmp)

Convert a string to a boolean while checking whether it is a valid boolean term. Valid terms are 'yes', 'no', 'true', 'false', 'on', 'off', and '1', '0'. Only lower case is accepted.

Parameters

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – string to be converted to logical
- **do_abort** – determines whether to call Error::one() or Error::all()
- **lmp** – pointer to top-level *LAMMPS* class instance

Returns
1 if string resolves to "true", otherwise 0

int LAMMPS_NS::utils::**logical**(const char *file, int line, const char *str, bool do_abort, *LAMMPS* *lmp)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Parameters

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – string to be converted to logical
- **do_abort** – determines whether to call Error::one() or Error::all()
- **lmp** – pointer to top-level *LAMMPS* class instance

Returns

1 if string resolves to "true", otherwise 0

4.15.3 String processing

The following are functions to help with processing strings and parsing files or arguments.

---

char *LAMMPS_NS::utils::**strdup**(const std::string &text)

Make C-style copy of string in new storage

This allocates a storage buffer and copies the C-style or C++ style string into it. The buffer is allocated with "new" and thus needs to be deallocated with "delete[]".

Parameters

text – string that should be copied

Returns

new buffer with copy of string

std::string LAMMPS_NS::utils::**lowercase**(const std::string &line)

Convert string to lowercase

Parameters

line – string that should be converted

Returns

new string with all lowercase characters

std::string LAMMPS_NS::utils::**uppercase**(const std::string &line)

Convert string to uppercase

Parameters

line – string that should be converted

Returns

new string with all uppercase characters

std::string LAMMPS_NS::utils::**trim**(const std::string &line)

Trim leading and trailing whitespace. Like TRIM() in Fortran.

Parameters

line – string that should be trimmed

Returns
new string without whitespace (string)

std::string LAMMPS_NS::utils::**trim_comment**(const std::string &line)

Return string with anything from the first '#' character onward removed

Parameters
line – string that should be trimmed

Returns
new string without comment (string)

std::string LAMMPS_NS::utils::**strcompress**(const std::string &text)

Compress whitespace in a string

Added in version 4Feb2025.

This function compresses whitespace in a string to just a single blank.

Parameters
text – the text to be compressed

Returns
string with whitespace compressed to single blanks

std::string LAMMPS_NS::utils::**strip_style_suffix**(const std::string &style, *LAMMPS* *lmp)

Remove style suffix from string if suffix flag is active

This will try to undo the effect from using the *suffix command* or the *-suffix/-sf* command-line flag and return correspondingly modified string.

Parameters

- **style** – string of style name
- **lmp** – pointer to the *LAMMPS* class (has suffix_flag and suffix strings)

Returns
processed string

std::string LAMMPS_NS::utils::**star_subst**(const std::string &name, bigint step, int pad)

Replace first '*' character in a string with a number, optionally zero-padded

If there is no '' *character in the string, return the original string. If the number requires more characters than the value of the *pad* argument, do not add zeros; otherwise add as many zeroes as needed to the left to make the the number representation *pad* characters wide.

Parameters

- **name** – string with file containing a '*' (or not)
- **step** – step number to replace the (first) '*'
- **pad** – zero-padding (may be zero)

Returns
processed string

inline bool LAMMPS_NS::utils::**has_utf8**(const std::string &line)

Check if a string will likely have UTF-8 encoded characters

UTF-8 uses the 7-bit standard ASCII table for the first 127 characters and all other characters are encoded as multiple bytes. For the multi-byte characters the first byte has either the highest two, three, or four bits set followed by a zero bit and followed by one, two, or three more bytes, respectively, where the highest bit is set and the second highest bit set to 0. The remaining bits combined are the character code, which is thus limited to 21-bits.

For the sake of efficiency this test only checks if a character in the string has the highest bit set and thus is very likely an UTF-8 character. It will not be able to tell this this is a valid UTF-8 character or whether it is a 2-byte, 3-byte, or 4-byte character.

See also

utils::utf8_subst()

Parameters

line – string that should be checked

Returns

true if string contains UTF-8 encoded characters (bool)

std::string LAMMPS_NS::utils::**utf8_subst**(const std::string &line)

Replace known UTF-8 characters with ASCII equivalents

See also

utils::has_utf8()

Parameters

line – string that should be converted

Returns

new string with ascii replacements (string)

size_t LAMMPS_NS::utils::**count_words**(const char *text)

Count words in C-string, ignore any whitespace matching " \t\r\n\f"

Parameters

text – string that should be searched

Returns

number of words found

size_t LAMMPS_NS::utils::**count_words**(const std::string &text)

Count words in string, ignore any whitespace matching " \t\r\n\f"

Parameters

text – string that should be searched

Returns

number of words found

size_t LAMMPS_NS::utils::**count_words**(const std::string &text, const std::string &separators)

Count words in string with custom choice of separating characters

Parameters

- **text** – string that should be searched
- **separators** – string containing characters that will be treated as whitespace

Returns
number of words found

size_t LAMMPS_NS::utils::**trim_and_count_words**(const std::string &text, const std::string &separators = " \t\r\n\f")

Count words in a single line, trim anything from '#' onward

Parameters

- **text** – string that should be trimmed and searched
- **separators** – string containing characters that will be treated as whitespace

Returns
number of words found

template<typename **T**>
std::string LAMMPS_NS::utils::**join**(const std::vector<*T*> &values, const std::string &sep)

Take list of values and join them with a given separator text.

This is the inverse operation of what the Tokenizer classes do. This is a generalization of the join_words() function and similar to fmt::join() but only supports the vector STL container, and to use the begin/end iterator version you have to use: `utils::join(std::vector(x.begin(), x.end()), sep);`. This approach can also be used to support other STL containers.

Parameters

- **values** – STL vector with values
- **sep** – separator string (may be empty)

Returns
string with the concatenated values and separators

std::string LAMMPS_NS::utils::**join_words**(const std::vector<std::string> &words, const std::string &sep)

Take list of words and join them with a given separator text.

This is the inverse operation of what the split_words() function and Tokenizer classes do.

Parameters

- **words** – STL vector with strings
- **sep** – separator string (may be empty)

Returns
string with the concatenated words and separators

std::vector<std::string> LAMMPS_NS::utils::**split_words**(const std::string &text)

Take text and split into non-whitespace words.

This can handle strings with single and double quotes, escaped quotes, and escaped codes within quotes, but due to using an STL container and STL strings is rather slow because of making copies. Designed for parsing command-lines and similar text and not for time critical processing. Use a tokenizer class if performance matters.

See also
Tokenizer, *ValueTokenizer*

Parameters
text – string that should be split

Returns
STL vector with the words

std::vector<std::string> LAMMPS_NS::utils::**split_lines**(const std::string &text)

Take multi-line text and split into lines

Parameters
text – string that should be split

Returns
STL vector with the lines

bool LAMMPS_NS::utils::**strsame**(const std::string &text1, const std::string &text2)

Compare two string while ignoring whitespace

Added in version 4Feb2025.

This function compares two strings while skipping over any kind of whitespace (blank, tab, newline, carriage return, etc.).

Parameters

- **text1** – the first text to be compared
- **text2** – the second text to be compared

Returns
true if the non-whitespace part of the two strings matches, false if not

bool LAMMPS_NS::utils::**strmatch**(const std::string &text, const std::string &pattern)

Match text against a simplified regex pattern

This function provides flexible and specific matching of a string against a pattern using a simplified regular expression. It is supposed to be a safe, more specific and simple to use API to find pattern matches that is compatible with both, C-style strings and C++ strings. The purpose is to replace uses of either strncmp() or strstr() in the code which are more complex to use and may have incorrect matches. sub-strings safely. With strncmp() for finding prefixes, the number of characters to match must be counted, which can lead to errors, while using "^pattern" will do the same by just adding the '^' prefix. Matching for suffixes using strstr() is not as specific as 'pattern$', and complex matches, e.g. "^rigid.*\/small.*", to match all small body optimized rigid fixes require only one test.

This function uses a mini regex-module adapted and customized from https://github.com/kokke/tiny-regex-c which is in the public domain. The regular expressions support the following standard and custom regex elements:

```
'.'        Dot, matches any character
'^'        Start anchor, matches beginning of string
'$'        End anchor, matches end of string
'*'        Asterisk, match zero or more (greedy)
```

```
'+'        Plus, match one or more (greedy)
'?'        Question, match zero or one (non-greedy)
'[abc]'    Character class, match if one of {'a', 'b', 'c'}
'[a-zA-Z]' Character ranges, the character set of the ranges { a-z | A-Z }
'\s'       Whitespace, \t \f \r \n \v and spaces
'\S'       Non-whitespace
'\w'       Alphanumeric, [a-zA-Z_0-9]
'\W'       Non-alphanumeric
'\d'       Digits, [0-9]
'\D'       Non-digits
'\i'       Integer chars, [0-9], '+' and '-'
'\I'       Non-integers
'\f'       Floating point number chars, [0-9], '.', 'e', 'E', '+' and '-'
'\F'       Non-floats
```

They do **not** support:

```
'[^abc]'   Inverted class
'a|b'      Branches
'(abc)+'   Groups
```

Please note that regular expressions are different from globbing.

The use of std::string arguments allows for simple concatenation even with char * type variables. Example: utils::strmatch(text, std::string("^") + charptr)

Parameters

- **text** – the text to be matched against the pattern
- **pattern** – the search pattern, which may contain regexp markers

Returns
true if the pattern matches, false if not

std::string LAMMPS_NS::utils::**strfind**(const std::string &text, const std::string &pattern)

Find sub-string that matches a simplified regex pattern

This function is a companion function to utils::strmatch(). Arguments and logic is the same, but instead of a boolean, it returns the sub-string that matches the regex pattern. There can be only one match. This can be used as a more flexible alternative to strstr().

Parameters

- **text** – the text to be matched against the pattern
- **pattern** – the search pattern, which may contain regexp markers

Returns
the string that matches the pattern or an empty one

bool LAMMPS_NS::utils::**is_integer**(const std::string &str)

Check if string can be converted to valid integer

Parameters
str – string that should be checked

Returns
true, if string contains valid a integer, false otherwise

bool LAMMPS_NS::utils::**is_double**(const std::string &str)

Check if string can be converted to valid floating-point number

Parameters
str – string that should be checked

Returns
true, if string contains valid number, false otherwise

bool LAMMPS_NS::utils::**is_id**(const std::string &str)

Check if string is a valid ID ID strings may contain only letters, numbers, and underscores.

Parameters
str – string that should be checked

Returns
true, if string contains valid id, false otherwise

int LAMMPS_NS::utils::**is_type**(const std::string &str)

Check if string is a valid type label, or numeric type, or numeric type range. Numeric type or type range may only contain digits or the '*' character. Type label strings may not contain a digit, or a '*', or a '#' character as the first character to distinguish them from comments and numeric types or type ranges. They also may not contain any whitespace. If the string is a valid numeric type or type range the function returns 0, if it is a valid type label the function returns 1, otherwise it returns -1.

Parameters
str – string that should be checked

Returns
0, 1, or -1, depending on whether the string is valid numeric type, valid type label or neither, respectively

---

4.15.4 Potential file functions

std::string LAMMPS_NS::utils::**get_potential_file_path**(const std::string &path)

Determine full path of potential file. If file is not found in current directory, search directories listed in LAMMPS_POTENTIALS environment variable

Parameters
path – file path

Returns
full path to potential file

std::string LAMMPS_NS::utils::**get_potential_date**(const std::string &path, const std::string &potential_name)

Read potential file and return DATE field if it is present

Parameters

- **path** – file path
- **potential_name** – name of potential that is being read

Returns
DATE field if present

std::string LAMMPS_NS::utils::**get_potential_units**(const std::string &path, const std::string &potential_name)

Read potential file and return UNITS field if it is present

Parameters

- **path** – file path
- **potential_name** – name of potential that is being read

Returns
UNITS field if present

int LAMMPS_NS::utils::**get_supported_conversions**(const int property)

Return bitmask of available conversion factors for a given property

Parameters
property – property to be converted

Returns
bitmask indicating available conversions

double LAMMPS_NS::utils::**get_conversion_factor**(const int property, const int conversion)

Return unit conversion factor for given property and selected from/to units

Parameters

- **property** – property to be converted
- **conversion** – constant indicating the conversion

Returns
conversion factor

FILE *LAMMPS_NS::utils::**open_potential**(const std::string &name, *LAMMPS* *lmp, int *auto_convert)

Open a potential file as specified by *name*

If opening the file directly fails, the function will search for it in the list of folder pointed to by the environment variable LAMMPS_POTENTIALS (if it is set).

If the potential file has a UNITS tag in the first line, the tag's value is compared to the current unit style setting. The behavior of the function then depends on the value of the *auto_convert* parameter. If it is a null pointer, then the unit values must match or else the open will fail with an error. Otherwise the bitmask that *auto_convert* points to is used check for compatibility with possible automatic conversions by the calling function. If compatible, the bitmask is set to the required conversion or utils::NOCONVERT.

Parameters

- **name** – file- or pathname of the potential file
- **lmp** – pointer to top-level *LAMMPS* class instance
- **auto_convert** – pointer to unit conversion bitmask or nullptr

Returns
FILE pointer of the opened potential file or nullptr

4.15.5 Argument processing

template<typename **TYPE**>
void `LAMMPS_NS::utils::`**bounds**(const char *file, int line, const std::string &str, bigint nmin, bigint nmax, *TYPE* &nlo, *TYPE* &nhi, Error *error, int failed = -2)

Compute index bounds derived from a string with a possible wildcard

This functions processes the string in *str* and set the values of *nlo* and *nhi* according to the following five cases:

- a single number, i: nlo = i; nhi = i;
- a single asterisk, *: nlo = nmin; nhi = nmax;
- a single number followed by an asterisk, i*: nlo = i; nhi = nmax;
- a single asterisk followed by a number, *i: nlo = nmin; nhi = i;
- two numbers with an asterisk in between. i*j: nlo = i; nhi = j;

Template Parameters
TYPE – the type of the index that is subject to the wildcard expansion

Parameters

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – string to be processed
- **nmin** – smallest possible lower bound
- **nmax** – largest allowed upper bound
- **nlo** – **[out]** lower bound
- **nhi** – **[out]** upper bound
- **error** – pointer to Error class for out-of-bounds messages
- **failed** – argument index with failed expansion (optional)

template<typename **TYPE**>
void `LAMMPS_NS::utils::`**bounds_typelabel**(const char *file, int line, const std::string &str, bigint nmin, bigint nmax, *TYPE* &nlo, *TYPE* &nhi, *LAMMPS* *lmp, int mode)

Same as utils::bounds(), but string may be a typelabel

Added in version 27June2024.

This functions adds the following case to *`utils::bounds()`*:

- a single type label, typestr: nlo = nhi = label2type(typestr)

Template Parameters
TYPE – the type of the index that is subject to the boundary expansion

Parameters

- **file** – name of source file for error message
- **line** – line number in source file for error message

- **str** – string to be processed
- **nmin** – smallest possible lower bound
- **nmax** – largest allowed upper bound
- **nlo** – **[out]** lower bound
- **nhi** – **[out]** upper bound
- **lmp** – pointer to top-level *LAMMPS* class instance
- **mode** – select labelmap using constants from *Atom* class

int LAMMPS_NS::utils::**expand_args**(const char *file, int line, int narg, char **arg, int mode, char **&earg, *LAMMPS* *lmp, int **argmap = nullptr)

Expand list of arguments when containing fix/compute wildcards

This function searches the list of arguments in *arg* for strings of the kind c_ID[*], f_ID[*], v_ID[*], i2_ID[*], d2_ID[*], or c_ID:gname:dname[*] referring to computes, fixes, vector style variables, custom per-atom arrays, or grids, respectively. Any such strings are replaced by one or more strings with the '*' character replaced by the corresponding possible numbers as determined from the fix, compute, variable, property, or grid instance. Unrecognized strings are just copied. If the *mode* parameter is set to 0, expand global vectors, but not global arrays; if it is set to 1, expand global arrays (by column) but not global vectors.

If any expansion happens, the earg list and all its strings are new allocations and must be freed explicitly by the caller. Otherwise arg and earg will point to the same address and no explicit de-allocation is needed by the caller.

The *argmap* pointer to an int pointer may be used to accept an array of integers mapping the arguments after the expansion to their original index. If this pointer is NULL (the default) than this map is not created. Otherwise, it must be deallocated by the calling code.

Parameters

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **narg** – number of arguments in current list
- **arg** – argument list, possibly containing wildcards
- **mode** – select between global vectors(=0) and arrays (=1)
- **earg** – new argument list with wildcards expanded
- **lmp** – pointer to top-level *LAMMPS* class instance
- **argmap** – pointer to integer pointer for mapping expanded indices to input (optional)

Returns

number of arguments in expanded list

std::vector<std::string> LAMMPS_NS::utils::**parse_grid_id**(const char *file, int line, const std::string &name, Error *error)

Parse grid reference into 3 sub-strings

Format of grid ID reference = id:gname:dname. Return vector with the 3 sub-strings.

Parameters

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **name** – complete grid ID

- **error** – pointer to Error class

Returns
std::vector<std::string> containing the 3 sub-strings

char *LAMMPS_NS::utils::**expand_type**(const char *file, int line, const std::string &str, int mode, *LAMMPS* *lmp)

Expand type label string into its equivalent numeric type

This function checks if a given string may be a type label and then searches the labelmap type indicated by the *mode* argument for the corresponding numeric type. If this is found, a copy of the numeric type string is made and returned. Otherwise a null pointer is returned. If a string is returned, the calling code must free it with delete[].

Parameters

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – type string to be expanded
- **mode** – select labelmap using constants from *Atom* class
- **lmp** – pointer to top-level *LAMMPS* class instance

Returns
pointer to expanded string or null pointer

4.15.6 Convenience functions

template<typename ...**Args**>
void LAMMPS_NS::utils::**logmesg**(*LAMMPS* *lmp, const std::string &format, *Args*&&... args)

Send formatted message to screen and logfile, if available

This function simplifies the repetitive task of outputting some message to both the screen and/or the log file. The template wrapper with {fmt} formatting and argument processing allows this function to work similar to :cpp:func:`utils::print() <LAMMPS_NS::utils::print>`.

Parameters

- **lmp** – pointer to *LAMMPS* class instance
- **format** – format string of message to be printed
- **args** – arguments to format string

void LAMMPS_NS::utils::**logmesg**(*LAMMPS* *lmp, const std::string &mesg)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Parameters

- **lmp** – pointer to *LAMMPS* class instance
- **mesg** – string with message to be printed

template<typename ...**Args**>

void LAMMPS_NS::utils::**print**(FILE *fp, const std::string &format, *Args*&&... args)

Write formatted message to file

Added in version 4Feb2025.

This function implements a version of (f)printf() that uses {fmt} formatting

Parameters

- **fp** – stdio FILE pointer
- **format** – format string of message to be printed
- **args** – arguments to format string

void LAMMPS_NS::utils::**print**(FILE *fp, const std::string &mesg)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Print string message without format

Parameters

- **fp** – stdio FILE pointer
- **mesg** – string with message to be printed

template<typename ...**Args**>
std::string LAMMPS_NS::utils::**sprintf**(const std::string &format, *Args*&&... args)

Format data into a string with printf() style formatting and return it

Added in version 2Sep2026.

This function formats its arguments according to a printf() style format string and returns the result as a `std::string`, similar to the (non-standard) `asprintf()` C library function. It is a convenient replacement for formatting into a fixed size buffer with `snprintf()` without the risk of truncation. The actual conversion is done by the `vsnprintf()` C library function, first into a fixed size internal buffer and - should that buffer be too small - a second time into a temporary buffer of exactly the required size. Thus the accepted format specifiers and modifiers and the resulting output are those of the C library. In case of an output error an empty string is returned.

Unlike its C library counterparts, this function also accepts `std::string` instances as arguments for `%s` conversions in addition to C-style strings, and arguments with class types that cannot be passed through a C-style variable argument list are rejected at compile time. It cannot detect, however, when an argument does not match its format specifier, so the same care as with `snprintf()` must be taken.

Note

The main application of this function is the output of numerical data with user provided format strings that are only known at runtime, as is the case for dump styles or thermo output. For all other string formatting tasks the functions using {fmt} style format strings, i.e. `fmt::format()`, *`utils::print()`*, or *`utils::logmesg()`*, are preferred since they detect format errors at runtime.

Parameters

- **format** – printf() style format string
- **args** – arguments to format string

Returns
string with formatted output

std::string LAMMPS_NS::utils::**check_format**(const std::string &format, const std::vector<*FmtArg*> &expect)

Check a printf() style format string against the expected argument types

Added in version 2Sep2026.

LAMMPS accepts printf() style format strings from users in multiple places, for example with *dump_modify format* or *thermo_modify format*. Passing an argument that does not match its conversion to a printf() style function has undefined behavior; in practice it silently produces incorrect output. Since the format strings are only known at runtime, they must be checked before they are used.

This function compares the conversions in *format* against the list of value types in *expect* and returns an empty string if they agree. If they do not, or if the format string is malformed, the returned string describes the problem and is meant to be included in an error message.

A format string may have *fewer* conversions than there are values, down to none at all: printf() simply ignores the surplus values, so literal text without any conversion is valid and may be used to label or decorate the output. Having *more* conversions than values is an error, since those would consume arguments that were never passed. For the same reason the `n` conversion, variable field widths or precisions given as `*`, length modifiers on `s` and `p` conversions, unknown conversion characters, and incomplete conversions at the end of the string are rejected. A `%%` sequence is a literal percent sign and consumes no value.

```
auto errmsg = utils::check_format(arg[2], {utils::FmtArg::FLOAT});
if (!errmsg.empty())
  error->all(FLERR, 2, "Invalid dump_modify format float argument: {}", errmsg);
```

Parameters

- **format** – printf() style format string
- **expect** – list of value types the format string must consume

Returns
empty string if the format string is valid, otherwise a description of the problem

std::string LAMMPS_NS::utils::**check_format**(const std::string &format, *FmtArg* expect)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Parameters

- **format** – printf() style format string
- **expect** – single value type the format string must consume

std::string LAMMPS_NS::utils::**adjust_format**(const std::string &format, const std::vector<*FmtArg*> &expect)

Adjust the length modifiers of a format string to the expected arguments

Added in version 2Sep2026.

The C library derives the size of the value consumed by an integer conversion from its length modifier, so `%d` and `%ld` must be used with an `int` and a `long` argument, respectively. Requiring users to get this right would make format strings depend on how LAMMPS was compiled, since types like `bigint` and `tagint` change size with the *size settings*. Worse, the correct modifier for a 64-bit integer is platform dependent: `int64_t` is `long int` on

LP64 platforms like Linux and macOS, but `long long int` on LLP64 platforms like Windows. The modifier applied here is therefore taken from `BIGINT_FORMAT`, which is built from the `PRId64` macro of `<cinttypes>` and thus spelled correctly on every platform.

This function therefore replaces the length modifier of every conversion in *format* with the one matching the corresponding entry of *expect*, so that a user may write `%d` regardless of the integer size in use. Any flags, field width, precision, and surrounding text are preserved. The format string should be validated with *utils::check_format()* first; a format string that does not match *expect* is returned unchanged.

Parameters

- **format** – printf() style format string
- **expect** – list of value types the format string is used with

Returns

format string with length modifiers adjusted

std::string LAMMPS_NS::utils::**adjust_format**(const std::string &format, *FmtArg* expect)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Parameters

- **format** – printf() style format string
- **expect** – single value type the format string is used with

enum class LAMMPS_NS::utils::**FmtArg**

Type of value consumed by a printf() style conversion

Added in version 2Sep2026.

Conversions are grouped by the kind of value they consume: the d, i, o, u, x, X, and c conversions consume integers, the e, E, f, F, g, G, a, and A conversions consume floating-point numbers, the s conversion consumes a string, and the p conversion consumes a pointer. For checking a format string with *utils::check_format()* the two integer types are equivalent, since a mismatch in the *width* of an integer argument is corrected by *utils::adjust_format()*.

Values:

enumerator **NONE**

no value, i.e. an invalid or literal conversion

enumerator **INTEGER**

value of type int

enumerator **BIGINT**

value of type bigint, i.e. a 64-bit integer

enumerator **FLOAT**

value of type double

enumerator **STRING**

string value, i.e. a char pointer

enumerator **POINTER**

pointer value

std::string LAMMPS_NS::utils::**errorurl**(int errorcode)

Return text redirecting the user to a specific paragraph in the manual

The *LAMMPS* manual contains detailed explanations for errors and warnings where a simple error message may not be sufficient. These can be reached through URLs with a numeric code > 0. This function creates the corresponding text to be included into the error message that redirects the user to that URL. Using an error code of 0 returns a message pointing to a URL discussing error messages in general.

Parameters
errorcode – non-negative number pointing to a paragraph in the manual

void LAMMPS_NS::utils::**missing_cmd_args**(const std::string &file, int line, const std::string &cmd, Error *error)

Print error message about missing arguments for command

This function simplifies the repetitive reporting missing arguments to a command.

Parameters

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **cmd** – name of the failing command
- **error** – pointer to Error class instance (for abort) or nullptr

std::string LAMMPS_NS::utils::**point_to_error**(*Input* *input, int failed)

Create string with last command and optionally pointing to arg with error

Added in version 4Feb2025.

This function is a helper function for error messages. It creates extra output in error messages. It will produce either two or three lines: the original last input line *before* variable substitutions, the corresponding pre-processed command (only when different) and one or more '^' characters pointing to the faulty argument as indicated by the *failed* argument. Any whitespace in the lines with the command output are compressed to a single blank by calling *strcompress()*

Parameters

- **input** – pointer to the *Input* class instance (for access to last command args)
- **failed** – index of the faulty argument (-1 to point to the command itself)

Returns
string with two or three lines to follow error messages

void LAMMPS_NS::utils::**flush_buffers**(*LAMMPS* *lmp)

Flush output buffers

This function calls fflush() on screen and logfile FILE pointers if available and thus tells the operating system to output all currently buffered data. This is local operation and independent from buffering by a file system or an MPI library.

std::string LAMMPS_NS::utils::**getsyserror**()

Return a string representing the current system error status

This is a wrapper around calling strerror(errno).

Returns
error string

std::string LAMMPS_NS::utils::**check_packages_for_style**(const std::string &style, const std::string &name, *LAMMPS* *lmp)

Report if a requested style is in a package or may have a typo

Parameters

- **style** – type of style that is to be checked for
- **name** – name of style that was not found
- **lmp** – pointer to top-level *LAMMPS* class instance

Returns
string usable for error messages

double LAMMPS_NS::utils::**timespec2seconds**(const std::string &timespec)

Convert a time string to seconds

The strings "off" and "unlimited" result in -1

Parameters
timespec – a string in the following format: ([[HH:]MM:]SS)

Returns
total in seconds

int LAMMPS_NS::utils::**date2num**(const std::string &date)

Convert a *LAMMPS* version date to a number

This will generate a number YYYYMMDD from a date string (with or without blanks) that is suitable for numerical comparisons, i.e. later dates will generate a larger number.

The day may or may not have a leading zero, the month is identified by the first 3 letters (so there may be more) and the year may be 2 or 4 digits (the missing 2 digits will be assumed as 20. That is 04 corresponds to 2004).

No check is made whether the date is valid.

Parameters
date – string in the format (Day Month Year)

Returns
date code

std::string LAMMPS_NS::utils::**current_date**()

Return current date as string

This will generate a string containing the current date in YYYY-MM-DD format.

Returns
string with current date

4.15.7 Customized standard functions

int LAMMPS_NS::utils::**binary_search**(const double needle, const int n, const double *haystack)

Binary search in a vector of ascending doubles of length N

If the value is smaller than the smallest value in the vector, 0 is returned. If the value is larger or equal than the largest value in the vector, N-1 is returned. Otherwise the index that satisfies the condition

haystack[index] <= value < haystack[index+1]

is returned, i.e. a value from 1 to N-2. Note that if there are tied values in the haystack, always the larger index is returned as only that satisfied the condition.

Parameters

- **needle** – search value for which are are looking for the closest index
- **n** – size of the haystack array
- **haystack** – array with data in ascending order.

Returns

index of value in the haystack array smaller or equal to needle

void LAMMPS_NS::utils::**merge_sort**(int *index, int num, void *ptr, int (*comp)(int, int, void*))

Custom merge sort implementation

This function provides a custom upward hybrid merge sort implementation with support to pass an opaque pointer to the comparison function, e.g. for access to class members. This avoids having to use global variables. For improved performance, it uses an in-place insertion sort on initial chunks of up to 64 elements and switches to merge sort from then on.

Parameters

- **index** – Array with indices to be sorted
- **num** – Length of the index array
- **ptr** – Pointer to opaque object passed to comparison function
- **comp** – Pointer to comparison function

4.16 Special Math functions

The MathSpecial namespace implements a selection of custom and optimized mathematical functions for a variety of applications.

double LAMMPS_NS::MathSpecial::**factorial**(const int n)

Fast tabulated factorial function

This function looks up pre-computed factorial values for arguments of n = 0 to a maximum of 167, which is the maximal value representable by a double precision floating point number. For other values of n a NaN value is returned.

Parameters

n – argument (valid: 0 <= n <= 167)

Returns

value of n! as double precision number or NaN

double LAMMPS_NS::MathSpecial::**exp2_x86**(double x)

Fast implementation of 2^x without argument checks for little endian CPUs

This function implements an optimized version of pow(2.0, x) that does not check for valid arguments and thus may only be used where arguments are well behaved. The implementation makes assumptions about the layout of double precision floating point numbers in memory and thus will only work on little endian CPUs. If little endian cannot be safely detected, the result of calling pow(2.0, x) will be returned. This function also is the basis for the fast exponential fm_exp(x).

Parameters
x – argument

Returns
value of 2^x as double precision number

double LAMMPS_NS::MathSpecial::**fm_exp**(double x)

Fast implementation of exp(x) for little endian CPUs

This function implements an optimized version of exp(x) for little endian CPUs. It calls the exp2_x86(x) function with a suitable prefactor to x to return exp(x). The implementation makes assumptions about the layout of double precision floating point numbers in memory and thus will only work on little endian CPUs. If little endian cannot be safely detected, the result of calling the exp(x) implementation in the standard math library will be returned.

Parameters
x – argument

Returns
value of e^x as double precision number

static inline double LAMMPS_NS::MathSpecial::**my_erfcx**(const double x)

Fast scaled error function complement exp(x*x)*erfc(x) for coul/long styles

This is a portable fast implementation of exp(x*x)*erfc(x) that can be used in coul/long pair styles as a replacement for the polynomial expansion that is/was widely used. Unlike the polynomial expansion, that is only accurate at the level of single precision floating point it provides full double precision accuracy, but at comparable speed (unlike the erfc() implementation shipped with GNU standard math library).

Parameters
x – argument

Returns
value of e^(x*x)*erfc(x)

static inline double LAMMPS_NS::MathSpecial::**expmsq**(double x)

Fast implementation of exp(-x*x) for little endian CPUs for coul/long styles

This function implements an optimized version of exp(-x*x) based on exp2_x86() for use with little endian CPUs. If little endian cannot be safely detected, the result of calling the exp(-x*x) implementation in the standard math library will be returned.

Parameters
x – argument

Returns
value of e^(-x*x) as double precision number

static inline double LAMMPS_NS::MathSpecial::**square**(const double &x)

Fast inline version of pow(x, 2.0)

Parameters
x – argument

Returns
x*x

static inline double LAMMPS_NS::MathSpecial::**cube**(const double &x)

Fast inline version of pow(x, 3.0)

Parameters
x – argument

Returns
x*x

static inline double LAMMPS_NS::MathSpecial::**powsign**(const int n)

static inline double LAMMPS_NS::MathSpecial::**powint**(const double &x, const int n)

static inline double LAMMPS_NS::MathSpecial::**powsinxx**(const double &x, int n)

4.17 Tokenizer classes

The purpose of the tokenizer classes is to simplify the recurring task of breaking lines of text down into words and/or numbers. Traditionally, LAMMPS code would be using the `strtok()` function from the C library for that purpose, but that function has two significant disadvantages: 1) it cannot be used concurrently from different LAMMPS instances since it stores its status in a global variable and 2) it modifies the string that it is processing. These classes were implemented to avoid both of these issues and also to reduce the amount of code that needs to be written.

The basic procedure is to create an instance of the tokenizer class with the string to be processed as an argument and then do a loop until all available tokens are read. The constructor has a default set of separator characters, but that can be overridden. The default separators are all "whitespace" characters, i.e. the space character, the tabulator character, the carriage return character, the linefeed character, and the form feed character.

Listing 1: Tokenizer class example listing entries of the PATH environment variable

```
#include "tokenizer.h"
#include <cstdlib>
#include <string>
#include <iostream>

using namespace LAMMPS_NS;

int main(int, char **)
{
    const char *path = getenv("PATH");

    if (path != nullptr) {
        Tokenizer p(path,":");
        while (p.has_next())
            std::cout << "Entry: " << p.next() << "\n";
    }
    return 0;
}
```

Most tokenizer operations cannot fail except for *LAMMPS_NS::Tokenizer::next()* (when used without first checking with *LAMMPS_NS::Tokenizer::has_next()*) and *LAMMPS_NS::Tokenizer::skip()*. In case of failure, the class

will throw an exception, so you may need to wrap the code using the tokenizer into a `try` / `catch` block to handle errors. The *LAMMPS_NS::ValueTokenizer* class may also throw an exception when a (type of) number is requested as next token that is not compatible with the string representing the next word.

Listing 2: ValueTokenizer class example with exception handling

```
#include "tokenizer.h"
#include <cstdlib>
#include <string>
#include <iostream>

using namespace LAMMPS_NS;

int main(int, char **)
{
    const char *text = "1 2 3 4 5 20.0 21 twentytwo 2.3";
    double num1(0),num2(0),num3(0),num4(0);

    ValueTokenizer t(text);
    // read 4 doubles after skipping over 5 numbers
    try {
        t.skip(5);
        num1 = t.next_double();
        num2 = t.next_double();
        num3 = t.next_double();
        num4 = t.next_double();
    } catch (TokenizerException &e) {
        std::cout << "Reading numbers failed: " << e.what() << "\n";
    }
    std::cout << "Values: " << num1 << " " << num2 << " " << num3 << " " << num4 << "\n";
    return 0;
}
```

This code example should produce the following output:

```
Reading numbers failed: Not a valid floating-point number: 'twentytwo'
Values: 20 21 0 0
```

---

class **Tokenizer**

Public Functions

Tokenizer(std::string str, std::string separators = TOKENIZER_DEFAULT_SEPARATORS)

Class for splitting text into words

This tokenizer will break down a string into sub-strings (i.e words) separated by the given separator characters. If the string contains certain known UTF-8 characters they will be replaced by their ASCII equivalents processing the string.

See also

ValueTokenizer, *utils::split_words()*, *utils::utf8_subst()*

Parameters

- **str** – string to be processed
- **_separators** – string with separator characters (default: " \t\r\n\f")

void **reset**()

Re-position the tokenizer state to the first word, i.e. the first non-separator character

void **skip**(int n = 1)

Skip over a given number of tokens

Parameters
n – number of tokens to skip over

bool **has_next**() const

Indicate whether more tokens are available

Returns
true if there are more tokens, false if not

bool **contains**(const std::string &str) const

Search the text to be processed for a sub-string.

This method does a generic sub-string match.

Parameters
str – string to be searched for

Returns
true if string was found, false if not

bool **matches**(const std::string &str) const

Search the text to be processed for regular expression match.

This method matches the current string against a regular expression using the *utils::strmatch()* function.

Parameters
str – regular expression to be matched against

Returns
true if string was found, false if not

std::string **next**()

Retrieve next token.

Returns
string with the next token

size_t **count**()

Count number of tokens in text.

Returns
number of counted tokens

std::vector<std::string> **as_vector**()

Retrieve the entire text converted to an STL vector of tokens.

Returns
The STL vector

class **TokenizerException** : public exception

General Tokenizer exception class

Subclassed by *InvalidFloatException*, *InvalidIntegerException*

Public Functions

TokenizerException() = delete

The default constructor is disabled

explicit **TokenizerException**(const std::string &msg, const std::string &token)

Thrown during retrieving or skipping tokens

Parameters

- **msg** – String with error message
- **token** – String of the token or word that caused the error

inline const char ***what**() const noexcept override

Retrieve message describing the thrown exception

This function provides the message that can be retrieved when the corresponding exception is caught.

Returns
String with error message

class **ValueTokenizer**

Public Functions

ValueTokenizer(const std::string &str, const std::string &separators = TOKENIZER_DEFAULT_SEPARATORS)

Class for reading text with numbers

See also
Tokenizer

See also

Tokenizer *InvalidIntegerException* *InvalidFloatException*

Parameters

- **str** – String to be processed
- **separators** – String with separator characters (default: " \t\r\n\f")

std::string **next_string**()

Retrieve next token

Returns
string with next token

tagint **next_tagint**()

Retrieve next token and convert to tagint

Returns
value of next token

bigint **next_bigint**()

Retrieve next token and convert to bigint

Returns
value of next token

int **next_int**()

Retrieve next token and convert to int

Returns
value of next token

double **next_double**()

Retrieve next token and convert to double

Returns
value of next token

bool **has_next**() const

Indicate whether more tokens are available

Returns
true if there are more tokens, false if not

bool **contains**(const std::string &value) const

Search the text to be processed for a sub-string.

This method does a generic sub-string match.

Parameters
value – string with value to be searched for

Returns
true if string was found, false if not

bool **matches**(const std::string &str) const

Search the text to be processed for regular expression match.

This method matches the current string against a regular expression using the *utils::strmatch()* function.

Parameters
str – regular expression to be matched against

Returns
true if string was found, false if not

void **skip**(int ntokens = 1)

Skip over a given number of tokens

Parameters
n – number of tokens to skip over

size_t **count**()

Count number of tokens in text.

Returns
number of counted tokens

class **InvalidIntegerException** : public *TokenizerException*

Exception thrown by ValueTokenizer when trying to convert an invalid integer string

Public Functions

inline explicit **InvalidIntegerException**(const std::string &token)

Thrown during converting string to integer number

Parameters
token – String of the token/word that caused the error

class **InvalidFloatException** : public *TokenizerException*

Exception thrown by ValueTokenizer when trying to convert an floating point string

Public Functions

inline explicit **InvalidFloatException**(const std::string &token)

Thrown during converting string to floating point number

Parameters
token – String of the token/word that caused the error

4.18 Argument parsing classes

The purpose of argument parsing classes it to simplify and unify how arguments of commands in LAMMPS are parsed and to make abstractions of repetitive tasks.

The *LAMMPS_NS::ArgInfo* class provides an abstraction for parsing references to compute or fix styles, variables or custom integer or double properties handled by *fix property/atom*. These would start with a "c_", "f_", "v_", "d_", "d2_", "i_", or "i2_" followed by the ID or name of than instance and may be postfixed with one or two array indices "[<number>]" with numbers > 0.

A typical code segment would look like this:

Listing 3: Usage example for ArgInfo class

```
int nvalues = 0;
for (iarg = 0; iarg < nargnew; iarg++) {
  ArgInfo argi(arg[iarg]);

  which[nvalues] = argi.get_type();
  argindex[nvalues] = argi.get_index1();
  ids[nvalues] = argi.copy_name();

  if ((which[nvalues] == ArgInfo::UNKNOWN)
      || (which[nvalues] == ArgInfo::NONE)
      || (argi.get_dim() > 1))
```

(continues on next page)

(continued from previous page)

```
    error->all(FLERR,"Illegal compute XXX command");

  nvalues++;
}
```

class **ArgInfo**

Public Types

enum **ArgTypes**

constants for argument types

Values:

enumerator **ERROR**

enumerator **UNKNOWN**

enumerator **NONE**

enumerator **X**

enumerator **V**

enumerator **F**

enumerator **COMPUTE**

enumerator **FIX**

enumerator **VARIABLE**

enumerator **KEYWORD**

enumerator **TYPE**

enumerator **MOLECULE**

enumerator **DNAME**

enumerator **INAME**

enumerator **DENSITY_NUMBER**

enumerator **DENSITY_MASS**

enumerator **MASS**

enumerator **TEMPERATURE**

enumerator **BIN1D**

enumerator **BIN2D**

enumerator **BIN3D**

enumerator **BINSPHERE**

enumerator **BINCYLINDER**

Public Functions

ArgInfo(const std::string &arg, int allowed = *COMPUTE* | *FIX* | *VARIABLE*)

Class for processing references to fixes, computes and variables

This class provides an abstraction for the repetitive task of parsing arguments that may contain references to fixes, computes, variables, or custom per-atom properties. It will identify the name and the index value in the first and second dimension, if present.

Parameters

- **arg** – string with possible reference
- **allowed** – integer with bitmap of allowed types of references

inline int **get_type**() const

get type of reference

Return a type constant for the reference. This may be either COMPUTE, FIX, VARIABLE (if not restricted to a subset of those by the "allowed" argument of the constructor) or NONE, if it if not a recognized or allowed reference, or UNKNOWN, in case some error happened identifying or parsing the values of the indices

Returns
integer with a constant from ArgTypes enumerator

inline int **get_dim**() const

get dimension of reference

This will return either 0, 1, 2 depending on whether the reference has no, one or two "[{number}]" postfixes.

Returns
integer with the dimensionality of the reference

inline int **get_index1**() const

get index of first dimension

This will return the number in the first "[{number}]" postfix or 0 if there is no postfix.

Returns
integer with index or the postfix or 0

inline int **get_index2**() const

get index of second dimension

This will return the number in the second "[{number}]" postfix or -1 if there is no second postfix.

Returns
integer with index of the postfix or -1

inline const char ***get_name**() const

return reference to the ID or name of the reference

This string is pointing to an internal storage element and is only valid to use while the ArgInfo class instance is in scope. If you need a long-lived string make a copy with copy_name().

Returns
C-style char * string

char ***copy_name**()

make copy of the ID of the reference as C-style string

The ID is copied into a buffer allocated with "new" and thus must be later deleted with "delete []" to avoid a memory leak. Because it is a full copy in a newly allocated buffer, the lifetime of this string extends beyond the the time the ArgInfo class is in scope.

Returns
copy of string as char *

4.19 Safe pointer classes

These are custom classes to support the Resource Acquisition Is Initialization (RAII) programming idiom in LAMMPS for certain types of pointers. Currently there is:

class **SafeFilePtr**

Class to automatically close a FILE pointer when it goes out of scope

This is a drop-in replacement for declaring a `FILE *` variable and can be passed to functions or used in logical expressions the same way. This is particularly useful when a code block will throw an exception, or has to close and re-open a file and similar. It helps to simplify code and reduces the risk of memory and file descriptor leaks.

Below are some usage examples:

```
// Replace:
FILE *fp = nullptr;
// With:
SafeFilePtr fp;

// You can use "fp" as usual:
```

(continues on next page)

(continued from previous page)

```
fp = fopen("some.file","r");
// a second assignment will automatically close the opened file
fp = fopen("other.file", "r");
// and assigning nullptr will just close it
fp = nullptr;

// There also is a custom constructor available as a shortcut
SafeFilePtr fp(fopen("some.file", "r"));

// You can indicate that a file was opened with popen() to call pclose() instead of␣
↪fclose()
SafeFilePtr fp;
if (platform::has_compress_extension(filename)) {
  fp.set_pclose();
  fp = platform::compressed_write(filename);
} else {
  fp = fopen(filename, "w");
}
if (!fp) error->one(FLERR, "Failed to open file {}: {}", filename,␣
↪utils::getsyserror());

// reading or writing works without needing to change the source code
fputs("write text to file\n", fp);
char buffer[100];
utils::sfgets(FLERR, buffer, 100, fp, filename, error);
```

Public Functions

SafeFilePtr &**operator=**(FILE *_fp)

Assign new file pointer and close old one if still open.

The value of use_pclose determines whether `pclose()` is called or `fclose()`. Assigning `nullptr` closes the file and resets use_pclose

Parameters
_fp – new file pointer, may be `nullptr`

Returns
reference to updated class instance

inline void **set_pclose**()

Flag that the file pointer needs to be closed with `pclose()` instead of `fclose()`

inline **operator FILE***() const

Custom type cast operator so that *SafeFilePtr* can be used where FILE * was used

Returns
currently stored/monitored file pointer

4.20 File reader classes

The purpose of the file reader classes is to simplify the recurring task of reading and parsing files. They can use the *ValueTokenizer* class to process the read in text. The *TextFileReader* is a more general version while *PotentialFileReader* is specialized to implement the behavior expected for looking up and reading/parsing files with potential parameters in LAMMPS. The potential file reader class requires a LAMMPS instance, requires to be run on MPI rank 0 only, will use the *utils::get_potential_file_path* function to look up and open the file, and will call the `LAMMPS_NS::Error` class in case of failures to read or to convert numbers, so that LAMMPS will be aborted. A third class, *STLReader*, is specialized on reading triangle mesh data from files in STL format.

Listing 4: Use of PotentialFileReader class in pair style coul/streitz

```
PotentialFileReader reader(lmp, file, "coul/streitz");
char * line;

while((line = reader.next_line(NPARAMS_PER_LINE))) {
  try {
    ValueTokenizer values(line);
    std::string iname = values.next_string();

    int ielement;
    for (ielement = 0; ielement < nelements; ielement++)
      if (iname == elements[ielement]) break;

    if (nparams == maxparam) {
      maxparam += DELTA;
      params = (Param *) memory->srealloc(params,maxparam*sizeof(Param),
                                          "pair:params");
    }

    params[nparams].ielement = ielement;
    params[nparams].chi = values.next_double();
    params[nparams].eta = values.next_double();
    params[nparams].gamma = values.next_double();
    params[nparams].zeta = values.next_double();
    params[nparams].zcore = values.next_double();

  } catch (TokenizerException & e) {
    error->one(FLERR, e.what());
  }
  nparams++;
}
```

A file that would be parsed by the reader code fragment looks like this:

```
# DATE: 2015-02-19 UNITS: metal CONTRIBUTOR: Ray Shan CITATION: Streitz and Mintmire,␣

---

class **TextFileReader**

Public Functions

TextFileReader(const std::string &filename, const std::string &filetype)

Class for reading and parsing text files

The value of the class member variable *ignore_comments* controls whether any text following the pound sign (#) should be ignored (true) or not (false). Default: true, i.e. ignore.

See also
TextFileReader

Parameters

- **filename** – Name of file to be read
- **filetype** – Description of file type for error messages

TextFileReader(FILE *fp, std::string filetype)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This function is useful in combination with *utils::open_potential()*.

> **Note**
>
> The FILE pointer is not closed in the destructor, but will be advanced when reading from it.

Parameters

- **fp** – File descriptor of the already opened file
- **filetype** – Description of file type for error messages

virtual **~TextFileReader**()

Closes the file

void **set_bufsize**(int)

adjust line buffer size

Parameters
newsize – New size of the internal line buffer

void **rewind**()

Reset file to the beginning

void **skip_line**()

Read the next line and ignore it

char ***next_line**(int nparams = 0)

Read the next line(s) until *nparams* words have been read.

This reads a line and counts the words in it, if the number is less than the requested number, it will read the next line, as well. Output will be a string with all read lines combined. The purpose is to somewhat replicate the reading behavior of formatted files in Fortran.

If the *ignore_comments* class member has the value *true*, then any text read in is truncated at the first '#' character.

Parameters
nparams – Number of words that must be read. Default: 0

Returns
String with the concatenated text

void **next_dvector**(double *list, int n)

Read lines until *n* doubles have been read and stored in array *list*

This reads lines from the file using the next_line() function, and splits them into floating-point numbers using the ValueTokenizer class and stores the number in the provided list.

Parameters

- **list** – Pointer to array with suitable storage for *n* doubles
- **n** – Number of doubles to be read

ValueTokenizer **next_values**(int nparams, const std::string &separators = TOKENIZER_DEFAULT_SEPARATORS)

Read text until *nparams* words are read and passed to a tokenizer object for custom parsing.

This reads lines from the file using the next_line() function, and splits them into floating-point numbers using the ValueTokenizer class and stores the number in the provided list.

Parameters

- **nparams** – Number of words to be read
- **separators** – String with list of separators.

Returns
ValueTokenizer object for read in text

Public Members

bool **ignore_comments**

Controls whether comments are ignored.

class **PotentialFileReader** : protected *Pointers*

Public Functions

PotentialFileReader(class *LAMMPS* *lmp, const std::string &filename, const std::string &potential_name, const std::string &name_suffix, const int auto_convert = 0)

Class for reading and parsing *LAMMPS* potential files

The value of the class member variable *ignore_comments* controls whether any text following the pound sign (#) should be ignored (true) or not (false). Default: true, i.e. ignore.

See also
TextFileReader

Parameters

- **lmp** – Pointer to *LAMMPS* instance
- **filename** – Name of file to be read
- **potential_name** – Name of potential style for error messages

- **name_suffix** – Suffix added to potential name in error messages
- **auto_convert** – Bitmask of supported unit conversions

~PotentialFileReader() override

Closes the file

void **set_bufsize**(int bufsize)

Set line buffer size of the internal TextFileReader class instance.

Parameters
bufsize – New size of the line buffer

void **ignore_comments**(bool value)

Set comment (= text after '#') handling preference for the file to be read

Parameters
value – Comment text is ignored if true, or not if false

void **rewind**()

Reset file to the beginning

void **skip_line**()

Read a line but ignore its content

char ***next_line**(int nparams = 0)

Read the next line(s) until *nparams* words have been read.

This reads a line and counts the words in it, if the number is less than the requested number, it will read the next line, as well. Output will be a string with all read lines combined. The purpose is to somewhat replicate the reading behavior of formatted files in Fortran.

Parameters
nparams – Number of words that must be read. Default: 0

Returns
String with the concatenated text

void **next_dvector**(double *list, int n)

Read lines until *n* doubles have been read and stored in array *list*

This reads lines from the file using the next_line() function, and splits them into floating-point numbers using the ValueTokenizer class and stores the number in the provided list.

Parameters

- **list** – Pointer to array with suitable storage for *n* doubles
- **n** – Number of doubles to be read

ValueTokenizer **next_values**(int nparams, const std::string &separators = TOKENIZER_DEFAULT_SEPARATORS)

Read text until *nparams* words are read and passed to a tokenizer object for custom parsing.

This reads lines from the file using the next_line() function, and splits them into floating-point numbers using the ValueTokenizer class and stores the number in the provided list.

Parameters

- **nparams** – Number of words to be read
- **separators** – String with list of separators.

Returns
ValueTokenizer object for read in text

double **next_double**()

Read next line and convert first word to a double

Returns
Value of first word in line as double

int **next_int**()

Read next line and convert first word to an int

Returns
Value of first word in line as int

tagint **next_tagint**()

Read next line and convert first word to a tagint

Returns
Value of first word in line as tagint

bigint **next_bigint**()

Read next line and convert first word to a bigint

Returns
Value of first word in line as bigint

std::string **next_string**()

Read next line and return first word

Returns
First word of read in line

The *STLReader* class reads triangle meshes from files in STL format, as used, for example, by the *create_atoms mesh* command or the *fix surface/global* command. Files in the plain text variant of the format are parsed with the help of the *TextFileReader* and *ValueTokenizer* classes, while files in the binary variant are read directly. Unlike the other file reader classes, the mesh data is not returned line by line, but the entire file is read and its triangles are returned in one call.

class **STLReader** : protected *Pointers*

Class for reading triangle meshes from files in STL format

A file in STL (stereolithography) format stores a triangle mesh as a flat list of triangles. Each triangle consists of an outward facing normal vector and the coordinates of its three vertices. There are two variants of the format: a plain text ("ASCII") version and a binary version. This class transparently supports both: the format is detected from the file contents and *not* from the file name.

Most functionality is in the static *STLReader::parse()* function, which is independent from any LAMMPS instance and thus can also be called from code that has no access to one. It reads and parses the entire file and returns the triangles as a vector of *STLReader::Triangle* data structures. All error conditions are reported by throwing an *STLReaderException*, so the calling code decides how errors are handled. Since the file is read in its entirety by every MPI process calling it, this is best suited for small to medium sized meshes.

Listing 5: Use of the STLReader class in the create_atoms command

```
#include "stl_reader.h"

std::vector<STLReader::Triangle> triangles;
try {
  std::string title;
  triangles = STLReader::parse(filename, &title);
  if (comm->me == 0)
    utils::logmesg(lmp, "Reading STL object {} with {} triangles from file {}\n",
                   title.empty() ? "(unnamed)" : title, triangles.size(), filename);
} catch (std::exception &e) {
  error->all(FLERR, Error::NOLASTLINE, "{}", e.what());
}

for (const auto &tri : triangles) {
  // process tri.normal[3] and tri.vert[3][3]
}
```

The *STLReader::read_file()* member function is an alternative for the case where the mesh should be read on MPI rank 0 only and then communicated to all MPI processes. It requires a class instance and thus a LAMMPS instance, aborts LAMMPS with an error message when the file cannot be read, and stores the vertices in an array that is managed by the class instance.

Public Functions

STLReader(class *LAMMPS**)

Create an STL reader class instance

A class instance is only required for the *STLReader::read_file()* member function. It owns the storage for the triangle vertices that this function returns, so the instance must be kept until the data has been copied or is no longer needed.

Parameters
lmp – Pointer to *LAMMPS* instance

~STLReader() override

Free the storage for the triangle vertices

int **read_file**(const char *filename, double **&caller_tris)

Read an STL file on MPI rank 0 and communicate the vertices to all ranks

The file is read and parsed on MPI rank 0 only and then the vertex coordinates are broadcast to all MPI processes; the facet normals are discarded. The storage for the vertices is allocated and owned by the class instance and thus freed by its destructor. Reading an empty or unreadable file aborts *LAMMPS* with an error message.

See also
STLReader::parse()

Parameters

- **filename** – Name of the STL file to be read
- **caller_tris** – Reference to a pointer that is set to the storage with 9 coordinates (3 vertices) per triangle

Returns
Number of triangles read

Public Static Functions

static std::vector<*Triangle*> **parse**(const std::string &filename, std::string *title_out = nullptr)

Read and parse an STL file and return its triangles

This function is independent from any *LAMMPS* instance and does not communicate, so it can be called from anywhere. It detects whether the file is in text or binary format from its contents: a binary STL file has a size of exactly 84 + 50*N bytes for N triangles, which is a more robust test than looking for the word "solid" at the beginning of the file, since the header of a binary file may legally start with that word, too.

Any error while opening, reading, or parsing the file is reported by throwing an *STLReaderException* with a suitable message. Files with zero triangles are *not* an error and result in an empty vector.

Parameters

- **filename** – Name of the STL file to be read
- **title_out** – Optional pointer to a string that is set to the name of the mesh stored in the file (may be an empty string)

Returns
Vector with the triangles read from the file

struct **Triangle**

Storage for a single triangle of an STL mesh

Public Members

double **normal**[3]

outward facing normal vector of the facet

double **vert**[3][3]

x-, y-, and z-coordinates of the 3 vertices

class **STLReaderException** : public exception

Exception thrown by the *STLReader* class for malformed or unreadable files

---

4.21 File writer classes

The file writer classes are the counterpart to the file reader classes: they collect the recurring work of producing a file in some established format in one place, so that the styles using it only have to supply the data.

The *VTKWriter* class writes the subset of the file formats of the VTK visualization toolkit that LAMMPS needs. It is used by the *dump vtk*, *dump grid/vtk*, and *fix saed/vtk* styles. Writing these files directly means that none of them requires the VTK library to be installed.

Both the "legacy" and the XML flavor of the format are supported, each with text or binary encoding, and binary data in the XML flavor is compressed when LAMMPS is built with the zlib library. The available datasets are a list of points, either as polydata or as an unstructured grid, a single hexahedron, a rectilinear grid, and a uniform grid. Reading VTK files is not supported and not needed.

Using the class always follows the same four steps: create a writer for the desired format, select exactly one dataset, attach any number of data arrays, and write. Anything inconsistent, such as an array whose length does not match the number of points, or a file that cannot be opened, is reported by throwing a *VTKWriterException*, so callers are expected to catch it and turn it into a LAMMPS error.

Listing 6: Use of the VTKWriter class for writing atom positions

```
std::vector<double> coords;      // 3 values per atom
std::vector<int> ids;            // 1 value per atom

for (int i = 0; i < atom->nlocal; ++i) {
  coords.push_back(atom->x[i][0]);
  coords.push_back(atom->x[i][1]);
  coords.push_back(atom->x[i][2]);
  ids.push_back(atom->tag[i]);
}

try {
  VTKWriter writer(VTKWriter::XML, false);
  writer.set_polydata(std::move(coords));
  writer.add_point_array("id", 1, std::move(ids));
  writer.write("positions.vtp");
} catch (VTKWriterException &e) {
  error->one(FLERR, e.what());
}
```

Coordinate and data vectors are taken by value, so callers that do not need their copy afterwards pass it with `std::move()`, as in the example, and no data is copied.

All floating point data, coordinates and data arrays alike, is stored in single precision by default, since that is what visualization programs work with. The constructor takes an optional precision argument, which the dump styles expose through their *dump_modify double* keyword. Because single precision only keeps about 7 significant digits, it becomes noticeable for very large coordinates. The class therefore records the largest coordinate magnitude that it wrote in single precision in *max_single_precision_value*, and *single_precision_resolution* turns that magnitude into the absolute resolution for a warning message, or 0.0 while single precision still resolves the coordinates well enough. Data arrays are not tracked, because their values only need the relative resolution that single precision always provides.

class **VTKWriter**

Write data files in the formats used by the VTK visualization toolkit

This class writes the subset of the VTK file formats that LAMMPS needs, without requiring the VTK library itself. Both the "legacy" format and the XML format are supported, each with ASCII or binary encoding. Reading VTK files is not supported.

Usage is always the same: create a writer for the desired format, select exactly one dataset type, attach any number of data arrays, and write. All inconsistencies (mismatched array lengths, missing dataset, a file that cannot be opened) are reported by throwing a `VTKWriterException`, so callers are expected to catch it and turn it into a LAMMPS error.

```
VTKWriter writer(VTKWriter::XML, false);
writer.set_polydata(coords);
writer.add_point_array("id", 1, ids);
try {
```

(continues on next page)

(continued from previous page)

```
  writer.write("dump.vtp");
} catch (VTKWriterException &e) {
  error->one(FLERR, e.what());
}
```

Public Functions

VTKWriter(Flavor flavor, bool binary, Precision precision = SINGLE)

Create a writer for one file.

All floating point data, that is point coordinates and data arrays alike, is stored in single precision by default, which is what visualization programs expect. See *max_single_precision_value()* for how to tell when that is not enough for the coordinates.

Parameters

- **flavor** – LEGACY for the simple legacy format, XML for the XML format
- **binary** – true to store the data as binary numbers instead of as text
- **precision** – precision used for all floating point data

void **set_title**(const std::string &title)

Set the title written into the header of legacy files, ignored for XML.

Parameters

title – descriptive text, truncated to the 256 characters the format allows

void **set_polydata**(std::vector<double> xyz)

Select points with one vertex cell each, written as POLYDATA / PolyData.

Parameters

xyz – coordinates, 3 values per point

void **set_unstructured_grid**(std::vector<double> xyz)

Select points with one vertex cell each, written as UNSTRUCTURED_GRID.

Parameters

xyz – coordinates, 3 values per point

void **set_hexahedron**(const double corners[8][3])

Select a single hexahedron cell, written as UNSTRUCTURED_GRID.

Parameters

corners – the 8 corners in VTK ordering, that is the bottom face counterclockwise followed by the top face counterclockwise

void **set_rectilinear_grid**(std::vector<double> xc, std::vector<double> yc, std::vector<double> zc)

Select a grid with non-uniform spacing.

Parameters

- **xc** – coordinates of the cell boundaries along x
- **yc** – coordinates of the cell boundaries along y
- **zc** – coordinates of the cell boundaries along z

void **set_image_data**(const int dim[3], const double origin[3], const double spacing[3])

Select a grid with uniform spacing, written as STRUCTURED_POINTS / ImageData.

Parameters

- **dim** – number of grid points in each dimension
- **origin** – coordinates of the first grid point
- **spacing** – distance between grid points in each dimension

void **set_active_scalars**(const std::string &name)

Mark a previously added array as the default one for coloring.

The array is written as SCALARS in legacy files and referenced by the Scalars attribute in XML files.

Parameters

name – name of an array that was added before

inline double **max_single_precision_value**() const

largest absolute value among the coordinates that are written in single precision, or 0.0 if there are none. callers use this to warn when the resolution of single precision is no longer sufficient, which happens for very large coordinates because they need absolute resolution. data arrays are not tracked: their values only need the relative resolution that single precision always provides.

Returns

largest coordinate magnitude written in single precision, 0.0 if there is none

inline int **number_of_points**() const

Number of points implied by the selected dataset.

Returns

number of points

inline int **number_of_cells**() const

Number of cells implied by the selected dataset.

Returns

number of cells

Public Static Functions

static double **single_precision_resolution**(double maxcoord, double angstrom)

Resolution of single precision storage at the given coordinate magnitude.

Callers pass the value reported by *max_single_precision_value()* and warn with the returned resolution when it is not zero. Keeping this test next to SINGLE_PRECISION_LIMIT ensures all callers warn consistently.

Parameters

- **maxcoord** – largest coordinate magnitude written in single precision
- **angstrom** – length units per Angstrom, that is force->angstrom

Returns

absolute resolution at that magnitude when it warrants a warning, 0.0 otherwise

static const char ***xml_real_type**(Precision precision)

XML type name for floating point data at the given precision.

Exposed so that the parallel summary files written by dump vtk always declare exactly the types that the piece files contain.

Parameters
precision – SINGLE or DOUBLE

Returns
"Float32" or "Float64"

static const char ***xml_byte_order**()

Byte order attribute written into XML files on this machine.

Returns
"LittleEndian" or "BigEndian"

Public Static Attributes

static constexpr double **SINGLE_PRECISION_LIMIT** = 1.0e4

Coordinates larger than this many length units keep fewer than 3 digits after the decimal point when stored in single precision, which has a relative resolution of about 1.2e-7. *single_precision_resolution()* scales this with force->angstrom so that the same physical resolution applies in every unit system.

class **VTKWriterException** : public exception

4.22 Type label support

4.22.1 Overview

The *LabelMap* class provides a two way mapping between symbolic type labels in input and output files and numeric types as they are used by LAMMPS internally. Instead of changing the numeric types in files to satisfy the requirements from LAMMPS for a given application, the symbolic types can remain and only the label map needs to be adjusted. When following the convention that the labels for bonded interactions are created by joining the constituent atom types with hyphens, this can significantly improve readability, maintainability, and re-usability of inputs and reduces the chance of errors.

The LabelMap class also provides automatic type inference for bonded interactions based on their constituent atom types. For instance, based on the atom type labels, the corresponding bond, angle, dihedral, or improper types can be inferred provided the corresponding type labels follow the convention that they are composed of the symbolic atom types connected by hyphens.

4.22.2 Integration with utils namespace

Several utility functions in the `utils` namespace work with type labels and interact with the LabelMap class:

- *utils::is_type()* - Validates whether a string is a valid type label.
- *utils::expand_type()* - Converts a type label string to its numeric equivalent using the LabelMap.
- *utils::bounds_typelabel()* - Extended version of `utils::bounds()` that accepts type labels in addition to numeric ranges. Uses `expand_type()` internally to convert labels to numeric bounds before processing.

These functions enable seamless integration of type labels throughout LAMMPS, allowing commands that accept type specifications to work with both numeric indices and symbolic labels. Below are some code examples.

Finding types from labels and vice versa

```
#include "label_map.h"
#include "atom.h"

// assuming this code is used inside a class that is derived from LAMMPS_NS::Pointers
LabelMap *lmap = atom->lmap;

// Forward lookup: Get numeric type from label
int ctype = lmap->find_type("C", Atom::ATOM);    // Returns atom type for "C"
int htype = lmap->find_type("H", Atom::ATOM);    // Returns atom type for "H"
int missing = lmap->find_type("X", Atom::ATOM);  // Returns -1 (not found)

// Reverse lookup: Get label from numeric type
const std::string &label1 = lmap->find_label(1, Atom::ATOM);  // Returns label for type 1
const std::string &label2 = lmap->find_label(2, Atom::BOND);  // Returns bond label for␣
↪type 2

// Check if all types have labels
bool complete = lmap->is_complete(Atom::ATOM);  // Returns true if all atom types labeled
```

Inferring bonded types from atom types

```
#include "label_map.h"
#include "atom.h"

LabelMap *lmap = atom->lmap;

// Assume we have: labelmap atom 1 C 2 H 3 N
// And: labelmap bond 1 C-H 2 C-C 3 C-N

// Infer bond type from numeric atom types
int bt1 = lmap->infer_bondtype(1, 2);  // Returns 1 (C-H bond)
int bt2 = lmap->infer_bondtype(1, 1);  // Returns 2 (C-C bond)
int bt3 = lmap->infer_bondtype(3, 1);  // Returns 3 (C-N bond, symmetric match)

// Infer bond type from atom type labels (handles symmetry automatically)
int bt4 = lmap->infer_bondtype({"C", "H"});  // Returns 1 (C-H)
int bt5 = lmap->infer_bondtype({"H", "C"});  // Returns 1 (symmetric match)
int bt6 = lmap->infer_bondtype({"C", "N"});  // Returns 3 (C-N)
```

Validating and expanding type labels

```
#include "utils.h"
#include "lammps.h"

using namespace LAMMPS_NS;

LAMMPS *lmp = /* ... */;

// Validate type label strings
int result1 = utils::is_type("C");     // Returns 1 (valid label)
int result2 = utils::is_type("123");   // Returns 0 (numeric type)
```

(continues on next page)

(continued from previous page)

```
int result3 = utils::is_type("*");     // Returns -1 (invalid - starts with *)
int result4 = utils::is_type("C H");   // Returns -1 (invalid - contains whitespace)

// Convert type label to numeric string
char *numstr = utils::expand_type(FLERR, "C", Atom::ATOM, lmp);
if (numstr) {
    // Use the numeric type string
    delete[] numstr;  // Must delete after use
}

// Convert type label to integer
int type = utils::expand_type_int(FLERR, "C", Atom::ATOM, lmp, true);
// The 'true' argument enables range verification

// Use bounds_typelabel for ranges with label support
int lo, hi;
utils::bounds_typelabel(FLERR, "C:H", 1, 10, lo, hi, lmp, Atom::ATOM);
// Expands "C:H" to numeric range, e.g., "1:2" -> lo=1, hi=2
```

4.22.3 LabelMap class reference

class **LabelMap** : protected *Pointers*

Manage type labels for atoms, bonds, angles, dihedrals, and impropers.

The *LabelMap* class provides functionality to map between string labels and numeric type indices for atoms, bonds, angles, dihedrals, and impropers in *LAMMPS*. This enables users to reference types by symbolic names (e.g., “C”, “H”, “C-H”) instead of numeric indices, improving readability and maintainability of input scripts.

Type labels for bonded interactions *may* (but are not required to) use a hyphen-delimited format indicating the types of the constituent atoms. Examples:

- Bond types: “atom1-atom2” (e.g., “C-H”, “N-O”)
- Angle types: “atom1-atom2-atom3” (e.g., “H-C-H”, “C-N-C”)
- Dihedral types: “atom1-atom2-atom3-atom4” (e.g., “C-C-N-H”)
- Improper types: “atom1-atom2-atom3-atom4” (e.g., “C-N-C-C”)

The class supports bidirectional lookup (label <-> type) and can infer bonded interaction types from constituent atom types when using a hyphen-delimited format convention.

Interaction type inference from hyphen-delimited labels

These methods infer bonded interaction types (bonds, angles, dihedrals, impropers) from constituent atom types using a hyphen-delimited format. This requires that type labels for bonded interactions were entered following this convention. The inference functions consider the symmetry of the interaction and thus atom types may be swapped accordingly and the bonded type will still be matched.

int **infer_bondtype**(int atype1, int atype2)

Infer bond type from two numeric atom types

Look up or create a bond type from two atom type indices by constructing a hyphen-delimited label (e.g., “C-H”) and searching the bond type labels.

Parameters

- **atype1** – First atom type index
- **atype2** – Second atom type index

Returns
Bond type index if types match in the specified order, negative bond type index if types match in reverse order, 0 if there is no match found

int **infer_bondtype**(const std::vector<std::string> &labels)

Infer bond type from atom type labels

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Look up a bond type from two atom type labels.

Parameters
labels – Vector of two atom type label strings

Returns
Bond type index if types match in the specified order, negative bond type index if types match in reverse order, 0 if there is no match found

int **infer_angletype**(int atype1, int atype2, int atype3)

Infer angle type from three numeric atom types

Look up or create an angle type from three atom type indices by constructing a hyphen-delimited label (e.g., "H1-C1-H2").

Parameters

- **atype1** – First atom type index
- **atype2** – Second atom type index (center atom)
- **atype3** – Third atom type index

Returns
Angle type index if types match in the specified order, negative angle type index if types match in reverse order, 0 if there is no match found

int **infer_angletype**(const std::vector<std::string> &labels)

Infer angle type from three atom type labels

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Look up an angle type from three atom type labels.

Parameters
labels – Vector of three atom type label strings

Returns
Angle type index if types match in the specified order, negative angle type index if types match in reverse order, 0 if there is no match found

int **infer_dihedraltype**(int atype1, int atype2, int atype3, int atype4)

Infer dihedral type from four numeric atom types

Look up a dihedral type from four atom type indices by constructing a hyphen-delimited label (e.g., "C-C-N-H").

Parameters

- **atype1** – First atom type index
- **atype2** – Second atom type index
- **atype3** – Third atom type index
- **atype4** – Fourth atom type index

Returns

Dihedral type index if types match in the specified order, negative dihedral type index if types match in reverse order, 0 if there is no match found

int **infer_dihedraltype**(const std::vector<std::string> &labels)

Infer dihedral type from atom type labels

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Look up a dihedral type from four atom type labels.

Parameters

labels – Vector of four atom type label strings

Returns

Dihedral type index if types match in the specified order, negative dihedral type index if types match in reverse order, 0 if there is no match found

int **infer_impropertype**(int atype1, int atype2, int atype3, int atype4, std::array<int, 4> *iorder = nullptr)

Infer improper type from four numeric atom types

Look up an improper type from four atom type indices by constructing a hyphen-delimited label (e.g., "C-N-C-C").

Parameters

- **atype1** – First atom type index (center atom)
- **atype2** – Second atom type index
- **atype3** – Third atom type index
- **atype4** – Fourth atom type index
- **iorder** – Order in which types were matched to improper type label

Returns

Improper type index if types match in the specified order, negative improper type index if types match but different order, 0 if there is no match found

int **infer_impropertype**(const std::vector<std::string> &labels, std::array<int, 4> *iorder = nullptr)

Infer improper type from atom type labels

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Look up an improper type from four atom type labels.

Parameters

- **labels** – Vector of four atom type label strings
- **iorder** – Order in which types were matched to improper type label

Returns
Improper type index if types match in the specified order, negative improper type index if types match but different order, 0 if there is no match found

I/O methods for label map persistence

void **write_data**(FILE *fp)

Write label map to data file

Output all type labels as sections to a *LAMMPS* data file.

Parameters
fp – File pointer for writing

void **read_restart**(FILE *fp)

Read label map from restart file

Restore label map data from a *LAMMPS* restart file.

Parameters
fp – File pointer for reading

void **write_restart**(FILE*)

Write label map to restart file

Save label map data to a *LAMMPS* restart file for later restoration.

Parameters
fp – File pointer for writing

void **check_labels**()

Check if type labels are self-consistent.

Public Functions

LabelMap(*LAMMPS* *lmp, int natomtypes, int nbondtypes, int nangletypes, int ndihedraltypes, int nimpropertypes)

Construct a *LabelMap* instance

Parameters

- **lmp** – Pointer to *LAMMPS* instance
- **natomtypes** – Number of atom types in map
- **nbondtypes** – Number of bond types in map
- **nangletypes** – Number of angle types in map
- **ndihedraltypes** – Number of dihedral types in map
- **nimpropertypes** – Number of improper types in map

void **modify_lmap**(int narg, char **arg)

Process labelmap command from input script

Add or modify type label mappings from the LAMMPS *labelmap* input command.

Parameters

- **narg** – Number of arguments
- **arg** – Array of argument strings

void **merge_lmap**(*LabelMap* *lmap, int mode)

Copy another *LabelMap* into this one

Merge type labels from another LabelMap instance into the current one. Currently used when combining data from multiple sources with *read_data add* or when replicating the system with *replicate*.

Parameters

- **lmap** – Pointer to source *LabelMap*
- **mode** – Merge mode flag

void **create_lmap2lmap**(*LabelMap* *lmap, int mode)

Create index mapping between two LabelMaps

Build a mapping structure (lmap2lmap) that translates type indices from another *LabelMap* to the current one based on matching labels.

Parameters

- **lmap** – Pointer to source *LabelMap*
- **mode** – Mapping mode flag

int **find_type**(const std::string&, int) const

Find numeric type from type label

Look up the numeric type index corresponding to a type label string.

Parameters

- **mylabel** – Type label string to search for
- **mode** – Type category: Atom::ATOM, Atom::BOND, Atom::ANGLE, Atom::DIHEDRAL, or Atom::IMPROPER

Returns
Numeric type index (1-based), or -1 if not found

const std::string &**find_label**(int, int) const

Find type label from numeric type

Reverse lookup: retrieve the type label string for a given numeric type.

Parameters

- **i** – Numeric type index (1-based)
- **mode** – Type category: Atom::ATOM, Atom::BOND, Atom::ANGLE, Atom::DIHEDRAL, or Atom::IMPROPER

Returns
Reference to type label string, or empty string if not found

bool **is_complete**(int) const

Check if all types have assigned labels

Verify that every type in the specified category has a corresponding label.

Parameters
mode – Type category: Atom::ATOM, Atom::BOND, Atom::ANGLE, Atom::DIHEDRAL, or Atom::IMPROPER

Returns
True if all types have labels, false otherwise

int **parse_typelabel**(int ntypes, const std::string &label, std::vector<std::string> &types)

Parse hyphen-delimited type label into components

Split a hyphen-delimited label (e.g., "C-N-H") into individual type strings. Validates that the number of components matches the expected count.

Parameters

- **ntypes** – Expected number of components
- **label** – Hyphen-delimited label string
- **types** – **[out]** Output vector to store component strings

Returns

0 on success, -1 if component count doesn't match ntypes

Public Members

int **checkflag**

Flag to check for self-consistent type labels.

4.23 Memory pool classes

The memory pool classes are used for cases where otherwise many small memory allocations would be needed and where the data would be either all used or all freed. One example for that is the storage of neighbor lists. The memory management strategy is based on the assumption that allocations will be in chunks of similar sizes. The allocation is then not done per individual call for a reserved chunk of memory, but for a "page" that can hold multiple chunks of data. A parameter for the maximum chunk size must be provided, as that is used to determine whether a new page of memory must be used.

The *MyPage* class offers two ways to reserve a chunk: 1) with *MyPage::get()* the chunk size needs to be known in advance, 2) with *MyPage::vget()* a pointer to the next chunk is returned, but its size is registered later with *MyPage::vgot()*.

Listing 7: Example of using *MyPage*

```
#include "my_page.h"
using namespace LAMMPS_NS;

MyPage<double> *dpage = new MyPage<double>;
// max size of chunk: 256, size of page: 10240 doubles (=81920 bytes)
dpage->init(256,10240);

double **build_some_lists(int num)
{
    dpage->reset();
    double **dlist = new double*[num];
    for (int i=0; i < num; ++i) {
        double *dptr = dpage.vget();
        int jnum = 0;
        for (int j=0; j < jmax; ++j) {
            // compute some dvalue for eligible loop index j
            dptr[j] = dvalue;
```

(continues on next page)

(continued from previous page)

```
            ++jnum;
        }
        if (dpage.status() != 0) {
            // handle out of memory or jnum too large errors
        }
        dpage.vgot(jnum);
        dlist[i] = dptr;
    }
    return dlist;
}
```

---

template<class **T**>

class **MyPage**

Templated class for storing chunks of datums in pages.

The size of the chunk may vary from call to call, but must be less or equal than the *maxchunk* setting. The chunks are not returnable like with malloc() (i.e. you cannot call free() on them individually). One can only reset and start over. The purpose of this class is to replace many small memory allocations via malloc() with a few large ones. Since the pages are never freed until the class is re-initialized, they can be re-used without having to re-allocate them by calling the *reset()* method.

The settings *maxchunk*, *pagesize*, and *pagedelta* control the memory allocation strategy. The *maxchunk* value represents the largest number of items per chunk allowed; using more will trigger an error. If there is less space than *maxchunk* left on the current page, a new page is allocated for the next chunk. The *pagesize* value represents how many items can fit on a single page. It should have space for multiple chunks of size *maxchunk*. The combination of these two parameters determines how much memory is wasted by either switching to the next page too soon or allocating too large pages that never get fully used. The *pagedelta* parameter determines how many pages are allocated in one go. In combination with the *pagesize* setting, this determines how often blocks of memory get allocated (fewer allocations will result in faster execution).

Note

This is a template class with explicit instantiation. If the class is used with a new data type, a new explicit instantiation may need to be added at the end of the file `src/my_page.cpp` to avoid symbol lookup errors.

Public Functions

MyPage()

Create a class instance

Need to call *init()* before use to define allocation settings

int **init**(int user_maxchunk = 1, int user_pagesize = 1024, int user_pagedelta = 1)

(Re-)initialize the set of pages and allocation parameters.

This also frees all previously allocated storage and allocates the first page(s).

Parameters

- **user_maxchunk** – Maximum allowed number of items for one chunk
- **user_pagesize** – Number of items on a single memory page

- **user_pagedelta** – Number of pages to allocate with one malloc

Returns
1 if there were invalid parameters, 2 if there was an allocation error or 0 if successful

T ***get**(int n = 1)

Pointer to location that can store N items.

This will allocate more pages as needed. If the parameter *N* is larger than the *maxchunk* setting, an error is flagged.

Parameters
n – number of items for which storage is requested

Returns
memory location or null pointer, if error or allocation failed

inline *T* ***vget**()

Get pointer to location that can store *maxchunk* items.

This will return the same pointer as the previous call to this function unless *vgot()* is called afterwards to record how many items of the chunk were actually used.

Returns
pointer to chunk of memory or null pointer if run out of memory

inline void **vgot**(int n)

Mark *N* items as used of the chunk reserved with a preceding call to *vget()*.

This will advance the internal pointer inside the current memory page. It is not necessary to call this function for *N* = 0, implying the reserved storage was not used. A following call to *vget()* will then reserve the same location again. It is an error if *N* > *maxchunk*.

Parameters
n – Number of items used in previously reserved chunk

void **reset**()

Reset state of memory pool without freeing any memory

inline double **size**() const

Return total size of allocated pages

Returns
total storage used in bytes

inline int **status**() const

Return error status

Returns
0 if no error, 1 requested chunk size > maxchunk, 2 if malloc failed

template<class **T**>

class **MyPoolChunk**

Templated class for storing chunks of datums in pages.

The size of the chunk may vary from call to call between the *minchunk* and *maxchunk* setting. Chunks may be returned to the pool for re-use. Chunks can be reserved in *nbin* different sizes between *minchunk* and *maxchunk*. The *chunksperpage* setting specifies how many chunks are stored on any page and the *pagedelta* setting determines how many pages are allocated in one go. Pages are never freed, so they can be re-used without re-allocation.

Note

This is a template class with explicit instantiation. If the class is used with a new data type, a new explicit instantiation may need to be added at the end of the file `src/my_pool_chunk.cpp` to avoid symbol lookup errors.

Public Functions

MyPoolChunk(int user_minchunk = 1, int user_maxchunk = 1, int user_nbin = 1, int user_chunkperpage = 1024, int user_pagedelta = 1)

Create a class instance and set memory pool parameters

Parameters

- **user_minchunk** – Minimal chunk size
- **user_maxchunk** – Maximal chunk size
- **user_nbin** – Number of bins of different chunk sizes
- **user_chunkperpage** – Number of chunks per page
- **user_pagedelta** – Number of pages to allocate in one go

~MyPoolChunk()

Destroy class instance and free all allocated memory

T ***get**(int &index)

Return pointer/index of unused chunk of size maxchunk

Parameters
index – Index of chunk in memory pool

Returns
Pointer to requested chunk of storage

T ***get**(int n, int &index)

Return pointer/index of unused chunk of size N

Parameters

- **n** – Size of chunk
- **index** – Index of chunk in memory pool

Returns
Pointer to requested chunk of storage

void **put**(int index)

Put indexed chunk back into memory pool via free list

Parameters
index – Memory chunk index returned by call to *get()*

double **size**() const

Return total size of allocated pages

Returns
total storage used in bytes

inline int **status**() const

Return error status

Returns

0 if no error, 1 if invalid input, 2 if malloc() failed, 3 if chunk > maxchunk

---

4.24 Eigensolver functions

The `MathEigen` sub-namespace of the `LAMMPS_NS` namespace contains functions and classes for eigensolvers. Currently only the *jacobi3 function* is used in various places in LAMMPS. That function is built on top of a group of more generic eigensolvers that are maintained in the `math_eigen_impl.h` header file. This header contains the implementation of three template classes:

1. "Jacobi" calculates all of the eigenvalues and eigenvectors of a dense, symmetric, real matrix.
2. The "PEigenDense" class only calculates the principal eigenvalue (i.e. the largest or smallest eigenvalue), and its corresponding eigenvector. However it is much more efficient than "Jacobi" when applied to large matrices (larger than 13x13). PEigenDense also can understand complex-valued Hermitian matrices.
3. The "LambdaLanczos" class is a generalization of "PEigenDense" which can be applied to arbitrary sparse matrices.

The "math_eigen_impl.h" code is an amalgamation of jacobi_pd by Andrew Jewett at Scripps Research (under CC0-1.0 license) and Lambda Lanczos by Yuya Kurebayashi at Tohoku University (under MIT license)

---

int `MathEigen::`**jacobi3**(double const *const *mat, double *eval, double **evec, int sort = -1)

A specialized function which finds the eigenvalues and eigenvectors of a 3x3 matrix (in double ** format).

Parameters

- **mat** – the 3x3 matrix you wish to diagonalize
- **eval** – store the eigenvalues here
- **evec** – store the eigenvectors here…
- **sort** – order eigenvalues and -vectors (-1 decreasing (default), 1 increasing, 0 unsorted)

Returns

0 if eigenvalue calculation converged, 1 if it failed

int `MathEigen::`**jacobi3**(double const mat[3][3], double *eval, double evec[3][3], int sort = -1)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

4.25 Communication buffer coding with *ubuf*

LAMMPS uses communication buffers where it collects data from various class instances and then exchanges the data with neighboring subdomains. For simplicity those buffers are defined as `double` buffers and used for doubles and integer numbers. This presents a unique problem when 64-bit integers are used. While the storage needed for a `double` is also 64-bit, it cannot be used by a simple assignment. To get around that limitation, LAMMPS uses the *ubuf* union. It is used in the various "pack" and "unpack" functions in the LAMMPS classes to store and retrieve integers that may be 64-bit from the communication buffers.

---

union **ubuf**

#include <lmptype.h> Data structure for packing 32-bit and 64-bit integers into double (communication) buffers

Using this union avoids aliasing issues by having member types (double, int) referencing the same buffer memory location.

The explicit constructor for 32-bit integers prevents compilers from (incorrectly) calling the double constructor when storing an int into a double buffer.

Usage:

Listing 8: To copy an integer into a double buffer:

```
double buf[2];
int    foo =   1;
tagint bar = 2<<40;
buf[1] = ubuf(foo).d;
buf[2] = ubuf(bar).d;
```

Listing 9: To copy from a double buffer back to an int:

```
foo = (int)    ubuf(buf[1]).i;
bar = (tagint) ubuf(buf[2]).i;
```

The typecasts prevent compiler warnings about possible truncation issues.

Public Functions

inline **ubuf**(const double &arg)

inline **ubuf**(const int64_t &arg)

inline **ubuf**(const int &arg)

Public Members

double **d**

int64_t **i**

4.26 Internal Styles

LAMMPS has a number of styles that are not meant to be used in an input file and thus are not documented in the *LAMMPS command documentation*. The differentiation between user commands and internal commands is through the case of the command name: user commands and styles are all lower case, internal styles are all upper case. Internal styles are not called from the input file, but their classes are instantiated by other styles. Often they are created by other styles to store internal data or to perform actions regularly at specific steps of the simulation.

The paragraphs below document some of those styles that have general utility and may be used to avoid redundant implementation.

4.26.1 DEPRECATED Styles

The styles called DEPRECATED (e.g. pair, bond, fix, compute, region, etc.) have the purpose to inform users that a specific style has been removed or renamed. This is achieved by creating an alias for the deprecated style to the corresponding class. For example, the fix style DEPRECATED is aliased to fix style ave/spatial and fix style ave/spatial/sphere with the following code:

```
FixStyle(DEPRECATED,FixDeprecated);
FixStyle(ave/spatial,FixDeprecated);
FixStyle(ave/spatial/sphere,FixDeprecated);
```

The individual class will then determine based on the style name what action to perform:

- inform that the style has been removed and what style replaces it, if any, and then error out
- inform that the style has been renamed and then either execute the replacement or error out
- inform that the style is no longer required, and it is thus ignored and continue

There is also a section in the user's guide for *removed commands and packages* with additional explanations.

4.26.2 Internal fix styles

These provide an implementation of features that would otherwise have been replicated across multiple styles. The used fix ID is generally derived from the compute or fix ID creating the fix with some string appended. When needed, the fix can be looked up with `Modify::get_fix_by_id()`, which returns a pointer to the fix instance. The data managed by the fix can be accessed just as for other fixes that can be used in input files.

fix DUMMY

Most fix classes cannot be instantiated before the simulation box has been created since they access data that is only available then. However, in some cases it is required that a fix must be at or close to the top of the list of all fixes. In those cases an instance of the DUMMY fix style may be created by calling `Modify::add_fix()` and then later replaced by the intended fix through calling `Modify::replace_fix()`.

fix OXDNA/LRF

Fix OXDNA/LRF calculates the local reference frame of ellipsoids from the quaternions. All oxDNA bond and pair styles require the Cartesian local reference frame during the force, torque and energy calculation. The fix is invoked internally at the pre-force stage and not to be used in an input script.

fix STORE/ATOM

Fix STORE/ATOM can be used as persistent storage of per-atom data.

Syntax

```
fix ID group-ID STORE/ATOM N1 N2 gflag rflag
```

- ID, group-ID are documented in *fix* command, group-ID is *ignored*
- STORE/ATOM = style name of this fix command
- N1 = 1, N2 = 0 : data is per-atom vector = single value per atom
- N1 > 1, N2 = 0 : data is per-atom array = N1 values per atom
- N1 > 0, N2 > 0 : data is per-atom tensor = N1xN2 values per atom
- gflag = 1 communicate per-atom values with ghost atoms, 0 do not update ghost atom data

- rflag = 1 store per-atom value in restart file, 0 do not store data in restart

Similar functionality is also available through using custom per-atom properties with *fix property/atom*. The choice between the two fixes should be based on whether the user should be able to access this per-atom data: if yes, then fix property/atom is preferred, otherwise fix STORE/ATOM.

fix STORE/GLOBAL

Fix STORE/GLOBAL can be used as persistent storage of global data with support for restarts

Syntax

```
fix ID group-ID STORE/GLOBAL N1 N2
```

- ID, group-ID are documented in *fix* command, group-ID is *ignored*
- STORE/GLOBAL = style name of this fix command
- N1 >=1 : number of global items to store
- N2 = 1 : data is global vector of length N1
- N2 > 1 : data is global N1xN2 array

fix STORE/LOCAL

Fix STORE/LOCAL can be used as persistent storage for local data

Syntax

```
fix ID group-ID STORE/LOCAL Nreset Nvalues
```

- ID, group-ID are documented in *fix* command
- STORE/LOCAL = style name of this fix command
- Nreset = frequency at which local data is available
- Nvalues = number of values per local item, that is the number of columns

4.27 Use of distributed grids within style classes

Added in version 22Dec2022.

The LAMMPS source code includes two classes which facilitate the creation and use of distributed grids. These are the Grid2d and Grid3d classes in the src/grid2d.cpp.h and src/grid3d.cpp.h files respectively. As the names imply, they are used for 2d or 3d simulations, as defined by the *dimension* command.

The *Howto_grid* page gives an overview of how distributed grids are defined from a user perspective, lists LAMMPS commands which use them, and explains how grid cell data is referenced from an input script. Please read that page first as it motivates the coding details discussed here.

This doc page is for users who wish to write new styles (input script commands) which use distributed grids. There are a variety of material models and analysis methods which use atoms (or coarse-grained particles) and grids in tandem.

A *distributed* grid means each processor owns a subset of the grid cells. In LAMMPS, the subset for each processor will be a sub-block of grid cells with low and high index bounds in each dimension of the grid. The union of the sub-blocks across all processors is the global grid.

More specifically, a grid point is defined for each cell (by default the center point), and a processor owns a grid cell if its point is within the processor's spatial subdomain. The union of processor subdomains is the global simulation box.

If a grid point is on the boundary of two subdomains, the lower processor owns the grid cell. A processor may also store copies of ghost cells which surround its owned cells.

4.27.1 Style commands

Style commands which can define and use distributed grids include the *compute*, *fix*, *pair*, and *kspace* styles. If you wish grid cell data to persist across timesteps, then use a fix. If you wish grid cell data to be accessible by other commands, then use a fix or compute. Currently in LAMMPS, the *pair_style amoeba*, *kspace_style pppm*, and *kspace_style msm* commands use distributed grids but do not require either of these capabilities; they thus create and use distributed grids internally. Note that a pair style which needs grid cell data to persist could be coded to work in tandem with a fix style which provides that capability.

The *size* of a grid is specified by the number of grid cells in each dimension of the simulation domain. In any dimension the size can be any value >= 1. Thus a 10x10x1 grid for a 3d simulation is effectively a 2d grid, where each grid cell spans the entire z-dimension. A 1x100x1 grid for a 3d simulation is effectively a 1d grid, where grid cells are a series of thin xz slabs in the y-dimension. It is even possible to define a 1x1x1 3d grid, though it may be inefficient to use it in a computational sense.

Note that the choice of grid size is independent of the number of processors or their layout in a grid of processor subdomains which overlays the simulations domain. Depending on the distributed grid size, a single processor may own many 1000s or no grid cells.

A command can define multiple grids, each of a different size. Each grid is an instantiation of the Grid2d or Grid3d class.

The command also defines what data it will store for each grid it creates and it allocates the multidimensional array(s) needed to store the data. No grid cell data is stored within the Grid2d or Grid3d classes.

If a single value per grid cell is needed, the data array will have the same dimension as the grid, i.e. a 2d array for a 2d grid, likewise for 3d. If multiple values per grid cell are needed, the data array will have one more dimension than the grid, i.e. a 3d array for a 2d grid, or 4d array for a 3d grid. A command can choose to define multiple data arrays for each grid it defines.

4.27.2 Grid data allocation and access

The simplest way for a command to allocate and access grid cell data is to use the *create_offset()* methods provided by the Memory class. Arguments for these methods can be values returned by the *setup_grid()* method (described below), which define the extent of the grid cells (owned+ghost) the processor owns. These 4 methods allocate memory for 2d (first two) and 3d (second two) grid data. The two methods that end in "_offset" allocate an array which stores a single value per grid cell. The two that end in "_last" allocate an array which stores *Nvalues* per grid cell.

```
// single value per cell for a 2d grid = 2d array
memory->create2d_offset(data2d_one, nylo_out, nyhi_out,
                        nxlo_out, nxhi_out, "data2d_one");

// nvalues per cell for a 2d grid = 3d array
memory->create3d_offset_last(data2d_multi, nylo_out, nyhi_out,
                             nxlo_out, nxhi_out, nvalues, "data2d_multi");

// single value per cell for a 3d grid = 3d array
memory->create3d_offset(data3d_one, nzlo_out, nzhi_out, nylo_out,
                        nyhi_out, nxlo_out, nxhi_out, "data3d_one");
```

(continues on next page)

(continued from previous page)

```
// nvalues per cell for a 3d grid = 4d array
memory->create4d_offset_last(data3d_multi, nzlo_out, nzhi_out, nylo_out,
                             nyhi_out, nxlo_out, nxhi_out, nvalues,
                             "data3d_multi");
```

Note that these multidimensional arrays are allocated as contiguous chunks of memory where the x-index of the grid varies fastest, then y, and the z-index slowest. For multiple values per grid cell, the Nvalues are contiguous, so their index varies even faster than the x-index.

The key point is that the "offset" methods create arrays which are indexed by the range of indices which are the bounds of the sub-block of the global grid owned by this processor. This means loops like these can be written in the caller code to loop over owned grid cells, where the "i" loop bounds are the range of owned grid cells for the processor. These are the bounds returned by the *setup_grid()* method:

```
for (int iy = iylo; iy <= iyhi; iy++)
  for (int ix = ixlo; ix <= ixhi; ix++)
    data2d_one[iy][ix] = 0.0;

for (int iy = iylo; iy <= iyhi; iy++)
  for (int ix = ixlo; ix <= ixhi; ix++)
    for (int m = 0; m < nvalues; m++)
      data2d_multi[iy][ix][m] = 0.0;

for (int iz = izlo; iz <= izhi; iz++)
  for (int iy = iylo; iy <= iyhi; iy++)
    for (int ix = ixlo; ix <= ixhi; ix++)
      data3d_one[iz][iy][ix] = 0.0;

for (int iz = izlo; iz <= izhi; iz++)
  for (int iy = iylo; iy <= iyhi; iy++)
    for (int ix = ixlo; ix <= ixhi; ix++)
       for (int m = 0; m < nvalues; m++)
          data3d_multi[iz][iy][ix][m] = 0.0;
```

Simply replacing the "i" bounds with "o" bounds, also returned by the *setup_grid()* method, would alter this code to loop over owned+ghost cells (the entire allocated grid).

4.27.3 Grid class constructors

The following subsections describe the public methods of the Grid3d class which a style command can invoke. The Grid2d methods are similar; simply remove arguments which refer to the z-dimension.

There are 2 constructors which can be used. They differ in the extra i/o xyz lo/hi arguments:

```
Grid3d(class LAMMPS *lmp, MPI_Comm gcomm, int gnx, int gny, int gnz)
Grid3d(class LAMMPS *lmp, MPI_Comm gcomm, int gnx, int gny, int gnz,
       int ixlo, int ixhi, int iylo, int iyhi, int izlo, int izhi,
       int oxlo, int oxhi, int oylo, int oyhi, int ozlo, int ozhi)
```

Both constructors take the LAMMPS instance pointer and a communicator over which the grid will be distributed. Typically this is the *world* communicator the LAMMPS instance is using. The *kspace_style msm* command creates a series of grids, each of different size, which are partitioned across different sub-communicators of processors. Both constructors are also passed the global grid size: *gnx* by *gny* by *gnz*.

The first constructor is used when the caller wants the Grid class to partition the global grid across processors; the Grid class defines which grid cells each processor owns and also which it stores as ghost cells. A subsequent call to *setup_grid()*, discussed below, returns this info to the caller.

The second constructor allows the caller to define the extent of owned and ghost cells, and pass them to the Grid class. The 6 arguments which start with "i" are the inclusive lower and upper index bounds of the owned (inner) grid cells this processor owns in each of the 3 dimensions within the global grid. Owned grid cells are indexed from 0 to N-1 in each dimension.

The 6 arguments which start with "o" are the inclusive bounds of the owned+ghost (outer) grid cells it stores. If the ghost cells are on the other side of a periodic boundary, then these indices may be < 0 or >= N in any dimension, so that oxlo <= ixlo and ixhi >= ixhi is always the case.

For example, if Nx = 100, then a processor might pass ixlo=50, ixhi=60, oxlo=48, oxhi=62 to the Grid class. Or ixlo=0, ixhi=10, oxlo=-2, oxhi=13. If a processor owns no grid cells in a dimension, then the ihi value should be specified as one less than the ilo value.

Note that the only reason to use the second constructor is if the logic for assigning ghost cells is too complex for the Grid class to compute, using the various set() methods described next. Currently only the kspace_style pppm/electrode and kspace_style msm commands use the second constructor.

4.27.4 Grid class set methods

The following methods affect how the Grid class computes which owned and ghost cells are assigned to each processor. *Set_shift_grid()* is the only method which influences owned cell assignment; all the rest influence ghost cell assignment. These methods are only used with the first constructor; they are ignored if the second constructor is used. These methods must be called before the *setup_grid()* method is invoked, because they influence its operation.

```
void set_shift_grid(double shift);
void set_distance(double distance);
void set_stencil_atom(int lo, int hi);
void set_shift_atom(double shift_lo, double shift_hi);
void set_stencil_grid(int lo, int hi);
void set_zfactor(double factor);
```

Processors own a grid cell if a point within the grid cell is inside the processor's subdomain. By default this is the center point of the grid cell. The *set_shift_grid()* method can change this. The *shift* argument is a value from 0.0 to 1.0 (inclusive) which is the offset of the point within the grid cell in each dimension. The default is 0.5 for the center of the cell. A value of 0.0 is the lower left corner point; a value of 1.0 is the upper right corner point. There is typically no need to change the default as it is optimal for minimizing the number of ghost cells needed.

If a processor maps its particles to grid cells, it needs to allow for its particles being outside its subdomain between reneighboring. The *distance* argument of the *set_distance()* method sets the furthest distance outside a processor's subdomain which a particle can move. Typically this is half the neighbor skin distance, assuming reneighboring is done appropriately. This distance is used in determining how many ghost cells a processor needs to store to enable its particles to be mapped to grid cells. The default value is 0.0.

Some commands, like the *kspace_style pppm* command, map values (charge in the case of PPPM) to a stencil of grid cells beyond the grid cell the particle is in. The stencil extent may be different in the low and high directions. The *set_stencil_atom()* method defines the maximum values of those 2 extents, assumed to be the same in each of the 3 dimensions. Both the lo and hi values are specified as positive integers. The default values are both 0.

Some commands, like the *kspace_style pppm* command, shift the position of an atom when mapping it to a grid cell, based on the size of the stencil used to map values to the grid (charge in the case of PPPM). The lo and hi arguments of the *set_shift_atom()* method are the minimum shift in the low direction and the maximum shift in the high direction, assumed to be the same in each of the 3 dimensions. The shifts should be fractions of a grid cell size with values

between 0.0 and 1.0 inclusive. The default values are both 0.0. See the src/pppm.cpp file for examples of these lo/hi values for regular and staggered grids.

Some methods like the *fix ttm/grid* command, perform finite difference kinds of operations on the grid, to diffuse electron heat in the case of the two-temperature model (TTM). This operation uses ghost grid values beyond the owned grid values the processor updates. The *set_stencil_grid()* method defines the extent of this stencil in both directions, assumed to be the same in each of the 3 dimensions. Both the lo and hi values are specified as positive integers. The default values are both 0.

The kspace_style pppm commands allow a grid to be defined which overlays a volume which extends beyond the simulation box in the z dimension. This is for the purpose of modeling a 2d-periodic slab (non-periodic in z) as if it were a larger 3d periodic system, extended (with empty space) in the z dimension. The *kspace_modify slab* command is used to specify the ratio of the larger volume to the simulation volume; a volume ratio of ~3 is typical. For this kind of model, the PPPM caller sets the global grid size *gnz* ~3x larger than it would be otherwise. This same ratio is passed by the PPPM caller as the *factor* argument to the Grid class via the *set_zfactor()* method (*set_yfactor()* for 2d grids). The Grid class will then assign ownership of the 1/3 of grid cells that overlay the simulation box to the processors which also overlay the simulation box. The remaining 2/3 of the grid cells are assigned to processors whose subdomains are adjacent to the upper z boundary of the simulation box.

4.27.5 Grid class setup_grid method

The *setup_grid()* method is called after the first constructor (above) to partition the grid across processors, which determines which grid cells each processor owns. It also calculates how many ghost grid cells in each dimension and each direction each processor needs to store.

Note that this method is NOT called if the second constructor above is used. In that case, the caller assigns owned and ghost cells to each processor.

Also note that this method must be invoked after any *set_*()* methods have been used, since they can influence the assignment of owned and ghost cells.

```
void setup_grid(int &ixlo, int &ixhi, int &iylo, int &iyhi, int &izlo, int &izhi,
                int &oxlo, int &oxhi, int &oylo, int &oyhi, int &ozlo, int &ozhi)
```

The 6 return arguments which start with "i" are the inclusive lower and upper index bounds of the owned (inner) grid cells this processor owns in each of the 3 dimensions within the global grid. Owned grid cells are indexed from 0 to N-1 in each dimension.

The 6 return arguments which start with "o" are the inclusive bounds of the owned+ghost cells it owns. If the ghost cells are on the other side of a periodic boundary, then these indices may be < 0 or >= N in any dimension, so that oxlo <= ixlo and ixhi >= ixhi is always the case.

4.27.6 More grid class set methods

The following 2 methods can be used to override settings made by the constructors above. If used, they must be called called before the *setup_comm()* method is invoked, since it uses the settings that these methods override. In LAMMPS these methods are called by by the *kspace_style msm* command for the grids it instantiates using the 2nd constructor above.

```
void set_proc_neighs(int pxlo, int pxhi, int pylo, int pyhi, int pzlo, int pzhi)
void set_caller_grid(int fxlo, int fxhi, int fylo, int fyhi, int fzlo, int fzhi)
```

The *set_proc_neighs()* method sets the processor IDs of the 6 neighboring processors for each processor. Normally these would match the processor grid neighbors which LAMMPS creates to overlay the simulation box (the default). However, MSM excludes non-participating processors from coarse grid communication when less processors are used. This method allows MSM to override the default values.

The *set_caller_grid()* method species the size of the data arrays the caller allocates. Normally these would match the extent of the ghost grid cells (the default). However the MSM caller allocates a larger data array (more ghost cells) for its finest-level grid, for use in other operations besides owned/ghost cell communication. This method allows MSM to override the default values.

4.27.7 Grid class get methods

The following methods allow the caller to query the settings for a specific grid, whether it created the grid or another command created it.

```
void get_size(int &nxgrid, int &nygrid, int &nzgrid);
void get_bounds_owned(int &xlo, int &xhi, int &ylo, int &yhi, int &zlo, int &zhi)
void get_bounds_ghost(int &xlo, int &xhi, int &ylo, int &yhi, int &zlo, int &zhi)
```

The *get_size()* method returns the size of the global grid in each dimension.

The *get_bounds_owned()* method return the inclusive index bounds of the grid cells this processor owns. The values range from 0 to N-1 in each dimension. These values are the same as the "i" values returned by *setup_grid()*.

The *get_bounds_ghost()* method return the inclusive index bounds of the owned+ghost grid cells this processor stores. The owned cell indices range from 0 to N-1, so these indices may be less than 0 or greater than or equal to N in each dimension. These values are the same as the "o" values returned by *setup_grid()*.

4.27.8 Grid class owned/ghost communication

If needed by the command, the following methods setup and perform communication of grid data to/from neighboring processors. The *forward_comm()* method sends owned grid cell data to the corresponding ghost grid cells on other processors. The *reverse_comm()* method sends ghost grid cell data to the corresponding owned grid cells on another processor. The caller can choose to sum ghost grid cell data to the owned grid cell or simply copy it.

```
void setup_comm(int &nbuf1, int &nbuf2)
void forward_comm(int caller, void *ptr, int which, int nper, int nbyte,
                  void *buf1, void *buf2, MPI_Datatype datatype);
void reverse_comm(int caller, void *ptr, int which, int nper, int nbyte,
                  void *buf1, void *buf2, MPI_Datatype datatype)
int ghost_adjacent();
```

The *setup_comm()* method must be called one time before performing *forward* or *reverse* communication (multiple times if needed). It returns two integers, which should be used to allocate two buffers. The *nbuf1* and *nbuf2* values are the number of grid cells whose data will be stored in two buffers by the Grid class when *forward* or *reverse* communication is performed. The caller should thus allocate them to a size large enough to hold all the data used in any single forward or reverse communication operation it performs. Note that the caller may allocate and communicate multiple data arrays for a grid it instantiates. This size includes the bytes needed for the data type of the grid data it stores, e.g. double precision values.

The *forward_comm()* and *reverse_comm()* methods send grid cell data from owned to ghost cells, or ghost to owned cells, respectively, as described above. The *caller* argument should be one of these values – Grid3d::COMPUTE, Grid3d::FIX, Grid3d::KSPACE, Grid3d::PAIR – depending on the style of the caller class. The *ptr* argument is the

"this" pointer to the caller class. These two arguments are used to call back to pack()/unpack() functions in the caller class, as explained below.

The *which* argument is a flag the caller can set which is passed to the caller's pack()/unpack() methods. This allows a single callback method to pack/unpack data for several different flavors of forward/reverse communication, e.g. operating on different grids or grid data.

The *nper* argument is the number of values per grid cell to be communicated. The *nbyte* argument is the number of bytes per value, e.g. 8 for double-precision values. The *buf1* and *buf2* arguments are the two allocated buffers described above. So long as they are allocated for the maximum size communication, they can be reused for any *forward_comm()/reverse_comm()* call. The *datatype* argument is the MPI_Datatype setting, which should match the buffer allocation and the *nbyte* argument. E.g. MPI_DOUBLE for buffers storing double precision values.

To use the *forward_grid()* method, the caller must provide two callback functions; likewise for use of the *reverse_grid()* methods. These are the 4 functions, their arguments are all the same.

```
void pack_forward_grid(int which, void *vbuf, int nlist, int *list);
void unpack_forward_grid(int which, void *vbuf, int nlist, int *list);
void pack_reverse_grid(int which, void *vbuf, int nlist, int *list);
void unpack_reverse_grid(int which, void *vbuf, int nlist, int *list);
```

The *which* argument is set to the *which* value of the *forward_comm()* or *reverse_comm()* calls. It allows the pack/unpack function to select what data values to pack/unpack. *Vbuf* is the buffer to pack/unpack the data to/from. It is a void pointer so that the caller can cast it to whatever data type it chooses, e.g. double precision values. *Nlist* is the number of grid cells to pack/unpack and *list* is a vector (nlist in length) of offsets to where the data for each grid cell resides in the caller's data arrays, which is best illustrated with an example from the src/EXTRA-FIX/fix_ttm_grid.cpp class which stores the scalar electron temperature for 3d system in a 3d grid (one value per grid cell):

```
void FixTTMGrid::pack_forward_grid(int /*which*/, void *vbuf, int nlist, int *list)
{
  auto buf = (double *) vbuf;
  double *src = &T_electron[nzlo_out][nylo_out][nxlo_out];
  for (int i = 0; i < nlist; i++) buf[i] = src[list[i]];
}
```

In this case, the *which* argument is not used, *vbuf* points to a buffer of doubles, and the electron temperature is stored by the FixTTMGrid class in a 3d array of owned+ghost cells called T_electron. That array is allocated by the *memory->create_3d_offset()* method described above so that the first grid cell it stores is indexed as T_electron[nzlo_out][nylo_out][nxlo_out]. The *nlist* values in *list* are integer offsets from that first grid cell. Setting *src* to the address of the first cell allows those offsets to be used to access the temperatures to pack into the buffer.

Here is a similar portion of code from the src/fix_ave_grid.cpp class which can store two kinds of data, a scalar count of atoms in a grid cell, and one or more grid-cell-averaged atom properties. The code from its *unpack_reverse_grid()* function for 2d grids and multiple per-atom properties per grid cell (*nvalues*) is shown here:

```
void FixAveGrid::unpack_reverse_grid(int /*which*/, void *vbuf, int nlist, int *list)
{
  auto buf = (double *) vbuf;
  double *count,*data,*values;
  count = &count2d[nylo_out][nxlo_out];
  data = &array2d[nylo_out][nxlo_out][0];
  m = 0;
  for (i = 0; i < nlist; i++) {
    count[list[i]] += buf[m++];
    values = &data[nvalues*list[i]];
    for (j = 0; j < nvalues; j++)
```

(continues on next page)

(continued from previous page)

```
    values[j] += buf[m++];
  }
}
```

Both the count and the multiple values per grid cell are communicated in *vbuf*. Note that *data* is now a pointer to the first value in the first grid cell. And *values* points to where the first value in *data* is for an offset of grid cells, calculated by multiplying *nvalues* by *list[i]*. Finally, because this is reverse communication, the communicated buffer values are summed to the caller values.

The *ghost_adjacent()* method returns a 1 if every processor can perform the necessary owned/ghost communication with only its nearest neighbor processors (4 in 2d, 6 in 3d). It returns a 0 if any processor's ghost cells extend further than nearest neighbor processors.

This can be checked by callers who have the option to change the global grid size to ensure more efficient nearest-neighbor-only communication if they wish. In this case, they instantiate a grid of a given size (resolution), then invoke *setup_comm()* followed by *ghost_adjacent()*. If the ghost cells are not adjacent, they destroy the grid instance and start over with a higher-resolution grid. Several of the *kspace_style pppm* command variants have this option.

4.27.9 Grid class remap methods for load balancing

The following methods are used when a load-balancing operation, triggered by the *balance* or *fix balance* commands, changes the partitioning of the simulation domain into processor subdomains.

In order to work with load-balancing, any style command (compute, fix, pair, or kspace style) which allocates a grid and stores per-grid data should define a *reset_grid()* method; it takes no arguments. It will be called by the two balance commands after they have reset processor subdomains and migrated atoms (particles) to new owning processors. The *reset_grid()* method will typically perform some or all of the following operations. See the src/fix_ave_grid.cpp and src/EXTRA_FIX/fix_ttm_grid.cpp files for examples of *reset_grid()* methods, as well as the *pack_remap_grid()* and *unpack_remap_grid()* functions.

First, the *reset_grid()* method can instantiate new grid(s) of the same global size, then call *setup_grid()* to partition them via the new processor subdomains. At this point, it can invoke the *identical()* method which compares the owned and ghost grid cell index bounds between two grids, the old grid passed as a pointer argument, and the new grid whose *identical()* method is being called. It returns 1 if the indices match on all processors, otherwise 0. If they all match, then the new grids can be deleted; the command can continue to use the old grids.

If not, then the command should allocate new grid data array(s) which depend on the new partitioning. If the command does not need to persist its grid data from the old partitioning to the new one, then the command can simply delete the old data array(s) and grid instance(s). It can then return.

If the grid data does need to persist, then the data for each grid needs to be "remapped" from the old grid partitioning to the new grid partitioning. The *setup_remap()* and *remap()* methods are used for that purpose.

```
int identical(Grid3d *old);
void setup_remap(Grid3d *old, int &nremap_buf1, int &nremap_buf2)
void remap(int caller, void *ptr, int which, int nper, int nbyte,
           void *buf1, void *buf2, MPI_Datatype datatype)
```

The arguments to these methods are identical to those for the *setup_comm()* and *forward_comm()* or *reverse_comm()* methods. However the returned *nremap_buf1* and *nremap2_buf* values will be different than the *nbuf1* and *nbuf2* values. They should be used to allocate two different remap buffers, separate from the owned/ghost communication buffers.

To use the *remap()* method, the caller must provide two callback functions:

```
void pack_remap_grid(int which, void *vbuf, int nlist, int *list);
void unpack_remap_grid(int which, void *vbuf, int list, int *list);
```

Their arguments are identical to those for the *pack_forward_grid()* and *unpack_forward_grid()* callback functions (or the reverse variants) discussed above. Normally, both these methods pack/unpack all the data arrays for a given grid. The *which* argument of the *remap()* method sets the *which* value for the pack/unpack functions. If the command instantiates multiple grids (of different sizes), it can be used within the pack/unpack methods to select which grid's data is being remapped.

Note that the *pack_remap_grid()* function must copy values from the OLD grid data arrays into the *vbuf* buffer. The *unpack_remap_grid()* function must copy values from the *vbuf* buffer into the NEW grid data arrays.

After the remap operation for grid cell data has been performed, the *reset_grid()* method can deallocate the two remap buffers it created, and can then exit.

4.27.10 Grid class I/O methods

There are two I/O methods in the Grid classes which can be used to read and write grid cell data to files. The caller can decide on the precise format of each file, e.g. whether header lines are prepended or comment lines are allowed. Fundamentally, the file should contain one line per grid cell for the entire global grid. Each line should contain identifying info as to which grid cell it is, e.g. a unique grid cell ID or the ix,iy,iz indices of the cell within a 3d grid. The line should also contain one or more data values which are stored within the grid data arrays created by the command

For grid cell IDs, the LAMMPS convention is that the IDs run from 1 to N, where N = Nx * Ny for 2d grids and N = Nx * Ny * Nz for 3d grids. The x-index of the grid cell varies fastest, then y, and the z-index varies slowest. So for a 10x10x10 grid the cell IDs from 901-1000 would be in the top xy layer of the z dimension.

The *read_file()* method does something simple. It reads a chunk of consecutive lines from the file and passes them back to the caller to process. The caller provides a *unpack_read_grid()* function for this purpose. The function checks the grid cell ID or indices and only stores grid cell data for the grid cells it owns.

The *write_file()* method does something slightly more complex. Each processor packs the data for its owned grid cells into a buffer. The caller provides a *pack_write_grid()* function for this purpose. The *write_file()* method then loops over all processors and each sends its buffer one at a time to processor 0, along with the 3d (or 2d) index bounds of its grid cell data within the global grid. Processor 0 calls back to the *unpack_write_grid()* function provided by the caller with the buffer. The function writes one line per grid cell to the file.

See the src/EXTRA_FIX/fix_ttm_grid.cpp file for examples of now both these methods are used to read/write electron temperature values from/to a file, as well as for implementations of the the pack/unpack functions described below.

Here are the details of the two I/O methods and the 3 callback functions. See the src/fix_ave_grid.cpp file for examples of all of them.

```
void read_file(int caller, void *ptr, FILE *fp, int nchunk, int maxline)
void write_file(int caller, void *ptr, int which,
                int nper, int nbyte, MPI_Datatype datatype
```

The *caller* argument in both methods should be one of these values – Grid3d::COMPUTE, Grid3d::FIX, Grid3d::KSPACE, Grid3d::PAIR – depending on the style of the caller class. The *ptr* argument in both methods is the "this" pointer to the caller class. These 2 arguments are used to call back to pack()/unpack() functions in the caller class, as explained below.

For the *read_file()* method, the *fp* argument is a file pointer to the file to be read from, opened on processor 0 by the caller. *Nchunk* is the number of lines to read per chunk, and *maxline* is the maximum number of characters per line. The Grid class will allocate a buffer for storing chunks of lines based on these values.

For the *write_file()* method, the *which* argument is a flag the caller can set which is passed back to the caller's pack()/unpack() methods. If the command instantiates multiple grids (of different sizes), this flag can be used within the pack/unpack methods to select which grid's data is being written out (presumably to different files). the *nper* argument is the number of values per grid cell to be written out. The *nbyte* argument is the number of bytes per value, e.g. 8 for double-precision values. The *datatype* argument is the MPI_Datatype setting, which should match the *nbyte* argument. E.g. MPI_DOUBLE for double precision values.

To use the *read_grid()* method, the caller must provide one callback function. To use the *write_grid()* method, it provides two callback functions:

```
int unpack_read_grid(int nlines, char *buffer)
void pack_write_grid(int which, void *vbuf)
void unpack_write_grid(int which, void *vbuf, int *bounds)
```

For *unpack_read_grid()* the *nlines* argument is the number of lines of character data read from the file and contained in *buffer*. The lines each include a newline character at the end. When the function processes the lines, it may choose to skip some of them (header or comment lines). It returns an integer count of the number of grid cell lines it processed. This enables the Grid class *read_file()* method to know when it has read the correct number of lines.

For *pack_write_grid()* and *unpack_write_grid()*, the *vbuf* argument is the buffer to pack/unpack data to/from. It is a void pointer so that the caller can cast it to whatever data type it chooses, e.g. double precision values. the *which* argument is set to the *which* value of the *write_file()* method. It allows the caller to choose which grid data to operate on.

For *unpack_write_grid()*, the *bounds* argument is a vector of 4 or 6 integer grid indices (4 for 2d, 6 for 3d). They are the xlo,xhi,ylo,yhi,zlo,zhi index bounds of the portion of the global grid which the *vbuf* holds owned grid cell data values for. The caller should loop over the values in *vbuf* with a double loop (2d) or triple loop (3d), similar to the code snippets listed above. The x-index varies fastest, then y, and the z-index slowest. If there are multiple values per grid cell, the index for those values varies fastest of all. The caller can add the x,y,z indices of the grid cell (or the corresponding grid cell ID) to the data value(s) written as one line to the output file.

4.27.11 Style class grid access methods

A style command can enable its grid cell data to be accessible from other commands. For example *fix ave/grid* or *dump grid* or *dump grid/vtk*. Those commands access the grid cell data by using a *grid reference* in their input script syntax, as described on the *Howto_grid* doc page. They look like this:

- c_ID:gname:dname
- c_ID:gname:dname[I]
- f_ID:gname:dname
- f_ID:gname:dname[I]

Each grid command instantiates has a unique *gname*, defined by the command. Likewise each grid cell data structure (scalar or vector) associated with a grid has a unique *dname*, also defined by the command.

To provide access to its grid cell data, a style command needs to implement the following 4 methods:

```
int get_grid_by_name(const std::string &name, int &dim);
void *get_grid_by_index(int index);
int get_griddata_by_name(int igrid, const std::string &name, int &ncol);
void *get_griddata_by_index(int index);
```

Currently only computes and fixes can implement these methods. If it does so, the compute of fix should also set the variable *pergrid_flag* to 1. See any of the compute or fix commands which set "pergrid_flag = 1" for examples of how these 4 functions can be implemented.

The *get_grid_by_name()* method takes a grid name as input and returns two values. The *dim* argument is returned as 2 or 3 for the dimensionality of the grid. The function return is a grid index from 0 to G-1 where *G* is the number of grids the command instantiates. A value of -1 is returned if the grid name is not recognized.

The *get_grid_by_index()* method is called after the *get_grid_by_name()* method, using the grid index it returned as its argument. This method will return a pointer to the Grid2d or Grid3d class. The caller can use this to query grid attributes, such as the global size of the grid, to ensure it is of the expected size.

The *get_griddata_by_name()* method takes a grid index *igrid* and a data name as input. It returns two values. The *ncol* argument is returned as a 0 if the grid data is a single value (scalar) per grid cell, or an integer M > 0 if there are M values (vector) per grid cell. Note that even if M = 1, it is still a 1-length vector, not a scalar. The function return is a data index from 0 to D-1 where *D* is the number of data sets associated with that grid by the command. A value of -1 is returned if the data name is not recognized.

The *get_griddata_by_index()* method is called after the *get_griddata_by_name()* method, using the data index it returned as its argument. This method will return a pointer to the multidimensional array which stores the requested data.

As in the discussion above of the Memory class *create_offset()* methods, the dimensionality of the array associated with the returned pointer depends on whether it is a 2d or 3d grid and whether there is a single or multiple values stored for each grid cell:

- single value per cell for a 2d grid = 2d array pointer
- multiple values per cell for a 2d grid = 3d array pointer
- single value per cell for a 3d grid = 3d array pointer
- multiple values per cell for a 3d grid = 4d array pointer

The caller will typically access the data by casting the void pointer to the corresponding array pointer and using nested loops in x,y,z between owned or ghost index bounds returned by the *get_bounds_owned()* or *get_bounds_ghost()* methods to index into the array. Example code snippets with this logic were listed above,

---

4.27.12 Final notes

Finally, here are some additional issues to pay attention to for writing any style command which uses distributed grids via the Grid2d or Grid3d class.

The command destructor should delete all instances of the Grid class, any buffers it allocated for forward/reverse or remap communication, and any data arrays it allocated to store grid cell data.

If a command is intended to work for either 2d or 3d simulations, then it should have logic to instantiate either 2d or 3d grids and their associated data arrays, depending on the dimension of the simulation box. The *fix ave/grid* command is an example of such a command.

When a command maps its particles to the grid and updates grid cell values, it should check that it is not updating or accessing a grid cell value outside the range of its owned+ghost cells, and generate an error message if that is the case. This could happen, for example, if a particle has moved further than half the neighbor skin distance, because the neighbor list update criterion are not adequate to prevent it from happening. See the src/KSPACE/pppm.cpp file and its *particle_map()* method for an example of this kind of error check.

4.28 Working with AI coding agents

- *Instruction files for coding agents*
- *Verify, do not trust*
- *Scope and organization of changes*
- *Git and licensing*
- *Keeping the instructions useful*

This page collects practical suggestions for using AI coding agents when working on the LAMMPS source code. They complement the general remarks on the *Information for Developers* page and reflect the experience of the LAMMPS developers. Since this is a rapidly evolving field, the suggestions will be revised as needed.

4.28.1 Instruction files for coding agents

The LAMMPS git repository contains instruction files that coding agents read automatically. They are organized so that only a small core is always read and more specific information is added when it is needed:

- `.github/copilot-instructions.md` is the always-read core: how to build and test LAMMPS, general conventions, the development workflow, and an index of the more specific guides.
- `.github/instructions/*.instructions.md` contain rules for specific parts of the source tree, e.g. the C++ sources, the documentation, the KOKKOS package, or the unit tests. The `applyTo:` line at the top of each file lists the paths it applies to.
- `.github/dev-docs/` contains longer background documents (e.g. on porting styles to the KOKKOS or OPENMP package, or on testing and verification strategies) that agents are told to read before starting the corresponding kind of work.

GitHub Copilot reads these files directly. Claude Code reads `.claude/CLAUDE.md`, which imports the core file, and the small files in `.claude/rules/` tell it which of the specific guides to read when it works on matching files. Most other coding agents read the `AGENTS.md` file in the top-level folder, which points to the same files.

These files are not included in the LAMMPS release tarballs. To work with a coding agent, use a git clone of the LAMMPS GitHub repository instead of an unpacked tarball. This is also the recommended way to prepare a contribution, since pull requests are submitted against the *develop* branch.

Information that only applies to your own setup, e.g. the location of your build folder, the names of your git remotes, or additional checkouts created with `git worktree`, should not go into these shared files. Keep it in a local file that is ignored by git, e.g. `CLAUDE.local.md` in the top-level folder for Claude Code.

4.28.2 Verify, do not trust

Coding agents are very good at producing code that looks plausible and at explaining convincingly why it is correct. Neither is proof that it works. The following habits have caught many errors in agent-written code:

- Ask for tests that demonstrate a bug fix: the new or modified test must fail with the unmodified code and pass with the fix.
- Run changes to parallel code with several MPI processes and, where applicable, several OpenMP threads. Changes to communication or threading that look correct by inspection often fail in actual parallel runs.
- For changes that are not supposed to change results (refactoring, code cleanup, porting), compare the output with that of the unmodified code, ideally to the last digit.
- Check that the unit tests actually ran: CTest reports a test as passed even when all of its test cases were skipped, e.g. because a required package was not included in the build.

- Build and test the code yourself (or have the agent do it) before accepting a change suggested in an automated code review; a suggestion can be plausible and still be wrong.

4.28.3 Scope and organization of changes

- Many styles exist in several variants (e.g. for the OPENMP, KOKKOS, GPU, or OPT package) that were created by copying and adapting code. After a bug is found, ask the agent to check the base style, all its accelerated variants, and similar styles for the same problem.
- Agents tend to "improve" code next to what they were asked to change. Ask them to report such findings instead of fixing them right away, so you can decide whether they belong into the same pull request.
- Several small, related fixes can be combined into one pull request; unrelated changes are easier to review in separate pull requests.

4.28.4 Git and licensing

- Do not let an agent rewrite history that was already pushed (no `git rebase`, `git commit --amend`, or `git push --force` on published branches); bring branches up to date by merging instead.
- Disclose the use of AI tools only in the corresponding section of the pull request template. Do not add AI attribution lines (like `Co-Authored-By:`) to commit messages or pull request descriptions.
- Code added to LAMMPS must be compatible with its license (GNU GPL, version 2). Agents may reproduce code from other projects they have seen during training; ask them to name the sources they used and do not accept code copied from software with an incompatible license.

4.28.5 Keeping the instructions useful

When a session reveals a lesson that applies beyond the current task (a pitfall, a convention, a debugging technique), consider adding it to the instruction files as part of a pull request. Keep the always-read core file short, put rules for specific parts of the source tree into the matching `.github/instructions` file (with a stub in `.claude/rules` for new files), and put longer background material into `.github/dev-docs`. Information that an agent can easily obtain by reading the source code does not need to be repeated there.

Part III

Command Reference

CHAPTER

ONE

COMMANDS

1.1 angle_coeff command

1.1.1 Syntax

```
angle_coeff N args
```

- N = numeric angle type (see asterisk form below), or type label
- args = coefficients for one or more angle types

1.1.2 Examples

```
angle_coeff 1 300.0 107.0
angle_coeff * 5.0
angle_coeff 2*10 5.0

labelmap angle 1 hydroxyl
angle_coeff hydroxyl 300.0 107.0
```

1.1.3 Description

Specify the angle force field coefficients for one or more angle types. The number and meaning of the coefficients depends on the angle style. Angle coefficients can also be set in the data file read by the *read_data* command or in a restart file.

N can be specified in one of two ways. An explicit numeric value can be used, as in the first example above. Or *N* can be a type label, which is an alphanumeric string defined by the *labelmap* command or in a section of a data file read by the *read_data* command.

For numeric values only, a wild-card asterisk can be used to set the coefficients for multiple angle types. This takes the form "*" or "*n" or "n*" or "m*n". If *N* is the number of angle types, then an asterisk with no numeric values means all types from 1 to *N*. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to *N* (inclusive). A middle asterisk means all types from m to n (inclusive).

Note that using an *angle_coeff* command can override a previous setting for the same angle type. For example, these commands set the coeffs for all angle types, then overwrite the coeffs for just angle type 2:

```
angle_coeff * 200.0 107.0 1.2
angle_coeff 2 50.0 107.0
```

A line in a data file that specifies angle coefficients uses the exact same format as the arguments of the *angle_coeff* command in an input script, except that wild-card asterisks should not be used since coefficients for all *N* types must

be listed in the file. For example, under the "Angle Coeffs" section of a data file, the line that corresponds to the first example above would be listed as

```
1 300.0 107.0
```

The *angle_style class2* is an exception to this rule, in that an additional argument is used in the input script to allow specification of the cross-term coefficients. See its doc page for details.

The list of all angle styles defined in LAMMPS is given on the *angle_style* doc page. They are also listed in more compact form on the *Commands angle* doc page.

On either of those pages, click on the style to display the formula it computes and its coefficients as specified by the associated *angle_coeff* command.

1.1.4 Restrictions

This command must come after the simulation box is defined by a *read_data*, *read_restart*, or *create_box* command.

An angle style must be defined before any angle coefficients are set, either in the input script or in a data file.

1.1.5 Related commands

angle_style

1.1.6 Default

none

1.2 angle_style command

1.2.1 Syntax

```
angle_style style
```

- style = *none* or *zero* or *hybrid* or *amoeba* or *charmm* or *class2* or *class2xe* or *class2/p6* or *cosine* or *cosine/buck6d* or *cosine/delta* or *cosine/periodic* or *cosine/shift* or *cosine/shift/exp* or *cosine/squared* or *cosine/squared/restricted* or *cross* or *dipole* or *fourier* or *fourier/simple* or *gaussian* or *harmonic* or *lepton* or *mm3* or *quartic* or *spica* or *table*

1.2.2 Examples

```
angle_style harmonic
angle_style charmm
angle_style hybrid harmonic cosine
```

1.2.3 Description

Set the formula(s) LAMMPS uses to compute angle interactions between triplets of atoms, which remain in force for the duration of the simulation. The list of angle triplets is read in by a *read_data* or *read_restart* command from a data or restart file.

Hybrid models where angles are computed using different angle potentials can be setup using the *hybrid* angle style.

The coefficients associated with a angle style can be specified in a data or restart file or via the *angle_coeff* command.

All angle potentials store their coefficient data in binary restart files which means angle_style and *angle_coeff* commands do not need to be re-specified in an input script that restarts a simulation. See the *read_restart* command for details on how to do this. The one exception is that angle_style *hybrid* only stores the list of sub-styles in the restart file; angle coefficients need to be re-specified.

Note

When both an angle and pair style is defined, the *special_bonds* command often needs to be used to turn off (or weight) the pairwise interaction that would otherwise exist between 3 bonded atoms.

In the formulas listed for each angle style, *theta* is the angle between the three atoms in the angle.

Here is an alphabetic list of angle styles defined in LAMMPS. Click on the style to display the formula it computes and coefficients specified by the associated *angle_coeff* command.

Click on the style to display the formula it computes, any additional arguments specified in the angle_style command, and coefficients specified by the associated *angle_coeff* command.

There are also additional accelerated pair styles included in the LAMMPS distribution for faster performance on CPUs, GPUs, and KNLs. The individual style names on the *Commands angle* page are followed by one or more of (g,i,k,o,t) to indicate which accelerated styles exist.

- *none* - turn off angle interactions
- *zero* - topology but no interactions
- *hybrid* - define multiple styles of angle interactions
- *amoeba* - AMOEBA angle
- *charmm* - CHARMM angle
- *class2* - COMPASS (class 2) angle
- *class2xe* - ClassII-xe (class 2) angle
- *class2/p6* - COMPASS (class 2) angle expanded to 6th order
- *cosine* - angle with cosine term
- *cosine/buck6d* - same as cosine with Buckingham term between 1-3 atoms
- *cosine/delta* - angle with difference of cosines
- *cosine/periodic* - DREIDING angle
- *cosine/shift* - angle cosine with a shift
- *cosine/shift/exp* - cosine with shift and exponential term in spring constant
- *cosine/squared* - angle with cosine squared term
- *cosine/squared/restricted* - angle with restricted cosine squared term
- *cross* - cross term coupling angle and bond lengths
- *dipole* - angle that controls orientation of a point dipole
- *fourier* - angle with multiple cosine terms
- *fourier/simple* - angle with a single cosine term

- *gaussian* - multi-centered Gaussian-based angle potential
- *harmonic* - harmonic angle
- *lepton* - angle potential from evaluating a string
- *mesocnt* - piecewise harmonic and linear angle for bending-buckling of nanotubes
- *mm3* - anharmonic angle
- *mwlc* - meltable wormlike chain
- *quartic* - angle with cubic and quartic terms
- *spica* - harmonic angle with repulsive SPICA pair style between 1-3 atoms
- *table* - tabulated by angle

1.2.4 Restrictions

Angle styles can only be set for atom_styles that allow angles to be defined.

Most angle styles are part of the MOLECULE package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info. The doc pages for individual bond potentials tell if it is part of a package.

1.2.5 Related commands

angle_coeff

1.2.6 Default

```
angle_style none
```

1.3 angle_write command

1.3.1 Syntax

```
angle_write atype N file keyword
```

- atype = angle type
- N = # of values
- file = name of file to write values to
- keyword = section name in file for this set of tabulated values

1.3.2 Examples

```
angle_write 1  500 table.txt Harmonic_1
angle_write 3 1000 table.txt Harmonic_3
```

1.3.3 Description

Added in version 8Feb2023.

Write energy and force values to a file as a function of angle for the currently defined angle potential. Force in this context means the force with respect to the angle, not the force on individual atoms. This is useful for plotting the potential function or otherwise debugging its values. The resulting file can also be used as input for use with *angle style table*.

If the file already exists, the table of values is appended to the end of the file to allow multiple tables of energy and force to be included in one file. The individual sections may be identified by the *keyword*.

The energy and force values are computed for angles ranging from 0 degrees to 180 degrees for 3 interacting atoms forming an angle type atype, using the appropriate *angle_coeff* coefficients. N evenly spaced angles are used.

For example, for N = 6, values are computed at $\theta = 0, 36, 72, 108, 144, 180$.

The file is written in the format used as input for the *angle_style table* option with *keyword* as the section name. Each line written to the file lists an index number (1-N), an angle (in degrees), an energy (in energy units), and a force (in force units per radians^2). In case a new file is created, the first line will be a comment with a "DATE:" and "UNITS:" tag with the current date and *units* settings. For subsequent invocations of the *angle_write* command for the same file, data will be appended and the current units settings will be compared to the data from the header, if present. The *angle_write* will refuse to add a table to an existing file if the units are not the same.

1.3.4 Restrictions

All force field coefficients for angle and other kinds of interactions must be set before this command can be invoked.

The table of the angle energy and force data data is created by using a separate, internally created, new LAMMPS instance with a dummy system of 3 atoms for which the angle potential energy is computed after transferring the angle style and coefficients and arranging the three atoms into the corresponding geometries. The angle force is then determined from the potential energies through numerical differentiation. As a consequence of this approach, not all angle styles are compatible. The following conditions must be met:

- The angle style must be able to write its coefficients to a data file. This condition excludes for example *angle style hybrid* and *angle style table*.
- The potential function must not have any terms that depend on geometry properties other than the angle. This condition excludes for example *angle style class2* all angle types for *angle style charmm* that have non-zero Urey-Bradley terms. Please note that the *write_angle* command has no way of checking for this condition, so the resulting tables may be bogus if the requirement is not met. It is thus recommended to make careful tests for any created tables.

1.3.5 Related commands

angle_style table, *bond_write*, *dihedral_write*, *angle_style*, *angle_coeff*

1.3.6 Default

none

1.4 atom_modify command

1.4.1 Syntax

```
atom_modify keyword values ...
```

- one or more keyword/value pairs may be appended

- keyword = *id* or *map* or *first* or *sort*

```
id value = yes or no
map value = yes or array or hash
first value = group-ID = group whose atoms will appear first in internal atom lists
sort values = Nfreq binsize
  Nfreq = sort atoms spatially every this many time steps
  binsize = bin size for spatial sorting (distance units)
```

1.4.2 Examples

```
atom_modify map yes
atom_modify map hash sort 10000 2.0
atom_modify first colloid
```

1.4.3 Description

Modify certain attributes of atoms defined and stored within LAMMPS, in addition to what is specified by the *atom_style* command. The *id* and *map* keywords must be specified before a simulation box is defined; other keywords can be specified any time.

The *id* keyword determines whether non-zero atom IDs can be assigned to each atom. If the value is *yes*, which is the default, IDs are assigned, whether you use the *create atoms* or *read_data* or *read_restart* commands to initialize atoms. If the value is *no* the IDs for all atoms are assumed to be 0.

If atom IDs are used, they must all be positive integers. They should also be unique, though LAMMPS does not check for this. Typically they should also be consecutively numbered (from 1 to Natoms), though this is not required. Molecular *atom styles* are those that store bond topology information (styles bond, angle, molecular, full). These styles require atom IDs since the IDs are used to encode the topology. Some other LAMMPS commands also require the use of atom IDs. E.g. some many-body pair styles use them to avoid double computation of the I-J interaction between two atoms.

The only reason not to use atom IDs is if you are running an atomic simulation so large that IDs cannot be uniquely assigned. For a default LAMMPS build this limit is 2^31 or about 2 billion atoms. However, even in this case, you can use 64-bit atom IDs, allowing 2^63 or about 9e18 atoms, if you build LAMMPS with the - DLAMMPS_BIGBIG switch. This is described on the *Build_settings* doc page. If atom IDs are not used, they must be specified as 0 for all atoms, e.g. in a data or restart file.

Note

If a *triclinic simulation box* is used, atom IDs are required, due to how neighbor lists are built.

The *map* keyword determines how atoms with specific IDs are found when required. For example, the bond (angle, etc) methods need to find the local index of an atom with a specific global ID which is a bond (angle, etc) partner. LAMMPS performs this operation efficiently by creating a "map", which is either an *array* or *hash* table, as described below.

When the *map* keyword is not specified in your input script, LAMMPS only creates a map for *atom_styles* for molecular systems which have permanent bonds (angles, etc). No map is created for atomic systems, since it is normally not needed. However some LAMMPS commands require a map, even for atomic systems, and will generate an error if one does not exist. The *map* keyword thus allows you to force the creation of a map.

Specifying a value of *yes* will create either an array-style or hash-style map, depending on the size of the system. If no atom ID is larger than 1 million, then an array-style map is used, otherwise a hash-style map is used. Specifying a value of *array* or *hash* creates an array-style or hash-style map respectively, regardless of the size of the system.

For an array-style map, each processor stores a lookup table of length N, where N is the largest atom ID in the system. This is a fast, simple method for many simulations, but requires too much memory for large simulations. For a hash-style map, a hash table is created on each processor, which finds an atom ID in constant time (independent of the global number of atom IDs). It can be slightly slower than the *array* map, but its memory cost is proportional to the number of atoms owned by a processor, i.e. N/P when N is the total number of atoms in the system and P is the number of processors.

The *first* keyword allows a *group* to be specified whose atoms will be maintained as the first atoms in each processor's list of owned atoms. This in only useful when the specified group is a small fraction of all the atoms, and there are other operations LAMMPS is performing that will be sped-up significantly by being able to loop over the smaller set of atoms. Otherwise the reordering required by this option will be a net slow-down. The *neigh_modify include* and *comm_modify group* commands are two examples of commands that require this setting to work efficiently. Several *fixes*, most notably time integration fixes like *fix nve*, also take advantage of this setting if the group they operate on is the group specified by this command. Note that specifying "all" as the group-ID effectively turns off the *first* option.

It is OK to use the *first* keyword with a group that has not yet been defined, e.g. to use the atom_modify first command at the beginning of your input script. LAMMPS does not use the group until a simulation is run.

The *sort* keyword turns on a spatial sorting or reordering of atoms within each processor's subdomain every *Nfreq* timesteps. If *Nfreq* is set to 0, then sorting is turned off. Sorting can improve cache performance and thus speed-up a LAMMPS simulation, as discussed in a paper by *(Meloni)*. Its efficacy depends on the problem size (atoms/processor), how quickly the system becomes disordered, and various other factors. As a general rule, sorting is typically more effective at speeding up simulations of liquids as opposed to solids. In tests we have done, the speed-up can range from zero to 3-4x.

Reordering is performed every *Nfreq* timesteps during a dynamics run or iterations during a minimization. More precisely, reordering occurs at the first reneighboring that occurs after the target timestep. The reordering is performed locally by each processor, using bins of the specified *binsize*. If *binsize* is set to 0.0, then a binsize equal to half the *neighbor* cutoff distance (force cutoff plus skin distance) is used, which is a reasonable value. After the atoms have been binned, they are reordered so that atoms in the same bin are adjacent to each other in the processor's 1d list of atoms. When using neighbor style *multi*, the default is half of the largest cutoff. However, testing is encouraged as smaller values may improve performance.

The goal of this procedure is for atoms to put atoms close to each other in the processor's one-dimensional list of atoms that are also near to each other spatially. This can improve cache performance when pairwise interactions and neighbor lists are computed. Note that if bins are too small, there will be few atoms/bin. Likewise if bins are too large, there will be many atoms/bin. In both cases, the goal of cache locality will be undermined.

Note

Running a simulation with sorting on versus off should not change the simulation results in a statistical sense. However, a different ordering will induce round-off differences, which will lead to diverging trajectories over time when comparing two simulations. Various commands, particularly those which use random numbers (e.g. *velocity create*, and *fix langevin*), may generate (statistically identical) results which depend on the order in which atoms are processed. The order of atoms in a *dump* file will also typically change if sorting is enabled.

Note

When running simple pair-wise potentials like Lennard Jones on GPUs with the KOKKOS package, using a larger binsize (e.g. 2x larger than default) and a more frequent reordering than default (e.g. every 100 time steps) may improve performance.

1.4.4 Restrictions

The *first* and *sort* options cannot be used together. Since sorting is on by default, it will be turned off if the *first* keyword is used with a group-ID that is not "all".

1.4.5 Related commands

none

1.4.6 Default

By default, *id* is yes. By default, atomic systems (no bond topology info) do not use a map. For molecular systems (with bond topology info), the default is to use a map of either *array* or *hash* style depending on the size of the system, as explained above for the *map yes* keyword/value option. By default, a *first* group is not defined. By default, sorting is enabled with a frequency of 1000 and a binsize of 0.0, which means the maximum neighbor cutoff will be used to set the bin size. If no neighbor cutoff is defined, sorting will be turned off.

(Meloni) Meloni, Rosati and Colombo, J Chem Phys, 126, 121102 (2007).

1.5 atom_style command

1.5.1 Syntax

```
atom_style style args
```

- style = *amoeba* or *angle* or *apip* or *atomic* or *body* or *bond* or *charge* or *dielectric* or *dipole* or *dpd* or *edpd* or *electron* or *ellipsoid* or *full* or *line* or *mdpd* or *molecular* or *oxdna* or *peri* or *smd* or *sph* or *sphere* or *bpm/sphere* or *spin* or *tdpd* or *tri* or *template* or *hybrid*

```
args = none for any style except the following
  apip arg = conservative/thermostat (optional) for conservative APIP/lambda␣
↪thermostat APIP
  body args = bstyle bstyle-args
    bstyle = style of body particles
    bstyle-args = additional arguments specific to the bstyle
                  see the Howto body doc
                  page for details
  sphere arg = 0/1 (optional) for static/dynamic particle radii
  bpm/sphere arg = 0/1 (optional) for static/dynamic particle radii
  tdpd arg = Nspecies
    Nspecies = # of chemical species
  template arg = template-ID
    template-ID = ID of molecule template specified in a separate molecule command
  hybrid args = list of one or more sub-styles, each with their args
  ellipsoid arg = superellipsoid (optional) for superellipsoids instead of␣
↪ellipsoids
```

- accelerated styles (with same args) = *angle/kk* or *atomic/kk* or *bond/kk* or *charge/kk* or *full/kk* or *molecular/kk* or *spin/kk*

1.5.2 Examples

```
atom_style atomic
atom_style bond
atom_style full
atom_style body nparticle 2 10
atom_style hybrid charge bond
atom_style hybrid charge body nparticle 2 5
atom_style spin
atom_style template myMols
atom_style hybrid template twomols charge
atom_style tdpd 2
```

1.5.3 Description

The *atom_style* command selects which per-atom attributes are associated with atoms in a LAMMPS simulation and thus stored and communicated with those atoms as well as read from and stored in data and restart files. Different models (e.g. *pair styles*) require access to specific per-atom attributes and thus require a specific atom style. For example, to compute Coulomb interactions, the atom must have a "charge" (aka "q") attribute.

A number of distinct atom styles exist that combine attributes. Some atom styles are a superset of other atom styles. Further attributes may be added to atoms either via using a hybrid style which provides a union of the attributes of the sub-styles, or via the *fix property/atom* command. The *atom_style* command must be used before a simulation is setup via a *read_data*, *read_restart*, or *create_box* command.

Note

Many of the atom styles discussed here are only enabled if LAMMPS was built with a specific package, as listed below in the Restrictions section.

Once a style is selected and the simulation box defined, it cannot be changed but only augmented with the *fix property/atom* command. So one should select an atom style general enough to encompass all attributes required. E.g. with atom style *bond*, it is not possible to define angles and use angle styles.

It is OK to use a style more general than needed, though it may be slightly inefficient because it will allocate and communicate additional unused data.

1.5.4 Atom style attributes

The atom style *atomic* has the minimum subset of per-atom attributes and is also the default setting. It encompasses the following per-atom attributes (name of the vector or array in the *Atom class* is given in parenthesis): atom-ID (tag), type (type), position (x), velocities (v), forces (f), image flags (image), group membership (mask). Since all atom styles are a superset of atom style *atomic*, they all include these attributes.

This table lists all the available atom styles, which attributes they provide, which *package* is required to use them, and what the typical applications are that use them. See the *read_data*, *create_atoms*, and *set* commands for details on how to set these various quantities. More information about many of the styles is provided in the Additional Information section below.

Atom style	Attributes	Required package	Applications
amoeba	*full* + "1-5 special neighbor data"	*AMOEBA*	AMOEBA/HIPPO force fields
angle	*bond* + "angle data"	*MOLECULE*	bead-spring polymers with stiffness
apip thermostat	*atomic* + apip_lambda, apip_lambda_required, apip_lambda_input, apip_lambda_const, apip_lambda_input_ta, apip_e_fast, apip_e_precise, apip_f_const_lambda, apip_f_dyn_lambda	*APIP*	adaptive-precision interatomic potentials(APIP) with a *lambda thermostat*, see *APIP howto*
apip conservative	*atomic* + apip_lambda, apip_lambda_required, apip_e_fast, apip_e_precise	*APIP*	conservative adaptive-precision interatomic potentials(APIP), see *APIP howto*
atomic	tag, type, x, v, f, image, mask		atomic liquids, solids, metals
body	*atomic* + radius, rmass, angmom, torque, body	*BODY*	arbitrary bodies, see *body howto*
bond	*atomic* + molecule, nspecial, special + "bond data"	*MOLECULE*	bead-spring polymers
bpm/sphere	*bond* + radius, rmass, omega, torque, quat	*BPM*	granular bonded particle models, see *BPM howto*
charge	*atomic* + q		atomic systems with charges
dielectric	*full* + mu, area, ed, em, epsilon, curvature, q_scaled	*DIELECTRIC*	systems with surface polarization
dipole	*charge* + mu	*DIPOLE*	atomic systems with charges and point dipoles
dpd	*atomic* + rho + "reactive DPD data"	*DPD-REACT*	reactive DPD
edpd	*atomic* + "eDPD data"	*DPD-MESO*	Energy conservative DPD (eDPD)
electron	*charge* + espin, eradius, ervel, erforce	*EFF*	Electron force field systems
ellipsoid	*atomic* + rmass, angmom, torque, ellipsoid		aspherical particles
full	*molecular* + q	*MOLECULE*	molecular force fields
line	*atomic* + molecule, radius, rmass, omega, torque, line		2-d rigid body particles
mdpd	*atomic* + rho, drho, vest	*DPD-MESO*	Many-body DPD (mDPD)
molecular	*angle* + "dihedral and improper data"	*MOLECULE*	apolar and uncharged molecules
oxdna	*atomic* + id5p	*CG-DNA*	coarse-grained DNA and RNA models
peri	*atomic* + rmass, vfrac, s0, x0	*PERI*	mesoscopic Peridynamics models
smd	*atomic* + molecule, radius, rmass + "smd data"	*MACHDYN*	Smooth Mach Dynamics models
rheo	*atomic* + rho, status	*RHEO*	solid and fluid RHEO particles
rheo/thermal	*atomic* + rho, status, energy, temperature	*RHEO*	RHEO particles with temperature
sph	*atomic* + "sph data"	*SPH*	Smoothed particle hydrodynamics models
sphere	*atomic* + radius, rmass, omega, torque		finite size spherical particles, e.g. granular models
spin	*atomic* + "magnetic moment data"	*SPIN*	magnetic particles

continues on next page

Table 1 – continued from previous page

Atom style	Attributes	Required package	Applications
tdpd	*atomic* + cc, cc_flux, vest	*DPD-MESO*	Transport DPD (tDPD)
template	*atomic* + molecule, molindex, molatom	*MOLECULE*	molecular systems where attributes are taken from *molecule files*
tri	*sphere* + molecule, angmom, tri		3-d triangulated rigid body LJ particles

Note

It is possible to add some attributes, such as a molecule ID and charge, to atom styles that do not have them built in using the *fix property/atom* command. This command also allows new custom-named attributes consisting of extra integer or floating-point values or vectors to be added to atoms. See the *fix property/atom* page for examples of cases where this is useful and details on how to initialize, access, and output these custom values.

1.5.5 Particle size and mass

All of the atom styles define point particles unless they (1) define finite-size spherical particles via the *radius* attribute, or (2) define finite-size aspherical particles (e.g. the *body*, *ellipsoid*, *line*, and *tri* styles). Most of these styles can also be used with mixtures of point and finite-size particles.

Note that the *radius* property may need to be provided as a *diameter* (e.g. in *molecule files* or *data files*). See the *Howto spherical* page for an overview of using finite-size spherical and aspherical particle models with LAMMPS.

Unless an atom style defines the per-atom *rmass* attribute, particle masses are defined on a per-type basis, using the *mass* command. This means each particle's mass is indexed by its atom *type*.

A few styles define the per-atom *rmass* attribute which can also be added using the *fix property/atom* command. In this case each particle stores its own mass. Atom styles that have a per-atom rmass may define it indirectly through setting particle diameter and density on a per-particle basis. If both per-type mass and per-atom *rmass* are defined (e.g. in a hybrid style), the per-atom mass will take precedence in any operation which which works with both flavors of mass.

1.5.6 Additional information about specific atom styles

Changed in version 30Mar2026.

For the *apip* style, one can choose between the style for conservative potentials and the style for the *lambda thermostat*. The *Howto apip* describes the differences between both use cases.

For the *body* style, the particles are arbitrary bodies with internal attributes defined by the "style" of the bodies, which is specified by the *bstyle* argument. Body particles can represent complex entities, such as surface meshes of discrete points, collections of sub-particles, deformable objects, etc.

The *Howto body* page describes the body styles LAMMPS currently supports, and provides more details as to the kind of body particles they represent. For all styles, each body particle stores moments of inertia and a quaternion 4-vector, so that its orientation and position can be time integrated due to forces and torques.

Note that there may be additional arguments required along with the *bstyle* specification, in the atom_style body command. These arguments are described on the *Howto body* doc page.

For the *dielectric* style, each particle can be either a physical particle (e.g. an ion), or an interface particle representing a boundary element between two regions of different dielectric constant. For interface particles, in addition to the properties associated with atom_style full, each particle also should be assigned a unit dipole vector (mu) representing

the direction of the induced dipole moment at each interface particle, an area (area/patch), the difference and mean of the dielectric constants of two sides of the interface along the direction of the normal vector (ed and em), the local dielectric constant at the boundary element (epsilon), and a mean local curvature (curv). Physical particles must be assigned these values, as well, but only their local dielectric constants will be used; see documentation for associated *pair styles* and *fixes*. The distinction between the physical and interface particles is only meaningful when *fix polarize* commands are applied to the interface particles. This style is part of the DIELECTRIC package.

For the *dipole* style, a point dipole vector mu is defined for each point particle. Note that if you wish the particles to be finite-size spheres as in a Stockmayer potential for a dipolar fluid, so that the particles can rotate due to dipole-dipole interactions, then you need to use the command *atom_style hybrid sphere dipole*, which will assign both a diameter and dipole moment to each particle. This also requires using an integrator with a "/sphere" suffix like *fix nve/sphere* or *fix nvt/sphere* and the "update dipole" or "update dlm" parameters to the fix commands.

The *dpd* style is for reactive dissipative particle dynamics (DPD) particles. Note that it is part of the DPD-REACT package, and is not required for use with the *pair_style dpd or dpd/stat* commands, which only require the attributes from atom_style *atomic*. Atom_style *dpd* extends DPD particle properties with internal temperature (dpdTheta), internal conductive energy (uCond), internal mechanical energy (uMech), and internal chemical energy (uChem).

The *edpd* style is for energy-conserving dissipative particle dynamics (eDPD) particles which store a temperature (edpd_temp), and heat capacity (edpd_cv).

For the *electron* style, the particles representing electrons are 3d Gaussians with a specified position and bandwidth or uncertainty in position, which is represented by the eradius = electron size.

For the *ellipsoid* style, particles can be ellipsoids which each stores a shape vector with the 3 diameters of the ellipsoid and a quaternion 4-vector with its orientation. Each particle stores a flag in the ellipsoid vector which indicates whether it is an ellipsoid (1) or a point particle (0).

Added in version 30Mar2026.

By adding the flag *superellipsoid* to the *ellipsoid* atom_style command, the particles can be superellipsoids, which are a generalization of ellipsoids with two additional blockiness parameters that control the shape. Superellipsoids also store the principal moments of inertia of the particle. The *superellipsoid* option is not supported by the KOKKOS package version of the *ellipsoid* atom style, which will stop with an error message when the option is used.

For the *line* style, particles can be are idealized line segments which store a per-particle mass and length and orientation (i.e. the end points of the line segment). Each particle stores a flag in the line vector which indicates whether it is a line segment (1) or a point particle (0).

The *mdpd* style is for many-body dissipative particle dynamics (mDPD) particles which store a density (rho) for considering density-dependent many-body interactions.

The *oxdna* style is for coarse-grained nucleotides and stores the 3'-to-5' polarity of the nucleotide strand, which is set through the bond topology in the data file. The first (second) atom in a bond definition is understood to point towards the 3'-end (5'-end) of the strand.

For the *peri* style, the particles are spherical and each stores a per-particle mass and volume.

The *smd* style is for Smooth Particle Mach dynamics. Both fluids and solids can be modeled. Particles store the mass and volume of an integration point, a kernel diameter used for calculating the field variables (e.g. stress and deformation) and a contact radius for calculating repulsive forces which prevent individual physical bodies from penetrating each other.

The *sph* style is for smoothed particle hydrodynamics (SPH) particles which store a density (rho), energy (esph), and heat capacity (cv).

For the *spin* style, a magnetic spin is associated with each atom. Those spins have a norm (their magnetic moment) and a direction.

The *tdpd* style is for transport dissipative particle dynamics (tDPD) particles which store a set of chemical concentration. An integer "cc_species" is required to specify the number of chemical species involved in a tDPD system.

The *wavepacket* style is similar to the *electron* style, but the electrons may consist of several Gaussian wave packets, summed up with coefficients cs= (cs_re,cs_im). Each of the wave packets is treated as a separate particle in LAMMPS, wave packets belonging to the same electron must have identical *etag* values.

The *sphere* and *bpm/sphere* styles allow particles to be either point particles or finite-size particles. If the *radius* attribute is > 0.0, the particle is a finite-size sphere. If the diameter = 0.0, it is a point particle. Note that by using the *disc* keyword with the *fix nve/sphere*, *fix nvt/sphere*, *fix nph/sphere*, *fix npt/sphere* commands for the *sphere* style, spheres can be effectively treated as 2d discs for a 2d simulation if desired. See also the *set density/disc* command. These styles also take an optional 0 or 1 argument. A value of 0 means the radius of each sphere is constant for the duration of the simulation (this is the default). A value of 1 means the radii may vary dynamically during the simulation, e.g. due to use of the *fix adapt* command.

The *template* style allows molecular topology (bonds,angles,etc) to be defined via a molecule template using the *molecule* command. The template stores one or more molecules with a single copy of the topology info (bonds,angles,etc) of each. Individual atoms only store a template index and template atom to identify which molecule and which atom-within-the-molecule they represent. Using the *template* style instead of the *bond*, *angle*, *molecular* styles can save memory for systems comprised of a large number of small molecules, all of a single type (or small number of types). See the paper by Grime and Voth, in *(Grime)*, for examples of how this can be advantageous for large-scale coarse-grained systems. The `examples/template` directory has a few demo inputs and examples showing the use of the *template* atom style versus *molecular*.

Note

When using the *template* style with a *molecule template* that contains multiple molecules, you should ensure the atom types, bond types, angle_types, etc in all the molecules are consistent. E.g. if one molecule represents H2O and another CO2, then you probably do not want each molecule file to define two atom types and a single bond type, because they will conflict with each other when a mixture system of H2O and CO2 molecules is defined, e.g. by the *read_data* command. Rather the H2O molecule should define atom types 1 and 2, and bond type 1. And the CO2 molecule should define atom types 3 and 4 (or atom types 3 and 2 if a single oxygen type is desired), and bond type 2.

For the *tri* style, particles can be planar triangles which each stores a per-particle mass and size and orientation (i.e. the corner points of the triangle). Each particle stores a flag in the tri vector which indicates whether it is a triangle (1) or a point particle (0).

Typically, simulations require only a single (non-hybrid) atom style. If some atoms in the simulation do not have all the properties defined by a particular style, use the simplest style that defines all the needed properties by any atom. For example, if some atoms in a simulation are charged, but others are not, use the *charge* style. If some atoms have bonds, but others do not, use the *bond* style.

The only scenario where the *hybrid* style is needed is if there is no single style which defines all needed properties of all atoms. For example, as mentioned above, if you want dipolar particles which will rotate due to torque, you need to use "atom_style hybrid sphere dipole". When a hybrid style is used, atoms store and communicate the union of all quantities implied by the individual styles.

When using the *hybrid* style, you cannot combine the *template* style with another molecular style that stores bond, angle, etc info on a per-atom basis.

LAMMPS can be extended with new atom styles as well as new body styles; see the corresponding manual page on *modifying & extending LAMMPS*.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages*

page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

1.5.7 Restrictions

This command cannot be used after the simulation box is defined by a *read_data* or *create_box* command.

Many of the styles listed above are only enabled if LAMMPS was built with a specific package, as listed below. See the *Build package* page for more info. The table above lists which package is required for individual atom styles.

1.5.8 Related commands

read_data, *pair_style*, *fix property/atom*, *set*

1.5.9 Default

The default atom style is *atomic*. If atom_style *sphere* or *bpm/sphere* is used, its default argument is 0. If atom_style *apip* is used, its default argument is 'thermostat'.

(Grime) Grime and Voth, to appear in J Chem Theory & Computation (2014).

1.6 balance command

1.6.1 Syntax

```
balance thresh style args ... keyword args ...
```

- thresh = imbalance threshold that must be exceeded to perform a re-balance
- one style/arg pair can be used (or multiple for *x*,*y*,*z*)
- style = *x* or *y* or *z* or *shift* or *rcb*

```
  x args = uniform or Px-1 numbers between 0 and 1
    uniform = evenly spaced cuts between processors in x dimension
    numbers = Px-1 ascending values between 0 and 1, Px - # of processors in x␣
  ↪dimension
    x can be specified together with y or z
  y args = uniform or Py-1 numbers between 0 and 1
    uniform = evenly spaced cuts between processors in y dimension
    numbers = Py-1 ascending values between 0 and 1, Py - # of processors in y␣
  ↪dimension
    y can be specified together with x or z
  z args = uniform or Pz-1 numbers between 0 and 1
    uniform = evenly spaced cuts between processors in z dimension
```

```
    numbers = Pz-1 ascending values between 0 and 1, Pz - # of processors in z␣
  ↪dimension
    z can be specified together with x or y
  shift args = dimstr Niter stopthresh
    dimstr = sequence of letters containing "x" or "y" or "z", each not more than once
    Niter = # of times to iterate within each dimension of dimstr sequence
    stopthresh = stop balancing when this imbalance threshold is reached
  rcb args = none
```

- zero or more keyword/arg pairs may be appended
- keyword = *weight* or *out*

```
  weight style args = use weighted particle counts for the balancing
    style = group or neigh or time or var or store
      group args = Ngroup group1 weight1 group2 weight2 ...
        Ngroup = number of groups with assigned weights
        group1, group2, ... = group IDs
        weight1, weight2, ...   = corresponding weight factors
      neigh factor = compute weight based on number of neighbors
        factor = scaling factor (> 0)
      time factor = compute weight based on time spend computing
        factor = scaling factor (> 0)
      var name = take weight from atom-style variable
        name = name of the atom-style variable
      store name = store weight in custom atom property defined by fix property/atom␣
  ↪command
        name = atom property name (without d_ prefix)
  sort arg = no or yes
  out arg = filename
    filename = write each processor's subdomain to a file
```

1.6.2 Examples

```
balance 0.9 x uniform y 0.4 0.5 0.6
balance 1.2 shift xz 5 1.1
balance 1.0 shift xz 5 1.1
balance 1.1 rcb
balance 1.0 shift x 10 1.1 weight group 2 fast 0.5 slow 2.0
balance 1.0 shift x 10 1.1 weight time 0.8 weight neigh 0.5 weight store balance
balance 1.0 shift x 20 1.0 out tmp.balance
```

1.6.3 Description

This command adjusts the size and shape of processor subdomains within the simulation box, to attempt to balance the number of atoms or particles and thus indirectly the computational cost (load) more evenly across processors. The load balancing is "static" in the sense that this command performs the balancing once, before or between simulations. The processor subdomains will then remain static during the subsequent run. To perform "dynamic" balancing, see the *fix balance* command, which can adjust processor subdomain sizes and shapes on-the-fly during a *run*.

Load-balancing is typically most useful if the particles in the simulation box have a spatially-varying density distribution or when the computational cost varies significantly between different particles. E.g. a model of a vapor/liquid interface, or a solid with an irregular-shaped geometry containing void regions, or *hybrid pair style simulations* which combine pair styles with different computational cost. In these cases, the LAMMPS default of dividing the simulation box volume into a regular-spaced grid of 3d bricks, with one equal-volume subdomain per processor, may assign numbers

of particles per processor in a way that the computational effort varies significantly. This can lead to poor performance when the simulation is run in parallel.

The balancing can be performed with or without per-particle weighting. With no weighting, the balancing attempts to assign an equal number of particles to each processor. With weighting, the balancing attempts to assign an equal aggregate computational weight to each processor, which typically induces a different number of atoms assigned to each processor. Details on the various weighting options and examples for how they can be used are *given below*.

Note that the *processors* command allows some control over how the box volume is split across processors. Specifically, for a Px by Py by Pz grid of processors, it allows choice of Px, Py, and Pz, subject to the constraint that Px * Py * Pz = P, the total number of processors. This is sufficient to achieve good load-balance for some problems on some processor counts. However, all the processor subdomains will still have the same shape and same volume.

The requested load-balancing operation is only performed if the current "imbalance factor" in particles owned by each processor exceeds the specified *thresh* parameter. The imbalance factor is defined as the maximum number of particles (or weight) owned by any processor, divided by the average number of particles (or weight) per processor. Thus an imbalance factor of 1.0 is perfect balance.

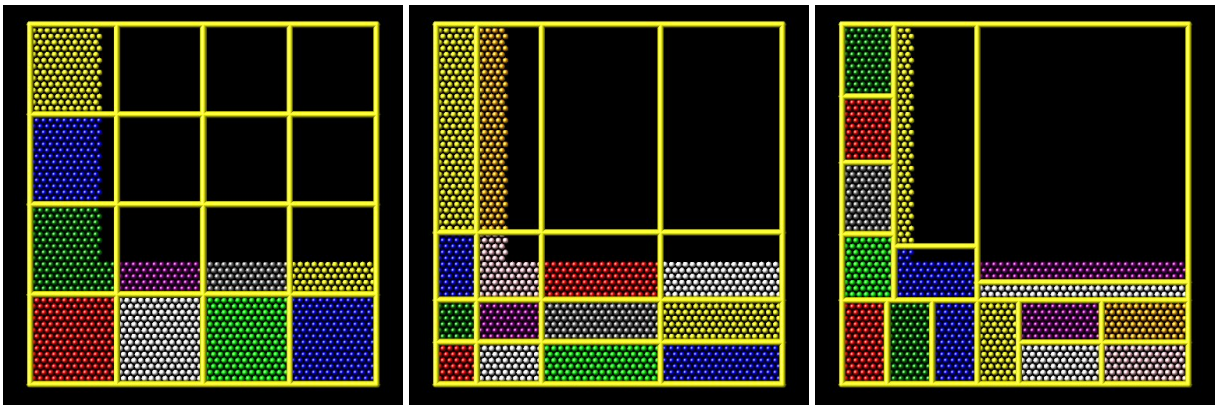
As an example, for 10000 particles running on 10 processors, if the most heavily loaded processor has 1200 particles, then the factor is 1.2, meaning there is a 20% imbalance. Note that a re-balance can be forced even if the current balance is perfect (1.0) be specifying a *thresh* < 1.0.

Note

Balancing is performed even if the imbalance factor does not exceed the *thresh* parameter if a "grid" style is specified when the current partitioning is "tiled". The meaning of "grid" vs "tiled" is explained below. This is to allow forcing of the partitioning to "grid" so that the *comm_style brick* command can then be used to replace a current *comm_style tiled* setting.

When the balance command completes, it prints statistics about the result, including the change in the imbalance factor and the change in the maximum number of particles on any processor. For "grid" methods (defined below) that create a logical 3d grid of processors, the positions of all cutting planes in each of the 3 dimensions (as fractions of the box length) are also printed.

Note



This command attempts to minimize the imbalance factor, as defined above. But depending on the method a perfect balance (1.0) may not be achieved. For example, "grid" methods (defined below) that create a logical 3d grid cannot achieve perfect balance for many irregular distributions of particles. Likewise, if a portion of the system is a perfect lattice, e.g. the initial system is generated by the *create_atoms* command, then "grid" methods may be unable to achieve exact balance. This is because entire lattice planes will be owned or not owned by a single processor.

Note

The imbalance factor is also an estimate of the maximum speed-up you can hope to achieve by running a perfectly balanced simulation versus an imbalanced one. In the example above, the 10000 particle simulation could run up to 20% faster if it were perfectly balanced, versus when imbalanced. However, computational cost is not strictly proportional to particle count, and changing the relative size and shape of processor subdomains may lead to additional computational and communication overheads, e.g. in the PPPM solver used via the *kspace_style* command. Thus you should benchmark the run times of a simulation before and after balancing.

The method used to perform a load balance is specified by one of the listed styles (or more in the case of *x*,*y*,*z*), which are described in detail below. There are 2 kinds of styles.

The *x*, *y*, *z*, and *shift* styles are "grid" methods which produce a logical 3d grid of processors. They operate by changing the cutting planes (or lines) between processors in 3d (or 2d), to adjust the volume (area in 2d) assigned to each processor, as in the following 2d diagram where processor subdomains are shown and particles are colored by the processor that owns them.

The leftmost diagram is the default partitioning of the simulation box across processors (one sub-box for each of 16 processors); the middle diagram is after a "grid" method has been applied. The *rcb* style is a "tiling" method which does not produce a logical 3d grid of processors. Rather it tiles the simulation domain with rectangular sub-boxes of varying size and shape in an irregular fashion so as to have equal numbers of particles (or weight) in each sub-box, as in the rightmost diagram above.

The "grid" methods can be used with either of the *comm_style* command options, *brick* or *tiled*. The "tiling" methods can only be used with *comm_style tiled*. Note that it can be useful to use a "grid" method with *comm_style tiled* to return the domain partitioning to a logical 3d grid of processors so that "comm_style brick" can afterwards be specified for subsequent *run* commands.

When a "grid" method is specified, the current domain partitioning can be either a logical 3d grid or a tiled partitioning. In the former case, the current logical 3d grid is used as a starting point and changes are made to improve the imbalance factor. In the latter case, the tiled partitioning is discarded and a logical 3d grid is created with uniform spacing in all dimensions. This becomes the starting point for the balancing operation.

When a "tiling" method is specified, the current domain partitioning ("grid" or "tiled") is ignored, and a new partitioning is computed from scratch.

The *x*, *y*, and *z* styles invoke a "grid" method for balancing, as described above. Note that any or all of these 3 styles can be specified together, one after the other, but they cannot be used with any other style. This style adjusts the position of cutting planes between processor subdomains in specific dimensions. Only the specified dimensions are altered.

The *uniform* argument spaces the planes evenly, as in the left diagrams above. The *numeric* argument requires listing Ps-1 numbers that specify the position of the cutting planes. This requires knowing Ps = Px or Py or Pz = the number of processors assigned by LAMMPS to the relevant dimension. This assignment is made (and the Px, Py, Pz values printed out) when the simulation box is created by the "create_box" or "read_data" or "read_restart" command and is influenced by the settings of the *processors* command.

Each of the numeric values must be between 0 and 1, and they must be listed in ascending order. They represent the fractional position of the cutting place. The left (or lower) edge of the box is 0.0, and the right (or upper) edge is 1.0. Neither of these values is specified. Only the interior Ps-1 positions are specified. Thus is there are 2 processors in the x dimension, you specify a single value such as 0.75, which would make the left processor's subdomain 3x larger than the right processor's subdomain.

The *shift* style invokes a "grid" method for balancing, as described above. It changes the positions of cutting planes between processors in an iterative fashion, seeking to reduce the imbalance factor, similar to how the *fix balance shift* command operates.

The *dimstr* argument is a string of characters, each of which must be an "x" or "y" or "z". Each character can appear zero or one time, since there is no advantage to balancing on a dimension more than once. You should normally only list dimensions where you expect there to be a density variation in the particles.

Balancing proceeds by adjusting the cutting planes in each of the dimensions listed in *dimstr*, one dimension at a time. For a single dimension, the balancing operation (described below) is iterated on up to *Niter* times. After each dimension finishes, the imbalance factor is re-computed, and the balancing operation halts if the *stopthresh* criterion is met.

A re-balance operation in a single dimension is performed using a recursive multisectioning algorithm, where the position of each cutting plane (line in 2d) in the dimension is adjusted independently. This is similar to a recursive bisectioning for a single value, except that the bounds used for each bisectioning take advantage of information from neighboring cuts if possible. At each iteration, the count of particles on either side of each plane is tallied. If the counts do not match the target value for the plane, the position of the cut is adjusted to be halfway between a low and high bound. The low and high bounds are adjusted on each iteration, using new count information, so that they become closer together over time. Thus as the recursion progresses, the count of particles on either side of the plane gets closer to the target value.

After the balanced plane positions are determined, if any pair of adjacent planes are closer together than the neighbor skin distance (as specified by the *neigh_modify* command), then the plane positions are shifted to separate them by at least this amount. This is to prevent particles being lost when dynamics are run with processor subdomains that are too narrow in one or more dimensions.

Once the re-balancing is complete and final processor subdomains assigned, particles are migrated to their new owning processor, and the balance procedure ends.

Note

At each re-balance operation, the bisectioning for each cutting plane (line in 2d) typically starts with low and high bounds separated by the extent of a processor's subdomain in one dimension. The size of this bracketing region shrinks by 1/2 every iteration. Thus if *Niter* is specified as 10, the cutting plane will typically be positioned to 1 part in 1000 accuracy (relative to the perfect target position). For *Niter* = 20, it will be accurate to 1 part in a million. Thus there is no need to set *Niter* to a large value. LAMMPS will check if the threshold accuracy is reached (in a dimension) is less iterations than *Niter* and exit early. However, *Niter* should also not be set too small, since it will take roughly the same number of iterations to converge even if the cutting plane is initially close to the target value.

The *rcb* style invokes a "tiled" method for balancing, as described above. It performs a recursive coordinate bisectioning (RCB) of the simulation domain. The basic idea is as follows.

The simulation domain is cut into 2 boxes by an axis-aligned cut in one of the dimensions, leaving one new sub-box on either side of the cut. Which dimension is chosen for the cut depends on the particle (weight) distribution within the parent box. Normally the longest dimension of the box is cut, but if all (or most) of the particles are at one end of the box, a cut may be performed in another dimension to induce sub-boxes that are more cube-ish (3d) or square-ish (2d) in shape.

After the cut is made, all the processors are also partitioned into 2 groups, half assigned to the box on the lower side of the cut, and half to the box on the upper side. (If the processor count is odd, one side gets an extra processor.) The cut is positioned so that the number of (weighted) particles in the lower box is exactly the number that the processors assigned to that box should own for load balance to be perfect. This also makes load balance for the upper box perfect. The positioning of the cut is done iteratively, by a bisectioning method (median search). Note that counting particles on either side of the cut requires communication between all processors at each iteration.

That is the procedure for the first cut. Subsequent cuts are made recursively, in exactly the same manner. The subset of processors assigned to each box make a new cut in one dimension of that box, splitting the box, the subset of processors, and the particles in the box in two. The recursion continues until every processor is assigned a sub-box of the entire simulation domain, and owns the (weighted) particles in that sub-box.

This subsection describes how to perform weighted load balancing using the *weight* keyword.

By default, all particles have a weight of 1.0, which means each particle is assumed to require the same amount of computation during a timestep. There are, however, scenarios where this is not a good assumption. Measuring the computational cost for each particle accurately would be impractical and slow down the computation. Instead the *weight* keyword implements several ways to influence the per-particle weights empirically by properties readily available or using the user's knowledge of the system. Note that the absolute value of the weights are not important; only their relative ratios affect which particle is assigned to which processor. A particle with a weight of 2.5 is assumed to require 5x more computational than a particle with a weight of 0.5. For all the options below the weight assigned to a particle must be a positive value; an error will be be generated if a weight is <= 0.0.

Below is a list of possible weight options with a short description of their usage and some example scenarios where they might be applicable. It is possible to apply multiple weight flags and the weightings they induce will be combined through multiplication. Most of the time, however, it is sufficient to use just one method.

The *group* weight style assigns weight factors to specified *groups* of particles. The *group* style keyword is followed by the number of groups, then pairs of group IDs and the corresponding weight factor. If a particle belongs to none of the specified groups, its weight is not changed. If it belongs to multiple groups, its weight is the product of the weight factors.

This weight style is useful in combination with pair style *hybrid*, e.g. when combining a more costly many-body potential with a fast pairwise potential. It is also useful when using *run_style respa* where some portions of the system have many bonded interactions and others none. It assumes that the computational cost for each group remains constant over time. This is a purely empirical weighting, so a series test runs to tune the assigned weight factors for optimal performance is recommended.

The *neigh* weight style assigns the same weight to each particle owned by a processor based on the total count of neighbors in the neighbor list owned by that processor. The motivation is that more neighbors means a higher computational cost. The style does not use neighbors per atom to assign a unique weight to each atom, because that value can vary depending on how the neighbor list is built.

The *factor* setting is applied as an overall scale factor to the *neigh* weights which allows adjustment of their impact on the balancing operation. The specified *factor* value must be positive. A value > 1.0 will increase the weights so that the ratio of max weight to min weight increases by *factor*. A value < 1.0 will decrease the weights so that the ratio of max weight to min weight decreases by *factor*. In both cases the intermediate weight values increase/decrease proportionally as well. A value = 1.0 has no effect on the *neigh* weights. As a rule of thumb, we have found a *factor* of about 0.8 often results in the best performance, since the number of neighbors is likely to overestimate the ideal weight.

This weight style is useful for systems where there are different cutoffs used for different pairs of interactions, or the density fluctuates, or a large number of particles are in the vicinity of a wall, or a combination of these effects. If a simulation uses multiple neighbor lists, this weight style will use the first suitable neighbor list it finds. It will not request or compute a new list. A warning will be issued if there is no suitable neighbor list available or if it is not current, e.g. if the balance command is used before a *run* or *minimize* command is used, in which case the neighbor list may not yet have been built. In this case no weights are computed. Inserting a *run 0 post no* command before issuing the *balance* command, may be a workaround for this case, as it will induce the neighbor list to be built.

The *time* weight style uses *timer data* to estimate weights. It assigns the same weight to each particle owned by a processor based on the total computational time spent by that processor. See details below on what time window is used. It uses the same timing information as is used for the *MPI task timing breakdown*, namely, for sections *Pair*, *Bond*, *Kspace*, and *Neigh*. The time spent in those portions of the timestep are measured for each MPI rank, summed, then divided by the number of particles owned by that processor. I.e. the weight is an effective CPU time/particle averaged over the particles on that processor.

The *factor* setting is applied as an overall scale factor to the *time* weights which allows adjustment of their impact on the balancing operation. The specified *factor* value must be positive. A value > 1.0 will increase the weights so that the ratio of max weight to min weight increases by *factor*. A value < 1.0 will decrease the weights so that the ratio of max weight to min weight decreases by *factor*. In both cases the intermediate weight values increase/decrease proportionally as well. A value = 1.0 has no effect on the *time* weights. As a rule of thumb, effective values to use are typically between 0.5 and 1.2. Note that the timer quantities mentioned above can be affected by communication which occurs in the middle of the operations, e.g. pair styles with intermediate exchange of data within the force computation, and likewise for KSpace solves.

When using the *time* weight style with the *balance* command, the timing data is taken from the preceding run command, i.e. the timings are for the entire previous run. For the *fix balance* command the timing data is for only the timesteps since the last balancing operation was performed. If timing information for the required sections is not available, e.g. at the beginning of a run, or when the *timer* command is set to either *loop* or *off*, a warning is issued. In this case no weights are computed.

Note

The *time* weight style is the most generic option, and should be tried first, unless the *group* style is easily applicable. However, since the computed cost function is averaged over all particles on a processor, the weights may not be highly accurate. This style can also be effective as a secondary weight in combination with either *group* or *neigh* to offset some of inaccuracies in either of those heuristics.

The *var* weight style assigns per-particle weights by evaluating an *atom-style variable* specified by *name*. This is provided as a more flexible alternative to the *group* weight style, allowing definition of a more complex heuristics based on information (global and per atom) available inside of LAMMPS. For example, atom-style variables can reference the position of a particle, its velocity, the volume of its Voronoi cell, etc.

The *store* weight style does not compute a weight factor. Instead it stores the current accumulated weights in a custom per-atom vector specified by *name*. This must be a vector defined as *d_name* via the *fix property/atom* command. This means the values in the vector can be read as part of a data file with the *read_data* command or specified with the *set* command. These weights can also be output in a *dump* file, so this is a way to examine, debug, or visualize the per-particle weights used during the load-balancing operation.

Note that the name of the custom per-atom vector is specified just as *name*, not as *d_name* as it is for other commands that use different kinds of custom atom vectors or arrays as arguments.

The *sort* keyword determines whether the communication of per-atom data to other processors during load-balancing will be random or deterministic. Random is generally faster; deterministic will ensure the new ordering of atoms on each processor is the same each time the same simulation is run. This can be useful for debugging purposes. Since the balance command is a one-time operation, the default is *yes* to perform sorting.

The *out* keyword writes a text file to the specified *filename* with the results of the balancing operation. The file contains the bounds of the subdomain for each processor after the balancing operation completes. The format of the file is compatible with the Pizza.py *mdump* tool which has support for manipulating and visualizing mesh files. An example is shown here for a balancing by 4 processors for a 2d problem:

```
ITEM: TIMESTEP
0
ITEM: NUMBER OF NODES
16
ITEM: BOX BOUNDS
0 10
0 10
```

(continues on next page)

(continued from previous page)

```
0 10
ITEM: NODES
1 1 0 0 0
2 1 5 0 0
3 1 5 5 0
4 1 0 5 0
5 1 5 0 0
6 1 10 0 0
7 1 10 5 0
8 1 5 5 0
9 1 0 5 0
10 1 5 5 0
11 1 5 10 0
12 1 10 5 0
13 1 5 5 0
14 1 10 5 0
15 1 10 10 0
16 1 5 10 0
ITEM: TIMESTEP
0
ITEM: NUMBER OF SQUARES
4
ITEM: SQUARES
1 1 1 2 3 4
2 1 5 6 7 8
3 1 9 10 11 12
4 1 13 14 15 16
```

The coordinates of all the vertices are listed in the NODES section, 5 per processor. Note that the 4 subdomains share vertices, so there will be duplicate nodes in the list.

The "SQUARES" section lists the node IDs of the 4 vertices in a rectangle for each processor (1 to 4).

For a 3d problem, the syntax is similar with 8 vertices listed for each processor, instead of 4, and "SQUARES" replaced by "CUBES".

1.6.4 Restrictions

For 2d simulations, the *z* style cannot be used. Nor can a "z" appear in *dimstr* for the *shift* style.

Balancing through recursive bisectioning (*rcb* style) requires *comm_style tiled*

1.6.5 Related commands

group, *processors*, *fix balance*, *comm_style*

1.6.6 Default

The default setting is sort = yes.

1.7 bond_coeff command

1.7.1 Syntax

```
bond_coeff N args
```

- N = numeric bond type (see asterisk form below), or type label
- args = coefficients for one or more bond types

1.7.2 Examples

```
bond_coeff 5 80.0 1.2
bond_coeff * 30.0 1.5 1.0 1.0
bond_coeff 1*4 30.0 1.5 1.0 1.0
bond_coeff 1 harmonic 200.0 1.0 # (for bond_style hybrid)

labelmap bond 5 carbonyl
bond_coeff carbonyl 80.0 1.2
```

1.7.3 Description

Specify the bond force field coefficients for one or more bond types. The number and meaning of the coefficients depends on the bond style. Bond coefficients can also be set in the data file read by the *read_data* command or in a restart file.

N can be specified in one of several ways. An explicit numeric value can be used, as in the first example above. Or *N* can be a type label, which is an alphanumeric string defined by the *labelmap* command or in a section of a data file read by the *read_data* command.

For numeric values only, a wild-card asterisk can be used to set the coefficients for multiple bond types. This takes the form "*" or "*n" or "n*" or "m*n". If *N* is the number of bond types, then an asterisk with no numeric values means all types from 1 to *N*. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to *N* (inclusive). A middle asterisk means all types from m to n (inclusive).

Note that using a bond_coeff command can override a previous setting for the same bond type. For example, these commands set the coeffs for all bond types, then overwrite the coeffs for just bond type 2:

```
bond_coeff * 100.0 1.2
bond_coeff 2 200.0 1.2
```

A line in a data file that specifies bond coefficients uses the exact same format as the arguments of the bond_coeff command in an input script, except that wild-card asterisks should not be used since coefficients for all *N* types must be listed in the file. For example, under the "Bond Coeffs" section of a data file, the line that corresponds to the first example above would be listed as

```
5 80.0 1.2
```

The list of all bond styles defined in LAMMPS is given on the *bond_style* doc page. They are also listed in more compact form on the *Commands bond* doc page.

On either of those pages, click on the style to display the formula it computes and its coefficients as specified by the associated bond_coeff command.

1.7.4 Restrictions

This command must come after the simulation box is defined by a *read_data*, *read_restart*, or *create_box* command.

A bond style must be defined before any bond coefficients are set, either in the input script or in a data file.

1.7.5 Related commands

- args = none for any style except *hybrid*
  - *hybrid* args = list of one or more styles

1.8.2 Examples

```
bond_style harmonic
bond_style fene
bond_style hybrid harmonic fene
```

1.8.3 Description

Set the formula(s) LAMMPS uses to compute bond interactions between pairs of atoms. In LAMMPS, a bond differs from a pairwise interaction, which are set via the *pair_style* command. Bonds are defined between specified pairs of atoms and remain in force for the duration of the simulation (unless new bonds are created or existing bonds break, which is possible in some fixes and bond potentials). The list of bonded atoms is read in by a *read_data* or *read_restart* command from a data or restart file. By contrast, pair potentials are typically defined between all pairs of atoms within a cutoff distance and the set of active interactions changes over time.

Hybrid models where bonds are computed using different bond potentials can be setup using the *hybrid* bond style.

The coefficients associated with a bond style can be specified in a data or restart file or via the *bond_coeff* command.

All bond potentials store their coefficient data in binary restart files which means bond_style and *bond_coeff* commands do not need to be re-specified in an input script that restarts a simulation. See the *read_restart* command for details on how to do this. The one exception is that bond_style *hybrid* only stores the list of sub-styles in the restart file; bond coefficients need to be re-specified.

> **Note**
>
> When both a bond and pair style is defined, the *special_bonds* command often needs to be used to turn off (or weight) the pairwise interaction that would otherwise exist between two bonded atoms.

In the formulas listed for each bond style, r is the distance between the two atoms in the bond.

Here is an alphabetic list of bond styles defined in LAMMPS. Click on the style to display the formula it computes and coefficients specified by the associated *bond_coeff* command.

Click on the style to display the formula it computes, any additional arguments specified in the bond_style command, and coefficients specified by the associated *bond_coeff* command.

There are also additional accelerated pair styles included in the LAMMPS distribution for faster performance on CPUs, GPUs, and KNLs. The individual style names on the *Commands bond* doc page are followed by one or more of (g,i,k,o,t) to indicate which accelerated styles exist.

- *none* - turn off bonded interactions
- *zero* - topology but no interactions
- *hybrid* - define multiple styles of bond interactions
- *bpm/peri* - peridynamic constitutive models (PMB/LPS/VES/EPS) on the BPM framework
- *bpm/rotational* - breakable bond with forces and torques based on deviation from reference state
- *bpm/spring* - breakable bond with forces based on deviation from reference length
- *bpm/spring/plastic* - a similar breakable bond with plastic yield
- *bpm/zero* - BPM bond that stores state and breaks but applies no force
- *class2* - COMPASS (class 2) bond
- *fene* - FENE (finite-extensible non-linear elastic) bond
- *fene/expand* - FENE bonds with variable size particles
- *fene/nm* - FENE bonds with a generalized Lennard-Jones potential
- *gaussian* - multicentered Gaussian-based bond potential
- *gromos* - GROMOS force field bond
- *harmonic* - harmonic bond
- *harmonic/restrain* - harmonic bond to restrain to original bond distance
- *harmonic/shift* - shifted harmonic bond
- *harmonic/shift/cut* - shifted harmonic bond with a cutoff
- *lepton* - bond potential from evaluating a string
- *mesocnt* - Harmonic bond wrapper with parameterization presets for nanotubes
- *mm3* - MM3 anharmonic bond
- *morse* - Morse bond
- *nonlinear* - nonlinear bond
- *oxdna/fene* - modified FENE bond suitable for DNA modeling

- *oxdna2/fene* - same as oxdna but used with different pair styles
- *oxdna3/fene* - same as oxdna but used with different pair styles
- *oxrna2/fene* - modified FENE bond suitable for RNA modeling
- *quartic* - breakable quartic bond
- *quartic/exp* - quartic bond with optional exponential repulsion
- *rheo/shell* - shell bond for oxidation modeling in RHEO
- *special* - enable special bond exclusions for 1-5 pairs and beyond
- *table* - tabulated by bond length

1.8.4 Restrictions

Bond styles can only be set for atom styles that allow bonds to be defined.

Most bond styles are part of the MOLECULE package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info. The doc pages for individual bond potentials tell if it is part of a package.

1.8.5 Related commands

1.8.6 Default

```
bond_style none
```

1.9 bond_write command

1.9.1 Syntax

```
bond_write btype N inner outer file keyword itype jtype
```

- btype = bond type
- N = # of values
- inner,outer = inner and outer bond length (distance units)
- file = name of file to write values to
- keyword = section name in file for this set of tabulated values
- itype,jtype = two atom types (optional)

1.9.2 Examples

```
bond_write 1 500 0.5 3.5 table.txt Harmonic_1
bond_write 3 1000 0.1 6.0 table.txt Morse
```

1.9.3 Description

Write energy and force values to a file as a function of distance for the currently defined *bond style* for a selected bond type. This is useful for plotting the potential function or otherwise debugging its values. The resulting file can also be used as input for use with *bond style table*.

If the file already exists, the table of values is appended to the end of the file to allow multiple tables of energy and force to be included in one file. The individual sections may be identified by the *keyword*.

The energy and force values are computed at distances from *inner* to *outer* for two interacting atoms forming a bond of type *btype*, using the appropriate *bond_coeff* coefficients. N evenly spaced distances are used.

For example, for N = 7, inner = 1.0, and outer = 4.0, values are computed at r = 1.0, 1.5, 2.0, 2.5, 3.0, 3.5, 4.0.

The file is written in the format used as input for the *bond_style table* option with *keyword* as the section name. Each line written to the file lists an index number (1-N), a distance (in distance units), an energy (in energy units), and a force (in force units). In case a new file is created, the first line will be a comment with a "DATE:" and "UNITS:" tag with the current date and *units* settings. For subsequent invocations of the *bond_write* command for the same file, data will be appended and the current units settings will be compared to the data from the header, if present. The *bond_write* command will refuse to add a table to an existing file if the units are not the same.

1.9.4 Restrictions

All force field coefficients for bond and other kinds of interactions must be set before this command can be invoked.

Due to how the bond force is computed, an inner value > 0.0 must be specified even if the potential has a finite value at r = 0.0.

1.10 boundary command

1.10.1 Syntax

```
boundary x y z
```

- x,y,z = *p* or *s* or *f* or *m*, one or two letters

```
p is periodic
f is non-periodic and fixed
s is non-periodic and shrink-wrapped
m is non-periodic and shrink-wrapped with a minimum value
```

1.10.2 Examples

```
boundary p p f
boundary p fs p
boundary s f fm
```

1.10.3 Description

Set the style of boundaries for the global simulation box in each dimension. A single letter assigns the same style to both the lower and upper face of the box. Two letters assigns the first style to the lower face and the second style to the upper face. The initial size of the simulation box is set by the *read_data*, *read_restart*, or *create_box* commands.

The style *p* means the box is periodic, so that particles interact across the boundary, and they can exit one end of the box and re-enter the other end. A periodic dimension can change in size due to constant pressure boundary conditions or box deformation (see the *fix npt* and *fix deform* commands). The *p* style must be applied to both faces of a dimension. For 2d simulations the z dimension must be periodic (which is the default).

The styles *f*, *s*, and *m* mean the box is non-periodic, so that particles do not interact across the boundary and do not move from one side of the box to the other.

For style *f*, the position of the face is fixed. If an atom moves outside the face it will be deleted on the next timestep that reneighboring occurs. This will typically generate an error unless you have set the *thermo_modify lost* option to allow for lost atoms.

For style *s*, the position of the face is set so as to encompass the atoms in that dimension (shrink-wrapping), no matter how far they move. Note that when the difference between the current box dimensions and the shrink-wrap box dimensions is large, this can lead to lost atoms at the beginning of a run when running in parallel. This is due to the large change in the (global) box dimensions also causing significant changes in the individual subdomain sizes. If these changes are farther than the communication cutoff, atoms will be lost. This is best addressed by setting initial box dimensions to match the shrink-wrapped dimensions more closely, by using *m* style boundaries (see below).

For style *m*, shrink-wrapping occurs, but is bounded by the value specified in the data or restart file or set by the *create_box* command. For example, if the upper z face has a value of 50.0 in the data file, the face will always be positioned at 50.0 or above, even if the maximum z-extent of all the atoms becomes less than 50.0. This can be useful if you start a simulation with an empty box or if you wish to leave room on one side of the box, e.g. for atoms to evaporate from a surface.

LAMMPS also allows use of triclinic (non-orthogonal) simulation boxes. See the *Howto triclinic* page for a description of both general and restricted triclinic boxes and how to define them. General triclinic boxes (arbitrary edge vectors **A**, **B**, and **C**) are converted internally to restricted triclinic boxes with tilt factors (xy,xz,yz) which skew an otherwise orthogonal box.

The boundary <boundary> command settings explained above for the 6 faces of an orthogonal box also apply in similar manner to the 6 faces of a restricted triclinic box (and thus to the corresponding 6 faces of a general triclinic box), with the following context.

if the second dimension of a tilt factor (e.g. y for xy) is periodic, then the periodicity is enforced with the tilt factor offset. This means that for y periodicity a particle which exits the lower y boundary is displaced in the x-direction by xy before it re-enters the upper y boundary. And vice versa if a particle exits the upper y boundary. Likewise the ghost atoms surrounding a particle near the lower y boundary include images of particles near the upper y-boundary which are displaced in the x-direction by xy. Similar rules apply for z-periodicity and the xz and/or yz tilt factors.

If the first dimension of a tilt factor is shrink-wrapped, then the shrink wrapping is applied to the tilted box face, to encompass the atoms. E.g. for a positive xy tilt, the xlo and xhi faces of the box are planes tilting in the +y direction as y increases. The position of these tilted planes are adjusted dynamically to shrink-wrap around the atoms to determine the xlo and xhi extents of the box.

1.10.4 Restrictions

This command cannot be used after the simulation box is defined by a *read_data* or *create_box* command or *read_restart* command. See the *change_box* command for how to change the simulation box boundaries after it has been defined.

For 2d simulations, the z dimension must be periodic.

1.10.5 Related commands

See the *thermo_modify* command for a discussion of lost atoms.

  lattice = distances are defined in lattice units
  box = distances are defined in simulation box units
```

1.11.2 Examples

```
change_box all xy final -2.0 z final 0.0 5.0 boundary p p f remap units box
change_box all x scale 1.1 y volume z volume remap
```

1.11.3 Description

Change the volume and/or shape and/or boundary conditions for the simulation box. Orthogonal simulation boxes have 3 adjustable size parameters (x,y,z). Triclinic (non-orthogonal) simulation boxes have 6 adjustable size/shape parameters (x,y,z,xy,xz,yz). Any or all of them can be adjusted independently by this command. Thus it can be used to expand or contract a box, or to apply a shear strain to a non-orthogonal box. It can also be used to change the boundary conditions for the simulation box, similar to the *boundary* command.

The size and shape of the initial simulation box are specified by the *create_box* or *read_data* or *read_restart* command used to setup the simulation. The size and shape may be altered by subsequent runs, e.g. by use of the *fix npt* or *fix deform* commands. The *create_box*, *read data*, and *read_restart* commands also determine whether the simulation box is orthogonal or triclinic and their doc pages explain the meaning of the xy,xz,yz tilt factors.

See the *Howto triclinic* page for a geometric description of triclinic boxes, as defined by LAMMPS, and how to transform these parameters to and from other commonly used triclinic representations.

The keywords used in this command are applied sequentially to the simulation box and the atoms in it, in the order specified.

Before the sequence of keywords are invoked, the current box size/shape is stored, in case a *remap* keyword is used to map the atom coordinates from a previously stored box size/shape to the current one.

After all the keywords have been processed, any shrink-wrap boundary conditions are invoked (see the *boundary* command) which may change simulation box boundaries, and atoms are migrated to new owning processors.

Note

This means that you cannot use the change_box command to enlarge a shrink-wrapped box, e.g. to make room to insert more atoms via the *create_atoms* command, because the simulation box will be re-shrink-wrapped before the change_box command completes. Instead you could do something like this, assuming the simulation box is non-periodic and atoms extend from 0 to 20 in all dimensions:

```
change_box all x final -10 20
create_atoms 1 single -5 5 5       # this will fail to insert an atom

change_box all x final -10 20 boundary f s s
create_atoms 1 single -5 5 5
change_box all boundary s s s      # this will work
```

Note

Unlike the earlier "displace_box" version of this command, atom remapping is NOT performed by default. This command allows remapping to be done in a more general way, exactly when you specify it (zero or more times) in the sequence of transformations. Thus if you do not use the *remap* keyword, atom coordinates will not be changed even if the box size/shape changes. If a uniformly strained state is desired, the *remap* keyword should be specified.

Note

It is possible to lose atoms with this command. E.g. by changing the box without remapping the atoms, and having atoms end up outside of non-periodic boundaries. It is also possible to alter bonds between atoms straddling a boundary in bad ways. E.g. by converting a boundary from periodic to non-periodic. It is also possible when remapping atoms to put them (nearly) on top of each other. E.g. by converting a boundary from non-periodic to periodic. All of these will typically lead to bad dynamics and/or generate error messages.

Changed in version 4Jul2026.

Atoms that end up outside of non-periodic boundaries as a result of this command are now handled according to the *thermo_modify lost* setting, the same policy used to detect lost atoms during a run: with the default *error* setting the command stops with a "lost atoms" error, *warn* prints a warning and deletes the atoms, and *ignore* deletes them silently. Previously such atoms were only reported with a warning and could be left in an inconsistent state (for example causing a subsequent *write_data* command to write a corrupted data file).

Note

The simulation box size/shape can be changed by arbitrarily large amounts by this command. This is not a problem, except that the mapping of processors to the simulation box is not changed from its initial 3d configuration; see the *processors* command. Thus, if the box size/shape changes dramatically, the mapping of processors to the simulation box may not end up as optimal as the initial mapping attempted to be. You may wish to re-balance the atoms by using the *balance* command if that is the case.

Note

You cannot use this command after reading a restart file (and before a run is performed) if the restart file stored per-atom information from a fix and any of the specified keywords change the box size or shape or boundary conditions. This is because atoms may be moved to new processors and the restart info will not migrate with them. LAMMPS will generate an error if this could happen. Only the *ortho* and *triclinic* keywords do not trigger this error. One solution is to perform a "run 0" command before using the change_box command. This clears the per-atom restart data, whether it has been re-assigned to a new fix or not.

Note

Because the keywords used in this command are applied one at a time to the simulation box and the atoms in it, care must be taken with triclinic cells to avoid exceeding the limits on skew after each transformation in the sequence. If skew is exceeded before the final transformation this can be avoided by changing the order of the sequence, or breaking the transformation into two or more smaller transformations. For more information on the allowed limits for box skew see the discussion on triclinic boxes on *Howto triclinic* doc page.

For the *x*, *y*, and *z* parameters, this is the meaning of their styles and values.

For style *final*, the final lo and hi box boundaries of a dimension are specified. The values can be in lattice or box distance units. See the discussion of the units keyword below.

For style *delta*, plus or minus changes in the lo/hi box boundaries of a dimension are specified. The values can be in lattice or box distance units. See the discussion of the units keyword below.

For style *scale*, a multiplicative factor to apply to the box length of a dimension is specified. For example, if the initial box length is 10, and the factor is 1.1, then the final box length will be 11. A factor less than 1.0 means compression.

The *volume* style changes the specified dimension in such a way that the overall box volume remains constant with respect to the operation performed by the preceding keyword. The *volume* style can only be used following a keyword that changed the volume, which is any of the *x*, *y*, *z* keywords. If the preceding keyword "key" had a *volume* style, then both it and the current keyword apply to the keyword preceding "key". I.e. this sequence of keywords is allowed:

```
change_box all x scale 1.1 y volume z volume
```

The *volume* style changes the associated dimension so that the overall box volume is unchanged relative to its value before the preceding keyword was invoked.

If the following command is used, then the z box length will shrink by the same 1.1 factor the x box length was increased by:

```
change_box all x scale 1.1 z volume
```

If the following command is used, then the y,z box lengths will each shrink by sqrt(1.1) to keep the volume constant. In this case, the y,z box lengths shrink so as to keep their relative aspect ratio constant:

```
change_box all x scale 1.1 y volume z volume
```

If the following command is used, then the final box will be a factor of 10% larger in x and y, and a factor of 21% smaller in z, so as to keep the volume constant:

```
change_box all x scale 1.1 z volume y scale 1.1 z volume
```

Note

For solids or liquids, when one dimension of the box is expanded, it may be physically undesirable to hold the other 2 box lengths constant since that implies a density change. For solids, adjusting the other dimensions via the *volume* style may make physical sense (just as for a liquid), but may not be correct for materials and potentials whose Poisson ratio is not 0.5.

For the *scale* and *volume* styles, the box length is expanded or compressed around its mid point.

For the *xy*, *xz*, and *yz* parameters, this is the meaning of their styles and values. Note that changing the tilt factors of a triclinic box does not change its volume.

For style *final*, the final tilt factor is specified. The value can be in lattice or box distance units. See the discussion of the units keyword below.

For style *delta*, a plus or minus change in the tilt factor is specified. The value can be in lattice or box distance units. See the discussion of the units keyword below.

All of these styles change the xy, xz, yz tilt factors. In LAMMPS, tilt factors (xy,xz,yz) for triclinic boxes are required to be no more than half the distance of the parallel box length. For example, if xlo = 2 and xhi = 12, then the x box length is 10 and the xy tilt factor must be between -5 and 5. Similarly, both xz and yz must be between -(xhi-xlo)/2 and +(yhi-ylo)/2. Note that this is not a limitation, since if the maximum tilt factor is 5 (as in this example), then configurations with tilt = . . . , -15, -5, 5, 15, 25, . . . are all equivalent. Any tilt factor specified by this command must be within these limits.

The *boundary* keyword takes arguments that have exactly the same meaning as they do for the *boundary* command. In each dimension, a single letter assigns the same style to both the lower and upper face of the box. Two letters assigns the first style to the lower face and the second style to the upper face.

The style *p* means the box is periodic; the other styles mean non-periodic. For style *f*, the position of the face is fixed. For style *s*, the position of the face is set so as to encompass the atoms in that dimension (shrink-wrapping), no matter how far they move. For style *m*, shrink-wrapping occurs, but is bounded by the current box edge in that dimension, so that the box will become no smaller. See the *boundary* command for more explanation of these style options.

Note that the "boundary" command itself can only be used before the simulation box is defined via a *read_data* or *create_box* or *read_restart* command. This command allows the boundary conditions to be changed later in your input script. Also note that the *read_restart* will change boundary conditions to match what is stored in the restart file. So if you wish to change them, you should use the change_box command after the read_restart command.

Note

Changing a periodic boundary to a non-periodic one will also cause the image flag for that dimension of all atoms to be reset to 0. LAMMPS will print a warning message, if that happens. Please note that this reset can lead to undesired changes when atoms are involved in bonded interactions that straddle periodic boundaries and thus the values of the image flag differs for those atoms.

The *ortho* and *triclinic* keywords convert the simulation box to be orthogonal or triclinic (non-orthogonal).

The simulation box is defined as either orthogonal or triclinic when it is created via the *create_box*, *read_data*, or *read_restart* commands.

These keywords allow you to toggle the existing simulation box from orthogonal to triclinic and vice versa. For example, an initial equilibration simulation can be run in an orthogonal box, the box can be toggled to triclinic, and then a *non-equilibrium MD (NEMD) simulation* can be run with deformation via the *fix deform* command.

If the simulation box is currently triclinic and has non-zero tilt in xy, yz, or xz, then it cannot be converted to an orthogonal box.

The *set* keyword saves the current box size/shape. This can be useful if you wish to use the *remap* keyword more than once or if you wish it to be applied to an intermediate box size/shape in a sequence of keyword operations. Note that the box size/shape is saved before any of the keywords are processed, i.e. the box size/shape at the time the create_box command is encountered in the input script.

The *remap* keyword remaps atom coordinates from the last saved box size/shape to the current box state. For example, if you stretch the box in the x dimension or tilt it in the xy plane via the *x* and *xy* keywords, then the *remap* command will dilate or tilt the atoms to conform to the new box size/shape, as if the atoms moved with the box as it deformed.

Note that this operation is performed without regard to periodic boundaries. Also, any shrink-wrapping of non-periodic boundaries (see the *boundary* command) occurs after all keywords, including this one, have been processed.

Only atoms in the specified group are remapped.

The *units* keyword determines the meaning of the distance units used to define various arguments. A *box* value selects standard distance units as defined by the *units* command, e.g. Angstroms for units = real or metal. A *lattice* value means the distance units are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacing.

1.11.4 Restrictions

If you use the *ortho* or *triclinic* keywords, then at the point in the input script when this command is issued, no *dumps* can be active, nor can a *fix deform* be active. This is because these commands test whether the simulation box is orthogonal when they are first issued. Note that these commands can be used in your script before a change_box command is issued, so long as an *undump* or *unfix* command is also used to turn them off.

1.11.5 Related commands

fix deform, *boundary*

1.11.6 Default

The option default is units = lattice.

1.12 clear command

1.12.1 Syntax

```
clear
```

1.12.2 Examples

```
# (commands for 1st simulation)
clear
# (commands for 2nd simulation)
```

1.12.3 Description

This command deletes all atoms, restores all settings to their default values, and frees all memory allocated by LAMMPS. Once a clear command has been executed, it is almost as if LAMMPS is completely reset, with some exceptions noted below. The command thus allows to run multiple jobs sequentially from a single input script, often with a loop.

The following settings are not affected by a clear command:

- working directory (*shell* command)
- log file status (*log* command)
- echo status (*echo* command)
- input script variables except for *atomfile* style variables (*variable* command).

1.12.4 Restrictions

1.13 comm_modify command

1.13.1 Syntax

```
comm_modify keyword value ...
```

- one or more keyword/value pairs may be appended
- keyword = *mode* or *cutoff* or *cutoff/multi* or *group* or *reduce/multi* or *vel*

```
mode value = single or multi = communicate atoms within a single or multiple␣
↪distances
cutoff value = Rcut (distance units) = communicate atoms from this far away
cutoff/multi collection value
   collection = atom collection or collection range (supports asterisk notation)
   value = Rcut (distance units) = communicate atoms for selected types from this␣
↪far away
reduce/multi arg = none = reduce number of communicated ghost atoms for multi style
group value = group-ID = only communicate atoms in the group
vel value = yes or no = do or do not communicate velocity info with ghost atoms
```

1.13.2 Examples

```
comm_modify mode multi reduce/multi
comm_modify mode multi group solvent
comm_modify mode multi cutoff/multi 1 10.0 cutoff/multi 2*4 15.0
comm_modify vel yes
comm_modify mode single cutoff 5.0 vel yes
comm_modify cutoff/multi * 0.0
```

1.13.3 Description

This command sets parameters that affect the inter-processor communication of atom information that occurs each timestep as coordinates and other properties are exchanged between neighboring processors and stored as properties of ghost atoms.

Note

These options apply to the currently defined comm style. When you specify a *comm_style* or *read_restart* command, all communication settings are restored to their default or stored values, including those previously reset by a comm_modify command. Thus if your input script specifies a comm_style or read_restart command, you should use the comm_modify command after it.

The *mode* keyword determines whether a single or multiple cutoff distances are used to determine which atoms to communicate.

The default mode is *single* which means each processor acquires information for ghost atoms that are within a single distance from its subdomain. The distance is by default the maximum of the neighbor cutoff across all atom type pairs.

For many systems this is an efficient algorithm, but for systems with widely varying cutoffs for different type pairs, the *multi* mode can be faster. In *multi*, each atom is assigned to a collection which should correspond to a set of atoms with similar interaction cutoffs. See the *neighbor* command for a detailed description of collections. In this case, each atom collection is assigned its own distance cutoff for communication purposes, and fewer atoms will be communicated. See the *neighbor multi* command for neighbor list construction options that may also be beneficial for simulations of this kind. The *multi* communication mode is only compatible with the *multi* neighbor style.

The *cutoff* keyword allows you to extend the ghost cutoff distance for communication mode *single*, which is the distance from the borders of a processor's subdomain at which ghost atoms are acquired from other processors. By default the ghost cutoff = neighbor cutoff = pairwise force cutoff + neighbor skin. See the *neighbor* command for more information about the skin distance. If the specified Rcut is greater than the neighbor cutoff, then extra ghost atoms will be acquired. If the provided cutoff is smaller, the provided value will be ignored, the ghost cutoff is set to the neighbor cutoff and a warning will be printed. Specifying a cutoff value of 0.0 will reset any previous value to the default. If bonded interactions exist and equilibrium bond length information is available, then also a heuristic based on that bond length is computed. It is used as communication cutoff, if there is no pair style present and no *comm_modify cutoff* command used. Otherwise a warning is printed, if this bond based estimate is larger than the communication cutoff used.

The *cutoff/multi* option is equivalent to *cutoff*, but applies to communication mode *multi* instead. Since the communication cutoffs are determined per atom collections, a collection specifier is needed and cutoff for one or multiple collections can be extended. Also ranges of collections using the usual asterisk notation can be given. Collections are indexed from 1 to N where N is the total number of collections. Note that the arguments for *cutoff/multi* are parsed right before each simulation to account for potential changes in the number of collections. Custom cutoffs are preserved between runs but if collections are redefined, one may want to re-specify the communication cutoffs. For granular pair styles,the default cutoff is set to the sum of the current maximum atomic radii for each collection.

The *reduce/multi* option applies to *multi* and sets the communication cutoff for a particle equal to the maximum interaction distance between particles in the same collection. This reduces the number of ghost atoms that need to be communicated. This method is only compatible with the *multi* neighbor style and requires a half neighbor list and Newton on. See the *neighbor multi* command for more information.

These are simulation scenarios in which it may be useful or even necessary to set a ghost cutoff > neighbor cutoff:

- a single polymer chain with bond interactions, but no pairwise interactions
- bonded interactions (e.g. dihedrals) extend further than the pairwise cutoff
- ghost atoms beyond the pairwise cutoff are needed for some computation

In the first scenario, a pairwise potential is not defined. Thus the pairwise neighbor cutoff will be 0.0. But ghost atoms are still needed for computing bond, angle, etc interactions between atoms on different processors, or when the interaction straddles a periodic boundary.

The appropriate ghost cutoff depends on the *newton bond* setting. For newton bond *off*, the distance needs to be the furthest distance between any two atoms in the bond, angle, etc. E.g. the distance between 1-4 atoms in a dihedral. For newton bond *on*, the distance between the central atom in the bond, angle, etc and any other atom is sufficient. E.g. the distance between 2-4 atoms in a dihedral.

In the second scenario, a pairwise potential is defined, but its neighbor cutoff is not sufficiently long enough to enable bond, angle, etc terms to be computed. As in the previous scenario, an appropriate ghost cutoff should be set.

In the last scenario, a *fix* or *compute* or *pairwise potential* needs to calculate with ghost atoms beyond the normal pairwise cutoff for some computation it performs (e.g. locate neighbors of ghost atoms in a manybody pair potential). Setting the ghost cutoff appropriately can ensure it will find the needed atoms.

Note

In these scenarios, if you do not set the ghost cutoff long enough, and if there is only one processor in a periodic dimension (e.g. you are running in serial), then LAMMPS may "find" the atom it is looking for (e.g. the partner atom in a bond), that is on the far side of the simulation box, across a periodic boundary. This will typically lead

to bad dynamics (i.e. the bond length is now the simulation box length). To detect if this is happening, see the *neigh_modify cluster* command.

The *group* keyword will limit communication to atoms in the specified group. This can be useful for models where no ghost atoms are needed for some kinds of particles. All atoms (not just those in the specified group) will still migrate to new processors as they move. The group specified with this option must also be specified via the *atom_modify first* command.

The *vel* keyword enables velocity information to be communicated with ghost particles. Depending on the *atom_style*, velocity info includes the translational velocity, angular velocity, and angular momentum of a particle. If the *vel* option is set to *yes*, then ghost atoms store these quantities; if *no* then they do not. The *yes* setting is needed by some pair styles which require the velocity state of both the I and J particles to compute a pairwise I,J interaction, as well as by some compute and fix commands.

Note that if the *fix deform* command is being used with its "remap v" option enabled, then the velocities for ghost atoms (in the fix deform group) mirrored across a periodic boundary will also include components due to any velocity shift that occurs across that boundary (e.g. due to dilation or shear).

1.13.4 Restrictions

Communication mode *multi* is currently only available for *comm_style brick*.

1.13.5 Related commands

comm_style, *neighbor*

1.13.6 Default

The option defaults are mode = single, group = all, cutoff = 0.0, vel = no. The cutoff default of 0.0 means that ghost cutoff = neighbor cutoff = pairwise force cutoff + neighbor skin.

1.14 comm_style command

1.14.1 Syntax

```
comm_style style
```

- style = *brick* or *tiled*

1.14.2 Examples

```
comm_style brick
comm_style tiled
```

1.14.3 Description

This command sets the style of inter-processor communication of atom information that occurs each timestep as coordinates and other properties are exchanged between neighboring processors and stored as properties of ghost atoms.

For the default *brick* style, the domain decomposition used by LAMMPS to partition the simulation box must be a regular 3d grid of bricks, one per processor. Each processor communicates with its 6 Cartesian neighbors in the grid to acquire information for nearby atoms.

For the *tiled* style, a more general domain decomposition can be used, as triggered by the *balance* or *fix balance* commands. The simulation box can be partitioned into non-overlapping rectangular-shaped "tiles" or varying sizes and shapes. Again there is one tile per processor. To acquire information for nearby atoms, communication must now be done with a more complex pattern of neighboring processors.

Note that this command does not actually define a partitioning of the simulation box (a domain decomposition), rather it determines what kinds of decompositions are allowed and the pattern of communication used to enable the decomposition. A decomposition is created when the simulation box is first created, via the *create_box* or *read_data* or *read_restart* commands. For both the *brick* and *tiled* styles, the initial decomposition will be the same, as described by *create_box* and *processors* commands. The decomposition can be changed via the *balance* or *fix balance* commands.

1.14.4 Restrictions

none

1.14.5 Related commands

comm_modify, *processors*, *balance*, *fix balance*

1.14.6 Default

The default style is brick.

1.15 compute command

1.15.1 Syntax

```
compute ID group-ID style args
```

- ID = user-assigned name for the computation
- group-ID = ID of the group of atoms to perform the computation on
- style = one of a list of possible style names (see below)
- args = arguments used by a particular style

1.15.2 Examples

```
compute 1 all temp
compute newtemp flow temp/partial 1 1 0
compute 3 all ke/atom
```

1.15.3 Description

Define a diagnostic computation that will be performed on a group of atoms. Quantities calculated by a compute are instantaneous values, meaning they are calculated from information about atoms on the current timestep or iteration, though internally a compute may store some information about a previous state of the system. Defining a compute does not perform the computation. Instead computes are invoked by other LAMMPS commands as needed (e.g., to calculate a temperature needed for a thermostat fix or to generate thermodynamic or dump file output). See the *Howto output* page for a summary of various LAMMPS output options, many of which involve computes.

The ID of a compute can only contain alphanumeric characters and underscores.

Computes calculate and store any of four *styles* of quantities: global, per-atom, local, or per-grid.

A global quantity is one or more system-wide values, e.g. the temperature of the system. A per-atom quantity is one or more values per atom, e.g. the kinetic energy of each atom. Per-atom values are set to 0.0 for atoms not in the specified compute group. Local quantities are calculated by each processor based on the atoms it owns, but there may be zero or more per atom, e.g. a list of bond distances. Per-grid quantities are calculated on a regular 2d or 3d grid which overlays a 2d or 3d simulation domain. The grid points and the data they store are distributed across processors; each processor owns the grid points which fall within its subdomain.

As a general rule of thumb, computes that produce per-atom quantities have the word "atom" at the end of their style, e.g. *ke/atom*. Computes that produce local quantities have the word "local" at the end of their style, e.g. *bond/local*. Computes that produce per-grid quantities have the word "grid" at the end of their style, e.g. *property/grid*. And styles with neither "atom" or "local" or "grid" at the end of their style name produce global quantities.

Global, per-atom, local, and per-grid quantities can also be of three *kinds*: a single scalar value (global only), a vector of values, or a 2d array of values. For per-atom, local, and per-grid quantities, a "vector" means a single value for each atom, each local entity (e.g. bond), or grid cell. Likewise an "array", means multiple values for each atom, each local entity, or each grid cell.

Note that a single compute can produce any combination of global, per-atom, local, or per-grid values. Likewise it can produce any combination of scalar, vector, or array output for each style. The exception is that for per-atom, local, and per-grid output, either a vector or array can be produced, but not both. The doc page for each compute explains the values it produces.

When a compute output is accessed by another input script command it is referenced via the following bracket notation, where ID is the ID of the compute:

c_ID	entire scalar, vector, or array
c_ID[I]	one element of vector, one column of array
c_ID[I][J]	one element of array

In other words, using one bracket reduces the dimension of the quantity once (vector → scalar, array → vector). Using two brackets reduces the dimension twice (array → scalar). Thus, for example, a command that uses global scalar compute values as input can also process elements of a vector or array. Depending on the command, this can either be done directly using the syntax in the table, or by first defining a *variable* of the appropriate style to store the quantity, then using the variable as an input to the command.

Note that commands and *variables* which take compute outputs as input typically do not allow for all styles and kinds of data (e.g., a command may require global but not per-atom values, or it may require a vector of values, not a scalar). This means there is typically no ambiguity about referring to a compute output as c_ID even if it produces, for example, both a scalar and vector. The doc pages for various commands explain the details, including how any ambiguities are resolved.

In LAMMPS, the values generated by a compute can be used in several ways:

- The results of computes that calculate a global temperature or pressure can be used by fixes that do thermostatting or barostatting or when atom velocities are created.
- Global values can be output via the *thermo_style custom* or *fix ave/time* command. Or the values can be referenced in a *variable equal* or *variable atom* command.
- Per-atom values can be output via the *dump custom* command. Or they can be time-averaged via the *fix ave/atom* command or reduced by the *compute reduce* command. Or the per-atom values can be referenced in an *atom-style variable*.
- Local values can be reduced by the *compute reduce* command, or histogrammed by the *fix ave/histo* command, or output by the *dump local* command.

The results of computes that calculate global quantities can be either "intensive" or "extensive" values. Intensive means the value is independent of the number of atoms in the simulation (e.g., temperature). Extensive means the value scales with the number of atoms in the simulation (e.g., total rotational kinetic energy). *Thermodynamic output* will normalize extensive values by the number of atoms in the system, depending on the "thermo_modify norm" setting. It will not normalize intensive values. If a compute value is accessed in another way (e.g., by a *variable*), you may want to know whether it is an intensive or extensive value. See the page for individual computes for further info.

LAMMPS creates its own computes internally for thermodynamic output. Three computes are always created, named "thermo_temp", "thermo_press", and "thermo_pe", as if these commands had been invoked in the input script:

```
compute thermo_temp all temp
compute thermo_press all pressure thermo_temp
compute thermo_pe all pe
```

Additional computes for other quantities are created if the thermo style requires it. See the documentation for the *thermo_style* command.

Fixes that calculate temperature or pressure, i.e. for thermostatting or barostatting, may also create computes. These are discussed in the documentation for specific *fix* commands.

In all these cases, the default computes LAMMPS creates can be replaced by computes defined by the user in the input script, as described by the *thermo_modify* and *fix modify* commands.

Properties of either a default or user-defined compute can be modified via the *compute_modify* command.

Computes can be deleted with the *uncompute* command.

Code for new computes can be added to LAMMPS; see the *Modify* page for details. The results of their calculations accessed in the various ways described above.

Each compute style has its own page which describes its arguments and what it does. Here is an alphabetic list of compute styles available in LAMMPS. They are also listed in more compact form on the *Commands compute* doc page.

There are also additional accelerated compute styles included in the LAMMPS distribution for faster performance on CPUs, GPUs, and KNLs. The individual style names on the *Commands compute* page are followed by one or more of (g,i,k,o,t) to indicate which accelerated styles exist.

- *ackland/atom* - determines the local lattice structure based on the Ackland formulation
- *adf* - angular distribution function of triples of atoms
- *aggregate/atom* - aggregate ID for each atom
- *angle* - energy of each angle sub-style
- *angle/local* - theta and energy of each angle
- *angmom/chunk* - angular momentum for each chunk
- *ave/sphere/atom* - compute local density and temperature around each atom
- *basal/atom* - calculates the hexagonal close-packed "c" lattice vector of each atom
- *body/local* - attributes of body sub-particles
- *bond* - energy of each bond sub-style
- *bond/local* - distance and energy of each bond
- *born/matrix* - second derivative or potential with respect to strain

- *centro/atom* - centro-symmetry parameter for each atom
- *centroid/stress/atom* - centroid based stress tensor for each atom
- *chunk/atom* - assign chunk IDs to each atom
- *chunk/spread/atom* - spreads chunk values to each atom in chunk
- *cluster/atom* - cluster ID for each atom
- *cna/atom* - common neighbor analysis (CNA) for each atom
- *cnp/atom* - common neighborhood parameter (CNP) for each atom
- *com* - center of mass of group of atoms
- *com/chunk* - center of mass for each chunk
- *composition/atom* - local composition for each atom
- *contact/atom* - contact count for each spherical particle
- *coord/atom* - coordination number for each atom
- *count/type* - count of atoms or bonds by type
- *damage/atom* - Peridynamic damage for each atom
- *dihedral* - energy of each dihedral sub-style
- *dihedral/local* - angle of each dihedral
- *dilatation/atom* - Peridynamic dilatation for each atom
- *dipole* - dipole vector and total dipole
- *dipole/chunk* - dipole vector and total dipole for each chunk
- *dipole/tip4p* - dipole vector and total dipole with TIP4P pair style
- *dipole/tip4p/chunk* - dipole vector and total dipole for each chunk with TIP4P pair style
- *displace/atom* - displacement of each atom
- *dpd* - total values of internal conductive energy, internal mechanical energy, chemical energy, and harmonic average of internal temperature
- *dpd/atom* - per-particle values of internal conductive energy, internal mechanical energy, chemical energy, and internal temperature
- *edpd/temp/atom* - per-atom temperature for each eDPD particle in a group
- *efield/atom* - electric field at each atom
- *efield/wolf/atom* - electric field at each atom
- *entropy/atom* - pair entropy fingerprint of each atom
- *erotate/asphere* - rotational energy of aspherical particles
- *erotate/rigid* - rotational energy of rigid bodies
- *erotate/sphere* - rotational energy of spherical particles
- *erotate/sphere/atom* - rotational energy for each spherical particle
- *event/displace* - detect event on atom displacement
- *fabric* - calculates fabric tensors from pair interactions
- *fep* - compute free energies for alchemical transformation from perturbation theory

- *fep/ta* - compute free energies for a test area perturbation
- *frenkel* - identify point defects by Wigner-Seitz analysis
- *force/tally* - force between two groups of atoms via the tally callback mechanism
- *fragment/atom* - fragment ID for each atom
- *gaussian/grid/local* - local array of Gaussian atomic contributions on a regular grid
- *global/atom* - assign global values to each atom from arrays of global values
- *group/group* - energy/force between two groups of atoms
- *gyration* - radius of gyration of group of atoms
- *gyration/chunk* - radius of gyration for each chunk
- *gyration/shape* - shape parameters from gyration tensor
- *gyration/shape/chunk* - shape parameters from gyration tensor for each chunk
- *hbond/local* - identify hydrogen bonds
- *heat/flux* - heat flux through a group of atoms
- *heat/flux/tally* - heat flux through a group of atoms via the tally callback mechanism
- *heat/flux/virial/tally* - virial heat flux between two groups via the tally callback mechanism
- *hexorder/atom* - bond orientational order parameter q6
- *hma* - harmonically mapped averaging for atomic crystals
- *improper* - energy of each improper sub-style
- *improper/local* - angle of each improper
- *inertia* - inertia tensor of group of atoms
- *inertia/chunk* - inertia tensor for each chunk
- *ke* - translational kinetic energy
- *ke/atom* - kinetic energy for each atom
- *ke/atom/eff* - per-atom translational and radial kinetic energy in the electron force field model
- *ke/eff* - kinetic energy of a group of nuclei and electrons in the electron force field model
- *ke/rigid* - translational kinetic energy of rigid bodies
- *mliap* - gradients of energy and forces with respect to model parameters and related quantities for training machine learning interatomic potentials
- *momentum* - translational momentum
- *msd* - mean-squared displacement of group of atoms
- *msd/chunk* - mean-squared displacement for each chunk
- *msd/nongauss* - MSD and non-Gaussian parameter of group of atoms
- *nbond/atom* - calculates number of bonds per atom
- *omega/chunk* - angular velocity for each chunk
- *orientorder/atom* - Steinhardt bond orientational order parameters Ql
- *pace* - atomic cluster expansion descriptors and related quantities

- *pair* - values computed by a pair style
- *pair/local* - distance/energy/force of each pairwise interaction
- *pe* - potential energy
- *pe/atom* - potential energy for each atom
- *pe/mol/tally* - potential energy between two groups of atoms separated into intermolecular and intramolecular components via the tally callback mechanism
- *pe/tally* - potential energy between two groups of atoms via the tally callback mechanism
- *plasticity/atom* - Peridynamic plasticity for each atom
- *pod/atom* - POD descriptors for each atom
- *podd/atom* - derivative of POD descriptors for each atom
- *pod/local* - local POD descriptors and their derivatives
- *pod/global* - global POD descriptors and their derivatives
- *pressure* - total pressure and pressure tensor
- *pressure/alchemy* - mixed system total pressure and pressure tensor for *fix alchemy* runs
- *pressure/uef* - pressure tensor in the reference frame of an applied flow field
- *property/atom* - convert atom attributes to per-atom vectors/arrays
- *property/chunk* - extract various per-chunk attributes
- *property/grid* - convert per-grid attributes to per-grid vectors/arrays
- *property/local* - convert local attributes to local vectors/arrays
- *ptm/atom* - determines the local lattice structure based on the Polyhedral Template Matching method
- *rattlers/atom* - identify under-coordinated rattler atoms
- *rdf* - radial distribution function $g(r)$ histogram of group of atoms
- *reaxff/atom* - extract ReaxFF bond information
- *reduce* - combine per-atom quantities into a single global value
- *reduce/chunk* - reduce per-atom quantities within each chunk
- *reduce/region* - same as compute reduce, within a region
- *rheo/property/atom* - convert atom attributes in RHEO package to per-atom vectors/arrays
- *rigid/local* - extract rigid body attributes
- *saed* - electron diffraction intensity on a mesh of reciprocal lattice nodes
- *slcsa/atom* - perform Supervised Learning Crystal Structure Analysis (SL-CSA)
- *slice* - extract values from global vector or array
- *smd/contact/radius* - contact radius for Smooth Mach Dynamics
- *smd/damage* - damage status of SPH particles in Smooth Mach Dynamics
- *smd/hourglass/error* - error associated with approximated relative separation in Smooth Mach Dynamics
- *smd/internal/energy* - per-particle enthalpy in Smooth Mach Dynamics
- *smd/plastic/strain* - equivalent plastic strain per particle in Smooth Mach Dynamics

- *smd/plastic/strain/rate* - time rate of the equivalent plastic strain in Smooth Mach Dynamics
- *smd/rho* - per-particle mass density in Smooth Mach Dynamics
- *smd/tlsph/defgrad* - deformation gradient in Smooth Mach Dynamics
- *smd/tlsph/dt* - CFL-stable time increment per particle in Smooth Mach Dynamics
- *smd/tlsph/num/neighs* - number of particles inside the smoothing kernel radius for Smooth Mach Dynamics
- *smd/tlsph/shape* - current shape of the volume of a particle for Smooth Mach Dynamics
- *smd/tlsph/strain* - Green–Lagrange strain tensor for Smooth Mach Dynamics
- *smd/tlsph/strain/rate* - rate of strain for Smooth Mach Dynamics
- *smd/tlsph/stress* - per-particle Cauchy stress tensor for SPH particles
- *smd/triangle/vertices* - coordinates of vertices corresponding to the triangle elements of a mesh for Smooth Mach Dynamics
- *smd/ulsph/effm* - per-particle effective shear modulus
- *smd/ulsph/num/neighs* - number of neighbor particles inside the smoothing kernel radius for Smooth Mach Dynamics
- *smd/ulsph/strain* - logarithmic strain tensor for Smooth Mach Dynamics
- *smd/ulsph/strain/rate* - logarithmic strain rate for Smooth Mach Dynamics
- *smd/ulsph/stress* - per-particle Cauchy stress tensor and von Mises equivalent stress in Smooth Mach Dynamics
- *smd/vol* - per-particle volumes and their sum in Smooth Mach Dynamics
- *snap* - gradients of SNAP energy and forces with respect to linear coefficients and related quantities for fitting SNAP potentials
- *sna/atom* - bispectrum components for each atom
- *sna/grid* - global array of bispectrum components on a regular grid
- *sna/grid/local* - local array of bispectrum components on a regular grid
- *snad/atom* - derivative of bispectrum components for each atom
- *snav/atom* - virial contribution from bispectrum components for each atom
- *sph/e/atom* - per-atom internal energy of Smooth-Particle Hydrodynamics atoms
- *sph/rho/atom* - per-atom density of Smooth-Particle Hydrodynamics atoms
- *sph/t/atom* - per-atom internal temperature of Smooth-Particle Hydrodynamics atoms
- *spin* - magnetic quantities for a system of atoms having spins
- *stress/atom* - stress tensor for each atom
- *stress/cartesian* - stress tensor in cartesian coordinates
- *stress/cylinder* - stress tensor in cylindrical coordinates
- *stress/mop* - normal components of the local stress tensor using the method of planes
- *stress/mop/profile* - profile of the normal components of the local stress tensor using the method of planes
- *stress/spherical* - stress tensor in spherical coordinates
- *stress/tally* - stress between two groups of atoms via the tally callback mechanism
- *tdpd/cc/atom* - per-atom chemical concentration of a specified species for each tDPD particle

- *temp* - temperature of group of atoms
- *temp/asphere* - temperature of aspherical particles
- *temp/body* - temperature of body particles
- *temp/chunk* - temperature of each chunk
- *temp/com* - temperature after subtracting center-of-mass velocity
- *temp/cs* - temperature based on the center-of-mass velocity of atom pairs that are bonded to each other
- *temp/deform* - temperature excluding box deformation velocity
- *temp/deform/eff* - temperature excluding box deformation velocity in the electron force field model
- *temp/drude* - temperature of Core–Drude pairs
- *temp/eff* - temperature of a group of nuclei and electrons in the electron force field model
- *temp/partial* - temperature excluding one or more dimensions of velocity
- *temp/profile* - temperature excluding a binned velocity profile
- *temp/ramp* - temperature excluding ramped velocity component
- *temp/region* - temperature of a region of atoms
- *temp/region/eff* - temperature of a region of nuclei and electrons in the electron force field model
- *temp/rotate* - temperature of a group of atoms after subtracting out their center-of-mass and angular velocities
- *temp/sphere* - temperature of spherical particles
- *temp/uef* - kinetic energy tensor in the reference frame of an applied flow field
- *ti* - thermodynamic integration free energy values
- *torque/chunk* - torque applied on each chunk
- *vacf* - velocity auto-correlation function of group of atoms
- *vacf/chunk* - velocity auto-correlation for the center of mass velocities of chunks of atoms
- *vcm/chunk* - velocity of center-of-mass for each chunk
- *viscosity/cos* - velocity profile under cosine-shaped acceleration
- *voronoi/atom* - Voronoi volume and neighbors for each atom
- *xrd* - X-ray diffraction intensity on a mesh of reciprocal lattice nodes

1.15.4 Restrictions

none

1.15.5 Related commands

uncompute, *compute_modify*, *fix ave/atom*, *fix ave/time*, *fix ave/histo*

1.15.6 Default

none

1.16 compute_modify command

1.16.1 Syntax

```
compute_modify compute-ID keyword value ...
```

- compute-ID = ID of the compute to modify
- one or more keyword/value pairs may be listed
- keyword = *extra/dof* or *dynamic/dof* or *temp*

```
extra/dof value = N
  N = # of extra degrees of freedom to subtract
dynamic/dof value = yes or no
  yes/no = do or do not re-compute the number of degrees of freedom (DOF)␣
↪contributing to the temperature
temp value = compute ID that calculates a temperature
```

1.16.2 Examples

```
compute_modify myTemp extra/dof 0
compute_modify newtemp dynamic/dof yes extra/dof 600
```

1.16.3 Description

Modify one or more parameters of a previously defined compute. Not all compute styles support all parameters.

The *extra/dof* keyword refers to how many degrees of freedom are subtracted (typically from 3*N*) as a normalizing factor in a temperature computation. Only computes that compute a temperature use this option. The default is 2 or 3 for *2d or 3d systems* which is a correction factor for an ensemble of velocities with zero total linear momentum. For compute temp/partial, if one or more velocity components are excluded, the value used for *extra/dof* is scaled accordingly. You can use a negative number for the *extra/dof* parameter if you need to add degrees-of-freedom. See the *compute temp/asphere* command for an example.

The *dynamic/dof* keyword determines whether the number of atoms *N* in the compute group and their associated degrees of freedom (DOF) are re-computed each time a temperature is computed. Only compute styles that calculate a temperature use this option. By default, *N* and their DOF are assumed to be constant. If you are adding atoms or molecules to the system (see the *fix pour*, *fix deposit*, and *fix gcmc* commands) or expect atoms or molecules to be lost (e.g. due to exiting the simulation box or via *fix evaporate*), then this option should be used to ensure the temperature is correctly normalized.

Added in version 11Feb2026.

The *temp* keyword is used with *compute temp/deform* to change the internal temperature compute.

1.16.4 Restrictions

none

1.16.5 Related commands

compute

1.16.6 Default

The option defaults are extra/dof = 2 or 3 for 2d or 3d systems, respectively, and dynamic/dof = *no*.

1.17 create_atoms command

1.17.1 Syntax

```
create_atoms type style args keyword values ...
```

- type = atom type (1-Ntypes or type label) of atoms to create (offset for molecule creation)
- style = *box* or *region* or *single* or *mesh* or *random*

```
box args = none
region args = region-ID
  region-ID = particles will only be created if contained in the region
single args = x y z
  x,y,z = coordinates of a single particle (distance units)
mesh args = STL-file
  STL-file = file with triangle mesh in STL format
random args = N seed region-ID
  N = number of particles to create
  seed = random # seed (positive integer)
  region-ID = create atoms within this region, use NULL for entire simulation box
```

- zero or more keyword/value pairs may be appended
- keyword = *mol* or *basis* or *ratio* or *subset* or *group* or *remap* or *var* or *set* or *radscale* or *meshmode* or *rotate* or *overlap* or *maxtry* or *units*

```
mol values = template-ID seed
  template-ID = ID of molecule template specified in a separate molecule command
  seed = random # seed (positive integer)
basis values = M itype
  M = which basis atom
  itype = atom type (1-Ntypes or type label) to assign to this basis atom
ratio values = frac seed

```

1.17.3 Description

This command creates atoms (or molecules) within the simulation box, either on a lattice, or at random points, or on a surface defined by a triangulated mesh. Or it creates a single atom (or molecule) at a specified point. It is an alternative to reading in atom coordinates explicitly via a *read_data* or *read_restart* command.

To use this command a simulation box must already exist, which is typically created via the *create_box* command. Before using this command, a lattice must typically also be defined using the *lattice* command, unless you specify the *single* or *mesh* style with units = box or the *random* style. To create atoms on a lattice for general triclinic boxes, see the discussion below.

For the remainder of this doc page, a created atom or molecule is referred to as a "particle".

If created particles are individual atoms, they are assigned the specified atom *type*, though this can be altered via the *basis* keyword as discussed below. If molecules are being created, the type of each atom in the created molecule is specified in a specified file read by the *molecule* command, and those values are added to the specified atom *type* (e.g., if *type* = 2 and the file specifies atom types 1, 2, and 3, then each created molecule will have atom types 3, 4, and 5).

Atoms outside the box

You cannot use this command to create atoms that are outside the simulation box; they will just be ignored by LAMMPS. This is true even if you are using shrink-wrapped box boundaries, as specified by the *boundary* com-

mand. However, you can first use the *change_box* command to temporarily expand the box, then add atoms via create_atoms, then finally use change_box command again if needed to re-shrink-wrap the new atoms. See the *change_box* doc page for an example of how to do this, using the create_atoms *single* style to insert a new atom outside the current simulation box.

For the *box* style, the create_atoms command fills the entire simulation box with particles on the lattice. If your simulation box is periodic, you should ensure its size is a multiple of the lattice spacings, to avoid unwanted atom overlaps at the box boundaries. If your box is periodic and a multiple of the lattice spacing in a particular dimension, LAMMPS is careful to put exactly one particle at the boundary (on either side of the box), not zero or two.

For the *region* style, a geometric volume is filled with particles on the lattice. This volume is what is both inside the simulation box and also consistent with the region volume. See the *region* command for details. Note that a region can be specified so that its "volume" is either inside or outside its geometric boundary. Also note that if a region is the same size as a periodic simulation box (in some dimension), LAMMPS does NOT implement the same logic described above for the *box* style, to ensure exactly one particle at periodic boundaries. If this is desired, you should either use the *box* style, or tweak the region size to get precisely the particles you want.

If the simulation box is formulated as a general triclinic box defined by arbitrary edge vectors **A**, **B**, **C**, then the *box* and *region* styles will create atoms on a lattice commensurate with those edge vectors. See the *Howto_triclinic* doc page for a detailed explanation of orthogonal, restricted triclinic, and general triclinic simulation boxes. As with the *create_box* command, the *lattice* command used by this command must be of style *custom* and use its *triclinic/general* option. The *a1, *a2*, *a3* settings of the *lattice* command define the edge vectors of a unit cell of the general triclinic lattice. The *create_box* command creates a simulation box which replicates that unit cell along each of the **A**, **B**, **C** edge vectors.

Note

LAMMPS allows specification of general triclinic simulation boxes as a convenience for users who may be converting data from solid-state crystallographic representations or from DFT codes for input to LAMMPS. However, as explained on the *Howto_triclinic* doc page, internally, LAMMPS only uses restricted triclinic simulation boxes. This means the box created by the *create_box* command as well as the atoms created by this command with their per-atom information (e.g. coordinates, velocities) are converted (rotated) from general to restricted triclinic form when the two commands are invoked. The *Howto_triclinic* doc page also discusses other LAMMPS commands which can input/output general triclinic representations of the simulation box and per-atom data.

The *box* style will fill the entire general triclinic box with particles on the lattice, as explained above.

Note

The *region* style also operates as explained above, but the check for particles inside the region is performed *after* the particle coordinates have been converted to the restricted triclinic box. This means the region must also be defined with respect to the restricted triclinic box, not the general triclinic box.

If the simulation box is general triclinic, the *single*, *random*, and *mesh* styles described next operate on the box *after* it has been converted to restricted triclinic. So all the settings for those styles should be made in that context.

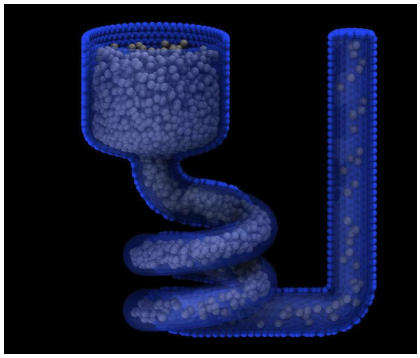
For the *single* style, a single particle is added to the system at the specified coordinates. This can be useful for debugging purposes or to create a tiny system with a handful of particles at specified positions. For a 2d simulation the specified z coordinate must be 0.0.

Changed in version 2Jun2022.

The *porosity* style has been renamed to *random* with added functionality.

For the *random* style, *N* particles are added to the system at randomly generated coordinates, which can be useful for generating an amorphous system. For 2d simulations, the z coordinates of all added atoms will be 0.0.

The particles are created one by one using the specified random number *seed*, resulting in the same set of particle coordinates, independent of how many processors are being used in the simulation. Unless the *overlap* keyword is specified, particles created by the *random* style will typically be highly overlapped. Various additional criteria can be used to accept or reject a random particle insertion; see the keyword discussion below. Multiple attempts per particle are made (see the *maxtry* keyword) until the insertion is either successful or fails. If this command fails to add all requested *N* particles, a warning will be output.



If the *region-ID* argument is specified as NULL, then the randomly created particles will be anywhere in the simulation box. If a *region-ID* is specified, a geometric volume is filled that is both inside the simulation box and is also consistent with the region volume. See the *region* command for details. Note that a region can be specified so that its "volume" is either inside or outside its geometric boundary.

Note that the create_atoms command adds particles to those that already exist. This means it can be used to add particles to a system previously read in from a data or restart file. Or the create_atoms command can be used multiple times, to add multiple sets of particles to the simulation. For example, grain boundaries can be created, by interleaving the create_atoms command with *lattice* commands specifying different orientations.

When this command is used, care should be taken to ensure the resulting system does not contain particles that are highly overlapped. Such overlaps will cause many interatomic potentials to compute huge energies and forces, leading to bad dynamics. There are several strategies to avoid this problem:

- Use the *delete_atoms overlap* command after create_atoms. For example, this strategy can be used to overlay and surround a large protein molecule with a volume of water molecules, then delete water molecules that overlap with the protein atoms.
- For the *random* style, use the optional *overlap* keyword to avoid overlaps when each new particle is created.
- Before running dynamics on an overlapped system, perform an *energy minimization*. Or run initial dynamics with *pair_style soft* or with *fix nve/limit* to un-overlap the particles, before running normal dynamics.

Added in version 2Jun2022.

For the *mesh* style, a file with a triangle mesh in STL format is read and one or more particles are placed into the area of each triangle. The reader supports both ASCII and binary files conforming to the format on the Wikipedia page. Binary STL files (e.g. as frequently offered for 3d-printing) can also be first converted to ASCII for editing with the *stl_bin2txt tool*. The use of the *units box* option is required. There are two algorithms available for placing atoms: *bisect* and *qrand*. They can be selected via the *meshmode* option; *bisect* is the default. If the atom style allows it, the radius will be set to a value depending on the algorithm and the value of the *radscale* parameter (see below), and the atoms created from the mesh are assigned a new molecule ID.

In *bisect* mode a particle is created at the center of each triangle unless the average distance of the triangle vertices from its center is larger than the *radthresh* value (default is lattice spacing in x-direction). In case the average distance is over the threshold, the triangle is recursively split into two halves along the the longest side until the threshold is reached. There will be at least one sphere per triangle. The value of *radthresh* is set as an argument to *meshmode bisect*. The average distance of the vertices from the center is also used to set the radius.

In *qrand* mode a quasi-random sequence is used to distribute particles on mesh triangles using an approach by *(Roberts)*. Particles are added to the triangle until the minimum number density is met or exceeded such that every triangle will have at least one particle. The minimum number density is set as an argument to the *qrand* option. The radius will be

set so that the sum of the area of the radius of the particles created in place of a triangle will be equal to the area of that triangle.

Note

The atom placement algorithms in the *mesh* style benefit from meshes where triangles are close to equilateral. It is therefore recommended to pre-process STL files to optimize the mesh accordingly. There are multiple open source and commercial software tools available with the capability to generate optimized meshes.

Note

In most cases the atoms created in *mesh* style will become an immobile or rigid object that would not be time integrated or moved by *fix move* or *fix rigid*. For computational efficiency *and* to avoid undesired contributions to pressure and potential energy due to close contacts, it is usually beneficial to exclude computing interactions between the created particles using *neigh_modify exclude*.

Individual atoms are inserted by this command, unless the *mol* keyword is used. It specifies a *template-ID* previously defined using the *molecule* command, which reads a file that defines the molecule. The coordinates, atom types, charges, etc, as well as any bond/angle/etc and special neighbor information for the molecule can be specified in the molecule file. See the *molecule* command for details. The only settings required to be in this file are the coordinates and types of atoms in the molecule.

Note

If you are using the *mol* keyword in combination with the *atom style template* command, they must use the same molecule template-ID.

Using a lattice to add molecules, e.g. via the *box* or *region* or *single* styles, is exactly the same as adding atoms on lattice points, except that entire molecules are added at each point, i.e. on the point defined by each basis atom in the unit cell as it tiles the simulation box or region. This is done by placing the geometric center of the molecule at the lattice point, and (by default) giving the molecule a random orientation about the point. The random *seed* specified with the *mol* keyword is used for this operation, and the random numbers generated by each processor are different. This means the coordinates of individual atoms (in the molecules) will be different when running on different numbers of processors, unlike when atoms are being created in parallel.

Note that with random rotations, it may be important to use a lattice with a large enough spacing that adjacent molecules will not overlap, regardless of their relative orientations. See the description of the *rotate* keyword below, which overrides the default random orientation and inserts all molecules at a specified orientation.

Note

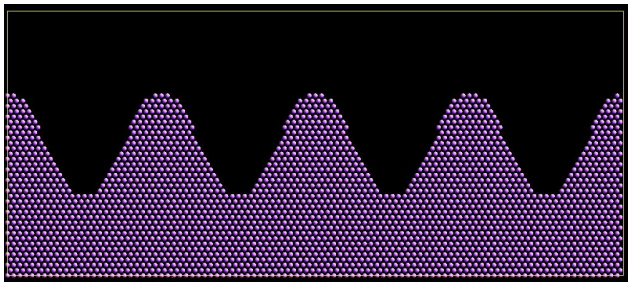
If the *create_box* command is used to create the simulation box, followed by the create_atoms command with its *mol* option for adding molecules, then you typically need to use the optional keywords allowed by the *create_box* command for extra bonds (angles,etc) or extra special neighbors. This is because by default, the *create_box* command sets up a non-molecular system that does not allow molecules to be added.

This is the meaning of the other optional keywords.

The *basis* keyword is only used when atoms (not molecules) are being created. It specifies an atom type that will be assigned to specific basis atoms as they are created that *overrides* the default atom type. See the *lattice* command for specifics on how basis atoms are defined for the unit cell of the lattice. By default, all created atoms are assigned the argument *type* as their atom type. To illustrate this please see the following 4 example *create_atom* command lines that all create the same system:

```
lattice diamond 4.36
create_atoms 1 box basis 1 1 basis 2 2 basis 3 1 basis 4 2 basis 5 1 basis 6 2 basis 7 1␣
↪basis 8 2
create_atoms 2 box basis 1 1 basis 2 2 basis 3 1 basis 4 2 basis 5 1 basis 6 2 basis 7 1␣
↪basis 8 2
create_atoms 1 box basis 2 2 basis 4 2 basis 6 2 basis 8 2
create_atoms 2 box basis 1 1 basis 3 1 basis 5 1 basis 7 1
```

The *ratio* and *subset* keywords can be used in conjunction with the *box* or *region* styles to limit the total number of particles inserted. The lattice defines a set of *Nlatt* eligible sites for inserting particles, which may be limited by the *region* style or the *var* and *set* keywords. For the *ratio* keyword, only the specified fraction of them ($0 \leq f \leq 1$) will be assigned particles. For the *subset* keyword only the specified *Nsubset* of them will be assigned particles. In both cases the assigned lattice sites are chosen randomly. An iterative algorithm is used that ensures the correct number of particles are inserted, in a perfectly random fashion. Which lattice sites are selected will change with the number of processors used.



Added in version 12Jun2025.

The *group* keyword adds the newly created atoms to the named *group*. If the group does not yet exist it will be created. There can be only one such group, thus if the *group* keyword is used multiple times, only the last one will be used. All created atoms are always added to the group "all".

The *remap* keyword only applies to the *single* style. If it is set to *yes*, then if the specified position is outside the simulation box, it will mapped back into the box, assuming the relevant dimensions are periodic. If it is set to *no*, no remapping is done and no particle is created if its position is outside the box.

The *var* and *set* keywords can be used together to provide a criterion for accepting or rejecting the addition of an individual atom, based on its coordinates. They apply to all styles except *single*. The *name* specified for the *var* keyword is the name of an *equal-style variable* that should evaluate to a zero or non-zero value based on one or two or three variables that will store the x, y, or z coordinates of an atom (one variable per coordinate). If used, these other variables must be specified by the *set* keyword. They are internal-style variable, because this command resets their values directly. The internal-style variables do not need to be defined in the input script (though they can be); if one (or more) is not defined, then the *set* option creates an *internal-style variable* with the specified name.

When an atom is about to be created, its (x, y, z) coordinates become the values for any *set* variable that is defined. The *var* variable is then evaluated. If the returned value is 0.0, the atom is not created. If it is non-zero, the atom is created.

As an example, these commands can be used in a 2d simulation, to create a sinusoidal surface. Note that the surface is "rough" due to individual lattice points being "above" or "below" the mathematical expression for the sinusoidal curve. If a finer lattice were used, the sinusoid would appear to be "smoother". Also note the use of the "xlat" and "ylat" *thermo_style* keywords, which converts lattice spacings to distance.

```
dimension   2
variable    x equal 100
variable    y equal 25
```

(continues on next page)

(continued from previous page)

```
lattice     hex 0.8442
region      box block 0 $x 0 $y -0.5 0.5
create_box  1 box

variable    v equal "(0.2*v_y*ylat * cos(v_xx/xlat * 2.0*PI*4.0/v_x) + 0.5*v_y*ylat - v_
↪yy) > 0.0"
create_atoms  1 box var v set x xx set y yy
write_dump  all atom sinusoid.lammpstrj
```

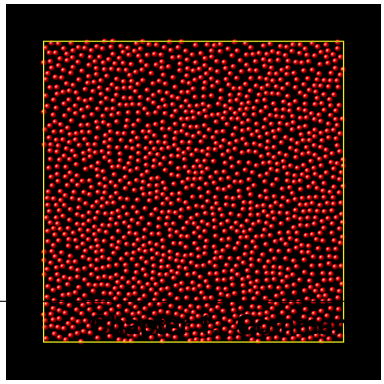
The *rotate* keyword allows specification of the orientation at which molecules are inserted. The axis of rotation is determined by the rotation vector (R_x, R_y, R_z) that goes through the insertion point. The specified *theta* determines the angle of rotation around that axis. Note that the direction of rotation for the atoms around the rotation axis is consistent with the right-hand rule: if your right-hand's thumb points along R, then your fingers wrap around the axis in the direction of rotation.

The *radscale* keyword only applies to the *mesh* style and adjusts the radius of created particles (see above), provided this is supported by the atom style. Its value is a prefactor (must be > 0.0, default is 1.0) that is applied to the atom radius inferred from the size of the individual triangles in the triangle mesh that the particle corresponds to.

Added in version 2Jun2022.

The *overlap* keyword only applies to the *random* style. It prevents newly created particles from being created closer than the specified *Doverlap* distance from any other particle. If particles have finite size (see *atom_style sphere* for example) *Doverlap* should be specified large enough to include the particle size in the non-overlapping criterion. If molecules are being randomly inserted, then an insertion is only accepted if each particle in the molecule meets the overlap criterion with respect to other particles (not including particles in the molecule itself).

Note



Checking for overlaps is a costly $\mathcal{O}(N(N+M))$ operation for inserting N new particles into a system with M existing particles. This is because distances to all M existing particles are computed for each new particle that is added. Thus the intended use of this keyword is to add relatively small numbers of particles to systems that remain at a relatively low density even after the new particles are created. Careful use of the *maxtry* keyword in combination with *overlap* is recommended. See the discussion above about systems with overlapped particles for alternate strategies that allow for overlapped insertions.

Added in version 2Jun2022.

The *maxtry* keyword only applies to the *random* style. It limits the number of attempts to generate valid coordinates for a single new particle that satisfy all requirements imposed by the *region*, *var*, and *overlap* keywords. The default is 10 attempts per particle before the loop over the requested N particles advances to the next particle. Note that if insertion success is unlikely (e.g., inserting new particles into a dense system using the *overlap* keyword), setting the *maxtry* keyword to a large value may result in this command running for a long time.

Here is an example for the *random* style using these commands

```
units         lj
dimension     2
region        box block 0 50 0 50 -0.5 0.5
create_box    1 box
create_atoms  1 random 2000 13487 NULL overlap 1.0 maxtry 50
pair_style    lj/cut 2.5
pair_coeff    1 1 1.0 1.0 2.5
```

to produce a system as shown in the image with 1520 particles (out of 2000 requested) that are moderately dense and which have no overlaps sufficient to prevent the LJ pair_style from running properly (because the overlap criterion is 1.0). The create_atoms command ran for 0.3 s on a single CPU core.

The *units* keyword determines the meaning of the distance units used by parameters for various styles. A *box* value selects standard distance units as defined by the *units* command (e.g., Å for units = *real* or *metal*. A *lattice* value means the distance units are in lattice spacings. These are affected settings:

- for *single* style: coordinates of the particle created
- for *random* style: overlap distance *Doverlap* by the *overlap* keyword
- for *mesh* style: *bisect* threshold value for *meshmode* = *bisect*
- for *mesh* style: *radthresh* value for *meshmode* = *bisect*
- for *mesh* style: *density* value for *meshmode* = *qrand*

Since *density* represents an area (distance ^2), the lattice spacing factor is also squared.

Atom IDs are assigned to created atoms in the following way. The collection of created atoms are assigned consecutive IDs that start immediately following the largest atom ID existing before the create_atoms command was invoked. This is done by the processor's communicating the number of atoms they each own, the first processor numbering its atoms from 1 to N_1, the second processor from N_1 + 1 to N_2, and so on, where N_1 is the number of atoms owned by the first processor, N_2 is the number owned by the second processor, and so forth. Thus, when the same simulation is performed on different numbers of processors, there is no guarantee a particular created atom will be assigned the same ID in both simulations. If molecules are being created, molecule IDs are assigned to created molecules in a similar fashion.

Aside from their ID, atom type, and *xyz* position, other properties of created atoms are set to default values, depending on which quantities are defined by the chosen *atom style*. See the *atom style* command for more details. See the *set* and *velocity* commands for info on how to change these values.

- charge = 0.0
- dipole moment magnitude = 0.0
- diameter = 1.0
- shape = 0.0 0.0 0.0
- density = 1.0
- volume = 1.0
- velocity = 0.0 0.0 0.0
- angular velocity = 0.0 0.0 0.0
- angular momentum = 0.0 0.0 0.0
- quaternion = (1,0,0,0)
- bonds, angles, dihedrals, impropers = none

If molecules are being created, these defaults can be overridden by values specified in the file read by the *molecule* command. That is, the file typically defines bonds (angles, etc.) between atoms in the molecule, and can optionally define charges on each atom.

Note that the *sphere* atom style sets the default particle diameter to 1.0 as well as the density. This means the mass for the particle is not 1.0, but is $\frac{\pi}{6}d^3 = 0.5236$, where d is the diameter. When using the *mesh* style, the particle diameter is adjusted from the size of the individual triangles in the triangle mesh.

Note that the *ellipsoid* atom style sets the default particle shape to (0.0 0.0 0.0) and the density to 1.0, which means it is a point particle, not an ellipsoid, and has a mass of 1.0.

Note that the *peri* style sets the default volume and density to 1.0 and thus also set the mass for the particle to 1.0.

The *set* command can be used to override many of these default settings.

1.17.4 Restrictions

An *atom_style* must be previously defined to use this command.

A rotation vector specified for a single molecule must be in the z-direction for a 2d model.

For *molecule templates* that are created from multiple files, i.e. contain multiple molecule *sets*, only the first set is used. To create multiple molecules the files currently need to be merged and different molecule IDs assigned with a Molecules section.

1.17.5 Related commands

lattice, *region*, *create_box*, *read_data*, *read_restart*

1.17.6 Default

The default for the *basis* keyword is that all created atoms are assigned the argument *type* as their atom type (when single atoms are being created). The other defaults are *remap* = no, *rotate* = random, *radscale* = 1.0, *radthresh* = x-lattice spacing, *overlap* not checked, *maxtry* = 10, and *units* = lattice.

1.18 create_bonds command

1.18.1 Syntax

```
create_bonds style args ... keyword value ...
```

- style = *many* or *single/bond* or *single/angle* or *single/dihedral* or *single/improper*

```
many args = group-ID group2-ID btype rmin rmax
  group-ID = ID of first group
  group2-ID = ID of second group, bonds will be between atoms in the 2 groups
  btype = bond type of created bonds
  rmin = minimum distance between pair of atoms to bond together
  rmax = maximum distance between pair of atoms to bond together
single/bond args = btype batom1 batom2
  btype = bond type of new bond
  batom1,batom2 = atom IDs for two atoms in bond
single/angle args = atype aatom1 aatom2 aatom3
  atype = angle type of new angle
  aatom1,aatom2,aatom3 = atom IDs for three atoms in angle
single/dihedral args = dtype datom1 datom2 datom3 datom4
  dtype = dihedral type of new dihedral
  datom1,datom2,datom3,datom4 = atom IDs for four atoms in dihedral
single/improper args = itype iatom1 iatom2 iatom3 iatom4
```

```
itype = improper type of new improper
iatom1,iatom2,iatom3,iatom4 = atom IDs for four atoms in improper
```

- zero or more keyword/value pairs may be appended
- keyword = *special*

```
special value = yes or no
```

1.18.2 Examples

```
create_bonds many all all 1 1.0 1.2
create_bonds many surf solvent 3 2.0 2.4
create_bonds single/bond 1 1 2
create_bonds single/angle 5 52 98 107 special no
create_bonds single/dihedral 2 4 19 27 101
create_bonds single/improper 3 23 26 31 57
```

1.18.3 Description

Create bonds between pairs of atoms that meet a specified distance criteria. Or create a single bond, angle, dihedral or improper between 2, 3, or 4 specified atoms.

The new bond (angle, dihedral, improper) interactions will then be computed during a simulation by the bond (angle, dihedral, improper) potential defined by the *bond_style*, *bond_coeff*, *angle_style*, *angle_coeff*, *dihedral_style*, *dihedral_coeff*, *improper_style*, *improper_coeff* commands.

The *many* style is useful for adding bonds to a system (e.g., between nearest neighbors in a lattice of atoms) without having to enumerate all the bonds in the data file read by the *read_data* command.

The *single* styles are useful for adding bonds, angles, dihedrals, and impropers to a system incrementally, then continuing a simulation.

Note that this command does not auto-create any angle, dihedral, or improper interactions when a bond is added, nor does it auto-create any bonds when an angle, dihedral, or improper is added. It also will not auto-create any angles when a dihedral or improper is added. Thus, the flexibility of this command is limited. It can be used several times to create different types of bond at different distances, but it cannot typically auto-create all the bonds or angles or dihedrals or impropers that would normally be defined in a data file for a complex system of molecules.

Note

If the system has no bonds (angles, dihedrals, impropers) to begin with, or if more bonds per atom are being added than currently exist, then you must ensure that the number of bond types and the maximum number of bonds per atom are set to large enough values, and similarly for angles, dihedrals, impropers, and special neighbors, otherwise an error may occur when too many bonds (angles, dihedrals, impropers) are added to an atom. If the *read_data* command is used to define the system, these parameters can be set via its optional *extra/bond/types*, *extra/bond/per/atom*, and similar keywords to the command. If the *create_box* command is used to define the system, these two parameters can be set via its optional *bond/types* and *extra/bond/per/atom* arguments, and similarly for angles, dihedrals, and impropers. See the corresponding documentation pages for these two commands for details.

The *many* style will create bonds between pairs of atoms I, J, where I is in one of the two specified groups and J is in the other. The two groups can be the same (e.g., group "all"). The created bonds will be of bond type *btype*, where *btype* must be a value between 1 and the number of bond types defined.

For a bond to be created, an I, J pair of atoms must be a distance D apart such that $r_{\min} \leq D \leq r_{\max}$.

The following settings must have been made in an input script before the *many* style is used:

- special_bonds weight for 1–2 interactions must be 0.0
- a *pair_style* must be defined
- no *kspace_style* defined
- minimum *pair_style* cutoff + *neighbor* skin $\geq r_{\max}$

These settings are required so that a neighbor list can be created to search for nearby atoms. Pairs of atoms that are already bonded cannot appear in the neighbor list, to avoid creation of duplicate bonds. The neighbor list for all atom type pairs must also extend to a distance that encompasses the *rmax* for new bonds to create. When using periodic boundary conditions, the box length in each periodic dimension must be larger than *rmax*, so that no bonds are created between the system and its own periodic image.

Note

If you want to create bonds between pairs of 1–3 or 1–4 atoms in the current bond topology, then you need to use *special_bonds lj 0 1 1* to ensure those pairs appear in the neighbor list. They will not appear with the default special_bonds settings, which are zero for 1–2, 1–3, and 1–4 atoms. 1–3 or 1–4 atoms are those which are two hops or three hops apart in the bond topology.

An additional requirement for this style is that your system must be ready to perform a simulation. This means, for example, that all *pair_style* coefficients be set via the *pair_coeff* command. A *bond_style* command and all bond coefficients must also be set, even if no bonds exist before this command is invoked. This is because the building of neighbor list requires initialization and setup of a simulation, similar to what a *run* command would require.

Note that you can change any of these settings after this command executes (e.g., if you wish to use long-range Coulombic interactions) via the *kspace_style* command for your subsequent simulation.

The *single/bond* style creates a single bond of type *btype* between two atoms with IDs *batom1* and *batom2*. *Btype* must be a value between 1 and the number of bond types defined.

The *single/angle* style creates a single angle of type *atype* between three atoms with IDs *aatom1*, *aatom2*, and *aatom3*. The ordering of the atoms is the same as in the *Angles* section of a data file read by the *read_data* command (i.e., the three atoms are ordered linearly within the angle; the central atom is *aatom2*). *Atype* must be a value between 1 and the number of angle types defined.

The *single/dihedral* style creates a single dihedral of type *dtype* between four atoms with IDs *datom1*, *datom2*, *datom3*, and *datom4*. The ordering of the atoms is the same as in the *Dihedrals* section of a data file read by the *read_data* command. I.e. the 4 atoms are ordered linearly within the dihedral. *dtype* must be a value between 1 and the number of dihedral types defined.

The *single/improper* style creates a single improper of type *itype* between four atoms with IDs *iatom1*, *iatom2*, *iatom3*, and *iatom4*. The ordering of the atoms is the same as in the *Impropers* section of a data file read by the *read_data* command. I.e. the 4 atoms are ordered linearly within the improper. *itype* must be a value between 1 and the number of improper types defined.

The keyword *special* controls whether an internal list of special bonds is created after one or more bonds, or a single angle, dihedral, or improper is added to the system.

The default value is *yes*. A value of *no* cannot be used with the *many* style.

This is an expensive operation since the bond topology for the system must be walked to find all 1–2, 1–3, and 1–4 interactions to store in an internal list, which is used when pairwise interactions are weighted; see the *special_bonds* command for details.

Thus if you are adding a few bonds or a large list of angles all at the same time, by using this command repeatedly, it is more efficient to only trigger the internal list to be created once, after the last bond (or angle, or dihedral, or improper) is added:

```
create_bonds single/bond 5 52 98 special no
create_bonds single/bond 5 73 74 special no
...
create_bonds single/bond 5 17 386 special no
create_bonds single/bond 4 112 183 special yes
```

Note that you **must** ensure the internal list is rebuilt after the last bond (angle, dihedral, improper) is added, *before* performing a simulation. Otherwise, pairwise interactions will not be properly excluded or weighted. LAMMPS does **not** check that you have done this correctly.

1.18.4 Restrictions

This command cannot be used with molecular systems defined using molecule template files via the *molecule* and *atom_style template* commands.

For style *many*, no *kspace style* must be defined. Also, the *rmax* value must be smaller than any periodic box length and the neighbor list cutoff (largest pair cutoff plus neighbor skin).

1.19.3 Description

This command creates a simulation box. It also partitions the box into a regular 3d grid of smaller sub-boxes, one per processor (MPI task). The geometry of the partitioning is based on the size and shape of the simulation box, the number of processors being used and the settings of the *processors* command. The partitioning can later be changed by the *balance* or *fix balance* commands.

Simulation boxes in LAMMPS can be either orthogonal or triclinic in shape. Orthogonal boxes are a brick in 3d (rectangle in 2d) with 6 faces that are each perpendicular to one of the standard xyz coordinate axes. Triclinic boxes are a parallelepiped in 3d (parallelogram in 2d) with opposite pairs of faces parallel to each other. LAMMPS supports two forms of triclinic boxes, restricted and general, which differ in how the box is oriented with respect to the xyz coordinate axes. See the *Howto triclinic* for a detailed description of all 3 kinds of simulation boxes.

The argument N is the number of atom types that will be used in the simulation.

Orthogonal and restricted triclinic boxes are created by specifying a region ID previously defined by the *region* command. General triclinic boxes are discussed below.

If the region is not of style *prism*, then LAMMPS encloses the region (block, sphere, etc.) with an axis-aligned orthogonal bounding box which becomes the simulation domain. For a 2d simulation, the zlo and zhi values of the simulation box must straddle zero.

If the region is of style *prism*, LAMMPS creates a non-orthogonal simulation domain shaped as a parallelepiped with triclinic symmetry. As defined by the *region prism* command, the parallelepiped has an "origin" at (xlo,ylo,zlo) and three edge vectors starting from the origin given by $\vec{a} = (x_{\rm hi} - x_{\rm lo}, 0, 0)$; $\vec{b} = (xy, y_{\rm hi} - y_{\rm lo}, 0)$; and $\vec{c} = (xz, yz, z_{\rm hi} - z_{\rm lo})$. In LAMMPS lingo, this is a restricted triclinic box because the three edge vectors cannot be defined in arbitrary (general) directions. The parameters xy, xz, and yz can be 0.0 or positive or negative values and are called "tilt factors" because they are the amount of displacement applied to faces of an originally orthogonal box to transform it into the parallelepiped. For a 2d simulation, the zlo and zhi values of the simulation box must straddle zero.

Typically a *prism* region used with the create_box command should have tilt factors (xy, xz, yz) that do not skew the box more than half the distance of the parallel box length. For example, if $x_{\rm lo} = 2$ and $x_{\rm hi} = 12$, then the x box length is 10 and the xy tilt factor must be between -5 and 5. Similarly, both xz and yz must be between $-(x_{\rm hi} - x_{\rm lo})/2$ and $+(y_{\rm hi} - y_{\rm lo})/2$. Note that this is not a limitation, since if the maximum tilt factor is 5 (as in this example), then configurations with tilt = $\ldots, -15, -5, 5, 15, 25, \ldots$ are all geometrically equivalent.

LAMMPS will issue a warning if the tilt factors of the created box do not meet this criterion. This is because simulations with large tilt factors may run inefficiently, since they require more ghost atoms and thus more communication. With very large tilt factors, LAMMPS may eventually produce incorrect trajectories and stop with errors due to lost atoms or similar issues.

See the *Howto triclinic* page for geometric descriptions of triclinic boxes and tilt factors, as well as how to transform the restricted triclinic parameters to and from other commonly used triclinic representations.

When a prism region is used, the simulation domain should normally be periodic in the dimension that the tilt is applied to, which is given by the second dimension of the tilt factor (e.g., *y* for *xy* tilt). This is so that pairs of atoms interacting across that boundary will have one of them shifted by the tilt factor. Periodicity is set by the *boundary* command. For example, if the *xy* tilt factor is non-zero, then the *y* dimension should be periodic. Similarly, the *z* dimension should be periodic if *xz* or *yz* is non-zero. LAMMPS does not require this periodicity, but you may lose atoms if this is not the case.

Note that if your simulation will tilt the box (e.g., via the *fix deform* command), the simulation box must be created as triclinic, even if the tilt factors are initially 0.0. You can also change an orthogonal box to a triclinic box or vice versa by using the *change box* command with its *ortho* and *triclinic* options.

Note

If the system is non-periodic (in a dimension), then you should not make the lo/hi box dimensions (as defined in your *region* command) radically smaller/larger than the extent of the atoms you eventually plan to create (e.g., via the *create_atoms* command). For example, if your atoms extend from 0 to 50, you should not specify the box bounds as −10000 and 10000. This is because as described above, LAMMPS uses the specified box size to lay out the 3d grid of processors. A huge (mostly empty) box will be sub-optimal for performance when using "fixed" boundary conditions (see the *boundary* command). When using "shrink-wrap" boundary conditions (see the *boundary* command), a huge (mostly empty) box may cause a parallel simulation to lose atoms the first time that LAMMPS shrink-wraps the box around the atoms.

As noted above, general triclinic boxes in LAMMPS allow the box to have arbitrary edge vectors **A**, **B**, **C**. The only restrictions are that the three vectors be distinct, non-zero, and not co-planar. They must also define a right-handed system such that (**A** x **B**) points in the direction of **C**. Note that a left-handed system can be converted to a right-handed system by simply swapping the order of any pair of the **A**, **B**, **C** vectors.

To create a general triclinic boxes, the region is specified as NULL and the next 6 parameters (alo,ahi,blo,bhi,clo,chi) define the three edge vectors **A**, **B**, **C** using additional information previously defined by the *lattice* command.

The lattice must be of style *custom* and use its *triclinic/general* option. This insures the lattice satisfies the restrictions listed above. The *a1, *a2, a3* settings of the *lattice* command define the edge vectors of a unit cell of the general triclinic lattice. This command uses them to define the three edge vectors and origin of the general triclinic box as:

- **A** = (ahi-alo) * *a1*
- **B** = (bhi-blo) * *a2*
- **C** = (chi-clo) * *a3*
- origin = (alo*a1 + blo*a2 + clo*a3)

For 2d general triclinic boxes, clo = -0.5 and chi = 0.5 is required.

Note

LAMMPS allows specification of general triclinic simulation boxes as a convenience for users who may be converting data from solid-state crystallographic representations or from DFT codes for input to LAMMPS. However,

as explained on the *Howto_triclinic* doc page, internally, LAMMPS only uses restricted triclinic simulation boxes. This means the box defined by this command and per-atom information (e.g. coordinates, velocities) defined by the *create_atoms* command are converted (rotated) from general to restricted triclinic form when the two commands are invoked. The <Howto_triclinic>` doc page also discusses other LAMMPS commands which can input/output general triclinic representations of the simulation box and per-atom data.

The optional keywords can be used to create a system that allows for bond (angle, dihedral, improper) interactions, or for molecules with special 1–2, 1–3, or 1–4 neighbors to be added later. These optional keywords serve the same purpose as the analogous keywords that can be used in a data file which are recognized by the *read_data* command when it sets up a system.

Note that if these keywords are not used, then the create_box command creates an atomic (non-molecular) simulation that does not allow bonds between pairs of atoms to be defined, or a *bond potential* to be specified, or for molecules with special neighbors to be added to the system by commands such as *create_atoms mol*, *fix deposit* or *fix pour*.

As an example, see the examples/deposit/in.deposit.molecule script, which deposits molecules onto a substrate. Initially there are no molecules in the system, but they are added later by the *fix deposit* command. The create_box command in the script uses the bond/types and extra/bond/per/atom keywords to allow this. If the added molecule contained more than one special bond (allowed by default), an extra/special/per/atom keyword would also need to be specified.

1.19.4 Restrictions

An *atom_style* and *region* must have been previously defined to use this command.

delete_atoms random fraction 0.3 no polymer NULL 482793 bond yes
delete_atoms random count 500 no ions NULL 482793
delete_atoms variable checkers
```

1.20.3 Description

Delete the specified atoms. This command can be used, for example, to carve out voids from a block of material or to delete created atoms that are too close to each other (e.g., at a grain boundary).

For style *group*, all atoms belonging to the group are deleted.

For style *region*, all atoms in the region volume are deleted. Additional atoms can be deleted if they are in a molecule for which one or more atoms were deleted within the region; see the *mol* keyword discussion below.

For style *overlap* pairs of atoms whose distance of separation is within the specified cutoff distance are searched for, and one of the two atoms is deleted. Only pairs where one of the two atoms is in the first group specified and the other atom is in the second group are considered. The atom that is in the first group is the one that is deleted.

Note that it is OK for the two group IDs to be the same (e.g., group *all*), or for some atoms to be members of both groups. In these cases, either atom in the pair may be deleted. Also note that if there are atoms which are members of both groups, the only guarantee is that at the end of the deletion operation, enough deletions will have occurred that no atom pairs within the cutoff will remain (subject to the group restriction). There is no guarantee that the minimum number of atoms will be deleted, or that the same atoms will be deleted when running on different numbers of processors.

For style *random* a subset of eligible atoms are deleted. Which atoms to delete are chosen randomly using the specified random number *seed*. Which atoms are deleted may vary when running on different numbers of processors.

For *ranstyle* = *fraction*, the specified fractional *value* (0.0 to 1.0) of eligible atoms are deleted. If *eflag* is set to *no*, then the number of deleted atoms will be approximate, but the operation will be fast. If *eflag* is set to *yes*, then the number deleted will match the requested fraction, but for large systems the selection of deleted atoms may take additional time to determine.

For *ranstyle* = *count*, the specified integer *value* is the number of eligible atoms are deleted. If *eflag* is set to *no*, then if the requested number is larger then the number of eligible atoms, a warning is issued and only the eligible atoms are deleted instead of the requested *value*. If *eflag* is set to *yes*, an error is triggered instead and LAMMPS will exit. For large systems the selection of atoms to delete may take additional time to determine, the same as for requesting an exact fraction with *pstyle* = *fraction*.

Which atoms are eligible for deletion for style *random* is determined by the specified *group-ID* and *region-ID*. To be eligible, an atom must be in both the specified group and region. If *group-ID* = all, there is effectively no group criterion. If *region-ID* is specified as NULL, no region criterion is imposed.

Added in version 4May2022.

For style *variable*, all atoms for which the atom-style variable with the given name evaluates to non-zero will be deleted. Additional atoms can be deleted if they are in a molecule for which one or more atoms were deleted within the region; see the *mol* keyword discussion below. This option allows complex selections of atoms not covered by the other options listed above.

Here is the meaning of the optional keywords.

If the *compress* keyword is set to *yes*, then after atoms are deleted, then atom IDs are re-assigned so that they run from 1 to the number of atoms in the system. This option is enabled by default for atomic systems. Note that in this case, the re-assignment of IDs is not really a compression, where gaps in atom IDs are removed by decrementing atom IDs that are larger. Instead the IDs for all atoms are erased, and new IDs are assigned so that the atoms owned by individual processors have consecutive IDs, as the *create_atoms* command explains. This is efficient, but incompatible with molecular systems.

Changed in version 10Sep2025.

For molecular systems (see the *atom_style* command), the atom ID re-assignment now calls the *reset_atoms id* command internally. For backward compatibility, the default setting is *no* in this case. This process does *not* preserve the order of atoms with respect to their atom IDs. See the *condense* keyword below.

Added in version 10Sep2025.

If the *condense* keyword set to *yes*, then after atoms are deleted, the atom IDs are re-assigned in such a way that the order of atom-IDs is preserved. This process is not efficient and cannot be used for very large systems and requires local storage that scales with the number of total atoms in the system. Also, the *compress* and the *condense* keywords cannot be used at the same time. Whichever of the two is used last will be applied.

A molecular system with fixed bonds, angles, dihedrals, or improper interactions, is one where the topology of the interactions is typically defined in the data file read by the *read_data* command, and where the interactions themselves are defined with the *bond_style*, *angle_style*, etc. commands.

Warning

If you delete atoms from a molecular system, you must be careful not to end up with bonded interactions that are stored by remaining atoms but which include deleted atoms. This will cause LAMMPS to generate a "missing atoms" error when the bonded interaction is computed. The *bond yes* and *mol yes* settings are recommended to avoid such inconsistencies.

If the *bond* keyword is set to *yes* then any bond or angle or dihedral or improper interaction that includes a deleted atom is also removed from the lists of such interactions stored by non-deleted atoms. Note that simply deleting interactions due to dangling bonds (e.g., at a surface) may result in a inaccurate or invalid model for the remaining atoms.

It the *mol* keyword is set to *yes*, then for every atom that is deleted, all other atoms in the same molecule (with the same molecule ID) will also be deleted. This is not done for atoms with molecule ID = 0, since such an ID is assumed to flag isolated atoms that are not part of molecules.

Note

The molecule deletion operation is invoked after all individual atoms have been deleted using the rules described above for each style. This means additional atoms may be deleted that are not in the group or region, that are not required by the overlap cutoff criterion, or that will create a higher fraction of porosity than was requested.

1.20.4 Restrictions

The *overlap* styles requires inter-processor communication to acquire ghost atoms and build a neighbor list. This means that your system must be ready to perform a simulation before using this command (force fields setup, atom masses set, etc.). Since a neighbor list is used to find overlapping atom pairs, it also means that you must define a *pair style* with the minimum force cutoff distance between any pair of atoms types (plus the *neighbor* skin) $\geq$ the specified overlap cutoff.

If the *special_bonds* command is used with a setting of 0, then a pair of bonded atoms (1–2, 1–3, or 1–4) will not appear in the neighbor list, and thus will not be considered for deletion by the *overlap* styles. You probably do not want to delete one atom in a bonded pair anyway.

The *bond yes* option cannot be used with molecular systems defined using molecule template files via the *molecule* and *atom_style template* commands.

1.20.5 Related commands

create_atoms, *reset_atoms id*

1.20.6 Default

The option defaults are compress = yes for atomic systems, otherwise compress = no; also bond = no and mol = no.

1.21 delete_bonds command

1.21.1 Syntax

```
delete_bonds group-ID style arg keyword ...
```

- group-ID = group ID
- style = *multi* or *atom* or *bond* or *angle* or *dihedral* or *improper* or *stats*

  ```
  multi arg = none
  atom arg = an atom type or range of types (see below)
  bond arg = a bond type or range of types (see below)
  angle arg = an angle type or range of types (see below)
  dihedral arg = a dihedral type or range of types (see below)
  improper arg = an improper type or range of types (see below)
  stats arg = none
  ```

- zero or more keywords may be appended
- keyword = *any* or *undo* or *remove* or *special*

  ```
  any arg = none = turn off interactions if any atoms are in the group (or on if undo␣
  →is also used)
  undo arg = none = turn specified bonds on instead of off
  remove arg = permanently remove bonds that have been turned off
  special arg = recompute pairwise 1-2, 1-3, and 1-4 lists
  ```

1.21.2 Examples

```
delete_bonds frozen multi remove
delete_bonds all atom 4 special
delete_bonds all bond 0*3 special
delete_bonds all stats

labelmap atom 4 hc
delete_bonds all atom hc special
```

1.21.3 Description

Turn off (or on) molecular topology interactions (i.e., bonds, angles, dihedrals, and/or impropers). This command is useful for deleting interactions that have been previously turned off by bond-breaking potentials. It is also useful for turning off topology interactions between frozen or rigid atoms. Pairwise interactions can be turned off via the *neigh_modify exclude* command. The *fix shake* command also effectively turns off certain bond and angle interactions.

For all styles, by default, an interaction is only turned off (or on) if all the atoms involved are in the specified group. See the *any* keyword to change the behavior.

Possible errors caused by using *delete_bonds*

Since this command by default only *turns off* bonded interactions, their definitions are still present and subject to the limitations due to LAMMPS' domain decomposition based parallelization. That is, when a bond is turned off, the two constituent atoms may move apart and may reach a distance where they can lead to a "bond atoms missing" error and crash the simulation. Adding the *remove* keyword (see below) is required to fully remove those interactions and prevent the error.

Several of the styles (*atom*, *bond*, *angle*, *dihedral*, *improper*) take a *type* as an argument. The specified *type* can be a *type label*. Otherwise, the type should be an integer from 0 to N, where N is the number of relevant types (atom types, bond types, etc.). A value of 0 is only relevant for style *bond*; see details below. For numeric types, a wildcard asterisk can be used in place of or in conjunction with the *type* argument to specify a range of types. This takes the form "*" or "*n" or "m*" or "m*n". If N is the number of types, then an asterisk with no numeric values means all types from 0 to N. A leading asterisk means all types from 0 to n (inclusive). A trailing asterisk means all types from m to N (inclusive). A middle asterisk means all types from m to n (inclusive). Note that it is fine to include a type of 0 for non-bond styles; it will simply be ignored.

For style *multi* all bond, angle, dihedral, and improper interactions of any type, involving atoms in the group, are turned off.

Style *atom* is the same as style *multi* except that in addition, one or more of the atoms involved in the bond, angle, dihedral, or improper interaction must also be of the specified atom type.

For style *bond*, only bonds are candidates for turn-off, and the bond must also be of the specified type. Styles *angle*, *dihedral*, and *improper* are treated similarly.

For style *bond*, you can set the type to 0 to delete bonds that have been previously broken by a bond-breaking potential (which sets the bond type to 0 when a bond is broken); for example, see the *bond_style quartic* command.

For style *stats* no interactions are turned off (or on); the status of all interactions in the specified group is simply reported. This is useful for diagnostic purposes if bonds have been turned off by a bond-breaking potential during a previous run.

Impact on special_bonds processing and exclusions

The default behavior of the delete_bonds command is to turn off interactions by toggling their type to a negative value, but not to permanently remove the interaction. For example, a bond_type of 2 is set to −2. The neighbor list creation routines will not include such an interaction in their interaction lists. The default is also to not alter the list of 1–2, 1–3, or 1–4 neighbors computed by the *special_bonds* command and used to weight pairwise force and energy calculations. This means that pairwise computations will proceed as if the bond (or angle, etc.) were still turned on.

Several keywords can be appended to the argument list to alter the default behaviors.

The *any* keyword changes the requirement that all atoms in the bond (angle, etc.) must be in the specified group in order to turn off the interaction. Instead, if any of the atoms in the interaction are in the specified group, it will be turned off (or on if the *undo* keyword is used).

The *undo* keyword inverts the delete_bonds command so that the specified bonds, angles, etc. are turned on if they are currently turned off. This means a negative value is toggled to positive. For example, for style *angle*, if *type* is specified as 2, then all angles with current type = −2 are reset to type = 2. Note that the *fix shake* command also sets bond and angle types negative, so this option should not be used on those interactions.

The *remove* keyword is invoked at the end of the delete_bonds operation. It causes turned-off bonds (angles, etc.) to be removed from each atom's data structure and then adjusts the global bond (angle, etc.) counts accordingly. Removal is a permanent change; removed bonds cannot be turned back on via the *undo* keyword. Removal does not alter the pairwise 1–2, 1–3, or 1–4 weighting list.

The *special* keyword is invoked at the end of the delete_bonds operation, after (optional) removal. It re-computes the pairwise 1–2, 1–3, 1–4 weighting list. The weighting list computation treats turned-off bonds the same as turned-on. Thus, turned-off bonds must be removed if you wish to change the weighting list.

Note

The choice of *remove* and *special* options affects how 1–2, 1–3, 1–4 pairwise interactions will be computed across bonds that have been modified by the delete_bonds command.

1.21.4 Restrictions

This command requires inter-processor communication to acquire ghost atoms, to coordinate the deleting of bonds, angles, etc. between atoms shared by multiple processors. This means that your system must be ready to perform a simulation before using this command (force fields setup, atom masses set, etc.). Just as would be needed to run dynamics, the force field you define should define a cutoff (e.g., through a *pair_style* command) which is long enough for a processor to acquire the ghost atoms its needs to compute bond, angle, etc. interactions.

If deleted bonds (or angles, etc.) are removed but the 1–2, 1–3, and 1–4 weighting list is not recomputed, this can cause a later *fix shake* command to fail due to an atom's bonds being inconsistent with the weighting list. This should only happen if the group used in the fix command includes both atoms in the bond, in which case you probably should be recomputing the weighting list.

1.21.5 Related commands

neigh_modify exclude, *special_bonds*, *fix shake*

1.21.6 Default

none

1.22 dielectric command

1.22.1 Syntax

```
dielectric value
```

- value = dielectric constant

1.22.2 Examples

```
dielectric 2.0
```

1.22.3 Description

Set the dielectric constant for Coulombic interactions (pairwise and long-range) to this value. The constant is unitless, since it is used to reduce the strength of the interactions. The value is used in the denominator of the formulas for Coulombic interactions (e.g., a value of 4.0 reduces the Coulombic interactions to 25% of their default strength). See the *pair_style* command for more details.

1.22.4 Restrictions

none

1.22.5 Related commands

pair_style

1.22.6 Default

dielectric 1.0
```

1.23 dihedral_coeff command

1.23.1 Syntax

```
dihedral_coeff N args
```

- N = numeric dihedral type (see asterisk form below) or alphanumeric type label
- args = coefficients for one or more dihedral types

1.23.2 Examples

```
dihedral_coeff 1 80.0 1 3
dihedral_coeff * 80.0 1 3 0.5
dihedral_coeff 2* 80.0 1 3 0.5

labelmap dihedral 1 backbone
dihedral_coeff backbone 80.0 1 3
```

1.23.3 Description

Specify the dihedral force field coefficients for one or more dihedral types. The number and meaning of the coefficients depends on the dihedral style. Dihedral coefficients can also be set in the data file read by the *read_data* command or in a restart file.

N can be specified in one of two ways. An explicit numeric value can be used, as in the first example above. Or *N* can be an alphanumeric type label, which is a string defined by the *labelmap* command or in a corresponding section of a data file read by the *read_data* command.

For numeric values only, a wild-card asterisk can be used to set the coefficients for multiple dihedral types. This takes the form "*" or "*n" or "n*" or "m*n". If *N* is the number of dihedral types, then an asterisk with no numeric values means all types from 1 to *N*. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to *N* (inclusive). A middle asterisk means all types from m to n (inclusive).

Note that using a dihedral_coeff command can override a previous setting for the same dihedral type. For example, these commands set the coeffs for all dihedral types, then overwrite the coeffs for just dihedral type 2:

```
dihedral_coeff * 80.0 1 3
dihedral_coeff 2 200.0 1 3
```

A line in a data file that specifies dihedral coefficients uses the exact same format as the arguments of the dihedral_coeff command in an input script, except that wild-card asterisks should not be used since coefficients for all *N* types must be listed in the file. For example, under the "Dihedral Coeffs" section of a data file, the line that corresponds to the first example above would be listed as

```
1 80.0 1 3
```

The *dihedral_style class2* is an exception to this rule, in that an additional argument is used in the input script to allow specification of the cross-term coefficients. See its doc page for details.

Note

When comparing the formulas and coefficients for various LAMMPS dihedral styles with dihedral equations defined by other force fields, note that some force field implementations divide/multiply the energy prefactor *K* by the multiple number of torsions that contain the *J*–*K* bond in an *I*-*J*-*K*-*L* torsion. LAMMPS does not do this (i.e., the listed dihedral equation applies to each individual dihedral). Thus, you need to define *K* appropriately to account for this difference, if necessary.

The list of all dihedral styles defined in LAMMPS is given on the *dihedral_style* doc page. They are also listed in more compact form on the *Commands dihedral* doc page.

On either of those pages, click on the style to display the formula it computes and its coefficients as specified by the associated dihedral_coeff command.

1.23.4 Restrictions

This command must come after the simulation box is defined by a *read_data*, *read_restart*, or *create_box* command.

A dihedral style must be defined before any dihedral coefficients are set, either in the input script or in a data file.

1.23.5 Related commands

dihedral_style

1.23.6 Default

none

1.24 dihedral_style command

1.24.1 Syntax

```
dihedral_style style
```

- style = *none* or *zero* or *hybrid* or *charmm* or *charmmfsw* or *class2* or *class2xe* or *cosine/shift/exp* or *cosine/squared/restricted* or *fourier* or *harmonic* or *helix* or *lepton* or *multi/harmonic* or *nharmonic* or *opls* or *spherical* or *table* or *table/cut*

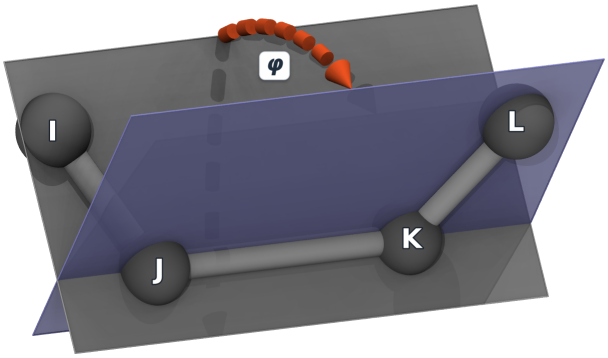
1.24.2 Examples

```
dihedral_style harmonic
dihedral_style multi/harmonic
dihedral_style hybrid harmonic charmm
```

1.24.3 Description

Set the formula(s) LAMMPS uses to compute dihedral interactions between quadruplets of atoms, which remain in force for the duration of the simulation. The list of dihedral quadruplets is read in by a *read_data* or *read_restart* command from a data or restart file.

Hybrid models where dihedrals are computed using different dihedral potentials can be setup using the *hybrid* dihedral style.



The coefficients associated with a dihedral style can be specified in a data or restart file or via the *dihedral_coeff* command.

All dihedral potentials store their coefficient data in binary restart files which means dihedral_style and *dihedral_coeff* commands do not need to be re-specified in an input script that restarts a simulation. See the *read_restart* command for details on how to do this. The one exception is that dihedral_style *hybrid* only stores the list of sub-styles in the restart file; dihedral coefficients need to be re-specified.

Note

When both a dihedral and pair style is defined, the *special_bonds* command often needs to be used to turn off (or weight) the pairwise interaction that would otherwise exist between four bonded atoms.

In the formulas listed for each dihedral style, *phi* is the torsional angle defined by the quadruplet of atoms. This angle has a sign convention as shown in this diagram:

where the I, J, K, L ordering of the four atoms that define the dihedral is from left to right and the angle φ points out of the page.

This sign convention effects several of the dihedral styles listed below (e.g., charmm, helix) in the sense that the energy formula depends on the sign of phi, which may be reflected in the value of the coefficients you specify.

Note

When comparing the formulas and coefficients for various LAMMPS dihedral styles with dihedral equations defined by other force fields, note that some force field implementations divide/multiply the energy prefactor K by the multiple number of torsions that contain the J–K bond in an I–J–K–L torsion. LAMMPS does not do this (i.e., the listed dihedral equation applies to each individual dihedral). Thus, you need to define K appropriately via the *dihedral_coeff* command to account for this difference if necessary.

Here is an alphabetic list of dihedral styles defined in LAMMPS. Click on the style to display the formula it computes and coefficients specified by the associated *dihedral_coeff* command.

Click on the style to display the formula it computes, any additional arguments specified in the dihedral_style command, and coefficients specified by the associated *dihedral_coeff* command.

There are also additional accelerated pair styles included in the LAMMPS distribution for faster performance on CPUs, GPUs, and KNLs. The individual style names on the *Commands dihedral* page are followed by one or more of (g,i,k,o,t) to indicate which accelerated styles exist.

- *none* - turn off dihedral interactions
- *zero* - topology but no interactions
- *hybrid* - define multiple styles of dihedral interactions
- *charmm* - CHARMM dihedral
- *charmmfsw* - CHARMM dihedral with force switching
- *class2* - COMPASS (class 2) dihedral

- *class2xe* - ClassII-xe (class 2) dihedral
- *cosine/shift/exp* - dihedral with exponential in spring constant
- *cosine/squared/restricted* - squared cosine dihedral with restricted term
- *fourier* - dihedral with multiple cosine terms
- *harmonic* - harmonic dihedral
- *helix* - helix dihedral
- *lepton* - dihedral potential from evaluating a string
- *multi/harmonic* - dihedral with 5 harmonic terms
- *nharmonic* - same as multi-harmonic with N terms
- *opls* - OPLS dihedral
- *quadratic* - dihedral with quadratic term in angle
- *spherical* - dihedral which includes angle terms to avoid singularities
- *table* - tabulated dihedral
- *table/cut* - tabulated dihedral with analytic cutoff

1.24.4 Restrictions

Dihedral styles can only be set for atom styles that allow dihedrals to be defined.

Most dihedral styles are part of the MOLECULE package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info. The doc pages for individual dihedral potentials tell if it is part of a package.

1.25 dihedral_write command

1.25.1 Syntax

```
dihedral_write dtype N file keyword
```

- dtype = dihedral type
- N = # of values
- file = name of file to write values to
- keyword = section name in file for this set of tabulated values

1.25.2 Examples

```
dihedral_write 1  500 table.txt Harmonic_1
dihedral_write 3 1000 table.txt Harmonic_3
```

1.25.3 Description

Added in version 8Feb2023.

Write energy and force values to a file as a function of the dihedral angle for the currently defined dihedral potential. Force in this context means the force with respect to the dihedral angle, not the force on individual atoms. This is useful for plotting the potential function or otherwise debugging its values. The resulting file can also be used as input for use with *dihedral style table*.

If the file already exists, the table of values is appended to the end of the file to allow multiple tables of energy and force to be included in one file. The individual sections may be identified by the *keyword*.

The energy and force values are computed for dihedrals ranging from 0 degrees to 360 degrees for 4 interacting atoms forming an dihedral type dtype, using the appropriate *dihedral_coeff* coefficients. N evenly spaced dihedrals are used. Since 0 and 360 degrees are the same dihedral angle, the latter entry is skipped.

For example, for N = 6, values would be computed at $\phi = 0, 60, 120, 180, 240, 300$.

The file is written in the format used as input for the *dihedral_style table* option with *keyword* as the section name. Each line written to the file lists an index number (1-N), an dihedral angle (in degrees), an energy (in energy units), and a force (in force units per radians^2). In case a new file is created, the first line will be a comment with a "DATE:" and "UNITS:" tag with the current date and *units* settings. For subsequent invocations of the *dihedral_write* command for the same file, data will be appended and the current units settings will be compared to the data from the header, if present. The *dihedral_write* will refuse to add a table to an existing file if the units are not the same.

1.25.4 Restrictions

All force field coefficients for dihedrals and other kinds of interactions must be set before this command can be invoked.

The table of the dihedral energy and force data data is created by using a separate, internally created, new LAMMPS instance with a dummy system of 4 atoms for which the dihedral potential energy is computed after transferring the dihedral style and coefficients and arranging the 4 atoms into the corresponding geometries. The dihedral force is then determined from the potential energies through numerical differentiation. As a consequence of this approach, not all dihedral styles are compatible. The following conditions must be met:

- The dihedral style must be able to write its coefficients to a data file. This condition excludes for example *dihedral style hybrid* and *dihedral style table*.
- The potential function must not have any terms that depend on geometry properties other than the dihedral. This condition excludes for example *dihedral style class2*. Please note that the *write_dihedral* command has no way of checking for this condition. It will check the style name against an internal list of known to be incompatible styles. The resulting tables may be bogus for unlisted dihedral styles if the requirement is not met. It is thus recommended to make careful tests for any created tables.

1.25.5 Related commands

1.26 dimension command

1.26.1 Syntax

```
dimension N
```

- N = 2 or 3

1.26.2 Examples

```
dimension 2
```

1.26.3 Description

Set the dimensionality of the simulation. By default LAMMPS runs 3d simulations. To run a 2d simulation, this command should be used prior to setting up a simulation box via the *create_box* or *read_data* commands. Restart files also store this setting.

See the discussion on the *Howto 2d* page for additional instructions on how to run 2d simulations.

Note

Some models in LAMMPS treat particles as finite-size spheres or ellipsoids, as opposed to point particles. In 2d, the particles will still be spheres or ellipsoids, not circular disks or ellipses, meaning their moment of inertia will be the same as in 3d.

1.26.4 Restrictions

This command must be used before the simulation box is defined by a *read_data* or *create_box* command.

```
displace_atoms group-ID style args keyword value ...
```

- group-ID = ID of group of atoms to displace
- style = *move* or *ramp* or *random* or *rotate*

```
move args = delx dely delz
  delx,dely,delz = distance to displace in each dimension (distance units)
  any of delx,dely,delz can be a variable (see below)
ramp args = ddim dlo dhi dim clo chi
  ddim = x or y or z
  dlo,dhi = displacement distance between dlo and dhi (distance units)
  dim = x or y or z
  clo,chi = lower and upper bound of domain to displace (distance units)
random args = dx dy dz seed
  dx,dy,dz = random displacement magnitude in each dimension (distance units)
  seed = random # seed (positive integer)
rotate args = Px Py Pz Rx Ry Rz theta
  Px,Py,Pz = origin point of axis of rotation (distance units)
  Rx,Ry,Rz = axis of rotation vector
  theta = angle of rotation (degrees)
```

- zero or more keyword/value pairs may be appended

```
keyword = units
  units value = box or lattice
```

1.27.2 Examples

```
displace_atoms top move 0 -5 0 units box
displace_atoms flow ramp x 0.0 5.0 y 2.0 20.5
```

1.27.3 Description

Displace a group of atoms. This can be used to move atoms a large distance before beginning a simulation or to randomize atoms initially on a lattice. For example, in a shear simulation, an initial strain can be imposed on the system. Or two groups of atoms can be brought into closer proximity.

The *move* style displaces the group of atoms by the specified 3d displacement vector. Any of the three quantities defining the vector components can be specified as an equal-style or atom-style *variable*. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated, and its value(s) used for the displacement(s). The scale factor implied by the *units* keyword will also be applied to the variable result.

Equal-style variables can specify formulas with various mathematical functions, and include *thermo_style* command keywords for the simulation box parameters and timestep and elapsed time. Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates or per-atom values read from a file. Note that if the variable references other *compute* or *fix* commands, those values must be up-to-date for the current timestep. See the "Variable Accuracy" section of the *variable* doc page for more details.

The *ramp* style displaces atoms a variable amount in one dimension depending on the atom's coordinate in a (possibly) different dimension. For example, the second example command displaces atoms in the x-direction an amount between 0.0 and 5.0 distance units. Each atom's displacement depends on the fractional distance its y coordinate is between 2.0 and 20.5. Atoms with y-coordinates outside those bounds will be moved the minimum (0.0) or maximum (5.0) amount.

The *random* style independently moves each atom in the group by a random displacement, uniformly sampled from a value between $-dx$ and $+dx$ in the x dimension, and similarly for y and z. Random numbers are used in such a way that the displacement of a particular atom is the same, regardless of how many processors are being used.

The *rotate* style rotates each atom in the group by the angle *theta* around a rotation axis $R = (R_x, R_y, R_z)$ that goes through a point $P = (P_x, P_y, P_z)$. The direction of rotation for the atoms around the rotation axis is consistent with the right-hand rule: if your right-hand thumb points along R, then your fingers wrap around the axis in the direction of positive theta.

If the defined *atom_style* assigns an orientation to each atom (*atom styles* ellipsoid, line, tri, body), then that property is also updated appropriately to correspond to the atom's rotation.

Distance units for displacements and the origin point of the *rotate* style are determined by the setting of *box* or *lattice* for the *units* keyword. *Box* means distance units as defined by the *units* command (e.g., Å for *real* or *metal* units). *Lattice* means distance units are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacing.

Note

Care should be taken not to move atoms on top of other atoms. After the move, atoms are remapped into the periodic simulation box if needed, and any shrink-wrap boundary conditions (see the *boundary* command) are enforced which may change the box size. Other than this effect, this command does not change the size or shape of the simulation box. See the *change_box* command if that effect is desired.

Note

Atoms can be moved arbitrarily long distances by this command. If the simulation box is non-periodic and shrink-wrapped (see the *boundary* command), this can change its size or shape. This is not a problem, except that the mapping of processors to the simulation box is not changed by this command from its initial 3d configuration; see the *processors* command. Thus, if the box size/shape changes dramatically, the mapping of processors to the simulation box may not end up as optimal as the initial mapping attempted to be.

1.27.4 Restrictions

For a 2d simulation, only rotations around the a vector parallel to the z-axis are allowed.

1.27.5 Related commands

lattice, *change_box*, *fix move*

1.27.6 Default

The option defaults are units = lattice.

1.28 dynamical_matrix command

Accelerator Variant: dynamical_matrix/kk

1.28.1 Syntax

```
dynamical_matrix group-ID style gamma args keyword value ...
```

- group-ID = ID of group of atoms to displace
- style = *regular* or *eskm*
- gamma = finite different displacement length (distance units)

- one or more keyword/arg pairs may be appended

  keyword = *file* or *binary*
    file name = name of output file for the dynamical matrix
    binary arg = *yes* or *no* or *gzip*

1.28.2 Examples

```
dynamical_matrix 1 regular 0.000001
dynamical_matrix 1 eskm 0.000001
dynamical_matrix 3 regular 0.00004 file dynmat.dat
dynamical_matrix 5 eskm 0.00000001 file dynamical.dat binary yes
```

1.28.3 Description

Calculate the dynamical matrix by finite difference of the selected group,

$$D = \frac{\Phi_{ij}^{\alpha\beta}}{\sqrt{M_i M_j}}$$

where D is the dynamical matrix and Φ is the force constant matrix defined by

$$\Phi_{ij}^{\alpha\beta} = \frac{\partial^2 U}{\partial x_{i,\alpha} \partial x_{j,\beta}}$$

The output for the dynamical matrix is printed three elements at a time. The three elements are the three β elements for a respective i/α/j combination. Each line is printed in order of j increasing first, α second, and i last.

If the style eskm is selected, the dynamical matrix will be in units of inverse squared femtoseconds. These units will then conveniently leave frequencies in THz.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

1.28.4 Restrictions

The command collects an array of nine times the number of atoms in a group on every single MPI rank, so the memory requirements can be very significant for large systems.

This command is part of the PHONON package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

1.28.5 Related commands

fix phonon, *fix numdiff* ,

compute hma uses an analytic formulation of the Hessian provided by a pair_style's Pair::single_hessian() function, if implemented.

1.28.6 Default

The default settings are file = "dynmat.dyn", binary = no

1.29 echo command

1.29.1 Syntax

```
echo style
```

- style = *none* or *screen* or *log* or *both*

1.29.2 Examples

```
echo both
echo log
```

1.29.3 Description

This command determines whether LAMMPS echoes each input script command to the screen and/or log file as it is read and processed. If an input script has errors, it can be useful to look at echoed output to see the last command processed.

The *command-line switch* -echo can be used in place of this command.

1.29.4 Restrictions

none

1.30 fenix command

1.30.1 Syntax

```
fenix keyword value ...
```

- keyword = *restart_file*, *restart_label*, *universal*, or *spares*

```
restart_file arg = file
   file = the file argument to pass to a jump command
restart_label arg = label
   label = the label argument to pass to a jump command
spares arg = N
   N = the number of ranks for Fenix to use as spares
universal arg = none
   initialize Fenix with universal scope
```

1.30.2 Examples

```
fenix spares 10
fenix spares 10 restart_label restart
fenix universal restart_label restart
```

1.30.3 Description

Added in version 2Sep2026.

This command initializes Fenix for online process recovery. From this point on, Fenix claims a number of ranks to be used as spares. The LAMMPS world is rebuilt without the spare ranks. Importantly, this means Fenix should be initialized before you perform any steps that rely on knowing the number of ranks or communicating. In general, the safest approach is to only have *variable* setup commands before calling this command.

On detecting a process failure, Fenix will automatically regain control. It will rebuild the LAMMPS world to the same number of ranks as before (when possible), using the spare ranks held at initialization. These spares take the place of the failed ranks, leaving surviving processes with the same rank number. Fenix then tears down LAMMPS and restarts according to whatever restart_file and restart_label are configured. The default restart file is "SELF". Upon restart, the *fenix_restarted* internal variable is defined and set to 1.

If this command is called more than once, subsequent invocations will update arguments. Fenix is not reinitialized, so changes to the spares argument are ignored.

By default, Fenix initializes assuming LAMMPS is run on a *single partition*. This is the best option for runs that do not involve partitions, or runs with partitions that run independently and thus have no communication between them. For runs with partitions that communicate, the *universal* flag is needed to ensure the universe's uworld is always valid to communicate on.

When the *universal* flag is not used, communication on the universe's uworld communicator may cause MPI to abort if any processes have failed. When the *universal* flag is used, you must not specify a number of spare ranks - instead, all ranks in the last partition are used as spares. When the *universal* flag is used, shrinking recovery (recovering when all spare ranks have been consumed) is not currently supported.

1.30.4 Restrictions

This command is part of the FENIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

1.30.5 Related commands

restart, *write restart*, *read restart*

1.30.6 Default

The default *restart_file* = SELF.

1.31 fix command

1.31.1 Syntax

```
fix ID group-ID style args
```

- ID = user-assigned name for the fix
- group-ID = ID of the group of atoms to apply the fix to
- style = one of a long list of possible style names (see below)
- args = arguments used by a particular style

1.31.2 Examples

```
fix 1 all nve
fix 3 all nvt temp 300.0 300.0 0.01
fix mine top setforce 0.0 NULL 0.0
```

1.31.3 Description

Set a fix that will be applied to a group of atoms. In LAMMPS, a "fix" is any operation that is applied to the system during timestepping or minimization. Examples include updating of atom positions and velocities due to time integration, controlling temperature, applying constraint forces to atoms, enforcing boundary conditions, computing diagnostics, etc. There are hundreds of fixes defined in LAMMPS and new ones can be added; see the *Modify* page for details.

Fixes perform their operations at different stages of the timestep. If two or more fixes operate at the same stage of the timestep, they are invoked in the order they were specified in the input script.

The ID of a fix can only contain alphanumeric characters and underscores.

Fixes can be deleted with the *unfix* command.

Note

The *unfix* command is the only way to turn off a fix; simply specifying a new fix with a similar style will not turn off the first one. This is especially important to realize for integration fixes. For example, using a *fix nve* command for a second run after using a *fix nvt* command for the first run will not cancel out the NVT time integration invoked by the "fix nvt" command. Thus, two time integrators would be in place!

If you specify a new fix with the same ID and style as an existing fix, the old fix is deleted and the new one is created (presumably with new settings). This is the same as if an "unfix" command were first performed on the old fix, except that the new fix is kept in the same order relative to the existing fixes as the old one originally was. Note that this operation also wipes out any additional changes made to the old fix via the *fix_modify* command.

The *fix modify* command allows settings for some fixes to be reset. See the page for individual fixes for details.

Some fixes store an internal "state" which is written to binary restart files via the *restart* or *write_restart* commands. This allows the fix to continue on with its calculations in a restarted simulation. See the *read_restart* command for info on how to re-specify a fix in an input script that reads a restart file. See the doc pages for individual fixes for info on which ones can be restarted.

Some fixes calculate and store any of four *styles* of quantities: global, per-atom, local, or per-grid.

A global quantity is one or more system-wide values, e.g. the energy of a wall interacting with particles. A per-atom quantity is one or more values per atom, e.g. the original coordinates of each atom at time 0. Per-atom values are set to 0.0 for atoms not in the specified fix group. Local quantities are calculated by each processor based on the atoms it owns, but there may be zero or more per atom, e.g. values for each bond. Per-grid quantities are calculated on a regular 2d or 3d grid which overlays a 2d or 3d simulation domain. The grid points and the data they store are distributed across processors; each processor owns the grid points which fall within its subdomain.

As a general rule of thumb, fixes that produce per-atom quantities have the word "atom" at the end of their style, e.g. *ave/atom*. Fixes that produce local quantities have the word "local" at the end of their style, e.g. *store/local*. Fixes that produce per-grid quantities have the word "grid" at the end of their style, e.g. *ave/grid*.

Global, per-atom, local, and per-grid quantities can also be of three *kinds*: a single scalar value (global only), a vector of values, or a 2d array of values. For per-atom, local, and per-grid quantities, a "vector" means a single value for each atom, each local entity (e.g. bond), or grid cell. Likewise an "array", means multiple values for each atom, each local entity, or each grid cell.

Note that a single fix can produce any combination of global, per-atom, local, or per-grid values. Likewise it can produce any combination of scalar, vector, or array output for each style. The exception is that for per-atom, local, and per-grid output, either a vector or array can be produced, but not both. The doc page for each fix explains the values it produces, if any.

When a fix output is accessed by another input script command it is referenced via the following bracket notation, where ID is the ID of the fix:

f_ID	entire scalar, vector, or array
f_ID[I]	one element of vector, one column of array
f_ID[I][J]	one element of array

In other words, using one bracket reduces the dimension of the quantity once (vector → scalar, array → vector). Using two brackets reduces the dimension twice (array → scalar). Thus, for example, a command that uses global scalar fix values as input can also process elements of a vector or array. Depending on the command, this can either be done directly using the syntax in the table, or by first defining a *variable* of the appropriate style to store the quantity, then using the variable as an input to the command.

Note that commands and *variables* which take fix outputs as input typically do not allow for all styles and kinds of data (e.g., a command may require global but not per-atom values, or it may require a vector of values, not a scalar). This means there is typically no ambiguity about referring to a fix output as c_ID even if it produces, for example, both a scalar and vector. The doc pages for various commands explain the details, including how any ambiguities are resolved.

In LAMMPS, the values generated by a fix can be used in several ways:

- Global values can be output via the *thermo_style custom* or *fix ave/time* command. Alternatively, the values can be referenced in an *equal-style variable* command.
- Per-atom values can be output via the *dump custom* command, or they can be time-averaged via the *fix ave/atom* command or reduced by the *compute reduce* command. Alternatively, per-atom values can be referenced in an *atom-style variable*.
- Local values can be reduced by the *compute reduce* command or histogrammed by the *fix ave/histo* command. They can also be output by the *dump local* command.

See the *Howto output* page for a summary of various LAMMPS output options, many of which involve fixes.

The results of fixes that calculate global quantities can be either "intensive" or "extensive" values. Intensive means the value is independent of the number of atoms in the simulation (e.g., temperature). Extensive means the value scales with the number of atoms in the simulation (e.g., total rotational kinetic energy). *Thermodynamic output* will normalize extensive values by the number of atoms in the system, depending on the "thermo_modify norm" setting. It will not normalize intensive values. If a fix value is accessed in another way (e.g., by a *variable*), you may want to know whether it is an intensive or extensive value. See the page for individual fix styles for further info.

Each fix style has its own page that describes its arguments and what it does, as listed below. Here is an alphabetical list of fix styles available in LAMMPS. They are also listed in more compact form on the *Commands fix* doc page.

There are also additional accelerated fix styles included in the LAMMPS distribution for faster performance on CPUs, GPUs, and KNLs. The individual style names on the *Commands fix* doc page are followed by one or more of (g,i,k,o,t) to indicate which accelerated styles exist.

- *accelerate/cos* - apply cosine-shaped acceleration to atoms
- *acks2/reaxff* - apply ACKS2 charge equilibration
- *adapt* - change a simulation parameter over time
- *adapt/fep* - enhanced version of fix adapt
- *addforce* - add a force to each atom
- *add/heat* - add a heat flux to each atom
- *addtorque/atom* - add a torque to a finite-size particles
- *addtorque/group* - add a torque to a group of atoms
- *alchemy* - perform an "alchemical transformation" between two partitions
- *align/self* - add torque to groups of atoms due to a self-alignment
- *amoeba/bitorsion* - torsion/torsion terms in AMOEBA force field
- *amoeba/pitorsion* - 6-body terms in AMOEBA force field
- *append/atoms* - append atoms to a running simulation
- *atom/swap* - Monte Carlo atom type swapping
- *atom_weight/apip* - compute atomic load of an *APIP potential* for load balancing
- *ave/atom* - compute per-atom time-averaged quantities
- *ave/chunk* - compute per-chunk time-averaged quantities
- *ave/correlate* - compute/output time correlations
- *ave/correlate/long* - alternative to *ave/correlate* that allows efficient calculation over long time windows
- *ave/grid* - compute per-grid time-averaged quantities
- *ave/histo* - compute/output time-averaged histograms
- *ave/histo/weight* - weighted version of fix ave/histo
- *ave/moments* - compute moments of scalar quantities
- *ave/time* - compute/output global time-averaged quantities
- *aveforce* - add an averaged force to each atom
- *balance* - perform dynamic load-balancing

- *baoab* - BAOAB Langevin dynamics integrator
- *brownian* - overdamped translational brownian motion
- *brownian/asphere* - overdamped translational and rotational brownian motion for ellipsoids
- *brownian/sphere* - overdamped translational and rotational brownian motion for spheres
- *bocs* - NPT style time integration with pressure correction
- *bond/break* - break bonds on the fly
- *bond/create* - create bonds on the fly
- *bond/create/angle* - create bonds on the fly with angle constraints
- *bond/react* - apply topology changes to model reactions
- *bond/swap* - Monte Carlo bond swapping
- *box/relax* - relax box size during energy minimization
- *charge/regulation* - Monte Carlo sampling of charge regulation
- *cmap* - CMAP torsion/torsion terms in CHARMM force field
- *colvars* - interface to the collective variables "Colvars" library
- *controller* - apply control loop feedback mechanism
- *damping/cundall* - Cundall non-viscous damping for granular simulations
- *deform* - change the simulation box size/shape
- *deform/pressure* - change the simulation box size/shape with additional loading conditions
- *deposit* - add new atoms above a surface
- *dpd/energy* - constant energy dissipative particle dynamics
- *drag* - drag atoms towards a defined coordinate
- *drude* - part of Drude oscillator polarization model
- *drude/transform/direct* - part of Drude oscillator polarization model
- *drude/transform/inverse* - part of Drude oscillator polarization model
- *dt/reset* - reset the timestep based on velocity, forces
- *edpd/source* - add heat source to eDPD simulations
- *efield* - impose electric field on system
- *efield/lepton* - impose electric field on system using a Lepton expression for the potential
- *efield/tip4p* - impose electric field on system with TIP4P molecules
- *ehex* - enhanced heat exchange algorithm
- *electrode/conp* - impose electric potential
- *electrode/conq* - impose total electric charge
- *electrode/thermo* - apply thermo-potentiostat
- *electron/stopping* - electronic stopping power as a friction force
- *electron/stopping/fit* - electronic stopping power as a friction force
- *enforce2d* - zero out z-dimension velocity and force

- *eos/cv* - applies a mesoparticle equation of state to relate the particle internal energy to the particle internal temperature
- *eos/table* - applies a tabulated mesoparticle equation of state to relate the particle internal energy to the particle internal temperature
- *eos/table/rx* - applies a tabulated mesoparticle equation of state to relate the concentration-dependent particle internal energy to the particle internal temperature
- *evaporate* - remove atoms from simulation periodically
- *external* - callback to an external driver program
- *ffl* - apply a Fast-Forward Langevin equation thermostat
- *filter/corotate* - implement corotation filter to allow larger timesteps with r-RESPA
- *flow/gauss* - Gaussian dynamics for constant mass flux
- *freeze* - freeze atoms in a granular simulation
- *gcmc* - grand canonical Monte Carlo insertions/deletions/translations/rotations
- *gemc* - Gibbs ensemble Monte Carlo exchanges/volumes/translations/rotations
- *gjf* - statistically correct Langevin temperature control using the GJ methods
- *gld* - generalized Langevin dynamics integrator
- *gle* - generalized Langevin equation thermostat
- *graphics/arrows* - add arrow graphics objects to *dump image* output
- *graphics/chunk* - add convex hull graphics for *chunks* to *dump image* output
- *graphics/isosurface* - add an isosurface for a group of atoms to *dump image* output
- *graphics/labels* - add images or text as graphics objects to *dump image* output
- *graphics/lines* - add a trace of atom positions to *dump image* output
- *graphics/objects* - add graphics objects to *dump image* output
- *graphics/periodic* - add selected periodic images of atoms and bonds to *dump image* output
- *graphics/replica* - add atoms from other replica to *dump image* output
- *gravity* - add gravity to atoms in a granular simulation
- *grem* - implements the generalized replica exchange method
- *halt* - terminate a dynamics run or minimization
- *heat* - add/subtract momentum-conserving heat
- *heat/flow* - plain time integration of heat flow with per-atom temperature updates
- *hmc* - Hybrid/Hamiltonian Monte Carlo (HMC) particle propagation
- *hyper/global* - global hyperdynamics
- *hyper/local* - local hyperdynamics
- *ilves* - ILVES constraints on bonds and/or angles
- *imd* - implements the “Interactive MD” (IMD) protocol
- *indent* - impose force due to an indenter
- *ipi* - enable LAMMPS to run as a client for i-PI path-integral simulations

- *lambda/apip* - compute switching parameter, that controls the precision of an *APIP potential*
- *lambda/la/csp/apip* - compute a conservative switching parameter, that controls the precision of an *APIP potential*
- *langevin* - Langevin temperature control
- *langevin/drude* - Langevin temperature control of Drude oscillators
- *langevin/eff* - Langevin temperature control for the electron force field model
- *langevin/spin* - Langevin temperature control for a spin or spin-lattice system
- *lb/fluid* - lattice-Boltzmann fluid on a uniform mesh
- *lb/momentum* - *fix momentum* replacement for use with a lattice-Boltzmann fluid
- *lb/viscous* - *fix viscous* replacement for use with a lattice-Boltzmann fluid
- *lineforce* - constrain atoms to move in a line
- *lambda_thermostat/apip* - apply energy conserving correction for an *APIP potential*
- *manifoldforce* - restrain atoms to a manifold during minimization
- *mdi/qm* - LAMMPS operates as a client for a quantum code via the MolSSI Driver Interface (MDI)
- *mdi/qmmm* - LAMMPS operates as client for QM/MM simulation with a quantum code via the MolSSI Driver Interface (MDI)
- *meso/move* - move mesoscopic SPH/SDPD particles in a prescribed fashion
- *mol/swap* - Monte Carlo atom type swapping with a molecule
- *momentum* - zero the linear and/or angular momentum of a group of atoms
- *momentum/chunk* - zero the linear and/or angular momentum of a chunk of atoms
- *move* - move atoms in a prescribed fashion
- *msst* - multi-scale shock technique (MSST) integration
- *mvv/dpd* - DPD using the modified velocity-Verlet integration algorithm
- *mvv/edpd* - constant energy DPD using the modified velocity-Verlet algorithm
- *mvv/tdpd* - constant temperature DPD using the modified velocity-Verlet algorithm
- *neb* - nudged elastic band (NEB) spring forces
- *neb/spin* - nudged elastic band (NEB) spring forces for spins
- *neighbor/swap* - kinetic Monte Carlo (kMC) atom swapping
- *nonaffine/displacement* - calculate nonaffine displacement of atoms
- *nph* - constant NPH time integration via Nose/Hoover
- *nph/asphere* - NPH for aspherical particles
- *nph/body* - NPH for body particles
- *nph/eff* - NPH for nuclei and electrons in the electron force field model
- *nph/sphere* - NPH for spherical particles
- *nphug* - constant-stress Hugoniostat integration
- *npt* - constant NPT time integration via Nose/Hoover
- *npt/asphere* - NPT for aspherical particles

- *npt/body* - NPT for body particles
- *npt/cauchy* - NPT with Cauchy stress
- *npt/eff* - NPT for nuclei and electrons in the electron force field model
- *npt/sphere* - NPT for spherical particles
- *npt/uef* - NPT style time integration with diagonal flow
- *numdiff* - numerically approximate atomic forces using finite energy differences
- *numdiff/virial* - numerically approximate virial stress tensor using finite energy differences
- *nve* - constant NVE time integration
- *nve/asphere* - NVE for aspherical particles
- *nve/asphere/noforce* - NVE for aspherical particles without forces
- *nve/body* - NVE for body particles
- *nve/dot* - rigid body constant energy time integrator for coarse grain models
- *nve/dotc/langevin* - Langevin style rigid body time integrator for coarse grain models
- *nve/eff* - NVE for nuclei and electrons in the electron force field model
- *nve/limit* - NVE with limited step length
- *nve/line* - NVE for line segments
- *nve/manifold/rattle* - NVE time integration for atoms constrained to a curved surface (manifold)
- *nve/noforce* - NVE without forces (update positions only)
- *nve/sphere* - NVE for spherical particles
- *nve/bpm/sphere* - NVE for spherical particles used in the BPM package
- *nve/spin* - NVE for a spin or spin-lattice system
- *nve/tri* - NVE for triangles
- *nvk* - constant kinetic energy time integration
- *nvt* - NVT time integration via Nose/Hoover
- *nvt/asphere* - NVT for aspherical particles
- *nvt/body* - NVT for body particles
- *nvt/eff* - NVE for nuclei and electrons in the electron force field model
- *nvt/manifold/rattle* - NVT time integration for atoms constrained to a curved surface (manifold)
- *nvt/sllod* - NVT for NEMD with SLLOD equations
- *nvt/sllod/eff* - NVT for NEMD with SLLOD equations for the electron force field model
- *nvt/sphere* - NVT for spherical particles
- *nvt/uef* - NVT style time integration with diagonal flow
- *oneway* - constrain particles on move in one direction
- *orient/bcc* - add grain boundary migration force for BCC
- *orient/fcc* - add grain boundary migration force for FCC
- *orient/eco* - add generalized grain boundary migration force

- *pafi* - constrained force averages on hyper-planes to compute free energies (PAFI)
- *pair* - access per-atom info from pair styles
- *phonon* - calculate dynamical matrix from MD simulations
- *pimd/langevin* - Feynman path-integral molecular dynamics with stochastic thermostat
- *pimd/nvt* - Feynman path-integral molecular dynamics with Nose-Hoover thermostat
- *pimd/langevin/bosonic* - Bosonic Feynman path-integral molecular dynamics for with stochastic thermostat
- *pimd/nvt/bosonic* - Bosonic Feynman path-integral molecular dynamics with Nose-Hoover thermostat
- *planeforce* - constrain atoms to move in a plane
- *plumed* - wrapper on PLUMED free energy library
- *polarize/bem/gmres* - compute induced charges at the interface between impermeable media with different dielectric constants with generalized minimum residual (GMRES)
- *polarize/bem/icc* - compute induced charges at the interface between impermeable media with different dielectric constants with the successive over-relaxation algorithm
- *polarize/functional* - compute induced charges at the interface between impermeable media with different dielectric constants with the energy variational approach
- *pour* - pour new atoms/molecules into a granular simulation domain
- *precession/spin* - apply a precession torque to each magnetic spin
- *press/berendsen* - pressure control by Berendsen barostat
- *press/langevin* - pressure control by Langevin barostat
- *print* - print text and variables during a simulation
- *propel/self* - model self-propelled particles
- *property/atom* - add customized per-atom values
- *python/invoke* - call a Python function during a simulation
- *python/move* - move particles using a Python function during a simulation run
- *qbmsst* - quantum bath multi-scale shock technique time integrator
- *qeq/comb* - charge equilibration for COMB potential
- *qeq/ctip* - charge equilibration for CTIP potential
- *qeq/dynamic* - charge equilibration via dynamic method
- *qeq/fire* - charge equilibration via FIRE minimizer
- *qeq/point* - charge equilibration via point method
- *qeq/reaxff* - charge equilibration for ReaxFF potential
- *qeq/rel/reaxff* - charge equilibration for ReaxFF potential with alternate efield implementation
- *qeq/shielded* - charge equilibration via shielded method
- *qeq/slater* - charge equilibration via Slater method
- *qmmm* - functionality to enable a quantum mechanics/molecular mechanics coupling
- *qmmm/xtb* - self-consistent GFN-xTB QM/MM with periodic PPPM electrostatics
- *qtb* - implement quantum thermal bath scheme

- *qtpie/reaxff* - apply QTPIE charge equilibration
- *rattle* - RATTLE constraints on bonds and/or angles
- *reaxff/bonds* - write out ReaxFF bond information
- *reaxff/species* - write out ReaxFF molecule information
- *recenter* - constrain the center-of-mass position of a group of atoms
- *restrain* - constrain a bond, angle, dihedral
- *rheo* - integrator for the RHEO package
- *rheo/thermal* - thermal integrator for the RHEO package
- *rheo/oxidation* - create oxidation bonds for the RHEO package
- *rheo/pressure* - pressure calculation for the RHEO package
- *rheo/viscosity* - viscosity calculation for the RHEO package
- *rhok* - add bias potential for long-range ordered systems
- *rigid* - constrain one or more clusters of atoms to move as a rigid body with NVE integration
- *rigid/meso* - constrain clusters of mesoscopic SPH/SDPD particles to move as a rigid body
- *rigid/nph* - constrain one or more clusters of atoms to move as a rigid body with NPH integration
- *rigid/nph/small* - constrain many small clusters of atoms to move as a rigid body with NPH integration
- *rigid/npt* - constrain one or more clusters of atoms to move as a rigid body with NPT integration
- *rigid/npt/small* - constrain many small clusters of atoms to move as a rigid body with NPT integration
- *rigid/nve* - constrain one or more clusters of atoms to move as a rigid body with alternate NVE integration
- *rigid/nve/small* - constrain many small clusters of atoms to move as a rigid body with alternate NVE integration
- *rigid/nvt* - constrain one or more clusters of atoms to move as a rigid body with NVT integration
- *rigid/nvt/small* - constrain many small clusters of atoms to move as a rigid body with NVT integration
- *rigid/small* - constrain many small clusters of atoms to move as a rigid body with NVE integration
- *rx* - solve reaction kinetic ODEs for a defined reaction set
- *saed/vtk* - time-average the intensities from *compute saed*
- *set* - reset an atom property via an atom-style variable every N steps
- *setforce* - set the force on each atom
- *setforce/spin* - set magnetic precession vectors on each atom
- *settorque/atom* - set the torque on each finite-size atom
- *sgcmc* - fix for hybrid semi-grand canonical MD/MC simulations
- *shake* - SHAKE constraints on bonds and/or angles
- *shardlow* - integration of DPD equations of motion using the Shardlow splitting
- *smd* - applied a steered MD force to a group
- *smd/adjust_dt* - calculate a new stable time increment for use with SMD integrators
- *smd/integrate_tlsph* - explicit time integration with total Lagrangian SPH pair style
- *smd/integrate_ulsph* - explicit time integration with updated Lagrangian SPH pair style

- *smd/move_tri_surf* - update position and velocity near rigid surfaces using SPH integrators
- *smd/setvel* - sets each velocity component, ignoring forces, for Smooth Mach Dynamics
- *smd/wall_surface* - create a rigid wall with a triangulated surface for use in Smooth Mach Dynamics
- *sph* - time integration for SPH/DPDE particles
- *sph/stationary* - update energy and density but not position or velocity in Smooth Particle Hydrodynamics
- *spring* - apply harmonic spring force to group of atoms
- *spring/chunk* - apply harmonic spring force to each chunk of atoms
- *spring/rg* - spring on radius of gyration of group of atoms
- *spring/self* - spring from each atom to its origin
- *srd* - stochastic rotation dynamics (SRD)
- *store/force* - store force on each atom
- *store/state* - store attributes for each atom
- *surface/global* - global granular surface model, each proc has copy
- *surface/local* - local granular surface model, distributed across procs
- *tdpd/source* - add external concentration source
- *temp/berendsen* - temperature control by Berendsen thermostat
- *temp/csld* - canonical sampling thermostat with Langevin dynamics
- *temp/csvr* - canonical sampling thermostat with Hamiltonian dynamics
- *temp/rescale* - temperature control by velocity rescaling
- *temp/rescale/eff* - temperature control by velocity rescaling in the electron force field model
- *tfmc* - perform force-bias Monte Carlo with time-stamped method
- *tgnvt/drude* - NVT time integration for Drude polarizable model via temperature-grouped Nose-Hoover
- *tgnpt/drude* - NPT time integration for Drude polarizable model via temperature-grouped Nose-Hoover
- *thermal/conductivity* - Mueller-Plathe kinetic energy exchange for thermal conductivity calculation
- *ti/spring* - perform thermodynamic integration between a solid and an Einstein crystal
- *tmd* - guide a group of atoms to a new configuration
- *ttm* - two-temperature model for electronic/atomic coupling (replicated grid)
- *ttm/cascade* - a two-temperature model for radiation damage cascades
- *ttm/grid* - two-temperature model for electronic/atomic coupling (distributed grid)
- *ttm/mod* - enhanced two-temperature model with additional options
- *ttm/thermal* - a two-temperature model for thermal transport
- *tune/kspace* - auto-tune *k*-space parameters
- *vector* - accumulate a global vector every *N* timesteps
- *viscosity* - Mueller-Plathe momentum exchange for viscosity calculation
- *viscous* - viscous damping for granular simulations
- *viscous/nonlinear* - nonlinear (Schiller-Naumann) viscous drag for granular simulations

- *viscous/sphere* - viscous damping on angular velocity for granular simulations
- *wall/body/polygon* - time integration for body particles of style *rounded/polygon*
- *wall/body/polyhedron* - time integration for body particles of style *rounded/polyhedron*
- *wall/colloid* - Lennard-Jones wall interacting with finite-size particles
- *wall/ees* - wall for ellipsoidal particles
- *wall/flow* - flow boundary conditions
- *wall/gran* - frictional wall(s) for granular simulations
- *wall/gran/region* - *fix wall/region* equivalent for use with granular particles
- *wall/harmonic* - harmonic spring wall
- *wall/harmonic/outside* - harmonic spring wall for containing particles
- *wall/lj1043* - Lennard-Jones 10–4–3 wall
- *wall/lj126* - Lennard-Jones 12–6 wall
- *wall/lj93* - Lennard-Jones 9–3 wall
- *wall/lepton* - Custom Lepton expression wall
- *wall/morse* - Morse potential wall
- *wall/piston* - moving reflective piston wall
- *wall/reflect* - reflecting wall(s)
- *wall/reflect/stochastic* - reflecting wall(s) with finite temperature
- *wall/region* - use region surface as wall
- *wall/region/ees* - use region surface as wall for ellipsoidal particles
- *wall/srd* - slip/no-slip wall for SRD particles
- *wall/table* - Tabulated potential wall wall
- *widom* - Widom insertions of atoms or molecules

1.31.4 Restrictions

Some fix styles are part of specific packages. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info. The doc pages for individual fixes tell if it is part of a package.

1.31.5 Related commands

unfix, *fix_modify*

1.31.6 Default

none

1.32 fix_modify command

1.32.1 Syntax

```
fix_modify fix-ID keyword value ...
```

- fix-ID = ID of the fix to modify
- one or more keyword/value pairs may be appended
- keyword = *bodyforces* or *dynamic/dof* or *energy* or *pad* or *press* or *respa* or *temp* or *virial* or *kick*

```
bodyforces value = early or late
  early/late = compute rigid-body forces/torques early or late in the timestep
dynamic/dof value = yes or no
  yes/no = do or do not re-compute the number of degrees of freedom (DOF) contributing to the temperature
energy value = yes or no
pad    arg = Nchar = # of characters to convert timestep to
press value = compute ID that calculates a pressure
respa value = 1 to max respa level or 0 (for outermost level)
temp value = compute ID that calculates a temperature
virial value = yes or no
vizsteps value = number of MD steps that generated graphics objects should remain visible for fixes that support it
kick value = yes or no
```

1.32.2 Examples

```
fix_modify 3 temp myTemp press myPress
fix_modify 1 energy yes
fix_modify tether respa 2
fix_modify myrxns vizsteps 100
```

1.32.3 Description

Modify one or more parameters of a previously defined fix. Specific fix styles support specific parameters. See the doc pages of an individual fix command for info on which fix_modify keywords it supports. This doc page only describes fix_modify keywords which are supported by multiple fixes. Additional keywords, specific to a single fix, are only described on that fix's doc page.

The *temp* keyword is used to determine how a fix computes temperature. The specified compute ID must have been previously defined by the user via the *compute* command and it must be a style of compute that calculates a temperature. All fixes that compute temperatures define their own compute by default, as described in their documentation. Thus this option allows the user to override the default method for computing T.

The *press* keyword is used to determine how a fix computes pressure. The specified compute ID must have been previously defined by the user via the *compute* command and it must be a style of compute that calculates a pressure. All fixes that compute pressures define their own compute by default, as described in their documentation. Thus this option allows the user to override the default method for computing P.

The *energy* keyword can be used with fixes that support it, which is explained at the bottom of their doc page. *Energy yes* will add a contribution to the potential energy of the system. More specifically, the fix's global or per-atom energy is included in the calculation performed by the *compute pe* or *compute pe/atom* commands. The former is what is used the *thermo_style* command for output of any quantity that includes the global potential energy of the system. Note that the *compute pe* and *compute pe/atom* commands also have an option to include or exclude the contribution from fixes.

For fixes that tally a global energy, it can also be printed with thermodynamic output by using the keyword f_ID in the thermo_style custom command, where ID is the fix-ID of the appropriate fix.

Note

If you are performing an *energy minimization* with one of these fixes and want the energy and forces it produces to be part of the optimization criteria, you must specify the *energy yes* setting.

Note

For most fixes that support the *energy* keyword, the default setting is *no*. For a few it is *yes*, when a user would expect that to be the case. The page of each fix gives the default.

The *virial* keyword can be used with fixes that support it, which is explained at the bottom of their doc page. *Virial yes* will add a contribution to the virial of the system. More specifically, the fix's global or per-atom virial is included in the calculation performed by the *compute pressure* or *compute stress/atom* commands. The former is what is used the *thermo_style* command for output of any quantity that includes the global pressure of the system. Note that the *compute pressure* and *compute stress/atom* commands also have an option to include or exclude the contribution from fixes.

Note

If you are performing an *energy minimization* with *box relaxation* and one of these fixes and want the virial contribution of the fix to be part of the optimization criteria, you must specify the *virial yes* setting.

Note

For most fixes that support the *virial* keyword, the default setting is *no*. For a few it is *yes*, when a user would expect that to be the case. The page of each fix gives the default.

For fixes that set or modify forces, it may be possible to select at which *r-RESPA* level the fix operates via the *respa* keyword. The RESPA level at which the fix is active can be selected. This is a number ranging from 1 to the number of levels. If the RESPA level is larger than the current maximum, the outermost level will be used, which is also the default setting. This default can be restored using a value of *0* for the RESPA level. The affected fix has to be enabled to support this feature; if not, *fix_modify* will report an error. Active fixes with a custom RESPA level setting are reported with their specified level at the beginning of a r-RESPA run.

The *dynamic/dof* keyword determines whether the number of atoms N in the fix group and their associated degrees of freedom are re-computed each time a temperature is computed. Only fix styles that calculate their own internal temperature use this option. Currently this is only the *fix rigid/nvt/small* and *fix rigid/npt/small* commands for the purpose of thermostatting rigid body translation and rotation. By default, N and their DOF are assumed to be constant. If you are adding atoms or molecules to the system (see the *fix pour*, *fix deposit*, and *fix gcmc* commands) or expect atoms or molecules to be lost (e.g. due to exiting the simulation box or via *fix evaporate*), then this option should be used to ensure the temperature is correctly normalized.

Note

Other thermostatting fixes, such as *fix nvt*, do not use the *dynamic/dof* keyword because they use a temperature compute to calculate temperature. See the *compute_modify dynamic/dof* command for a similar way to ensure

correct temperature normalization for those thermostats.

The *bodyforces* keyword determines whether the forces and torques acting on rigid bodies are computed *early* at the post-force stage of each timestep (right after per-atom forces have been computed and communicated among processors), or *late* at the final-integrate stage of each timestep (after any other fixes have finished their post-force tasks). Only the rigid-body integration fixes use this option, which includes *fix rigid* and *fix rigid/small*, and their variants.

The default is *late*. If there are other fixes that add forces to individual atoms, then the rigid-body constraints will include these forces when time-integrating the rigid bodies. If *early* is specified, then new fixes can be written that use or modify the per-body force and torque, before time-integration of the rigid bodies occurs. Note however this has the side effect, that fixes such as *fix addforce*, *fix setforce*, *fix spring*, which add forces to individual atoms will have no effect on the motion of the rigid bodies if they are specified in the input script after the fix rigid command. LAMMPS will give a warning if that is the case.

Added in version 2Apr2025.

The *pad* keyword only applies when a fix produces a file and the output filename is specified with a wildcard "*" character which becomes the timestep. If *pad* is 0, which is the default, the timestep is converted into a string of unpadded length (e.g., 100 or 12000 or 2000000). When *pad* is specified with *Nchar* $>$ 0, the string is padded with leading zeroes so they are all the same length = *Nchar*. For example, pad 7 would yield 0000100, 0012000, 2000000. This can be useful so that post-processing programs can easily read the files in ascending timestep order. Please see the documentation of the individual fix styles if this keyword is supported.

Added in version 11Feb2026.

The *vizsteps* keyword only applies when a fix produces event based graphics objects, e.g. atoms that were involved in a reaction or a Monte Carlo swap, move, or insert. It determines for how many time steps the graphics objects will remain visible in the corresponding *dump image output*.

The *kick* keyword can only be used with *fix nvt/sllod* and *fix nvt/sllod/eff*. If *kick* is *yes* and velocity is stored in the laboratory frame, the velocity profile consistent with *fix deform* will be superimposed at the start of the next run. If velocity is stored in the peculiar frame, the *kick* flag is ignored.

1.32.4 Restrictions

none

1.32.5 Related commands

fix, *compute temp*, *compute pressure*, *thermo_style*

1.32.6 Default

The option defaults are temp = ID defined by fix, press = ID defined by fix, energy = no, virial = different for each fix style, respa = 0, bodyforce = late.

1.33 fitpod command

1.33.1 Syntax

```
fitpod Ta_param.pod Ta_data.pod Ta_coefficients.pod
```

- fitpod = style name of this command
- Ta_param.pod = an input file that describes proper orthogonal descriptors (PODs)

- Ta_data.pod = an input file that specifies DFT data used to fit a POD potential
- Ta_coefficients.pod (optional) = an input file that specifies trainable coefficients of a POD potential

1.33.2 Examples

```
fitpod Ta_param.pod Ta_data.pod
fitpod Ta_param.pod Ta_data.pod Ta_coefficients.pod
```

1.33.3 Description

Added in version 22Dec2022.

Fit a machine-learning interatomic potential (ML-IAP) based on proper orthogonal descriptors (POD); please see *(Nguyen and Rohskopf)*, *(Nguyen2023)*, *(Nguyen2024)*, and *(Nguyen and Sema)* for details. The fitted POD potential can be used to run MD simulations via *pair_style pod*.

Two input files are required for this command. The first input file describes a POD potential parameter settings, while the second input file specifies the DFT data used for the fitting procedure. All keywords except *species* have default values. If a keyword is not set in the input file, its default value is used. The table below has one-line descriptions of all the keywords that can be used in the first input file (i.e. `Ta_param.pod`)

Keyword	Default	Type	Description
species	(none)	STRING	Chemical symbols for all elements in the system and have to match XYZ training files.
pbc	1 1 1	INT	three integer constants specify boundary conditions
rin	0.5	REAL	a real number specifies the inner cut-off radius
rcut	5.0	REAL	a real number specifies the outer cut-off radius
bessel_polynomial_degree	4	INT	the maximum degree of Bessel polynomials
inverse_polynomial_degree	8	INT	the maximum degree of inverse radial basis functions
number_of_environment_clusters	1	INT	the number of clusters for environment-adaptive potentials
number_of_principal_components	2	INT	the number of principal components for dimensionality reduction
onebody	1	BOOL	turns on/off one-body potential
twobody_number_radial_basis_functions	8	INT	number of radial basis functions for two-body potential
threebody_number_radial_basis_functions	6	INT	number of radial basis functions for three-body potential
threebody_angular_degree	5	INT	angular degree for three-body potential
fourbody_number_radial_basis_functions	4	INT	number of radial basis functions for four-body potential
fourbody_angular_degree	3	INT	angular degree for four-body potential
fivebody_number_radial_basis_functions	0	INT	number of radial basis functions for five-body potential
fivebody_angular_degree	0	INT	angular degree for five-body potential
sixbody_number_radial_basis_functions	0	INT	number of radial basis functions for six-body potential
sixbody_angular_degree	0	INT	angular degree for six-body potential
sevenbody_number_radial_basis_functions	0	INT	number of radial basis functions for seven-body potential
sevenbody_angular_degree	0	INT	angular degree for seven-body potential

Note that both the number of radial basis functions and angular degree must decrease as the body order increases. The next table describes all keywords that can be used in the second input file (i.e. `Ta_data.pod` in the example above):

Keyword	Default	Type	Description
file_format	extxyz	STRING	only the extended xyz format (extxyz) is currently supported
file_extension	xyz	STRING	extension of the data files
path_to_training_data_set	(none)	STRING	specifies the path to training data files in double quotes
path_to_test_data_set	""	STRING	specifies the path to test data files in double quotes
path_to_environment_configuration_set	""	STRING	specifies the path to environment configuration files in double quotes
fraction_training_data_set	1.0	REAL	a real number (<= 1.0) specifies the fraction of the training set used to fit POD
randomize_training_data_set	0	BOOL	turns on/off randomization of the training set
fraction_test_data_set	1.0	REAL	a real number (<= 1.0) specifies the fraction of the test set used to validate POD
randomize_test_data_set	0	BOOL	turns on/off randomization of the test set
fitting_weight_energy	100.0	REAL	a real constant specifies the weight for energy in the least-squares fit
fitting_weight_force	1.0	REAL	a real constant specifies the weight for force in the least-squares fit
fitting_regularization_parameter	1.0e-10	REAL	a real constant specifies the regularization parameter in the least-squares fit
error_analysis_for_training_data_set	0	BOOL	turns on/off error analysis for the training data set
error_analysis_for_test_data_set	0	BOOL	turns on/off error analysis for the test data set
basename_for_output_files	pod	STRING	a basename string added to the output files
precision_for_pod_coefficients	8	INT	number of digits after the decimal points for numbers in the coefficient file
group_weights	global	STRING	`table` uses group weights defined for each group named by filename

All keywords except *path_to_training_data_set* have default values. If a keyword is not set in the input file, its default value is used. After successful training, a number of output files are produced, if enabled:

- <basename>`_training_errors.pod` reports the errors in energy and forces for the training data set
- <basename>`_training_analysis.pod` reports detailed errors for all training configurations
- <basename>`_test_errors.pod` reports errors for the test data set
- <basename>`_test_analysis.pod` reports detailed errors for all test configurations
- <basename>`_coefficients.pod` contains the coefficients of the POD potential

After training the POD potential, `Ta_param.pod` and <basename>`_coefficients.pod` are the two files needed to use the POD potential in LAMMPS. See *pair_style pod* for using the POD potential. Examples about training and using POD potentials are found in the directory lammps/examples/PACKAGES/pod and the Github repo https://github.com/cesmix-mit/pod-examples.

Loss Function Group Weights

The *group_weights* keyword in the `data.pod` file is responsible for weighting certain groups of configurations in the loss function. For example:

```
group_weights table
Displaced_A15 100.0 1.0
Displaced_BCC 100.0 1.0
Displaced_FCC 100.0 1.0
Elastic_BCC   100.0 1.0
Elastic_FCC   100.0 1.0
GSF_110       100.0 1.0
GSF_112       100.0 1.0
Liquid        100.0 1.0
Surface       100.0 1.0
Volume_A15    100.0 1.0
Volume_BCC    100.0 1.0
Volume_FCC    100.0 1.0
```

This will apply an energy weight of `100.0` and a force weight of `1.0` for all groups in the `Ta` example. The groups are named by their respective filename. If certain groups are left out of this table, then the globally defined weights from the `fitting_weight_energy` and `fitting_weight_force` keywords will be used.

1.33.4 POD Potential

We consider a multi-element system of N atoms with N_e unique elements. We denote by r_n and Z_n position vector and type of an atom n in the system, respectively. Note that we have $Z_n \in \{1, \ldots, N_e\}$, $R = (r_1, r_2, \ldots, r_N) \in \mathbb{R}^{3N}$, and $Z = (Z_1, Z_2, \ldots, Z_N) \in \mathbb{N}^N$. The total energy of the POD potential is expressed as $E(R, Z) = \sum_{i=1}^{N} E_i(R_i, Z_i)$, where

$$E_i(R_i, Z_i) \;=\; \sum_{m=1}^{M} c_m \mathcal{D}_{im}(R_i, Z_i)$$

Here c_m are trainable coefficients and $\mathcal{D}_{im}(R_i, Z_i)$ are per-atom POD descriptors. Summing the per-atom descriptors over i yields the global descriptors $d_m(R, Z) = \sum_{i=1}^{N} \mathcal{D}_{im}(R_i, Z_i)$. It thus follows that $E(R, Z) = \sum_{m=1}^{M} c_m d_m(R, Z)$.

The per-atom POD descriptors include one, two, three, four, five, six, and seven-body descriptors, which can be specified in the first input file. Furthermore, the per-atom POD descriptors also depend on the number of environment clusters specified in the first input file. Please see *(Nguyen2024)* and *(Nguyen and Sema)* for the detailed description of the per-atom POD descriptors.

1.33.5 Training

A POD potential is trained using the least-squares regression against density functional theory (DFT) data. Let J be the number of training configurations, with N_j being the number of atoms in the j-th configuration. The training configurations are extracted from the extended XYZ files located in a directory (i.e., path_to_training_data_set in the second input file). Let $\{E_j^\star\}_{j=1}^J$ and $\{F_j^\star\}_{j=1}^J$ be the DFT energies and forces for J configurations. Next, we calculate the global descriptors and their derivatives for all training configurations. Let d_{jm}, $1 \le m \le M$, be the global descriptors associated with the j-th configuration, where M is the number of global descriptors. We then form a matrix $A \in \mathbb{R}^{J \times M}$ with entries $A_{jm} = d_{jm}/N_j$ for $j = 1, \ldots, J$ and $m = 1, \ldots, M$. Moreover, we form a matrix $B \in \mathbb{R}^{\mathcal{N} \times M}$ by stacking the derivatives of the global descriptors for all training configurations from top to bottom, where $\mathcal{N} = 3\sum_{j=1}^{J} N_j$.

The coefficient vector c of the POD potential is found by solving the following least-squares problem

$$\min_{c \in \mathbb{R}^M} w_E \|Ac - \bar{E}^\star\|^2 + w_F \|Bc + F^\star\|^2 + w_R \|c\|^2,$$

where w_E and w_F are weights for the energy (*fitting_weight_energy*) and force (*fitting_weight_force*), respectively; and w_R is the regularization parameter (*fitting_regularization_parameter*). Here $\bar{E}^\star \in \mathbb{R}^J$ is a vector of with entries $\bar{E}_j^\star = E_j^\star/N_j$ and $F^\star$ is a vector of $\mathcal{N}$ entries obtained by stacking $\{F_j^\star\}_{j=1}^J$ from top to bottom.

1.33.6 Validation

POD potential can be validated on a test dataset in a directory specified by setting path_to_test_data_set in the second input file. It is possible to validate the POD potential after the training is complete. This is done by providing the coefficient file as an input to *fitpod*, for example,

```
fitpod Ta_param.pod Ta_data.pod Ta_coefficients.pod
```

1.33.7 Restrictions

This command is part of the ML-POD package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

1.33.8 Related commands

pair_style pod, *compute pod/atom*, *compute podd/atom*, *compute pod/local*, *compute pod/global*

1.33.9 Default

The keyword defaults are also given in the description of the input files.

1.34 geturl command

1.34.1 Syntax

```
geturl url keyword args ...
```

- url = URL of the file to download
- zero or more keyword argument pairs may be provided
- keyword = *output* or *overwrite* or *timeout* or *verify* or *verbose*

  output filename = write to *filename* instead of inferring the name from the URL
  overwrite yes/no = if *yes* overwrite the output file in case it exists, do not if *no*
  timeout time = stop download if not completed within given time in seconds
  verify yes/no = verify SSL certificate and hostname if *yes*, do not if *no*
  verbose yes/no = if *yes* write verbose debug output from libcurl to screen, do not if *no*

1.34.2 Examples

```
geturl https://www.ctcms.nist.gov/potentials/Download/1990--Ackland-G-J-Vitek-V--Cu/2/Cu2.eam.fs
geturl https://github.com/lammps/lammps/blob/develop/bench/in.lj output in.bench-lj
```

1.34.3 Description

Added in version 29Aug2024.

Download a file from an URL to the local disk. This is implemented with the libcurl library which supports a large variety of protocols including "http", "https", "ftp", "scp", "sftp", "file". The transfer will only be performed on MPI rank 0.

Changed in version 2Sep2026.

The *output* keyword can be used to set the filename. By default, the string after the last '/' is used or 'index.html'.

The *overwrite* keyword determines whether a file should be overwritten if it already exists. If the argument is *no*, then the download will be skipped if the file exists.

The *timeout* keyword can be used to modify the timeout for downloads in seconds. After the timeout, the download will stop, even if incomplete. The default time value is 300, i.e. 5 minutes. Setting the timeout to 0 means to wait forever.

The *verify* keyword determines whether `libcurl` will validate the SSL certificate and hostname for encrypted connections. Turning this off may be required when using a proxy or connecting to a server with a self-signed SSL certificate.

The *verbose* keyword determines whether a detailed protocol of the steps performed by libcurl is written to the screen. Using the argument *yes* can be used to debug connection issues when the *geturl* command does not behave as expected. If the argument is *no*, geturl will operate silently and only report the error status number provided by libcurl, in case of a failure.

Using *geturl* with proxies for http or https

The libcurl library supports routing traffic through proxies by setting suitable environment variables (e.g. `http_proxy` or `https_proxy`) as required by some institutional or corporate security protocols. In that case you probably also want to use the *verify no* setting.

Using a proxy may also be needed if you are running on an HPC cluster where only the login or head nodes have access to the internet, but not the compute nodes. In this case the following input can be adapted and used for your local HPC environment:

```
variable headnode getenv PBS_O_HOST     # use SLURM_SUBMIT_HOST when using SLURM␣
↪instead of Torque/PBS
shell ssh -N -f -D 8001 ${headnode}     # start SOCKS5 proxy with backgrounded ssh␣
↪connection to cluster head node
shell putenv http_proxy=socks5://localhost:8001 https_proxy=socks5://localhost:8001
geturl https://download.lammps.org/tars/SHA256SUMS # download a file using proxy
shell head SHA256SUMS                # check if the download was successful
```

1.34.4 Restrictions

This command is part of the EXTRA-COMMAND package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info. It also requires that LAMMPS was built with support for the libcurl library. See the page about *Compiling LAMMPS with libcurl support* for further info. If support for libcurl is not included, using *geturl* will trigger an error.

group boundary intersect upper flow
group boundary delete
group mine dynamic all region myRegion every 100
group solvation dynamic peptide within 3.5 include molecule every 100 exclude peptide
```

1.35.3 Description

Identify a collection of atoms as belonging to a group. The group ID can then be used in other commands such as *fix*, *compute*, *dump*, or *velocity* to act on those atoms together.

If the group ID already exists, the group command adds the specified atoms to the group.

Note

By default groups are static, meaning the atoms are permanently assigned to the group. For example, if the *region* style is used to assign atoms to a group, the atoms will remain in the group even if they later move out of the region. As explained below, the *dynamic* style can be used to make a group dynamic so that a periodic determination is made as to which atoms are in the group. Since many LAMMPS commands operate on groups of atoms, you should think carefully about whether making a group dynamic makes sense for your model.

A group with the ID *all* is predefined. All atoms belong to this group. This group cannot be deleted, or made dynamic.

The *delete* style removes the named group and un-assigns all atoms that were assigned to that group. Since there is a restriction (see below) that no more than 32 groups can be defined at any time, the *delete* style allows you to remove groups that are no longer needed, so that more can be specified. You cannot delete a group if it has been used to define a current *fix* or *compute* or *dump*.

The *clear* style un-assigns all atoms that were assigned to that group. This may be dangerous to do during a simulation run (e.g., using the *run every* command if a fix or compute or other operation expects the atoms in the group to remain constant), but LAMMPS does not check for this.

The *empty* style creates an empty group, which is useful for commands like *fix gcmc* or with complex scripts that add atoms to a group.

The *region* style puts all atoms in the region volume into the group. Note that this is a static one-time assignment. The atoms remain assigned (or not assigned) to the group even if they later move out of the region volume. For extended triangle or line-segment particle, the center point of the triangle or line-segment is used to determine whether the particle is in the region or not.

The *type*, *id*, and *molecule* styles put all atoms with the specified atom types, atom IDs, or molecule IDs into the group. These three styles can use arguments specified in one of two formats.

The first format is a list of values (types or IDs). For example, the second command in the examples above puts all atoms of type 3 or 4 into the group named *water*. Each numeric entry in the list can be a colon-separated sequence `A:B` or `A:B:C`, as in two of the examples above. A "sequence" generates a sequence of values (types or IDs), with an optional increment. The first example with `500:1000` has the default increment of 1 and would add all atom IDs from 500 to 1000 (inclusive) to the group sub, along with 10, 25, and 50 since they also appear in the list of values. The second example with `100:10000:10` uses an increment of 10 and would thus add atoms IDs 100, 110, 120, . . . , 9990, 10000 to the group sub.

The second format is a *logical* followed by one or two values (type or ID). The 7 valid logicals are listed above. All the logicals except <> take a single argument. The third example above adds all atoms with IDs from 1 to 150 to the group named *sub*. The logical <> means "between" and takes 2 arguments. The fourth example above adds all atoms belonging to molecules with IDs from 50 to 250 (inclusive) to the group named polyA. For the *type* style, type labels are converted into numeric types before being evaluated.

The *variable* style evaluates a variable to determine which atoms to add to the group. It must be an *atom-style variable* previously defined in the input script. If the variable evaluates to a non-zero value for a particular atom, then that atom is added to the specified group.

Atom-style variables can specify formulas that include thermodynamic quantities, per-atom values such as atom coordinates, or per-atom quantities calculated by computes, fixes, or other variables. They can also include Boolean logic where two numeric values are compared to yield a 1 or 0 (effectively a true or false). Thus, using the *variable* style is a general way to flag specific atoms to include or exclude from a group.

For example, these lines define a variable "eatom" that calculates the potential energy of each atom and includes it in the group if its potential energy is above the threshold value −3.0.

```
compute         1 all pe/atom
compute         2 all reduce sum c_1
thermo_style    custom step temp pe c_2
run             0 post no

variable        eatom atom "c_1 > -3.0"
group           hienergy variable eatom
```

Note that these lines

```
compute         2 all reduce sum c_1
thermo_style    custom step temp pe c_2
run             0 post no
```

are necessary to ensure that the "eatom" variable is current when the group command invokes it. Because the eatom variable computes the per-atom energy via the pe/atom compute, it will only be current if a run has been performed which evaluated pairwise energies, and the pe/atom compute was actually invoked during the run. Printing the thermodynamic info for compute 2 ensures that this is the case, since it sums the pe/atom compute values (in the reduce compute) to output them to the screen. See the "Variable Accuracy" section of the *variable* page for more details on ensuring that variables are current when they are evaluated between runs.

The *include* style with its arg *molecule* adds atoms to a group that have the same molecule ID as atoms already in the group. The molecule ID = 0 is ignored in this operation, since it is assumed to flag isolated atoms that are not part of molecules. An example of where this operation is useful is if the *region* style has been used previously to add atoms to a group that are within a geometric region. If molecules straddle the region boundary, then atoms outside the region that are part of molecules with atoms inside the region will not be in the group. Using the group command a second time with *include molecule* will add those atoms that are outside the region to the group.

Note

The *include molecule* operation is relatively expensive in a parallel sense. This is because it requires communication of relevant molecule IDs between all the processors and each processor to loop over its atoms once per processor, to compare its atoms to the list of molecule IDs from every other processor. Hence it scales as N, rather than N/P as most of the group operations do, where N is the number of atoms, and P is the number of processors.

The *subtract* style takes a list of two or more existing group names as arguments. All atoms that belong to the first group, but not to any of the other groups are added to the specified group.

The *union* style takes a list of one or more existing group names as arguments. All atoms that belong to any of the listed groups are added to the specified group.

The *intersect* style takes a list of two or more existing group names as arguments. Atoms that belong to every one of the listed groups are added to the specified group.

The *dynamic* style flags an existing or new group as dynamic. This means atoms will be (re)assigned to the group periodically as a simulation runs. This is in contrast to static groups where atoms are permanently assigned to the group. The way the assignment occurs is as follows. Only atoms in the group specified as the parent group via the parent-ID are initially assigned to the dynamic group before the following selection conditions are applied. The *include* and *within* keywords can then trigger including additional atoms which may be outside the parent group.

If the *region* keyword is used, atoms not in the specified region are removed from the dynamic group.

If the *var* keyword is used, the variable name must be an atom-style or atomfile-style variable. The variable is evaluated and atoms whose per-atom values are 0.0, are removed from the dynamic group.

If the *property* keyword is used, the name refers to a custom integer or floating point per-atom vector defined via the *fix property/atom* command. This means the values in the vector can be read as part of a data file with the *read_data* command or specified with the *set* command. Or accessed and changed via the *library interface to LAMMPS*, or by styles you add to LAMMPS (pair, fix, compute, etc) which access the custom vector and modify its values. Which means the values can be modified between or during simulations. Atoms whose values in the custom vector are zero are removed from the dynamic group. Note that the name of the custom per-atom vector is specified just as *name*, not as *i_name* or *d_name* as it is for other commands that use different kinds of custom atom vectors or arrays as arguments.

The assignment of atoms to a dynamic group is done at the beginning of each run and on every timestep that is a multiple of *N*, which is the argument for the *every* keyword (*N* = 1 is the default). For an energy minimization, via the *minimize* command, an assignment is made at the beginning of the minimization, but not during the iterations of the minimizer.

Added in version 30Mar2026.

The optional *exclude* keyword has a group ID as argument and after all other atom selections for the dynamic group have been performed, it removes selected atoms that are in the specified group from the dynamic group. This can for example be used to first select additional solvent atoms up to a given distance from a group using the *within* keyword (see below), but then exclude the non-solvent atoms.

Added in version 11Feb2026.

The optional *include* keyword with its argument *molecule* adds atoms to a dynamic group that have the same molecule ID as atoms already in the group. Atoms with the molecule ID = 0 are ignored in this operation, since that ID is generally assumed to flag isolated atoms that are not part of molecules. An example of where this operation is useful is if the dynamic group is defined using a *region*. If molecules straddle the region boundary, then atoms outside the region that are part of molecules with atoms inside the region will be added to the group (see above).

Added in version 30Mar2026.

The optional *within* keyword with its *cutoff* argument adds atoms to a dynamic group that are within the given cutoff distance from any of the atoms selected for the dynamic group. Since this requires processing a neighbor list and computing distances for potentially many pairs of atoms plus and additional forward communication step, this can be an expensive operation that should be used in combination with the *every* option and a value of (e.g. 10 or larger) to reduce the overhead for updating the selection. Outside of flow simulations and similar, atoms will mostly oscillate around their positions and diffuse on a much larger timescale, so infrequent group updates will not be a problem. Also when selecting atoms for output to a *dump file* it is not necessary to update the selection more often than the dump interval.

The point in the timestep at which atoms are assigned to a dynamic group is **after** interatomic forces have been computed, but **before** any fixes which alter forces or otherwise update the system have been invoked. This means that atom positions have been updated, neighbor lists and ghost atoms are current, and both intermolecular and intramolecular forces have been calculated based on the new coordinates. Thus the region criterion, if applied, should be accurate. Also, any computes invoked by an atom-style variable should use updated information for that timestep (e.g., potential energy/atom or coordination number/atom). Similarly, fixes or computes which are invoked after that point in the timestep, should operate on the new group of atoms.

Note

If the *region* keyword is used to determine what atoms are in the dynamic group, atoms can move outside of the simulation box between reneighboring events. Thus if you want to include all atoms on the left side of the simulation box, you probably want to set the left boundary of the region to be outside the simulation box by some reasonable amount (e.g., up to the cutoff of the potential), else they may be excluded from the dynamic region.

Here is an example of using a dynamic group to shrink the set of atoms being integrated by using a spherical region with a variable radius (shrinking from 18 to 5 over the course of the run). This could be used to model a quench of the system, freezing atoms outside the shrinking sphere, then converting the remaining atoms to a static group and running further.

```
variable        nsteps equal 5000
variable        rad equal 18-(step/v_nsteps)*(18-5)
region          ss sphere 20 20 0 v_rad
group           mobile dynamic all region ss
fix             1 mobile nve
run             ${nsteps}
group           mobile static
run             ${nsteps}
```

Note

All fixes and computes take a group ID as an argument, but they do not all allow for use of a dynamic group. If you get an error message that this is not allowed, but feel that it should be for the fix or compute in question, then please post your reasoning to the LAMMPS forum at MatSci and we can look into changing it. The same applies if you come across inconsistent behavior when dynamic groups are allowed.

The *static* style removes the setting for a dynamic group, converting it to a static group (the default). The atoms in the static group are those currently in the dynamic group.

1.35.4 Restrictions

There can be no more than 32 groups defined at one time, including "all".

The parent group of a dynamic group cannot itself be a dynamic group.

1.35.5 Related commands

dump, *fix*, *region*, *velocity*

1.35.6 Default

All atoms belong to the "all" group.

1.36 group2ndx command

1.37 ndx2group command

1.37.1 Syntax

```
group2ndx file args
ndx2group file args
```

- file = name of index file to write out or read in
- args = zero or more group IDs may be appended

1.37.2 Examples

```
group2ndx allindex.ndx
group2ndx someindex.ndx upper lower mobile
ndx2group someindex.ndx
ndx2group someindex.ndx mobile
```

1.37.3 Description

Write or read a Gromacs style index file in text format that associates atom IDs with the corresponding group definitions. This index file can be used with in combination with Gromacs analysis tools or to import group definitions into the *fix colvars* input file.

It can also be used to save and restore group definitions for static groups using the individual atom IDs. This may be important if the original group definition depends on a region or otherwise on the geometry and thus cannot be easily recreated.

Another application would be to import atom groups defined for Gromacs simulation into LAMMPS. When translating Gromacs topology and geometry data to LAMMPS.

The *group2ndx* command will write group definitions to an index file. Without specifying any group IDs, all groups will be written to the index file. When specifying group IDs, only those groups will be written to the index file. In order to follow the Gromacs conventions, the group *all* will be renamed to *System* in the index file.

The *ndx2group* command will create or update group definitions from those stored in an index file. Without specifying any group IDs, all groups except *System* will be read from the index file and the corresponding groups recreated. If a group of the same name already exists, it will be completely reset. When specifying group IDs, those groups, if present, will be read from the index file and restored.

1.37.4 File Format

The file format is equivalent and compatible with what is produced by the Gromacs make_ndx command. and follows the Gromacs definition of an ndx file

Each group definition begins with the group name in square brackets with blanks, e.g. [water] and is then followed by the list of atom indices, which may be spread over multiple lines. Here is a small example file:

```
[ Oxygen ]
1  4  7
[ Hydrogen ]
2  3  5  6
8  9
[ Water ]
1 2 3 4 5 6 7 8 9
```

The index file defines 3 groups: Oxygen, Hydrogen, and Water and the latter happens to be the union of the first two.

1.37.5 Restrictions

These commands require that atoms have atom IDs, since this is the information that is written to the index file.

These commands are part of the EXTRA-COMMAND package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

1.37.6 Related commands

group, *dump*, *fix colvars*

1.37.7 Default

none

1.38 hyper command

1.38.1 Syntax

```
hyper N Nevent fix-ID compute-ID keyword values ...
```

- N = # of timesteps to run
- Nevent = check for events every this many steps
- fix-ID = ID of a fix that applies a global or local bias potential, can be NULL
- compute-ID = ID of a compute that identifies when an event has occurred
- zero or more keyword/value pairs may be appended
- keyword = *min* or *dump* or *rebond*

```
min values = etol ftol maxiter maxeval
  etol = stopping tolerance for energy, used in quenching
  ftol = stopping tolerance for force, used in quenching
  maxiter = max iterations of minimize, used in quenching
  maxeval = max number of force/energy evaluations, used in quenching
dump value = dump-ID
```

```
      dump-ID = ID of dump to trigger whenever an event takes place
    rebond value = Nrebond
      Nrebond = frequency at which to reset bonds, even if no event has occurred
```

1.38.2 Examples

```
compute event all event/displace 1.0
fix HG mobile hyper/global 3.0 0.3 0.4 800.0
hyper 5000 100 HG event min 1.0e-6 1.0e-6 100 100 dump 1 dump 5
```

1.38.3 Description

Run a bond-boost hyperdynamics (HD) simulation where time is accelerated by application of a bias potential to one or more pairs of nearby atoms in the system. This command can be used to run both global and local hyperdynamics. In global HD a single bond within the system is biased on each timestep. In local HD multiple bonds (separated by a sufficient distance) can be biased simultaneously at each timestep. In the bond-boost hyperdynamics context, a "bond" is not a covalent bond between a pair of atoms in a molecule. Rather it is simply a pair of nearby atoms as discussed below.

Both global and local HD are described in *(Voter2013)* by Art Voter and collaborators. Similar to parallel replica dynamics (PRD), global and local HD are methods for performing accelerated dynamics that are suitable for infrequent-event systems that obey first-order kinetics. A good overview of accelerated dynamics methods (AMD) for such systems in given in *(Voter2002)* from the same group. To quote from the review paper: "The dynamical evolution is characterized by vibrational excursions within a potential basin, punctuated by occasional transitions between basins. The transition probability is characterized by p(t) = k*exp(-kt) where k is the rate constant."

Both HD and PRD produce a time-accurate trajectory that effectively extends the timescale over which a system can be simulated, but they do it differently. HD uses a single replica of the system and accelerates time by biasing the interaction potential in a manner such that each timestep is effectively longer. PRD creates Nr replicas of the system and runs dynamics on each independently with a normal unbiased potential until an event occurs in one of the replicas. The time between events is reduced by a factor of Nr replicas. For both methods, per CPU second, more physical time elapses and more events occur. See the *prd* page for more info about PRD.

An HD run has several stages, which are repeated each time an event occurs, as explained below. The logic for an HD run is as follows:

```
quench
create initial list of bonds

while (time remains):
  run dynamics for Nevent steps
  quench
  check for an event
  if event occurred: reset list of bonds
  restore pre-quench state
```

The list of bonds is the list of atom pairs of atoms that are within a short cutoff distance of each other after the system energy is minimized (quenched). This list is created and reset by a *fix hyper/global* or *fix hyper/local* command specified as *fix-ID*. At every dynamics timestep, the same fix selects one of more bonds to apply a bias potential to.

Note

The style of fix associated with the specified *fix-ID* determines whether you are running the global versus local hyperdynamics algorithm.

Dynamics (with the bias potential) is run continuously, stopping every *Nevent* steps to check if a transition event has occurred. The specified *N* for total steps must be a multiple of *Nevent*. check is performed by quenching the system and comparing the resulting atom coordinates to the coordinates from the previous basin.

A quench is an energy minimization and is performed by whichever algorithm has been defined by the *min_style* command. Minimization parameters may be set via the *min_modify* command and by the *min* keyword of the hyper command. The latter are the settings that would be used with the *minimize* command. Note that typically, you do not need to perform a highly-converged minimization to detect a transition event, though you may need to in order to prevent a set of atoms in the system from relaxing to a saddle point.

The event check is performed by a compute with the specified *compute-ID*. Currently there is only one compute that works with the hyper command, which is the *compute event/displace* command. Other event-checking computes may be added. *Compute event/displace* checks whether any atom in the compute group has moved further than a specified threshold distance. If so, an event has occurred.

If this happens, the list of bonds is reset, since some bond pairs are likely now too far apart, and new pairs are likely close enough to be considered a bond. The pre-quenched state of the system (coordinates and velocities) is restored, and dynamics continue.

At the end of the hyper run, a variety of statistics are output to the screen and logfile. These include info relevant to both global and local hyperdynamics, such as the number of events and the elapsed hyper time (accelerated time), And it includes info specific to one or the other, depending on which style of fix was specified by *fix-ID*.

The optional keywords operate as follows.

As explained above, the *min* keyword can be used to specify parameters for the quench. Their meaning is the same as for the *minimize* command

The *dump* keyword can be used to trigger a specific dump command with the specified *dump-ID* to output a snapshot each time an event is detected. It can be specified multiple times with different *dump-ID* values, as in the example above. These snapshots will be for the quenched state of the system on a timestep that is a multiple of *Nevent*, i.e. a timestep after the event has occurred. Note that any dump command in the input script will also output snapshots at whatever timestep interval it defines via its *N* argument; see the *dump* command for details. This means if you only want a particular dump to output snapshots when events are detected, you should specify its *N* as a value larger than the length of the hyperdynamics run.

As in the code logic above, the bond list is normally only reset when an event occurs. The *rebond* keyword will force a reset of the bond list every *Nrebond* steps, even if an event has not occurred. *Nrebond* must be a multiple of *Nevent*. This can be useful to check if more frequent resets alter event statistics, perhaps because the parameters chosen for defining what is a bond and what is an event are producing bad dynamics in the presence of the bias potential.

1.38.4 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the *Build package* doc page for more info.

1.38.5 Related commands

fix hyper/global, *fix hyper/local*, *compute event/displace*, *prd*

1.38.6 Default

The option defaults are min = 0.1 0.1 40 50 and time = steps.

(Voter2013) S. Y. Kim, D. Perez, A. F. Voter, J Chem Phys, 139, 144110 (2013).

(Voter2002) Voter, Montalenti, Germann, Annual Review of Materials Research 32, 321 (2002).

1.39 if command

1.39.1 Syntax

```
if boolean then t1 t2 ... elif boolean f1 f2 ... elif boolean f1 f2 ... else e1 e2 ...
```

- boolean = a Boolean expression evaluated as TRUE or FALSE (see below)
- then = required word
- t1,t2,...,tN = one or more LAMMPS commands to execute if condition is met, each enclosed in quotes
- elif = optional word, can appear multiple times
- f1,f2,...,fN = one or more LAMMPS commands to execute if elif condition is met, each enclosed in quotes (optional arguments)
- else = optional argument
- e1,e2,...,eN = one or more LAMMPS commands to execute if no condition is met, each enclosed in quotes (optional arguments)

1.39.2 Examples

```
if "${steps} > 1000" then quit
if "${myString} == a10" then quit
if "$x <= $y" then "print 'X is smaller = $x'" else "print 'Y is smaller = $y'"
if "(${eng} > 0.0) || ($n < 1000)" then &
  "timestep 0.005" &
elif $n<10000 &
  "timestep 0.01" &
else &
  "timestep 0.02" &
  "print 'Max step reached'"
if "${eng} > ${eng_previous}" then "jump file1" else "jump file2"
```

1.39.3 Description

This command provides an if-then-else capability within an input script. A Boolean expression is evaluated and the result is TRUE or FALSE. Note that as in the examples above, the expression can contain variables, as defined by the *variable* command, which will be evaluated as part of the expression. Thus a user-defined formula that reflects the current state of the simulation can be used to issue one or more new commands.

If the result of the Boolean expression is TRUE, then one or more commands (t1, t2, ..., tN) are executed. If it is FALSE, then Boolean expressions associated with successive elif keywords are evaluated until one is found to be true, in which case its commands (f1, f2, ..., fN) are executed. If no Boolean expression is TRUE, then the commands associated with the else keyword, namely (e1, e2, ..., eN), are executed. The elif and else keywords and their associated commands are optional. If they are not specified and the initial Boolean expression is FALSE, then no commands are executed.

The syntax for Boolean expressions is described below.

Each command (t1, f1, e1, etc.) can be any valid LAMMPS input script command. If the command is more than one word, it must enclosed in quotes, so it will be treated as a single argument, as in the examples above.

Note

If a command itself requires a quoted argument (e.g., a *print* command), then double and single quotes can be used and nested in the usual manner, as in the examples above and below. The *Commands parse* page has more details on using quotes in arguments. Only one of level of nesting is allowed, but that should be sufficient for most use cases.

Note that by using the line continuation character "&", the if command can be spread across many lines, though it is still a single command:

```
if "$a < $b" then &
  "print 'Minimum value = $a'" &
  "run 1000" &
else &
  'print "Minimum value = $b"' &
  "minimize 0.001 0.001 1000 10000"
```

Note that if one of the commands to execute is *quit*, as in the first example above, then executing the command will cause LAMMPS to halt.

Note that by jumping to a label in the same input script, the if command can be used to break out of a loop. See the *variable delete* command for info on how to delete the associated loop variable, so that it can be reused later in the input script.

Here is an example of a loop which checks every 1000 steps if the system temperature has reached a certain value, and if so, breaks out of the loop to finish the run. Note that any variable could be checked, so long as it is current on the timestep when the run completes. As explained on the *variable* doc page, this can be ensured by including the variable in thermodynamic output.

```
variable myTemp equal temp
label loop
variable a loop 1000
run 1000
if "${myTemp} < 300.0" then "jump SELF break"
next a
jump SELF loop
label break
print "ALL DONE"
```

Here is an example of a double loop which uses the if and *jump* commands to break out of the inner loop when a condition is met, then continues iterating through the outer loop.

```
label       loopa
variable    a loop 5
  label     loopb
  variable  b loop 5
    print     "A,B = $a,$b"
    run       10000
    if        "$b > 2" then "jump SELF break"
  next      b
  jump      in.script loopb
  label       break
  variable    b delete
next        a
```

(continues on next page)

(continued from previous page)

```
jump        SELF loopa
```

The Boolean expressions for the if and elif keywords have a C-like syntax. Note that each expression is a single argument within the if command. Thus if you want to include spaces in the expression for clarity, you must enclose the entire expression in quotes.

An expression is built out of numbers (which start with a digit or period or minus sign) or strings (which start with a letter and can contain alphanumeric characters, underscores, or forward slashes):

```
0.2, 100, 1.0e20, -15.4, ...
InP, myString, a123, ab_23_cd, lj/cut, ...
```

and Boolean operators:

```
A == B, A != B, A < B, A <= B, A > B, A >= B, A && B, A || B, A |^ B, !A
```

Each A and B is a number or string or a variable reference like `$a` or `${abc}`, or A or B can be another Boolean expression.

Note that all variables used will be substituted for before the Boolean expression in evaluated. A variable can produce a number, like an *equal-style variable*, or it can produce a string, like an *index-style variable*.

The Boolean operators == and != can operate on a pair or strings or numbers. They cannot compare a number to a string. All the other Boolean operations can only operate on numbers.

Expressions are evaluated left to right and have the usual C-style precedence: the unary logical NOT operator ! has the highest precedence, the 4 relational operators <, <=, >, and >= are next; the two remaining relational operators == and != are next; then the logical AND operator &&; and finally the logical OR operator || and logical XOR (exclusive or) operator |^ have the lowest precedence. Parenthesis can be used to group one or more portions of an expression and/or enforce a different order of evaluation than what would occur with the default precedence.

When the six relational operators (first six in list above) compare two numbers, they return either a 1.0 or 0.0 depending on whether the relationship between A and B is TRUE or FALSE.

When the three logical operators (last three in list above) compare two numbers, they also return either a 1.0 or 0.0 depending on whether the relationship between A and B is TRUE or FALSE (or just A). The logical AND operator will return 1.0 if both its arguments are non-zero, else it returns 0.0. The logical OR operator will return 1.0 if either of its arguments is non-zero, else it returns 0.0. The logical XOR operator will return 1.0 if one of its arguments is zero and the other non-zero, else it returns 0.0. The logical NOT operator returns 1.0 if its argument is 0.0, else it returns 0.0. The 3 logical operators can only be used to operate on numbers, not on strings.

The overall Boolean expression produces a TRUE result if the numeric result is non-zero. If the result is zero, the expression result is FALSE.

Note

If the Boolean expression is a single numeric value with no Boolean operators, it will be FALSE if the value = 0.0, otherwise TRUE. If the Boolean expression is a single string, an error message will be issued.

1.39.4 Restrictions

none

1.39.5 Related commands

variable, *print*

1.39.6 Default

none

1.40 improper_coeff command

1.40.1 Syntax

```
improper_coeff N args
```

- N = numeric improper type (see asterisk form below), or type label
- args = coefficients for one or more improper types

1.40.2 Examples

```
improper_coeff 1 300.0 0.0
improper_coeff * 80.2 -1 2
improper_coeff *4 80.2 -1 2

labelmap improper 1 benzene
improper_coeff benzene 300.0 0.0
```

1.40.3 Description

Specify the improper force field coefficients for one or more improper types. The number and meaning of the coefficients depends on the improper style. Improper coefficients can also be set in the data file read by the *read_data* command or in a restart file.

N can be specified in one of two ways. An explicit numeric value can be used, as in the first example above. Or *N* can be a type label, which is an alphanumeric string defined by the *labelmap* command or in a section of a data file read by the *read_data* command.

For numeric values only, a wild-card asterisk can be used to set the coefficients for multiple improper types. This takes the form "*" or "*n" or "n*" or "m*n". If *N* = the number of improper types, then an asterisk with no numeric values means all types from 1 to *N*. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to *N* (inclusive). A middle asterisk means all types from m to n (inclusive).

Note that using an improper_coeff command can override a previous setting for the same improper type. For example, these commands set the coeffs for all improper types, then overwrite the coeffs for just improper type 2:

```
improper_coeff * 300.0 0.0
improper_coeff 2 50.0 0.0
```

A line in a data file that specifies improper coefficients uses the exact same format as the arguments of the improper_coeff command in an input script, except that wild-card asterisks should not be used since coefficients for all *N* types must be listed in the file. For example, under the "Improper Coeffs" section of a data file, the line that corresponds to the first example above would be listed as

```
1 300.0 0.0
```

The *improper_style class2* is an exception to this rule, in that an additional argument is used in the input script to allow specification of the cross-term coefficients. See its doc page for details.

The list of all improper styles defined in LAMMPS is given on the *improper_style* doc page. They are also listed in more compact form on the *Commands improper* doc page.

On either of those pages, click on the style to display the formula it computes and its coefficients as specified by the associated improper_coeff command.

1.40.4 Restrictions

This command must come after the simulation box is defined by a *read_data*, *read_restart*, or *create_box* command.

An improper style must be defined before any improper coefficients are set, either in the input script or in a data file.

1.40.5 Related commands

improper_style

none

1.41 improper_style command

1.41.1 Syntax

```
improper_style style
```

- style = *none* or *hybrid* or *class2* or *cvff* or *harmonic*

1.41.2 Examples

```
improper_style harmonic
improper_style cvff
improper_style hybrid cvff harmonic
```

1.41.3 Description

Set the formula(s) LAMMPS uses to compute improper interactions between quadruplets of atoms, which remain in force for the duration of the simulation. The list of improper quadruplets is read in by a *read_data* or *read_restart* command from a data or restart file. Note that the ordering of the 4 atoms in an improper quadruplet determines the definition of the improper angle used in the formula for each style. See the doc pages of individual styles for details.

Hybrid models where impropers are computed using different improper potentials can be setup using the *hybrid* improper style.

The coefficients associated with an improper style can be specified in a data or restart file or via the *improper_coeff* command.

All improper potentials store their coefficient data in binary restart files which means improper_style and *improper_coeff* commands do not need to be re-specified in an input script that restarts a simulation. See the *read_restart* command for details on how to do this. The one exception is that improper_style *hybrid* only stores the list of sub-styles in the restart file; improper coefficients need to be re-specified.

Note

When both an improper and pair style is defined, the *special_bonds* command often needs to be used to turn off (or weight) the pairwise interaction that would otherwise exist between a group of 4 bonded atoms.

Here is an alphabetic list of improper styles defined in LAMMPS. Click on the style to display the formula it computes and coefficients specified by the associated *improper_coeff* command.

Click on the style to display the formula it computes, any additional arguments specified in the improper_style command, and coefficients specified by the associated *improper_coeff* command.

There are also additional accelerated pair styles included in the LAMMPS distribution for faster performance on CPUs, GPUs, and KNLs. The individual style names on the *Commands improper* page are followed by one or more of (g,i,k,o,t) to indicate which accelerated styles exist.

- *none* - turn off improper interactions
- *zero* - topology but no interactions
- *hybrid* - define multiple styles of improper interactions
- *amoeba* - AMOEBA out-of-plane improper
- *class2* - COMPASS (class 2) improper
- *cossq* - improper with a cosine squared term
- *cvff* - CVFF improper
- *distance* - improper based on distance between atom planes
- *distharm* - improper that is harmonic in the out-of-plane distance
- *fourier* - improper with multiple cosine terms
- *harmonic* - harmonic improper
- *inversion/harmonic* - harmonic improper with Wilson-Decius out-of-plane definition
- *ring* - improper which prevents planar conformations
- *umbrella* - DREIDING improper
- *sqdistharm* - improper that is harmonic in the square of the out-of-plane distance

---

1.41.4 Restrictions

Improper styles can only be set for atom_style choices that allow impropers to be defined.

Most improper styles are part of the MOLECULE package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info. The doc pages for individual improper potentials tell if it is part of a package.

1.42 include command

1.42.1 Syntax

```
include file
```

- file = filename of new input script to switch to

1.42.2 Examples

```
include newfile
include in.run2
```

1.42.3 Description

This command opens a new input script file and begins reading LAMMPS commands from that file. When the new file is finished, the original file is returned to. Include files can be nested as deeply as desired. If input script A includes script B, and B includes A, then LAMMPS could run for a long time.

If the filename is a variable (see the *variable* command), different processor partitions can run different input scripts.

1.42.4 Restrictions

1.43 info command

1.43.1 Syntax

```
info args
```

- args = one or more of the following keywords: *out*, *all*, *system*, *memory*, *communication*, *computes*, *dumps*, *fixes*, *groups*, *regions*, *variables*, *coeffs*, *styles*, *time*, *accelerator*, *fft* or *configuration*
- *out* values = *screen*, *log*, *append* filename, *overwrite* filename
- *styles* values = *all*, *angle*, *atom*, *bond*, *compute*, *command*, *dump*, *dihedral*, *fix*, *improper*, *integrate*, *kspace*, *minimize*, *pair*, *region*

1.43.2 Examples

```
info system
info groups computes variables
info all out log
info all out append info.txt
info styles all
info styles atom styles command
```

1.43.3 Description

Print out information about the current internal state of the running LAMMPS process. This can be helpful when debugging or validating complex input scripts. Several output categories are available and one or more output categories may be requested. All category keywords take no arguments, only *out* and *styles* take arguments as shown below. The keywords are cumulative, may be abbreviated, and unknown keywords are ignored.

The *out* flag controls where the output is sent. It can only be sent to one target. By default this is the screen, if it is active. The *log* argument selects the log file instead. With the *append* and *overwrite* option, followed by a filename, the output is written to that file, which is either appended to or overwritten, respectively.

The *all* flag activates printing all categories listed below.

The *configuration* category prints some information about the LAMMPS version as well as architecture and OS it is run on.

The *memory* category prints some information about the current memory allocation of MPI rank 0 (this the amount of dynamically allocated memory reported by LAMMPS classes). Where supported, also some OS specific information about the size of the reserved memory pool size (this is where malloc() and the new operator request memory from) and the maximum resident set size is reported (this is the maximum amount of physical memory occupied so far).

The *system* category prints a general system overview listing. This includes the unit style, atom style, number of atoms, bonds, angles, dihedrals, and impropers and the number of the respective types, box dimensions and properties, force computing styles and more.

The *communication* category prints a variety of information about communication and parallelization: the MPI library version level, the number of MPI ranks and OpenMP threads, the communication style and layout, the processor grid dimensions, ghost atom communication mode, cutoff, and related settings.

The *computes* category prints a list of all currently defined computes, their IDs and styles and groups they operate on.

The *dumps* category prints a list of all currently active dumps, their IDs, styles, filenames, groups, and dump frequencies.

The *fixes* category prints a list of all currently defined fixes, their IDs and styles and groups they operate on.

The *groups* category prints a list of all currently defined groups.

The *regions* category prints a list of all currently defined regions, their IDs and styles and whether "inside" or "outside" atoms are selected.

The *variables* category prints a list of all currently defined variables, their names, styles, definition and last computed value, if available.

The *coeffs* category prints a list for each defined force style (pair, bond, angle, dihedral, improper) indicating which of the corresponding coefficients have been set. This can be very helpful to debug error messages like "All pair coeffs are not set".

The *accelerator* category prints out information about compile time settings of included accelerator support for the GPU, KOKKOS, INTEL, and OPENMP packages.

Added in version 7Feb2024.

The *fft* category prints out information about the included 3d-FFT support. This lists the 3d-FFT engine, FFT precision, FFT library used by the FFT engine. If the KOKKOS package is included, the settings used for the KOKKOS package are displayed as well.

The *styles* category prints the list of styles available in the current LAMMPS binary. The *styles* keyword without option is the same as using the "all" option. One of the following options may be used to control which category of styles is printed out. To select multiple categories, the styles keyword needs to be used multiple times with the desired categories:

- all
- angle
- atom
- bond
- compute
- command
- dump
- dihedral
- fix
- improper
- integrate
- kspace
- minimize
- pair
- region

Changed in version 2Sep2026.

A style that is currently provided by a loaded *plugin* is marked with a trailing asterisk (*) in the listing.

The *time* category prints the accumulated CPU and wall time for the process that writes output (usually MPI rank 0).

1.43.4 Restrictions

1.43.5 Related commands

print

1.43.6 Default

The *out* option has the default *screen*.

The *styles* option has the default *all*.

1.44 jump command

1.44.1 Syntax

```
jump file label
```

- file = filename of new input script to switch to
- label = optional label within file to jump to

1.44.2 Examples

```
jump newfile
jump in.run2 runloop
jump SELF runloop
```

1.44.3 Description

This command closes the current input script file, opens the file with the specified name, and begins reading LAMMPS commands from that file. Unlike the *include* command, the original file is not returned to, although by using multiple jump commands it is possible to chain from file to file or back to the original file.

If the word "SELF" is used for the filename, then the current input script is re-opened and read again.

Note

The SELF option is not guaranteed to work when the current input script is being read through stdin (standard input), e.g.

```
lmp_g++ < in.script
```

since the SELF option invokes the C-library rewind() call, which may not be supported for stdin on some systems or by some MPI implementations. This can be worked around by using the *-in command-line switch*, e.g.

```
lmp_g++ -in in.script
```

or by using the *-var command-line switch* to pass the script name as a variable to the input script. In the latter case, a *variable* called "fname" could be used in place of SELF, e.g.

```
lmp_g++ -var fname in.script < in.script
```

The second argument to the jump command is optional. If specified, it is treated as a label and the new file is scanned (without executing commands) until the label is found, and commands are executed from that point forward. This can be used to loop over a portion of the input script, as in this example. These commands perform 10 runs, each of 10000 steps, and create 10 dump files named file.1, file.2, etc. The *next* command is used to exit the loop after 10 iterations. When the "a" variable has been incremented for the tenth time, it will cause the next jump command to be skipped.

```
variable a loop 10
label loop
dump 1 all atom 100 file.$a
run 10000
undump 1
```

(continues on next page)

(continued from previous page)

```
next a
jump in.lj loop
```

If the jump *file* argument is a variable, the jump command can be used to cause different processor partitions to run different input scripts. In this example, LAMMPS is run on 40 processors, with 4 partitions of 10 procs each. An in.file containing the example variable and jump command will cause each partition to run a different simulation.

```
mpirun -np 40 lmp_ibm -partition 4x10 -in in.file

variable f world script.1 script.2 script.3 script.4
jump $f
```

Here is an example of a loop which checks every 1000 steps if the system temperature has reached a certain value, and if so, breaks out of the loop to finish the run. Note that any variable could be checked, so long as it is current on the timestep when the run completes. As explained on the *variable* doc page, this can be ensured by including the variable in thermodynamic output.

```
variable myTemp equal temp
label loop
variable a loop 1000
run 1000
if "${myTemp} < 300.0" then "jump SELF break"
next a
jump SELF loop
label break
print "ALL DONE"
```

Here is an example of a double loop which uses the if and *jump* commands to break out of the inner loop when a condition is met, then continues iterating through the outer loop.

```
label       loopa
variable    a loop 5
  label     loopb
  variable  b loop 5
    print     "A,B = $a,$b"
    run       10000
    if        "$b > 2" then "jump SELF break"
  next      b
  jump      in.script loopb
  label       break
  variable    b delete
next        a
jump        SELF loopa
```

1.44.4 Restrictions

If you jump to a file and it does not contain the specified label, LAMMPS will come to the end of the file and exit.

1.44.5 Related commands

variable, *include*, *label*, *next*

1.44.6 Default

1.45 kim command

1.45.1 Syntax

```
kim sub-command args
```

- sub-command = *init* or *interactions* or *query* or *param* or *property*
- args = arguments used by a particular sub-command

1.45.2 Examples

```
kim init args
kim interactions args
kim query args
kim param args
kim property args
```

1.45.3 Description

The *kim command* includes a set of sub-commands that allow LAMMPS users to use interatomic models (IM) (potentials and force fields) and their predictions for various physical properties archived in the Open Knowledgebase of Interatomic Models (OpenKIM) repository.

Using OpenKIM provides LAMMPS users with immediate access to a large number of verified IMs and their predictions. OpenKIM IMs have multiple benefits including reliability, reproducibility and convenience.

There are two types of IMs archived in OpenKIM:

1. The first type is called a *KIM Portable Model* (PM). A KIM PM is an independent computer implementation of an IM written in one of the languages supported by KIM (C, C++, Fortran) that conforms to the KIM Application Programming Interface (KIM API) Portable Model Interface (PMI) standard. A KIM PM will work seamlessly with any simulation code that supports the KIM API/PMI standard (including LAMMPS; see complete list of supported codes).
2. The second type is called a *KIM Simulator Model* (SM). A KIM SM is an IM that is implemented natively within a simulation code (*simulator*) that supports the KIM API Simulator Model Interface (SMI); in this case LAMMPS. A separate SM package is archived in OpenKIM for each parameterization of the IM, which includes all of the necessary parameter files, LAMMPS commands, and metadata (supported species, units, etc.) needed to run the IM in LAMMPS.

With these two IM types, OpenKIM can archive and test almost all IMs that can be used by LAMMPS. (It is easy to contribute new IMs to OpenKIM, see the upload instructions.)

OpenKIM IMs are uniquely identified by a KIM ID. The extended KIM ID consists of a human-readable prefix identifying the type of IM, authors, publication year, and supported species, separated by two underscores from the KIM ID itself, which begins with an IM code (*MO* for a KIM Portable Model, and *SM* for a KIM Simulator Model) followed by a unique 12-digit code and a 3-digit version identifier. By convention SM prefixes begin with *Sim_* to readily identify them.

```
SW_StillingerWeber_1985_Si__MO_405512056662_005
Sim_LAMMPS_ReaxFF_StrachanVanDuinChakraborty_2003_CHNO__SM_107643900657_001
```

Each OpenKIM IM has a dedicated "Model Page" on OpenKIM providing all the information on the IM including a title, description, authorship and citation information, test and verification check results, visualizations of results, a wiki with documentation and user comments, and access to raw files, and other information. The URL for the Model Page is constructed from the extended KIM ID of the IM:

```
https://openkim.org/doc/schema/kim\unhbox\voidb@x\kern\z@\char‘\protect\
discretionary{\char\defaulthyphenchar}{}{}ids/#extended\unhbox\voidb@x\kern\z@\char‘\
protect\discretionary{\char\defaulthyphenchar}{}{}kim\unhbox\voidb@x\kern\z@\char‘\
protect\discretionary{\char\defaulthyphenchar}{}{}ids
```

For example, for the Stillinger-Weber potential listed above the Model Page is located at:

```
https://openkim.org/id/SW_StillingerWeber_1985_Si__MO_405512056662_005
```

See the current list of KIM PMs and SMs archived in OpenKIM. This list is sorted by species and can be filtered to display only IMs for certain species combinations.

See Obtaining KIM Models to learn how to install a pre-built binary of the OpenKIM Repository of Models.

Note

It is also possible to locally install IMs not archived in OpenKIM, in which case their names do not have to conform to the KIM ID format.

1.45.4 Using OpenKIM IMs with LAMMPS (*kim init*, *kim interactions*)

Two sub-commands are employed when using OpenKIM IMs in LAMMPS, one to select the IM and perform necessary initialization (*kim init*), and the second to set up the IM for use by executing any necessary LAMMPS commands (*kim interactions*). Both are required.

Syntax

```
kim init model user_units unitarg
kim interactions typeargs
```

- model = name of the KIM interatomic model (the KIM ID for models archived in OpenKIM)
- user_units = the LAMMPS *units* style assumed in the LAMMPS input script
- unitarg = *unit_conversion_mode* (optional)
- typeargs = atom type to species mapping (one entry per atom type) or *fixed_types* for models with a preset fixed mapping

Examples

```
kim init SW_StillingerWeber_1985_Si__MO_405512056662_005 metal
kim interactions Si

kim init Sim_LAMMPS_ReaxFF_StrachanVanDuinChakraborty_2003_CHNO__SM_107643900657_001 real
kim init Sim_LAMMPS_ReaxFF_StrachanVanDuinChakraborty_2003_CHNO__SM_107643900657_001␣
↪metal unit_conversion_mode
kim interactions C H O

kim init Sim_LAMMPS_IFF_PCFF_HeinzMishraLinEmami_2015Ver1v5_
↪FccmetalsMineralsSolventsPolymers__SM_039297821658_000 real
kim interactions fixed_types
```

See the *examples/kim* directory for example input scripts that use KIM PMs and KIM SMs.

OpenKIM IM Initialization (*kim init*)

The *kim* command followed by *init* sub-command must be issued **before** the simulation box is created (normally at the top of the file). This command sets the OpenKIM IM that will be used and may issue additional commands changing LAMMPS default settings that are required for using the selected IM (such as *units* or *atom_style*). If needed, those settings can be overridden, however, typically a script containing a *kim init* command would not include *units* and *atom_style* commands.

The required arguments of *kim init* are the *model* name of the IM to be used in the simulation (for an IM archived in OpenKIM this is its extended KIM ID, and the *user_units*, which are the LAMMPS *units style* used in the input script. (Any dimensioned numerical values in the input script and values read in from files are expected to be in the *user_units* system.)

The selected IM can be either a *KIM PM or a KIM SM*. For a KIM SM, the *kim init* command verifies that the SM is designed to work with LAMMPS (and not another simulation code). In addition, the LAMMPS version used for defining the SM and the LAMMPS version being currently run are printed to help diagnose any incompatible changes to input script or command syntax between the two LAMMPS versions.

Based on the selected model *kim init* may modify the *atom_style*. Some SMs have requirements for this setting. If this is the case, then *atom_style* will be set to the required style. Otherwise, the value is left unchanged (which in the absence of an *atom_style* command in the input script is the *default atom_style value*).

Regarding units, the *kim init* behaves in different ways depending on whether or not *unit conversion mode* is activated as indicated by the optional *unitarg* argument. If unit conversion mode is **not** active, then *user_units* must either match the required units of the IM or the IM must be able to adjust its units to match. (The latter is only possible with some KIM PMs; SMs can never adjust their units.) If a match is possible, the LAMMPS *units* command is called to set the units to *user_units*. If the match fails, the simulation is terminated with an error. The *kim init* command also sets the default value for the *skin* (extra distance beyond force cutoff) as 2.0 Angstroms and sets the default value for the *timestep* size as 1.0 femtosecond.

Here is an example of a LAMMPS script to compute the cohesive energy of a face-centered cubic (fcc) lattice for the MEAM potential by Pascuet and Fernandez (2015) for Al.

```
kim           init Sim_LAMMPS_MEAM_PascuetFernandez_2015_Al__SM_811588957187_000 metal
boundary      p p p
lattice       fcc 4.049
region        simbox block 0 1 0 1 0 1 units lattice
create_box    1 simbox
create_atoms  1 box
mass          1 26.981539
```

(continues on next page)

(continued from previous page)

```
kim           interactions Al
run           0
variable      Ec equal (pe/count(all))
print         "Cohesive Energy = ${Ec} eV"
```

The above script will end with an error in the *kim init* line if the IM is changed to another potential for Al that does not work with *metal* units. To address this, *kim init* offers the *unit_conversion_mode* as shown below.

If unit conversion mode *is* active, then *kim init* calls the LAMMPS *units* command to set the units to the IM's required or preferred units. Conversion factors between the IM's units and the *user_units* are defined for all *physical quantities* (mass, distance, etc.). (Note that converting to or from the "lj" unit style is not supported.) These factors are stored as *internal style variables* with the following standard names:

```
_u_mass
_u_distance
_u_time
_u_energy
_u_velocity
_u_force
_u_torque
_u_temperature
_u_pressure
_u_viscosity
_u_charge
_u_dipole
_u_efield
_u_density
```

If desired, the input script can be designed to work with these conversion factors so that the script will work without change with any OpenKIM IM. (This approach is used in the OpenKIM Testing Framework.)

For example, the script given above for the cohesive energy of fcc Al can be rewritten to work with any IM regardless of units. The following script constructs an fcc lattice with a lattice parameter defined in meters, computes the total energy, and prints the cohesive energy in Joules regardless of the units of the IM.

```
kim           init Sim_LAMMPS_MEAM_PascuetFernandez_2015_Al__SM_811588957187_000 si unit_
↪conversion_mode
boundary      p p p
lattice       fcc $(4.049e-10*v__u_distance)
region        simbox block 0 1 0 1 0 1 units lattice
create_box    1 simbox
create_atoms  1 box
mass          1 $(4.480134e-26*v__u_mass)
kim           interactions Al
neighbor      $(2e-10*v__u_distance) bin
run           0
variable      Ec_in_J equal (pe/count(all))/v__u_energy
print         "Cohesive Energy = ${Ec_in_J} J"
```

Note the multiplication by *v__u_distance* and *v__u_mass* to convert from SI units (specified in the *kim init* command) to whatever units the IM uses (metal in this case), and the division by *v__u_energy* to convert from the IM's energy units to SI units (Joule). This script will work correctly for any IM for Al (KIM PM or SM) selected by the *kim init* command.

Care must be taken to apply unit conversion to dimensional variables read in from a file. For example, if a configuration

of atoms is read in from a dump file using the *read_dump* command, the following can be done to convert the box and all atomic positions to the correct units:

```
change_box all x scale ${_u_distance} &
               y scale ${_u_distance} &
               z scale ${_u_distance} &
               xy final $(xy*v__u_distance) &
               xz final $(xz*v__u_distance) &
               yz final $(yz*v__u_distance) &
               remap
```

Note

Unit conversion will only work if the conversion factors are placed in all appropriate places in the input script. It is up to the user to do this correctly.

OpenKIM IM Execution (*kim interactions*)

The second and final step in using an OpenKIM IM is to execute the *kim interactions* command. This command must be preceded by a *kim init* command and a command that defines the number of atom types N (such as *create_box*). The *kim interactions* command has one argument *typeargs*. This argument contains either a list of N chemical species, which defines a mapping between atom types in LAMMPS to the available species in the OpenKIM IM, or the keyword *fixed_types* for models that have a preset fixed mapping (i.e. the mapping between LAMMPS atom types and chemical species is defined by the model and cannot be changed). In the latter case, the user must consult the model documentation to see how many atom types there are and how they map to the chemical species.

For example, consider an OpenKIM IM that supports Si and C species. If the LAMMPS simulation has four atom types, where the first three are Si, and the fourth is C, the following *kim interactions* command would be used:

```
kim interactions Si Si Si C
```

Alternatively, for a model with a fixed mapping the command would be:

```
kim interactions fixed_types
```

The *kim interactions* command performs all the necessary steps to set up the OpenKIM IM selected in the *kim init* command. The specific actions depend on whether the IM is a KIM PM or a KIM SM. For a KIM PM, a *pair_style kim* command is executed followed by the appropriate *pair_coeff* command. For example, for the Ercolessi and Adams (1994) KIM PM for Al set by the following commands:

```
kim init EAM_Dynamo_ErcolessiAdams_1994_Al__MO_123629422045_005 metal
...
...  box specification lines skipped
...
kim interactions Al
```

the *kim interactions* command executes the following LAMMPS input commands:

```
pair_style kim EAM_Dynamo_ErcolessiAdams_1994_Al__MO_123629422045_005
pair_coeff * * Al
```

For a KIM SM, the generated input commands may be more complex and require that LAMMPS is built with the required packages included for the type of potential being used. The set of commands to be executed is defined in the

SM specification file, which is part of the SM package. For example, for the Strachan et al. (2003) ReaxFF SM set by the following commands:

```
kim init Sim_LAMMPS_ReaxFF_StrachanVanDuinChakraborty_2003_CHNO__SM_107643900657_000 real
...
...  box specification lines skipped
...
kim interactions C H N O
```

the *kim interactions* command executes the following LAMMPS input commands:

```
pair_style reaxff lmp_control safezone 2.0 mincap 100
pair_coeff * * ffield.reax.rdx C H N O
fix reaxqeq all qeq/reaxff 1 0.0 10.0 1.0e-6 param.qeq
```

Note

The files *lmp_control*, *ffield.reax.rdx* and *param.qeq* are specific to the Strachan et al. (2003) ReaxFF parameterization and are archived as part of the SM package in OpenKIM.

Note

Parameters like cutoff radii and charge tolerances, which have an effect on IM predictions, are also included in the SM definition ensuring reproducibility.

Note

When using *kim init* and *kim interactions* to select and set up an OpenKIM IM, other LAMMPS commands for the same functions (such as pair_style, pair_coeff, bond_style, bond_coeff, fixes related to charge equilibration, etc.) should normally not appear in the input script.

Note

kim interactions must be called each time after the *change_box* command to provide the correct settings (it should be called with the same *typeargs* as the first call.) The reason is that changing a periodic boundary to a non-periodic one, or in general, using the *change_box* command after the interactions are set via *kim interactions* or *pair_coeff* commands might affect some of the settings. For example, SM models containing Coulombic terms in the interactions require different settings if a periodic boundary changes to a non-periodic one. In other cases, the second call to *kim interactions* does not affect any other settings.

1.45.5 Using OpenKIM Web Queries in LAMMPS (*kim query*)

The *kim query* command performs a web query to retrieve the predictions of an IM set by *kim init* for material properties archived in OpenKIM, or to obtain a list of available models that support a given set of atomic species.

Syntax

```
kim query variable formatarg query_function queryargs
```

- variable(s) = single name or list of names of (string style) LAMMPS variable(s) where a query result or parameter get result is stored. Variables that do not exist will be created by the command
- formatarg = *list* or *split* or *index* (optional)

```
list = returns a single string with a list of space separated values
       (e.g. "1.0 2.0 3.0"), which is placed in a LAMMPS variable as
       defined by the variable argument. [default]
split = returns the values separately in new variables with names based
       on the prefix specified in variable and a number appended to
       indicate which element in the list of values is in the variable
index = returns a variable style index that can be incremented via the
       next command.  This enables the construction of simple loops
```

- query_function = name of the OpenKIM web API query function to be used
- queryargs = a series of *keyword*=*value* pairs that represent the web query; supported keywords depend on the query function

Examples

```
kim query a0 get_lattice_constant_cubic crystal=[fcc] species=[Al] units=[angstrom]
kim query model index get_available_models species=[Al] potential_type=[eam]
```

The result of the query is stored in one or more *string style variables* as determined by the optional *formatarg* argument. For the "list" setting of *formatarg* (or if *formatarg* is not specified), the result is returned as a space-separated list of values in *variable*. The *formatarg* keyword "split" separates the result values into individual variables of the form *prefix_I*, where *prefix* is set to the *kim query variable* argument and *I* ranges from 1 to the number of returned values. The number and order of the returned values is determined by the type of query performed. The *formatarg* keyword "index" returns a *variable style index* that can be incremented via the *next* command. This enables the construction of simple loops over the returned values by the type of query performed.

Note

kim query only supports queries that return a single result or an array of values. More complex queries that return a JSON structure are not currently supported. An attempt to use *kim query* in such cases will generate an error.

The second required argument *query_function* is the name of the query function to be called (e.g. *get_lattice_constant_cubic*). All following *arguments* are parameters handed over to the web query in the format *keyword=value*, where *value* is always an array of one or more comma-separated items in brackets. The list of supported keywords and the type and format of their values depend on the query function used. The current list of query functions is available on the OpenKIM webpage at https://openkim.org/doc/usage/kim-query.

Note

The *get_available_models* function's output is post-processed by LAMMPS so that only the names of models that are currently installed are stored in the variable. Matching models that are not installed are instead written to the LAMMPS log file.

Note

All query functions, except *get_available_models*, require the *model* keyword, which identifies the IM whose predictions are being queried. *kim query* automatically generates the *model* keyword based on the IM set in by *kim init*, and it can be overwritten if specified as an argument to the *kim query*. Where *kim init* is not specified, the *model* keyword must be provided as an argument to the *kim query*.

Note

Each *query_function* is associated with a default method (implemented as a KIM Test) used to compute this property. In cases where there are multiple methods in OpenKIM for computing a property, a *method* keyword can be provided to select the method of choice. See the query documentation to see which methods are available for a given *query_function*.

kim query Usage Examples and Further Clarifications

The data obtained by *kim query* commands can be used as part of the setup or analysis phases of LAMMPS simulations. Some examples are given below.

Define an equilibrium fcc crystal

```
kim      init EAM_Dynamo_ErcolessiAdams_1994_Al__MO_123629422045_005 metal
boundary p p p
kim      query a0 get_lattice_constant_cubic crystal=[fcc] species=[Al] units=[angstrom]
lattice  fcc ${a0}
...
```

```
units   metal
kim     query a0 get_lattice_constant_cubic crystal=[fcc] species=[Al] units=[angstrom]␣
↪model=[EAM_Dynamo_ErcolessiAdams_1994_Al__MO_123629422045_005]
lattice fcc ${a0}
...
```

The *kim query* command retrieves from OpenKIM the equilibrium lattice constant predicted by the Ercolessi and Adams (1994) potential for the fcc structure and places it in variable *a0*. This variable is then used on the next line to set up the crystal. By using *kim query*, the user is saved the trouble and possible error of tracking this value down, or of having to perform an energy minimization to find the equilibrium lattice constant.

Note

In *unit_conversion_mode* the results obtained from a *kim query* would need to be converted to the appropriate units system. For example, in the above script, the lattice command would need to be changed to: "lattice fcc $(v_a0*v__u_distance)".

Define an equilibrium hcp crystal

```
kim      init EAM_Dynamo_MendelevAckland_2007v3_Zr__MO_004835508849_000 metal
boundary p p p
kim      query latconst split get_lattice_constant_hexagonal crystal=[hcp] species=[Zr]␣
↪units=[angstrom]
lattice  custom ${latconst_1} a1 0.5 -0.866025 0 a2 0.5 0.866025 0 a3 0 0 $(latconst_2/
↪latconst_1) &
         basis 0.333333 0.666666 0.25 basis 0.666666 0.333333 0.75
...
```

In this case the *kim query* returns two arguments (since the hexagonal close packed (hcp) structure has two independent lattice constants). The *formatarg* keyword "split" places the two values into the variables *latconst_1* and *latconst_2*. (These variables are created if they do not already exist.)

Define a crystal at finite temperature accounting for thermal expansion

```
kim      init EAM_Dynamo_ErcolessiAdams_1994_Al__MO_123629422045_005 metal
boundary p p p
kim      query a0 get_lattice_constant_cubic crystal=[fcc] species=[Al] units=[angstrom]
kim      query alpha get_linear_thermal_expansion_coefficient_cubic crystal=[fcc]␣
↪species=[Al] units=[1/K] temperature=[293.15] temperature_units=[K]
variable DeltaT equal 300
lattice  fcc $(v_a0*v_alpha*v_DeltaT)
...
```

As in the previous example, the equilibrium lattice constant is obtained for the Ercolessi and Adams (1994) potential. However, in this case the crystal is scaled to the appropriate lattice constant at room temperature (293.15 K) by using the linear thermal expansion constant predicted by the potential.

Note

When passing numerical values as arguments (as in the case of the temperature in the above example) it is also possible to pass a tolerance indicating how close to the value is considered a match. If no tolerance is passed a default value is used. If multiple results are returned (indicating that the tolerance is too large), *kim query* will return an error. See the query documentation to see which numerical arguments and tolerances are available for a given *query_function*.

Compute defect formation energy

```
kim      init EAM_Dynamo_ErcolessiAdams_1994_Al__MO_123629422045_005 metal
...
... Build fcc crystal containing some defect and compute the total energy
... which is stored in the variable *Etot*
...
kim      query Ec get_cohesive_energy_cubic crystal=[fcc] species=[Al] units=[eV]
variable Eform equal ${Etot} - count(all)*${Ec}
...
```

The defect formation energy *Eform* is computed by subtracting the ideal fcc cohesive energy of the atoms in the system from *Etot*. The ideal fcc cohesive energy of the atoms is obtained from OpenKIM for the Ercolessi and Adams (1994) potential.

Retrieve equilibrium fcc crystal of all EAM potentials that support a specific species

```
kim   query model index get_available_models species=[Al] potential_type=[eam]
label model_loop
kim   query latconst get_lattice_constant_cubic crystal=[fcc] species=[Al]␣
 ↪units=[angstrom] model=[${model}]
print "FCC lattice constant (${model} potential) = ${latconst}"
...
...   do something with current value of latconst
...
next  model
jump  SELF model_loop
```

In this example, the *index* mode of *formatarg* is used. The first *kim query* returns the list of all available EAM potentials that support the *Al* species and archived in OpenKIM. The result of the query operation is stored in the LAMMPS variable *model* as an index *variable*. This variable is used later to access the values one at a time within a loop as shown in the example. The second *kim query* command retrieves from OpenKIM the equilibrium lattice constant predicted by each potential for the fcc structure and places it in variable *latconst*.

Note

kim query commands return results archived in OpenKIM. These results are obtained using programs for computing material properties (KIM Tests and KIM Test Drivers) that were contributed to OpenKIM. In order to give credit to Test developers, the number of times results from these programs are queried is tracked. No other information about the nature of the query or its source is recorded.

1.45.6 Accessing KIM Model Parameters from LAMMPS (*kim param*)

All IMs are functional forms containing a set of parameters. These parameters' values are typically selected to best reproduce a training set of quantum mechanical calculations or available experimental data. For example, a Lennard-Jones potential intended to model argon might have the values of its two parameters, epsilon, and sigma, fit to the dimer dissociation energy or thermodynamic properties at a critical point of the phase diagram.

Normally a user employing an IM should not modify its parameters since, as noted above, these are selected to reproduce material properties. However, there are cases where accessing and modifying IM parameters is desired, such as for assessing uncertainty, fitting an IM, or working with an ensemble of IMs. As explained *above*, IMs archived in OpenKIM are either Portable Models (PMs) or Simulator Models (SMs). KIM PMs are complete independent implementations of an IM, whereas KIM SMs are wrappers to an IM implemented within LAMMPS. Two different mechanisms are provided for accessing IM parameters in these two cases:

- For a KIM PM, the *kim param* command can be used to *get* and *set* the values of the PM's parameters as explained below.
- For a KIM SM, the user should consult the documentation page for the specific IM and follow instructions there for how to modify its parameters (if possible).

The *kim param get* and *kim param set* commands provide an interface to access and change the parameters of a KIM PM that "publishes" its parameters and makes them publicly available (see the KIM API documentation for details).

Note

The *kim param set/get* command must be preceded by a *kim interactions* command (or alternatively by a *pair_style kim* and *pair_coeff* commands). The *kim param set* command may be used wherever a *pair_coeff* command may occur.

Syntax

```
kim param get param_name index_range variable formatarg
kim param set param_name index_range values
```

- param_name = name of a KIM portable model parameter (which is published by the PM and available for access). The specific string used to identify a parameter is defined by the PM. For example, for the Stillinger-Weber (SW) potential in OpenKIM, the parameter names are *A, B, p, q, sigma, gamma, cutoff, lambda, costheta0*
- index_range = KIM portable model parameter index range (an integer for a single element, or pair of integers separated by a colon for a range of elements)
- variable(s) = single name or list of names of (string style) LAMMPS variable(s) where a query result or parameter get result is stored. Variables that do not exist will be created by the command
- formatarg = *list* or *split* or *explicit* (optional)

  list = returns a single string with a list of space separated values
  (e.g. "1.0 2.0 3.0"), which is placed in a LAMMPS variable as
  defined by the *variable* argument
  split = returns the values separately in new variables with names based
  on the prefix specified in *variable* and a number appended to
  indicate which element in the list of values is in the variable
  explicit = returns the values separately in one more more variable names
  provided as arguments that precede *formatarg* (default)

- values = new value(s) to replace the current value(s) of a KIM portable model parameter

Note

The list of all the parameters that a PM exposes for access/mutation are automatically written to the lammps log file when *kim init* is called.

Each published parameter of a KIM PM takes the form of an array of numerical values. The array can contain one element for a single-valued parameter, or a set of values. For example, the multispecies SW potential for the Zn-Cd-Hg-S-Se-Te system has the same parameter names as the single-species SW potential, but each parameter array contains 21 entries that correspond to the parameter values used for each pairwise combination of the model's six supported species (this model does not have parameters specific to individual ternary combinations of its supported species).

The *index_range* argument may either be an integer referring to a specific element within the array associated with the parameter specified by *param_name*, or a pair of integers separated by a colon that refer to a slice of this array. In both

cases, one-based indexing is used to refer to the entries of the array.

The result of a *get* operation for a specific *index_range* is stored in one or more *LAMMPS string style variables* as determined by the optional *formatarg* argument *documented above.* If not specified, the default for *formatarg* is "explicit" for the *kim param* command.

For the case where the result is an array with multiple values (i.e. *index_range* contains a range), the optional "split" or "explicit" *formatarg* keywords can be used to separate the results into multiple variables; see the examples below. Multiple parameters can be retrieved with a single call to *kim param get* by repeating the argument list following *get*.

For a *set* operation, the *values* argument contains the new value(s) for the element(s) of the parameter specified by *index_range*. For the case where multiple values are being set, *values* contains a set of values separated by spaces. Multiple parameters can be set with a single call to *kim param set* by repeating the argument list following *set*.

kim param Usage Examples and Further Clarifications

Examples of getting and setting KIM PM parameters with further clarifications are provided below.

Getting a scalar parameter

```
kim init SW_StillingerWeber_1985_Si__MO_405512056662_005 metal
...
kim interactions Si
kim param get A 1 VARA
```

or

```
...
pair_style kim SW_StillingerWeber_1985_Si__MO_405512056662_005
pair_coeff * * Si
kim param get A 1 VARA
```

In these cases, the value of the SW *A* parameter is retrieved and placed in the LAMMPS variable *VARA*. The variable *VARA* can be used in the remainder of the input script in the same manner as any other LAMMPS variable.

Getting multiple scalar parameters with a single call

```
...
kim interactions Si
kim param get A 1 VARA B 1 VARB
```

In this example, it is shown how to retrieve the *A* and *B* parameters of the SW potential and store them in the LAMMPS variables *VARA* and *VARB*.

Getting a range of values from a parameter

There are several options when getting a range of values from a parameter determined by the *formatarg* argument.

```
kim init SW_ZhouWardMartin_2013_CdTeZnSeHgS__MO_503261197030_002 metal
...
kim interactions Te Zn Se
kim param get lambda 7:9 LAM_TeTe LAM_TeZn LAM_TeSe
```

In this case, *formatarg* is not specified and therefore the default "explicit" mode is used. (The behavior would be the same if the word *explicit* were added after *LAM_TeSe*.) Elements 7, 8 and 9 of parameter lambda retrieved by the *get* operation are placed in the LAMMPS variables *LAM_TeTe*, *LAM_TeZn* and *LAM_TeSe*, respectively.

Note

In the above example, elements 7-9 of the lambda parameter correspond to Te-Te, Te-Zm and Te-Se interactions. This can be determined by visiting the model page for the specified potential and looking at its parameter file linked to at the bottom of the page (file with .param ending) and consulting the README documentation provided with the driver for the PM being used. A link to the driver is provided at the top of the model page.

```
...
kim      interactions Te Zn Se
kim      param get lambda 15:17 LAMS list
variable LAM_VALUE index ${LAMS}
label    loop_on_lambda
...
...      do something with the current value of lambda
...
next     LAM_VALUE
jump     SELF loop_on_lambda
```

In this case, the "list" mode of *formatarg* is used. The result of the *get* operation is stored in the LAMMPS variable *LAMS* as a string containing the three retrieved values separated by spaces, e.g "1.0 2.0 3.0". This can be used in LAMMPS with an *index* variable to access the values one at a time within a loop as shown in the example. At each iteration of the loop *LAM_VALUE* contains the current value of lambda.

```
...
kim interactions Te Zn Se
kim param get lambda 15:17 LAM split
```

In this case, the "split" mode of *formatarg* is used. The three values retrieved by the *get* operation are stored in the three LAMMPS variables *LAM_15*, *LAM_16* and *LAM_17*. The provided name "LAM" is used as prefix and the location in the lambda array is appended to create the variable names.

Setting a scalar parameter

```
kim init SW_StillingerWeber_1985_Si__MO_405512056662_005 metal
...
kim interactions Si
kim param set gamma 1 2.6
```

Here, the SW potential's gamma parameter is set to 2.6. Note that the *get* and *set* commands work together, so that a *get* following a *set* operation will return the new value that was set. For example,

```
...
kim interactions Si
kim param get gamma 1 ORIG_GAMMA
kim param set gamma 1 2.6
kim param get gamma 1 NEW_GAMMA
...
print "original gamma = ${ORIG_GAMMA}, new gamma = ${NEW_GAMMA}"
```

Here, *ORIG_GAMMA* will contain the original gamma value for the SW potential, while *NEW_GAMMA* will contain the value 2.6.

Setting multiple scalar parameters with a single call

```
kim      init SW_ZhouWardMartin_2013_CdTeZnSeHgS__MO_503261197030_002 metal
...
kim      interactions Cd Te
variable VARG equal 2.6
variable VARS equal 2.0951
kim      param set gamma 1 ${VARG} sigma 3 ${VARS}
```

In this case, the first element of the *gamma* parameter and third element of the *sigma* parameter are set to 2.6 and 2.0951, respectively. This example also shows how LAMMPS variables can be used when setting parameters.

Setting a range of values of a parameter

```
kim init SW_ZhouWardMartin_2013_CdTeZnSeHgS__MO_503261197030_002 metal
...
kim interactions Cd Te Zn Se Hg S
kim param set sigma 2:6 2.35214 2.23869 2.04516 2.43269 1.80415
```

In this case, elements 2 through 6 of the parameter *sigma* are set to the values 2.35214, 2.23869, 2.04516, 2.43269 and 1.80415 in order.

1.45.7 Writing material properties in standard KIM Property Instance format (*kim property*)

The OpenKIM system includes a collection of Tests (material property calculation codes), Models (interatomic potentials), Predictions, and Reference Data (DFT or experiments). Specifically, a KIM Test is a computation that when coupled with a KIM Model generates the prediction of that model for a specific material property rigorously defined by a KIM Property Definition (see the KIM Properties Framework for further details). A prediction of a material property for a given model is a specific numerical realization of a property definition, referred to as a "Property Instance." The objective of the *kim property* command is to make it easy to output material properties in a standardized, machine readable, format that can be easily ingested by other programs. Additionally, it aims to make it as easy as possible to convert a LAMMPS script that computes a material property into a KIM Test that can then be uploaded to openkim.org

A developer interested in creating a KIM Test using a LAMMPS script should first determine whether a property definition that applies to their calculation already exists in OpenKIM by searching the properties page. If none exists, it is possible to use a locally defined property definition contained in a file until it can be uploaded to the official repository (see below). Once one or more applicable property definitions have been identified, the *kim property create*, *kim property modify*, *kim property remove*, and *kim property destroy*, commands provide an interface to create, set, modify, remove, and destroy instances of them within a LAMMPS script.

Syntax

```
kim property create  instance_id property_id
kim property modify  instance_id key key_name key_name_key key_name_value
kim property remove  instance_id key key_name
kim property destroy instance_id
kim property dump    file
```

- instance_id = a positive integer identifying the KIM property instance; (note that the results file can contain multiple property instances)
- property_id = identifier of a KIM Property Definition, which can be (1) a property short name, (2) the full unique ID of the property (including the contributor and date), (3) a file name corresponding to a local property definition file
- key_name = one of the keys belonging to the specified KIM property definition

- key_name_key = a key belonging to a key-value pair (standardized in the KIM Properties Framework)
- key_name_value = value to be associated with a key_name_key in a key-value pair
- file = name of a file to write the currently defined set of KIM property instances to

Examples of each of the three *property_id* cases are shown below,

```
kim property create 1 atomic-mass
kim property create 2 cohesive-energy-relation-cubic-crystal
```

```
kim property create 1 tag:brunnels@noreply.openkim.org,2016-05-11:property/atomic-mass
kim property create 2 tag:staff@noreply.openkim.org,2014-04-15:property/cohesive-energy-
↪relation-cubic-crystal
```

```
kim property create 1 new-property.edn
kim property create 2 /home/mary/marys-kim-properties/dissociation-energy.edn
```

In the last example, "new-property.edn" and "/home/mary/marys-kim-properties/dissociation-energy.edn" are the names of files that contain user-defined (local) property definitions.

A KIM property instance takes the form of a "map", i.e. a set of key-value pairs akin to Perl's hash, Python's dictionary, or Java's Hashtable. It consists of a set of property key names, each of which is referred to here by the *key_name* argument, that are defined as part of the relevant KIM Property Definition and include only lowercase alphanumeric characters and dashes. The value paired with each property key is itself a map whose possible keys are defined as part of the KIM Properties Framework; these keys are referred to by the *key_name_key* argument and their associated values by the *key_name_value* argument. These values may either be scalars or arrays, as stipulated in the property definition.

Note

Each map assigned to a *key_name* must contain the *key_name_key* "source-value" and an associated *key_name_value* of the appropriate type (as defined in the relevant KIM Property Definition). For keys that are defined as having physical units, the "source-unit" *key_name_key* must also be given a string value recognized by GNU units.

Once a *kim property create* command has been given to instantiate a property instance, maps associated with the property's keys can be edited using the *kim property modify* command. In using this command, the special keyword "key" should be given, followed by the property key name and the key-value pair in the map associated with the key that is to be set. For example, the atomic-mass property definition consists of two property keys named "mass" and "species." An instance of this property could be created like so:

```
kim property create 1 atomic-mass
kim property modify 1 key species source-value Al
kim property modify 1 key mass    source-value 26.98154
kim property modify 1 key mass    source-unit amu
```

or, equivalently,

```
kim property create 1 atomic-mass
kim property modify 1 key species source-value Al       &
                      key mass    source-value 26.98154 &
                                  source-unit  amu
```

kim property Usage Examples and Further Clarifications

Create

```
kim property create instance_id property_id
```

The *kim property create* command takes as input a property instance ID and the property definition name, and creates an initial empty property instance data structure. For example,

```
kim property create 1 atomic-mass
kim property create 2 cohesive-energy-relation-cubic-crystal
```

creates an empty property instance of the "atomic-mass" property definition with instance ID 1 and an empty instance of the "cohesive-energy-relation-cubic-crystal" property with ID 2. A list of published property definitions in OpenKIM can be found on the properties page.

One can also provide the name of a file in the current working directory or the path of a file containing a valid property definition. For example,

```
kim property create 1 new-property.edn
```

where "new-property.edn" refers to a file name containing a new property definition that does not exist in OpenKIM.

If the *property_id* given cannot be found in OpenKIM and no file of this name containing a valid property definition can be found, this command will produce an error with an appropriate message. Calling *kim property create* with the same instance ID multiple times will also produce an error.

Modify

```
kim property modify instance_id key key_name key_name_key key_name_value
```

The *kim property modify* command incrementally builds the property instance by receiving property definition keys along with associated arguments. Each *key_name* is associated with a map containing one or more key-value pairs (in the form of *key_name_key-key_name_value* pairs). For example,

```
kim property modify 1 key species source-value Al
kim property modify 1 key mass    source-value 26.98154
kim property modify 1 key mass    source-unit  amu
```

where the special keyword "key" is followed by a *key_name* ("species" or "mass" in the above) and one or more key-value pairs. These key-value pairs may continue until either another "key" keyword is given or the end of the line is reached. Thus, the above could equivalently be written as

```
kim property modify 1 key species source-value Al       &
                      key mass    source-value 26.98154 &
                      key mass    source-unit  amu
```

As an example of modifying multiple key-value pairs belonging to the map of a single property key, the following command modifies the map of the "cohesive-potential-energy" property key to contain the key "source-unit" which is assigned a value of "eV" and the key "digits" which is assigned a value of 5,

```
kim property modify 2 key cohesive-potential-energy source-unit eV digits 5
```

Note

The relevant data types of the values in the map are handled automatically based on the specification of the key in the KIM Property Definition. In the example above, this means that the value "eV" will automatically be interpreted as a string while the value 5 will be interpreted as an integer.

The values contained in maps can either be scalars, as in all of the examples above, or arrays depending on which is stipulated in the corresponding Property Definition. For one-dimensional arrays, a single one-based index must be supplied that indicates which element of the array is to be modified. For multidimensional arrays, multiple indices must be given depending on the dimensionality of the array.

Note

All array indexing used by *kim property modify* is one-based, i.e. the indices are enumerated 1, 2, 3, ...

Note

The dimensionality of arrays are defined in the the corresponding Property Definition. The extent of each dimension of an array can either be a specific finite number or indefinite and determined at run time. If an array has a fixed extent, attempting to modify an out-of-range index will fail with an error message.

For example, the "species" property key of the cohesive-energy-relation-cubic-crystal property is a one-dimensional array that can contain any number of entries based on the number of atoms in the unit cell of a given cubic crystal. To assign an array containing the string "Al" four times to the "source-value" key of the "species" property key, we can do so by issuing:

```
kim property modify 2 key species source-value 1 Al
kim property modify 2 key species source-value 2 Al
kim property modify 2 key species source-value 3 Al
kim property modify 2 key species source-value 4 Al
```

Note

No declaration of the number of elements in this array was given; *kim property modify* will automatically handle memory management to allow an arbitrary number of elements to be added to the array.

Note

In the event that *kim property modify* is used to set the value of an array index without having set the values of all lesser indices, they will be assigned default values based on the data type associated with the key in the map:

Data type	Default value
int	0
float	0.0
string	""
file	""

For example, doing the following:

```
kim property create 2 cohesive-energy-relation-cubic-crystal
kim property modify 2 key species source-value 4 Al
```

will result in the "source-value" key in the map for the property key "species" being assigned the array ["", "", "", "Al"].

For convenience, the index argument provided may refer to an inclusive range of indices by specifying two integers separated by a colon (the first integer must be less than or equal to the second integer, and no whitespace should be included). Thus, the snippet above could equivalently be written:

```
kim property modify 2 key species source-value 1:4 Al Al Al Al
```

Calling this command with a non-positive index, e.g. `kim property modify 2 key species source-value 0 Al`, or an incorrect number of input arguments, e.g. `kim property modify 2 key species source-value 1:4 Al Al`, will result in an error.

As an example of modifying multidimensional arrays, consider the "basis-atoms" key in the cohesive-energy-relation-cubic-crystal property definition. This is a two-dimensional array containing the fractional coordinates of atoms in the unit cell of the cubic crystal. In the case of, e.g. a conventional fcc unit cell, the "source-value" key in the map associated with this key should be assigned the following value:

```
[[0.0, 0.0, 0.0],
 [0.5, 0.5, 0.0],
 [0.5, 0.0, 0.5],
 [0.0, 0.5, 0.5]]
```

While each of the twelve components could be set individually, we can instead set each row at a time using colon notation:

```
kim property modify 2 key basis-atom-coordinates source-value 1 1:3 0.0 0.0 0.0
kim property modify 2 key basis-atom-coordinates source-value 2 1:3 0.5 0.5 0.0
kim property modify 2 key basis-atom-coordinates source-value 3 1:3 0.5 0.0 0.5
kim property modify 2 key basis-atom-coordinates source-value 4 1:3 0.0 0.5 0.5
```

Where the first index given refers to a row and the second index refers to a column. We could, instead, choose to set each column at a time like so:

```
kim property modify 2 key basis-atom-coordinates source-value 1:4 1 0.0 0.5 0.5 0.0 &
                      key basis-atom-coordinates source-value 1:4 2 0.0 0.5 0.0 0.5 &
                      key basis-atom-coordinates source-value 1:4 3 0.0 0.0 0.5 0.5
```

Note

Multiple calls of *kim property modify* made for the same instance ID can be combined into a single invocation, meaning the following are both valid:

```
kim property modify 2 key basis-atom-coordinates source-value 1 1:3 0.0 0.0 0.0 &
                      key basis-atom-coordinates source-value 2 1:3 0.5 0.5 0.0 &
                      key basis-atom-coordinates source-value 3 1:3 0.5 0.0 0.5 &
                      key basis-atom-coordinates source-value 4 1:3 0.0 0.5 0.5
```

```
kim property modify 2 key short-name source-value 1 fcc                          &
                      key species source-value 1:4 Al Al Al Al                   &
                      key a source-value 1:5 3.9149 4.0000 4.032 4.0817 4.1602   &
                            source-unit angstrom                                 &
                            digits 5                                             &
                      key basis-atom-coordinates source-value 1 1:3 0.0 0.0 0.0 &
                      key basis-atom-coordinates source-value 2 1:3 0.5 0.5 0.0 &
                      key basis-atom-coordinates source-value 3 1:3 0.5 0.0 0.5 &
                      key basis-atom-coordinates source-value 4 1:3 0.0 0.5 0.5
```

Note

For multidimensional arrays, only one colon-separated range is allowed in the index listing. Therefore,

```
kim property modify 2 key basis-atom-coordinates 1 1:3 0.0 0.0 0.0
```

is valid but

```
kim property modify 2 key basis-atom-coordinates 1:2 1:3 0.0 0.0 0.0 0.0 0.0 0.0
```

is not.

Note

After one sets a value in a map with the *kim property modify* command, additional calls will overwrite the previous value.

Remove

```
kim property remove instance_id key key_name
```

The *kim property remove* command can be used to remove a property key from a property instance. For example,

```
kim property remove 2 key basis-atom-coordinates
```

Destroy

```
kim property destroy instance_id
```

The *kim property destroy* command deletes a previously created property instance ID. For example,

```
kim property destroy 2
```

Note

If this command is called with an instance ID that does not exist, no error is raised.

Dump

The *kim property dump* command can be used to write the content of all currently defined property instances to a file:

```
kim property dump file
```

For example,

```
kim property dump results.edn
```

> **Note**
>
> Issuing the *kim property dump* command clears all existing property instances from memory.

1.45.8 Citation of OpenKIM IMs

When publishing results obtained using OpenKIM IMs researchers are requested to cite the OpenKIM project *(Tadmor)*, KIM API *(Elliott)*, and the specific IM codes used in the simulations, in addition to the relevant scientific references for the IM. The citation format for an IM is displayed on its page on OpenKIM along with the corresponding BibTex file, and is automatically added to the LAMMPS citation reminder.

Citing the IM software (KIM infrastructure and specific PM or SM codes) used in the simulation gives credit to the researchers who developed them and enables open source efforts like OpenKIM to function.

1.45.9 Restrictions

The *kim* command is part of the KIM package. It is only enabled if LAMMPS is built with that package. A requirement for the KIM package, is the KIM API library that must be downloaded from the OpenKIM website and installed before LAMMPS is compiled. When installing LAMMPS from binary, the kim-api package is a dependency that is automatically downloaded and installed. The *kim query* command requires the *libcurl* library to be installed. The *kim property* command requires *Python* 3.6 or later and the *kim-property* python package to be installed. See the KIM section of the *Packages details* for details.

Furthermore, when using *kim* command to run KIM SMs, any packages required by the native potential being used or other commands or fixes that it invokes must be installed.

kspace_modify scafacos tolerance energy
```

1.46.3 Description

Set parameters used by the kspace solvers defined by the *kspace_style* command. Not all parameters are relevant to all kspace styles.

The *collective* keyword applies only to PPPM. It is set to *no* by default, If this option is set to *yes*, LAMMPS will use MPI collective operations to remap data for 3d-FFT operations instead of the default point-to-point communication. This is faster on machines that have an efficient implementation of MPI collective operations *and* adequate hardware.

Added in version 4Jul2026.

The *collective/self/copy* keyword applies only to PPPM and only when *collective* is set to *yes*. It controls whether data remapped to the same MPI rank (the "self" contribution) is handled via a direct pack/unpack rather than being included in the `MPI_Alltoallv` collective. If set to *yes*, LAMMPS always handles the self contribution with a direct copy. If set to *no*, the self contribution is included in the `MPI_Alltoallv` along with data destined for other ranks. If set to *onerank*, the direct copy is used only when running on a single MPI rank, which avoids unnecessary collective overhead when all data maps to the same rank.

Added in version 10Dec2025.

The *nonblocking* keyword applies only to PPPM. It is set to *no* by default. If this option is set to *yes*, LAMMPS will use non-blocking point-to-point MPI operations to remap data for 3d-FFT operations instead of the default blocking point-to-point communication. This allows for better utilization of full network bandwidth by overlapping communication to multiple other ranks at the same time, as well as overlapping receiving/unpacking data and sending data.

The *compute* keyword allows Kspace computations to be turned off, even though a *kspace_style* is defined. This is not useful for running a real simulation, but can be useful for debugging purposes or for computing only partial forces that do not include the Kspace contribution. You can also do this by simply not defining a *kspace_style*, but a Kspace-compatible *pair_style* requires a kspace style to be defined. This keyword gives you that option.

The *cutoff/adjust* keyword applies only to MSM. If this option is turned on, the Coulombic cutoff will be automatically adjusted at the beginning of the run to give the desired estimated error. Other cutoffs such as LJ will not be affected. If the grid is not set using the *mesh* command, this command will also attempt to use the optimal grid that minimizes cost using an estimate given by *(Hardy)*. Note that this cost estimate is not exact, somewhat experimental, and still may not yield the optimal parameters.

The *diff* keyword specifies the differentiation scheme used by the PPPM method to compute forces on particles given electrostatic potentials on the PPPM mesh. The *ik* approach is the default for PPPM and is the original formulation used in *(Hockney)*. It performs differentiation in Kspace, and uses 3 FFTs to transfer each component of the computed fields back to real space for total of 4 FFTs per timestep.

The analytic differentiation *ad* approach uses only 1 FFT to transfer information back to real space for a total of 2 FFTs per timestep. It then performs analytic differentiation on the single quantity to generate the 3 components of the electric field at each grid point. This is sometimes referred to as "smoothed" PPPM. This approach requires a somewhat larger PPPM mesh to achieve the same accuracy as the *ik* method. Currently, only the *ik* method (default) can be used for a triclinic simulation cell with PPPM. The *ad* method is always used for MSM.

Note

Currently, not all PPPM styles support the *ad* option. Support for those PPPM variants will be added later.

The *disp/auto* option controls whether the pppm/disp is allowed to generate PPPM parameters automatically. If set to *no*, parameters have to be specified using the *gewald/disp*, *mesh/disp*, *force/disp/real* or *force/disp/kspace* keywords, or the code will stop with an error message. When this option is set to *yes*, the error message will not appear and the simulation will start. For a typical application, using the automatic parameter generation will provide simulations that are either inaccurate or slow. Using this option is thus not recommended. For guidelines on how to obtain good parameters, see the *long-range dispersion howto* discussion.

The *fftbench* keyword applies only to PPPM. It is off by default. If this option is turned on, LAMMPS will perform a short FFT benchmark computation and report its timings, and will thus finish some seconds later than it would if this option were off.

The *force/disp/real* and *force/disp/kspace* keywords set the force accuracy for the real and reciprocal space computations for the dispersion part of pppm/disp. As shown in *(Isele-Holder2)*, optimal performance and accuracy in the results is obtained when these values are different.

The *force* keyword overrides the relative accuracy parameter set by the *kspace_style* command with an absolute accuracy. The accuracy determines the RMS error in per-atom forces calculated by the long-range solver and is thus specified in force units. A negative value for the accuracy setting means to use the relative accuracy parameter. The accuracy setting is used in conjunction with the pairwise cutoff to determine the number of K-space vectors for style *ewald*, the FFT grid size for style *pppm*, or the real space grid size for style *msm*.

The *gewald* keyword sets the value of the Ewald or PPPM G-ewald parameter for charge as *rinv* in reciprocal distance units. Without this setting, LAMMPS chooses the parameter automatically as a function of cutoff, precision, grid spacing, etc. This means it can vary from one simulation to the next which may not be desirable for matching a KSpace solver to a pre-tabulated pairwise potential. This setting can also be useful if Ewald or PPPM fails to choose a good grid spacing and G-ewald parameter automatically. If the value is set to 0.0, LAMMPS will choose the G-ewald parameter automatically. MSM does not use the *gewald* parameter.

The *gewald/disp* keyword sets the value of the Ewald or PPPM G-ewald parameter for dispersion as *rinv* in reciprocal distance units. It has the same meaning as the *gewald* setting for Coulombics.

The *kmax/ewald* keyword sets the number of kspace vectors in each dimension for kspace style *ewald*. The three values must be positive integers, or else (0,0,0), which unsets the option. When this option is not set, the Ewald sum scheme chooses its own kspace vectors, consistent with the user-specified accuracy and pairwise cutoff. In any case, if kspace style *ewald* is invoked, the values used are printed to the screen and the log file at the start of the run.

The *mesh* keyword sets the grid size for kspace style *pppm* or *msm*. In the case of PPPM, this is the FFT mesh, and each dimension must be factorizable into powers of 2, 3, and 5. In the case of MSM, this is the finest scale real-space mesh, and each dimension must be factorizable into powers of 2. When this option is not set, the PPPM or MSM solver chooses its own grid size, consistent with the user-specified accuracy and pairwise cutoff. Values for x,y,z of 0,0,0 unset the option.

The *mesh/disp* keyword sets the grid size for kspace style *pppm/disp*. This is the FFT mesh for long-range dispersion and ach dimension must be factorizable into powers of 2, 3, and 5. When this option is not set, the PPPM solver chooses its own grid size, consistent with the user-specified accuracy and pairwise cutoff. Values for x,y,z of 0,0,0 unset the option.

The *minorder* keyword allows LAMMPS to reduce the *order* setting if necessary to keep the communication of ghost grid point limited to exchanges between nearest-neighbor processors. See the discussion of the *overlap* keyword for details. If the *overlap* keyword is set to *yes*, which is the default, this is never needed. If it set to *no* and overlap occurs, then LAMMPS will reduce the order setting, one step at a time, until the ghost grid overlap only extends to nearest neighbor processors. The *minorder* keyword limits how small the *order* setting can become. The minimum allowed value for PPPM is 2, which is the default. If *minorder* is set to the same value as *order* then no reduction is allowed, and LAMMPS will generate an error if the grid communication is non-nearest-neighbor and *overlap* is set to *no*. The *minorder* keyword is not currently supported in MSM.

The *mix/disp* keyword selects the mixing rule for the dispersion coefficients. With *pair*, the dispersion coefficients of unlike types are computed as indicated with *pair_modify*. With *geom*, geometric mixing is enforced on the dispersion coefficients in the kspace coefficients. When using the arithmetic mixing rule, this will speed-up the simulations but introduces some error in the force computations, as shown in *(Wennberg)*. With *none*, it is assumed that no mixing rule is applicable. Splitting of the dispersion coefficients will be performed as described in *(Isele-Holder2)*. The *none* splitting is only available with the PPPM dispersion solver; with *ewald/disp* the *none* value is rejected, while *pair* (the default) and *geom* are honored.

This splitting can be influenced with the *splittol* keywords. Only the eigenvalues that are larger than tol compared to the largest eigenvalues are included. Using this keywords the original matrix of dispersion coefficients is approximated. This leads to faster computations, but the accuracy in the reciprocal space computations of the dispersion part is decreased.

The *order* keyword determines how many grid spacings an atom's charge extends when it is mapped to the grid in kspace style *pppm* or *msm*. The default for this parameter is 5 for PPPM and 8 for MSM, which means each charge spans 5 or 8 grid cells in each dimension, respectively. For the LAMMPS implementation of MSM, the order can range from 4 to 10 and must be even. For PPPM, the minimum allowed setting is 2 and the maximum allowed setting is 7. The larger the value of this parameter, the smaller that LAMMPS will set the grid size, to achieve the requested accuracy. Conversely, the smaller the order value, the larger the grid size will be. Note that there is an inherent trade-off involved: a small grid will lower the cost of FFTs or MSM direct sum, but a larger order parameter will increase the cost of interpolating charge/fields to/from the grid.

The PPPM order parameter may be reset by LAMMPS when it sets up the FFT grid if the implied grid stencil extends beyond the grid cells owned by neighboring processors. Typically this will only occur when small problems are run on large numbers of processors. A warning will be generated indicating the order parameter is being reduced to allow LAMMPS to run the problem. Automatic adjustment of the order parameter is not supported in MSM.

The *order/disp* keyword determines how many grid spacings an atom's dispersion term extends when it is mapped to the grid in kspace style *pppm/disp*. It has the same meaning as the *order* setting for Coulombics.

The *overlap* keyword can be used in conjunction with the *minorder* keyword with the PPPM styles to adjust the amount of communication that occurs when values on the FFT grid are exchanged between processors. This communication is distinct from the communication inherent in the parallel FFTs themselves, and is required because processors interpolate charge and field values using grid point values owned by neighboring processors (i.e. ghost point communication). If the *overlap* keyword is set to *yes* then this communication is allowed to extend beyond nearest-neighbor processors, e.g. when using lots of processors on a small problem. If it is set to *no* then the communication will be limited to nearest-neighbor processors and the *order* setting will be reduced if necessary, as explained by the *minorder* keyword discussion. The *overlap* keyword is always set to *yes* in MSM.

The *pressure/scalar* keyword applies only to MSM. If this option is turned on, only the scalar pressure (i.e. (Pxx + Pyy + Pzz)/3.0) will be computed, which can be used, for example, to run an isotropic barostat. Computing the full pressure tensor with MSM is expensive, and this option provides a faster alternative. The scalar pressure is computed using a relationship between the Coulombic energy and pressure *(Hummer)* instead of using the virial equation. This option cannot be used to access individual components of the pressure tensor, to compute per-atom virial, or with suffix kspace/pair styles of MSM, like OMP or GPU.

The *scafacos* keyword is used for settings that are passed to the ScaFaCoS library when using *kspace_style scafacos*.

The *tolerance* option affects how the *accuracy* specified with the *kspace_style* command is interpreted by ScaFaCoS. The following values may be used:

- energy = absolute accuracy in total Coulombic energy
- energy_rel = relative accuracy in total Coulombic energy
- potential = absolute accuracy in total Coulombic potential
- potential_rel = relative accuracy in total Coulombic potential
- field = absolute accuracy in electric field
- field_rel = relative accuracy in electric field

The values with suffix _rel indicate the tolerance is a relative tolerance; the other values impose an absolute tolerance on the given quantity. Absolute tolerance in this case means, that for a given quantity q and a given absolute tolerance of t_a the result should be between q-t_a and q+t_a. For a relative tolerance t_r the relative error should not be greater than t_r, i.e. abs(1 - (result/q)) < t_r. As a consequence of this, the tolerance type should be checked, when performing computations with a high absolute field / energy. E.g. if the total energy in the system is 1000000.0 an absolute tolerance of 1e-3 would mean that the result has to be between 999999.999 and 1000000.001, which would be equivalent to a relative tolerance of 1e-9.

The energy and energy_rel values, set a tolerance based on the total Coulombic energy of the system. The potential and potential_rel set a tolerance based on the per-atom Coulombic energy. The field and field_rel tolerance types set a tolerance based on the electric field values computed by ScaFaCoS. Since per-atom forces are derived from the per-atom electric field, this effectively sets a tolerance on the forces, similar to other LAMMPS KSpace styles, as explained on the *kspace_style* doc page.

Note that not all ScaFaCoS solvers support all tolerance types. These are the allowed values for each method:

- fmm = energy and energy_rel
- p2nfft = field (1d-,2d-,3d-periodic systems) or potential (0d-periodic)
- p3m = field

- ewald = field
- direct = has no tolerance tuning

If the tolerance type is not changed, the default values for the tolerance type are the first values in the above list, e.g. energy is the default tolerance type for the fmm solver.

The *fmm_tuning* option is only relevant when using the FMM method. It activates (value=1) or deactivates (value=0) an internal tuning mechanism for the FMM solver. The tuning operation runs sequentially and can be very time-consuming. Usually it is not needed for systems with a homogeneous charge distribution. The default for this option is therefore *0*. The FMM internal tuning is performed once, when the solver is set up.

The *slab* keyword allows an Ewald or PPPM solver to be used for a systems that are periodic in x,y but non-periodic in z - a *boundary* setting of "boundary p p f". This is done by treating the system as if it were periodic in z, but inserting empty volume between atom slabs and removing dipole inter-slab interactions so that slab-slab interactions are effectively turned off. The volfactor value sets the ratio of the extended dimension in z divided by the actual dimension in z. It must be a value >= 1.0. A value of 1.0 (the default) means the slab approximation is not used.

The recommended value for volfactor is 3.0. A larger value is inefficient; a smaller value introduces unwanted slab-slab interactions. The use of fixed boundaries in z means that the user must prevent particle migration beyond the initial z-bounds, typically by providing a wall-style fix. The methodology behind the *slab* option is explained in the paper by *(Yeh)*. The *slab* option is also extended to non-neutral systems *(Ballenegger)*.

Added in version 4Jul2026.

As an alternative to specifying a fixed volfactor, the keyword *auto* can be used to determine the extended z dimension from the current normalized force tolerance, the lateral dimensions of the simulation cell, and the active Coulombic gewald parameter. This is useful for quasi-2D systems where the amount of extra vacuum required for the slab correction depends on both the requested tolerance and the box geometry. Here the tolerance entering the formula is made dimensionless by dividing the current absolute force accuracy by the force between two unit charges separated by 1 Angstrom in the active unit style. The automatic choice is not artificially clamped above 1.0, so it can in principle approach the original box size if the formula permits. The quasi-2D error estimate used for the automatic choice is discussed in *(Gao2025)* and *(Gan2025)*. For related error estimates and parameter-selection guidance in the more general dielectric-confined setting, see *(Gao2025)*. The *auto* setting is currently supported by *kspace_style ewald*, *pppm*, *pppm/cg*, *pppm/tip4p*, *pppm/stagger*, and the corresponding OpenMP/GPU/Intel variants that reuse the same slab-correction setup. The KOKKOS variants do not support it and will stop with an error if it is requested; use an explicit volfactor with those.

An alternative slab option can be invoked with the *nozforce* keyword in lieu of the volfactor. This turns off all kspace forces in the z direction. The *nozforce* option is not supported by MSM. For MSM, any combination of periodic, non-periodic, or shrink-wrapped boundaries can be set using *boundary* (the slab approximation is not needed). The *slab* keyword with a *volfactor* value (the Yeh-Berkowitz EW3DC correction) supports triclinic (non-orthogonal) simulation cells for *kspace_style ewald*, *ewald/disp*, *pppm*, *pppm/cg*, and *pppm/kk* (and the OpenMP variants that reuse the same slab-correction setup). Because the slab normal must be the Cartesian z axis, only an *xy* tilt is allowed: a triclinic slab box with a non-zero *xz* or *yz* tilt is rejected with an error. The z box length must be held fixed for the duration of the run. Triclinic cells are not yet supported with the *slab* keyword for the *pppm/tip4p*, *pppm/stagger*, *esp*, *pppm/gpu*, or *pppm/intel* styles, nor for the *slab nozforce* and *slab ew2d* options.

The slab correction has also been extended to point dipole interactions *(Klapp)* in *kspace_style ewald/disp*, *ewald/dipole*, and *pppm/dipole*. This dipole slab correction is currently limited to orthogonal (non-triclinic) simulation cells.

Changed in version 4Jul2026: The *slab* correction with a *volfactor* value now supports triclinic simulation cells for the *ewald*, *ewald/disp*, *pppm*, *pppm/cg*, and *pppm/kk* styles.

Note

If you wish to apply an electric field in the Z-direction, in conjunction with the *slab* keyword, you can do it either by adding explicit oppositely charged particles to the +/- Z surfaces, or by using the *fix efield* command.

The *force/disp/real* and *force/disp/kspace* keywords set the force accuracy for the real and reciprocal space computations for the dispersion part of pppm/disp. As shown in *(Isele-Holder2)*, optimal performance and accuracy in the results is obtained when these values are different.

The *disp/auto* option controls whether the pppm/disp is allowed to generate PPPM parameters automatically. If set to *no*, parameters have to be specified using the *gewald/disp*, *mesh/disp*, *force/disp/real* or *force/disp/kspace* keywords, or the code will stop with an error message. When this option is set to *yes*, the error message will not appear and the simulation will start. For a typical application, using the automatic parameter generation will provide simulations that are either inaccurate or slow. Using this option is thus not recommended. For guidelines on how to obtain good parameters, see the *Howto dispersion* doc page.

1.46.4 Restrictions

The *collective* and *nonblocking* keywords cannot both be enabled at the same time. Whichever of the two keywords is enabled last will disable the other.

The *collective/self/copy* keyword has no effect unless *collective* is set to *yes*.

1.46.5 Related commands

kspace_style, *boundary*

1.46.6 Default

The option defaults are as follows:

- collective = no
- collective/self/copy = onerank
- nonblocking = no
- compute = yes
- cutoff/adjust = yes (MSM)
- diff = ik (PPPM)
- disp/auto = no
- fftbench = no (PPPM)
- force = -1.0
- force/disp/kspace = -1.0
- force/disp/real = -1.0
- gewald = gewald/disp = 0.0
- mesh = mesh/disp = 0 0 0
- minorder = 2

- mix/disp = pair
- order = 10 (MSM)
- order = order/disp = 5 (PPPM)
- order = order/disp = 7 (PPPM/intel)
- overlap = yes
- pressure/scalar = yes (MSM)
- slab = 1.0
- split = 0
- tol = 1.0e-6

For scafacos settings, the scafacos tolerance option depends on the method chosen, as documented above. The scafacos fmm_tuning default = 0.

1.47.3 Description

Define a long-range solver for LAMMPS to use each timestep to compute long-range Coulombic interactions or long-range $1/r^6$ interactions. Most of the long-range solvers perform their computation in K-space, hence the name of this command.

When such a solver is used in conjunction with an appropriate pair style, the cutoff for Coulombic or $1/r^N$ interactions is effectively infinite. If the Coulombic case, this means each charge in the system interacts with charges in an infinite array of periodic images of the simulation domain.

Note that using a long-range solver requires use of a matching *pair style* to perform consistent short-range pairwise calculations. This means that the name of the pair style contains a matching keyword to the name of the KSpace style,

as in this table:

Pair style	KSpace style
coul/long	ewald or pppm
coul/esp	esp
coul/msm	msm
lj/long or buck/long	disp (for dispersion)
tip4p/long	tip4p
dipole/long	dipole

The *ewald* style performs a standard Ewald summation as described in any solid-state physics text.

Added in version 4Jul2026.

The *ewald/gpu* style is a GPU-accelerated version of the *ewald* style. Unlike *pppm/gpu*, it requires no FFTs and therefore avoids the bandwidth-intensive grid communication of the PPPM method, which makes it competitive with *pppm/gpu* for smaller system sizes despite the less favorable scaling of the Ewald method with system size. The reciprocal-space structure factors, per-atom forces, and per-atom energy and virial are computed on the device; only the small structure-factor vector is reduced across MPI ranks on the host. Non-orthogonal (triclinic) simulation boxes are not supported. For best accuracy the *mixed* or *double* precision builds of the GPU package are recommended; the *single* precision build is not recommended for the Ewald summation because of round-off in the structure-factor sums.

The *ewald/disp* style adds a long-range dispersion sum option for $1/r^6$ potentials and is useful for simulation of interfaces *(In 't Veld)*. It also performs standard Coulombic Ewald summations, but in a more efficient manner than the *ewald* style. The $1/r^6$ capability means that Lennard-Jones or Buckingham potentials can be used without a cutoff, i.e. they become full long-range potentials.

The *ewald/disp/dipole* style can also be used with point-dipoles, see *(Toukmaji)*.

The *ewald/dipole* style adds long-range standard Ewald summations for dipole-dipole interactions, see *(Toukmaji)*.

The *ewald/dipole/spin* style adds long-range standard Ewald summations for magnetic dipole-dipole interactions between magnetic spins.

The *esp* style implements the Ewald Summation with Prolates (ESP) method *(Liang2025)*, a fast Ewald-summation approach that can reduce the cost of long-range electrostatics compared to PPPM and PME. Without any loss of accuracy, ESP alters the fast Ewald pipeline in two places. First, for kernel splitting it uses prolate spheroidal wave functions (PSWFs) instead of Gaussians, which, thanks to the optimal concentration of PSWFs among band-limited functions, significantly reduces the required Fourier grid. With everything else equal, the FFT length drops by about a factor of two per dimension at high accuracy ($\approx 8\times$ in 3D). The residual kernel also vanishes at the real-space cutoff, eliminating any need for an "energy shift." Second, for particle-mesh operations ESP employs PSWFs in place of the B-splines used by PPPM. For comparable accuracy without k-space upsampling, PSWFs require fewer neighboring grid points (e.g., ≈ 8 vs ≈ 12 for five-digit accuracy). In contrast, PPPM solvers typically sets the spreading/interpolation order to order:math:=*5*, which forces substantial Fourier-space upsampling. Consequently, at the same cutoff radius, it often needs a much larger FFT grid, whereas ESP achieves similar accuracy with far shorter transforms, yielding roughly a sixfold reduction in FFT length when other parameters are held fixed.

The *pppm* style invokes a particle-particle particle-mesh solver *(Hockney)* which maps atom charge to a 3d mesh, uses 3d FFTs to solve Poisson's equation on the mesh, then interpolates electric fields on the mesh points back to the atoms. It is closely related to the particle-mesh Ewald technique (PME) *(Darden)* used in AMBER and CHARMM. The cost of traditional Ewald summation scales as $N^{\frac{3}{2}}$ where N is the number of atoms in the system. The PPPM solver scales as $N \log N$ due to the FFTs, so it is almost always a faster choice *(Pollock)*.

The *pppm/cg* style is identical to the *pppm* style except that it has an optimization for systems where most particles are uncharged. Similarly the *msm/cg* style implements the same optimization for *msm*. The optional *smallq* argument defines the cutoff for the absolute charge value which determines whether a particle is considered charged or not. Its default value is 1.0e-5.

The *pppm/dipole* style invokes a particle-particle particle-mesh solver for dipole-dipole interactions, following the method of *(Cerda)*. When charges are present in the system, charge-charge and charge-dipole interactions are also computed.

The *pppm/dipole/spin* style invokes a particle-particle particle-mesh solver for magnetic dipole-dipole interactions between magnetic spins.

The *pppm/tip4p* style is identical to the *pppm* style except that it adds a charge at the massless fourth site in each TIP4P water molecule. It should be used with *pair styles* with a *tip4p/long* in their style name.

Added in version 2Sep2026.

The *pppm/xtb* and *pppm/tip4p/xtb* styles provide the corresponding PPPM electrostatics together with the source-to-sensor potential projection required by *fix qmmm/xtb*. They are part of the QMMM-XTB package and are intended for use with that fix. Other calculations performed by these styles are inherited from *pppm* and *pppm/tip4p*, respectively.

The *pppm/stagger* style performs calculations using two different meshes, one shifted slightly with respect to the other. This can reduce force aliasing errors and increase the accuracy of the method for a given mesh size. Or a coarser mesh can be used for the same target accuracy, which saves CPU time. However, there is a trade-off since FFTs on two meshes are now performed which increases the computation required. See *(Cerutti)*, *(Neelov)*, and *(Hockney)* for details of the method.

For high relative accuracy, using staggered PPPM allows the mesh size to be reduced by a factor of 2 in each dimension as compared to regular PPPM (for the same target accuracy). This can give up to a 4x speedup in the KSpace time (8x less mesh points, 2x more expensive). However, for low relative accuracy, the staggered PPPM mesh size may be essentially the same as for regular PPPM, which means the method will be up to 2x slower in the KSpace time (simply 2x more expensive). For more details and timings, see the *Speed tips* doc page.

Note

Using *pppm/stagger* may not give the same increase in the accuracy of energy and pressure as it does in forces, so some caution must be used if energy and/or pressure are quantities of interest, such as when using a barostat.

The *pppm/disp* and *pppm/disp/tip4p* styles add a mesh-based long-range dispersion sum option for 1/r^6 potentials *(Isele-Holder)*, similar to the *ewald/disp* style. The 1/r^6 capability means that Lennard-Jones or Buckingham potentials can be used without a cutoff, i.e. they become full long-range potentials.

For these styles, you will possibly want to adjust the default choice of parameters by using the *kspace_modify* command. This can be done by either choosing the Ewald and grid parameters, or by specifying separate accuracies for the real and kspace calculations. When not making any settings, the simulation will stop with an error message. Further information on the influence of the parameters and how to choose them is described in *(Isele-Holder)*, *(Isele-Holder2)* and the *Howto dispersion* doc page.

Added in version 4Jul2026.

The *pppm/rk* kspace style is a variant of *pppm* designed for a heterogeneous multicore pppm computation of long-range forces. The heterogeneity is in the sense that the MPI communicator is partitioned into two classes of MPI processes. Thus, the use of *pppm/rk* requires the use of the command line *-partition* option. E.g.,

```
mpirun -n 100 lmp -partition 96 4 -in in.somescript
```

The R-process class of processes primarily computes the short-range forces and atom-wise updates, the latter of which includes the accumulation of charge densities. In the above command-line example, there would be 96 R-processes and 4 K-processes. The K-process class is mainly responsible for solving the Poisson equations with 3d FFT. The number of K-processes divides the number of R-processes, and the total number of processes is furthermore partitioned orthogonally into inter-RK blocks (as seen also in the *VerletSplit* class). Each inter-RK block communicator has one representative K process, with the rest of the processes being R processes.

The *pppm/rk* kspace style must be paired with an analogous *rk* type run style, e.g., *verlet/split/rk*. An error is generated otherwise. Also, *pppm/rk* does not currently support group/group computation (*group_group_enable==0*).

This approach is based on the enhanced baseline decomposition of *(Dandurand)* and works cited within.

Note

All of the PPPM styles can be used with single-precision FFTs by using the compiler switch -DFFT_SINGLE for the FFT_INC setting in your low-level Makefile. This setting also changes some of the PPPM operations (e.g. mapping charge to mesh and interpolating electric fields to particles) to be performed in single precision. This option can speed-up long-range calculations, particularly in parallel or on GPUs. The use of the -DFFT_SINGLE flag is discussed on the *Build settings* doc page. MSM does not currently support the -DFFT_SINGLE compiler switch.

The *electrode* styles add methods that are required for the constant potential method implemented in *fix electrode/**. The styles *ewald/electrode*, *pppm/electrode* and *pppm/electrode/intel* are available. These styles do not support the *kspace_modify slab nozforce* command.

The *msm* style invokes a multi-level summation method MSM solver, *(Hardy)* or *(Hardy2)*, which maps atom charge to a 3d mesh, and uses a multi-level hierarchy of coarser and coarser meshes on which direct Coulomb solvers are done. This method does not use FFTs and scales as *N*. It may therefore be faster than the other K-space solvers for relatively large problems when running on large core counts. MSM can also be used for non-periodic boundary conditions and for mixed periodic and non-periodic boundaries.

MSM is most competitive versus Ewald and PPPM when only relatively low accuracy forces, about 1e-4 relative error or less accurate, are needed. Note that use of a larger Coulombic cutoff (i.e. 15 Angstroms instead of 10 Angstroms) provides better MSM accuracy for both the real space and grid computed forces.

Currently calculation of the full pressure tensor in MSM is expensive. Using the *kspace_modify pressure/scalar yes* command provides a less expensive way to compute the scalar pressure (Pxx + Pyy + Pzz)/3.0. The scalar pressure can be used, for example, to run an isotropic barostat. If the full pressure tensor is needed, then calculating the pressure at every timestep or using a fixed pressure simulation with MSM will cause the code to run slower.

The *scafacos* style is a wrapper on the ScaFaCoS Coulomb solver library which provides a variety of solver methods which can be used with LAMMPS. The paper by *(Sutmann2)* gives an overview of ScaFaCoS.

ScaFaCoS was developed by a consortium of German research facilities with a BMBF (German Ministry of Science and Education) funded project in 2009-2012. Participants of the consortium were the Universities of Bonn, Chemnitz, Stuttgart, and Wuppertal as well as the Forschungszentrum Juelich.

The library is available for download at "http://www.scafacos.de/" or can be cloned from the git-repository "https://github.com/scafacos/scafacos".

In order to use this KSpace style, you must download and build the ScaFaCoS library, then build LAMMPS with the SCAFACOS package installed package which links LAMMPS to the ScaFaCoS library. See details on *this page*.

Note

Unlike other KSpace solvers in LAMMPS, ScaFaCoS computes all Coulombic interactions, both short- and long-range. Thus you should NOT use a Coulombic pair style when using kspace_style scafacos. This also means the total Coulombic energy (short- and long-range) will be tallied for *thermodynamic output* command as part of the *elong* keyword; the *ecoul* keyword will be zero.

Note

See the current restriction below about use of ScaFaCoS in LAMMPS with molecular charged systems or the TIP4P water model.

The specified *method* determines which ScaFaCoS algorithm is used. These are the ScaFaCoS methods currently available from LAMMPS:

- *fmm* = Fast Multi-Pole method
- *p2nfft* = FFT-based Coulomb solver
- *ewald* = Ewald summation
- *direct* = direct O(N^2) summation
- *p3m* = PPPM

We plan to support additional ScaFaCoS solvers from LAMMPS in the future. For an overview of the included solvers, refer to *(Sutmann)*

The specified *accuracy* is similar to the accuracy setting for other LAMMPS KSpace styles, but is passed to ScaFaCoS, which can interpret it in different ways for different methods it supports. Within the ScaFaCoS library the *accuracy* is treated as a tolerance level (either absolute or relative) for the chosen quantity, where the quantity can be either the Columic field values, the per-atom Columic energy or the total Columic energy. To select from these options, see the *kspace_modify scafacos accuracy* doc page.

The *kspace_modify scafacos* command also explains other ScaFaCoS options currently exposed to LAMMPS.

Added in version 12Jun2025.

The *zero* style does not do any calculations, but is compatible with all pair styles that require some version of a kspace style. The accuracy argument is required for some internal calculations but has no impact of forces or energy, since those will always be zero.

The specified *accuracy* determines the relative RMS error in per-atom forces calculated by the long-range solver. It is set as a dimensionless number, relative to the force that two unit point charges (e.g. 2 monovalent ions) exert on each other at a distance of 1 Angstrom. This reference value was chosen as representative of the magnitude of electrostatic forces in atomic systems. Thus an accuracy value of 1.0e-4 means that the RMS error will be a factor of 10000 smaller than the reference force.

The accuracy setting is used in conjunction with the pairwise cutoff to determine the number of K-space vectors for style *ewald* or the grid size for style *esp*, *pppm* or *msm*.

For style *esp*, one accuracy value requests the overall relative force accuracy and is used as the PSWF kernel-splitting target. LAMMPS applies a tighter internal default to the PSWF spreading/interpolation target so that the automatically selected FFT grid and stencil order meet the requested accuracy. A second value can be specified to set the spreading/interpolation target explicitly.

Note that styles *esp* and *pppm* only computes the grid size at the beginning of a simulation, so if the length or triclinic tilt of the simulation cell increases dramatically during the course of the simulation, the accuracy of the simulation may degrade. Likewise, if the *kspace_modify slab* option is used with shrink-wrap boundaries in the z-dimension, and the box size changes dramatically in z. For example, for a triclinic system with all three tilt factors set to the maximum limit, the PPPM grid should be increased roughly by a factor of 1.5 in the y direction and 2.0 in the z direction as compared to the same system using a cubic orthogonal simulation cell. One way to handle this issue if you have a long simulation where the box size changes dramatically, is to break it into shorter simulations (multiple *run* commands). This works because the grid size is re-computed at the beginning of each run. Another way to ensure the described accuracy requirement is met is to run a short simulation at the maximum expected tilt or length, note the required grid size, and then use the *kspace_modify mesh* command to manually set the ESP/PPPM grid size to this value for the long run. The simulation then will be "too accurate" for some portion of the run.

RMS force errors in real space for *ewald* and *pppm* are estimated using equation 18 of *(Kolafa)*, which is also referenced as equation 9 of *(Petersen2)*. RMS force errors in K-space for *ewald* are estimated using equation 11 of *(Petersen2)*, which is similar to equation 32 of *(Kolafa)*. RMS force errors in K-space for *pppm* are estimated using equation 38 of *(Deserno)*. RMS force errors for *msm* are estimated using ideas from chapter 3 of *(Hardy)*, with equation 3.197 of particular note. When using *msm* with non-periodic boundary conditions, it is expected that the error estimation will be too pessimistic. RMS force errors for dipoles when using *ewald/disp* or *ewald/dipole* are estimated using equations 33 and 46 of *(Wang3)*. The RMS force errors for *pppm/dipole* are estimated using the equations in *(Cerda)*.

See the *kspace_modify* command for additional options of the K-space solvers that can be set, including a *force* option for setting an absolute RMS error in forces, as opposed to a relative RMS error.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

Note

For the GPU package, the *pppm/gpu* style performs charge assignment and force interpolation calculations on the GPU. These processes are performed either in single or double precision, depending on whether the -DFFT_SINGLE setting was specified in your low-level Makefile, as discussed above. The FFTs themselves are still calculated on the CPU. If *pppm/gpu* is used with a GPU-enabled pair style, part of the PPPM calculation can be performed concurrently on the GPU while other calculations for non-bonded and bonded force calculation are performed on the CPU.

Note

For the KOKKOS package, the *pppm/kk* style performs charge assignment and force interpolation calculations, along with the FFTs themselves, on the GPU or (optionally) threaded on the CPU when using OpenMP and FFTW3.

The specific FFT library is selected using the FFT_KOKKOS CMake parameter. See the *Build settings* doc page for how to select a 3rd-party FFT library.

The *pppm/tip4p/kk* style performs the same on-device work for TIP4P systems: the off-atom M (massless charge) site is located, the charge is mapped to the grid from that site, and the resulting force and per-atom energy/virial are redistributed back onto the O atom and its two H atoms, all in device kernels. Like *pppm/kk* it requires *newton on* and does not (yet) support *kspace_modify diff ad* or triclinic (non-orthogonal) boxes; use the non-accelerated *pppm/tip4p* style for those cases.

1.47.4 Restrictions

Note that the long-range electrostatic solvers in LAMMPS assume conducting metal (tinfoil) boundary conditions for both charge and dipole interactions. Vacuum boundary conditions are not currently supported.

The *ewald/disp*, *ewald*, *esp*, *pppm*, *pppm/disp*, and *msm* styles support non-orthogonal (triclinic symmetry) simulation boxes. However, triclinic simulation cells may not yet be supported by all suffix versions of these styles.

The *pppm/xtb* and *pppm/tip4p/xtb* styles currently require an orthorhombic simulation box, as does *fix qmmm/xtb*.

Changed in version 2Sep2026.

The *pppm/cg/omp* style now supports triclinic simulation boxes in the same way as the *pppm/cg* and *pppm/omp* styles.

Changed in version 4Jul2026.

Triclinic (non-orthogonal) box support was added to the *pppm/disp* style and its *pppm/disp/tip4p*, *pppm/disp/omp*, and *pppm/disp/tip4p/omp* variants. It requires *ik* differentiation (the default; the *kspace_modify diff ad* option is not supported together with a triclinic box). The *kspace_modify slab* correction is supported for a triclinic box only in the EW3DC *volfactor* form and only with an *xy* tilt (xz = yz = 0, so the slab normal remains the z axis); *slab nozforce* and *slab ew2d* are not available for a triclinic box. For the *tip4p* variants the slab correction is not (yet) available together with a triclinic box, and (as for all TIP4P styles) the communication cutoff must be large enough to reconstruct the M-site, see the *TIP4P howto*.

Most of the base kspace styles are part of the KSPACE package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

The *msm/dielectric* and *pppm/dielectric* kspace styles are part of the DIELECTRIC package. They are only enabled if LAMMPS was built with that package **and** the KSPACE package. See the *Build package* page for more info.

For MSM, a simulation must be 3d and one can use any combination of periodic, non-periodic, but not shrink-wrapped boundaries (specified using the *boundary* command).

For Ewald, ESP and PPPM, a simulation must be 3d and periodic in all dimensions. The only exception is if the slab option is set with *kspace_modify*, in which case the xy dimensions must be periodic and the z dimension must be non-periodic.

The scafacos KSpace style will only be enabled if LAMMPS is built with the SCAFACOS package. See the *Build package* doc page for more info.

The use of ScaFaCos in LAMMPS does not yet support molecular charged systems where the short-range Coulombic interactions between atoms in the same bond/angle/dihedral are weighted by the *special_bonds* command. Likewise it does not support the "TIP4P water style" where a fictitious charge site is introduced in each water molecule. Finally, the methods *p3m* and *ewald* do not support computing the virial, so this contribution is not included.

```

1.48.3 Description

Label this line of the input script with the chosen ID. Unless a jump command was used previously, this does nothing. But if a *jump* command was used with a label argument to begin invoking this script file, then all commands in the script prior to this line will be ignored. I.e. execution of the script will begin at this line. This is useful for looping over a section of the input script as discussed in the *jump* command.

1.48.4 Restrictions

none

1.48.5 Related commands

jump, *next*

1.48.6 Default

1.49 labelmap command

1.49.1 Syntax

```
labelmap option args
```

- *option* = *atom* or *bond* or *angle* or *dihedral* or *improper* or *clear* or *write* or *check_labels*

  ```
  clear = no args
  write arg = filename
  atom or bond or angle or dihedral or improper
    args = list of one or more numeric-type/type-label pairs
  check_labels value = string
    string = string containing any of the following characters: 'b', 'a', 'd', or 'i'
  ```

1.49.2 Examples

```
labelmap atom 1 c1 2 hc 3 cp 4 nt
labelmap atom 3 carbon 4 'c3"' 5 "c1'" 6 "c#"
labelmap atom $(label2type(atom,carbon)) C  # change type label from 'carbon' to 'C'
labelmap clear
labelmap write mymap.include
labelmap bond 1 carbonyl 2 nitrile 3 """ c1'-c2" """
```

1.49.3 Description

Added in version 15Sep2022.

Define alphanumeric type labels to associate with one or more numeric atom, bond, angle, dihedral or improper types. A collection of type labels for all atom types, bond types, etc. is stored as a label map.

The label map can also be defined by the *read_data* command when it reads these sections in a data file: Atom Type Labels, Bond Type Labels, etc. See the *Howto type labels* doc page for a general discussion of how type labels can be used. See *(Gissinger)* for a discussion of the type label implementation in LAMMPS and its uses.

Valid type labels can contain any alphanumeric character, but must not start with a number, a '#', or a '*' character. They can contain other standard ASCII characters such as angular or square brackets '<' and '>' or '[' and ']', parenthesis '(' and ')', dash '-', underscore '_', plus '+' and equals '=' signs and more. They must not contain blanks or any other whitespace. Note that type labels must be put in single or double quotation marks if they contain the '#' character or if they contain a double (") or single quotation mark ('). If the label contains both a single and a double quotation mark, then triple quotation (""") must be used. When enclosing a type label with quotation marks, the LAMMPS input parser may require adding leading or trailing blanks around the type label so it can identify the enclosing quotation marks. Those blanks will be removed when defining the label.

A *labelmap* command can only modify the label map for one type-kind (atom types, bond types, etc). Any number of numeric-type/type-label pairs may follow. If a type label already exists for the same numeric type, it will be overwritten. Type labels must be unique; assigning the same type label to multiple numeric types within the same type-kind is not allowed. When reading and writing data files, it is required that there is a label defined for *every* numeric type within a given type-kind in order to write out the type label section for that type-kind.

The *clear* option resets the label map and thus discards all previous settings.

The *write* option takes a filename as argument and writes the current label mappings to a file as a sequence of *labelmap* commands, so the file can be copied into a new LAMMPS input file or read in using the *include* command.

Added in version 30Mar2026.

The *check_labels* keyword provides a warning if the type label of a bond, angle, dihedral, or improper defined in the simulation is not consistent with the atom types of its constituent atoms. This consistency check is performed only once, when the simulation is initialized by the first *run* or *minimize* command after this *labelmap* command. The *check_labels* value is a single string that should contain one or more of the characters 'b', 'a', 'd', and 'i', which correspond to bonds, angles, dihedrals, and impropers, respectively. For example, the keyword/value pair 'check_labels badi' will check all the type labels of all higher-order interactions, while 'check_labels adi' will only check type labels for angles, dihedrals, and impropers. The *check_labels* keyword requires a specific *type label* format to infer the types of higher-order interactions. Bond, angle, dihedral, and improper type labels must contain their constituent atom types delimited by hyphens, e.g., 'c2-c2-c2-n' for a dihedral that contains three atoms of type 'c2' and one atom of 'n'. If the constituent atoms do not have these atom types in the proper order, a warning will be generated when using this *check_types* keyword. Interactions that have been disabled, e.g., via *fix_shake*, will not be checked.

1.49.4 Restrictions

This command must come after the simulation box is defined by a *read_data*, *read_restart*, or *create_box* command.

Label maps are considered experimental when using the KOKKOS package.

```

1.50.3 Description

Define a lattice for use by other commands. In LAMMPS, a lattice is simply a set of points in space, determined by a unit cell with basis atoms, that is replicated infinitely in all dimensions. The arguments of the lattice command can be used to define a wide variety of crystallographic lattices.

A lattice is used by LAMMPS in two ways. First, the *create_atoms* command creates atoms on the lattice points inside the simulation box. Note that the *create_atoms* command allows different atom types to be assigned to different basis atoms of the lattice. Second, the lattice spacing in the x,y,z dimensions implied by the lattice, can be used by other commands as distance units (e.g. *create_box*, *region* and *velocity*), which are often convenient to use when the underlying problem geometry is atoms on a lattice.

The lattice style must be consistent with the dimension of the simulation - see the *dimension* command. Styles *sc* or *bcc* or *fcc* or *hcp* or *diamond* are for 3d problems. Styles *sq* or *sq2* or *hex* are for 2d problems. Style *custom* can be used for either 2d or 3d problems.

A lattice consists of a unit cell, a set of basis atoms within that cell, and a set of transformation parameters (scale, origin, orient) that map the unit cell into the simulation box. The vectors a1,a2,a3 are the edge vectors of the unit cell. This

is the nomenclature for "primitive" vectors in solid-state crystallography, but in LAMMPS the unit cell they determine does not have to be a "primitive cell" of minimum volume.

Note that the lattice command can be used multiple times in an input script. Each time it is invoked, the lattice attributes are re-defined and are used for all subsequent commands (that use lattice attributes). For example, a sequence of lattice, *region*, and *create_atoms* commands can be repeated multiple times to build a poly-crystalline model with different geometric regions populated with atoms in different lattice orientations.

A lattice of style *none* does not define a unit cell and basis set, so it cannot be used with the *create_atoms* command. However it does define a lattice spacing via the specified scale parameter. As explained above the lattice spacings in x,y,z can be used by other commands as distance units. No additional keyword/value pairs can be specified for the *none* style. By default, a "lattice none 1.0" is defined, which means the lattice spacing is the same as one distance unit, as defined by the *units* command.

Lattices of style *sc*, *fcc*, *bcc*, and *diamond* are 3d lattices that define a cubic unit cell with edge length = 1.0. This means a1 = 1 0 0, a2 = 0 1 0, and a3 = 0 0 1. Style *hcp* has a1 = 1 0 0, a2 = 0 sqrt(3) 0, and a3 = 0 0 sqrt(8/3). The placement of the basis atoms within the unit cell are described in any solid-state physics text. A *sc* lattice has 1 basis atom at the lower-left-bottom corner of the cube. A *bcc* lattice has 2 basis atoms, one at the corner and one at the center of the cube. A *fcc* lattice has 4 basis atoms, one at the corner and 3 at the cube face centers. A *hcp* lattice has 4 basis atoms, two in the z = 0 plane and 2 in the z = 0.5 plane. A *diamond* lattice has 8 basis atoms.

Lattices of style *sq* and *sq2* are 2d lattices that define a square unit cell with edge length = 1.0. This means a1 = 1 0 0 and a2 = 0 1 0. A *sq* lattice has 1 basis atom at the lower-left corner of the square. A *sq2* lattice has 2 basis atoms, one at the corner and one at the center of the square. A *hex* style is also a 2d lattice, but the unit cell is rectangular, with a1 = 1 0 0 and a2 = 0 sqrt(3) 0. It has 2 basis atoms, one at the corner and one at the center of the rectangle.

A lattice of style *custom* allows you to specify a1, a2, a3, and a list of basis atoms to put in the unit cell. By default, a1 and a2 and a3 are 3 orthogonal unit vectors (edges of a unit cube). But you can specify them to be of any length and non-orthogonal to each other, so that they describe a tilted parallelepiped. Via the *basis* keyword you add atoms, one at a time, to the unit cell. Its arguments are fractional coordinates (0.0 <= x,y,z < 1.0). For 2d simulations, the fractional z coordinate for any basis atom must be 0.0.

The position vector x of a basis atom within the unit cell is a linear combination of the unit cell's 3 edge vectors, i.e. x = bx a1 + by a2 + bz a3, where bx,by,bz are the 3 values specified for the *basis* keyword.

This subsection discusses the arguments that determine how the idealized unit cell is transformed into a lattice of points within the simulation box.

The *scale* argument determines how the size of the unit cell will be scaled when mapping it into the simulation box. I.e. it determines a multiplicative factor to apply to the unit cell, to convert it to a lattice of the desired size and distance units in the simulation box. The meaning of the *scale* argument depends on the *units* being used in your simulation.

For all unit styles except *lj*, the scale argument is specified in the distance units defined by the unit style. For example, in *real* or *metal* units, if the unit cell is a unit cube with edge length 1.0, specifying scale = 3.52 would create a cubic lattice with a spacing of 3.52 Angstroms. In *cgs* units, the spacing would be 3.52 cm.

For unit style *lj*, the scale argument is the Lennard-Jones reduced density, typically written as rho*. LAMMPS converts this value into the multiplicative factor via the formula "factor^dim = rho/rho*", where rho = N/V with V = the volume of the lattice unit cell and N = the number of basis atoms in the unit cell (described below), and dim = 2 or 3 for the dimensionality of the simulation. Effectively, this means that if LJ particles of size sigma = 1.0 are used in the simulation, the lattice of particles will be at the desired reduced density.

The *origin* option specifies how the unit cell will be shifted or translated when mapping it into the simulation box. The x,y,z values are fractional values (0.0 <= x,y,z < 1.0) meaning shift the lattice by a fraction of the lattice spacing in each dimension. The meaning of "lattice spacing" is discussed below. For 2d simulations, the *origin* z value must be 0.0.

The *orient* option specifies how the unit cell will be rotated when mapping it into the simulation box. The *dim* argument is one of the 3 coordinate axes in the simulation box. The other 3 arguments are the crystallographic direction in the lattice that you want to orient along that axis, specified as integers. E.g. "orient x 2 1 0" means the x-axis in the simulation box will be the [210] lattice direction, and similarly for y and z. The 3 lattice directions you specify do not have to be unit vectors, but they must be mutually orthogonal and obey the right-hand rule, i.e. (X cross Y) points in the Z direction. For 2d simulations, the *orient* x and y vectors must define 0 for their 3rd component. Similarly the *orient* z vector must define 0 for its 1st and 2nd components.

Note

The preceding paragraph describing lattice directions is only valid for orthogonal cubic unit cells (or square in 2d). If you are using a *hcp* or *hex* lattice or the more general lattice style *custom* with non-orthogonal a1,a2,a3 vectors, then you should think of the 3 *orient* vectors as creating a 3x3 rotation matrix which is applied to a1,a2,a3 to rotate the original unit cell to a new orientation in the simulation box.

The *triclinic/general* option specifies that the defined lattice is for use with a general triclinic simulation box, as opposed to an orthogonal or restricted triclinic box. The *Howto triclinic* doc page explains all 3 kinds of simulation boxes LAMMPS supports.

If this option is specified, a *custom* lattice style must be used. The *a1*, *a2*, *a3* vectors should define the edge vectors of a single unit cell of the lattice with one or more basis atoms. They edge vectors can be arbitrary so long as they are non-zero, distinct, and not co-planar. In addition, they must define a right-handed system, such that (*a1* cross *a2*) points in the direction of *a3*. Note that a left-handed system can be converted to a right-handed system by simply swapping the order of any pair of the *a1*, *a2*, *a3* vectors. For 2d simulations, the *a3* vector must be specified as (0.0,0.0,1.0), which is its default value.

If this option is used, the *origin* and *orient* settings must have their default values. Namely (0.0,0.0,0.0) for the *origin* and (100), (010), (001) for the *orient* vectors.

The *create_box* command can be used to create a general triclinic box that replicates the *a1*, *a2*, *a3* unit cell vectors in each direction to create the 3 arbitrary edge vectors of the overall simulation box. It requires a lattice with the *triclinic/general* option.

Likewise, the *create_atoms* command can be used to add atoms (or molecules) to a general triclinic box which lie on the lattice points defined by *a1*, *a2*, *a3* and the unit cell basis atoms. To do this, it also requires a lattice with the *triclinic/general* option.

Note

LAMMPS allows specification of general triclinic lattices and simulation boxes as a convenience for users who may be converting data from solid-state crystallographic representations or from DFT codes for input to LAMMPS. However, as explained on the *Howto_triclinic* doc page, internally, LAMMPS only uses restricted triclinic simulation boxes. This means the box and per-atom information (e.g. coordinates, velocities) defined by the *create_box* and *create_atoms* commands are converted from general to restricted triclinic form when the two commands are invoked. It also means that any other commands which use lattice spacings from this command (e.g. the region command), will be operating on a restricted triclinic simulation box, even if the *triclinic/general* option was used to define the lattice. See the next section for details.

Several LAMMPS commands have the option to use distance units that are inferred from "lattice spacings" in the x,y,z box directions. E.g. the *region* command can create a block of size 10x20x20, where 10 means 10 lattice spacings in the x direction.

Note

Though they are called lattice spacings, all the commands that have a "units lattice" option, simply use the 3 values as scale factors on the distance units defined by the *units* command. Thus if you do not like the lattice spacings computed by LAMMPS (e.g. for a non-orthogonal or rotated unit cell), you can define the 3 values to be whatever you wish, via the *spacing* option.

If the *spacing* option is not specified, the lattice spacings are computed by LAMMPS in the following way. A unit cell of the lattice is mapped into the simulation box (scaled and rotated), so that it now has (perhaps) a modified size and orientation. The lattice spacing in X is defined as the difference between the min/max extent of the x coordinates of the 8 corner points of the modified unit cell (4 in 2d). Similarly, the Y and Z lattice spacings are defined as the difference in the min/max of the y and z coordinates.

Note

If the *triclinic/general* option is specified, the unit cell defined by *a1*, *a2*, *a3* edge vectors is first converted to a restricted triclinic orientation, which is a rotation operation. The min/max extent of the 8 corner points is then determined, as described in the preceding paragraph, to set the lattice spacings. As explained for the *triclinic/general* option above, this is because any use of the lattice spacings by other commands will be for a restricted triclinic simulation box, not a general triclinic box.

Note that if the unit cell is orthogonal with axis-aligned edges (no rotation via the *orient* keyword), then the lattice spacings in each dimension are simply the scale factor (described above) multiplied by the length of a1,a2,a3. Thus a *hex* style lattice with a scale factor of 3.0 Angstroms, would have a lattice spacing of 3.0 in x and 3*sqrt(3.0) in y.

Note

For non-orthogonal unit cells and/or when a rotation is applied via the *orient* keyword, then the lattice spacings computed by LAMMPS are typically less intuitive. In particular, in these cases, there is no guarantee that a particular lattice spacing is an integer multiple of the periodicity of the lattice in that direction. Thus, if you create an orthogonal periodic simulation box whose size in a dimension is a multiple of the lattice spacing, and then fill it with atoms via the *create_atoms* command, you will NOT necessarily create a periodic system. I.e. atoms may overlap incorrectly at the faces of the simulation box.

The *spacing* option sets the 3 lattice spacings directly. All must be non-zero (use 1.0 for dz in a 2d simulation). The specified values are multiplied by the multiplicative factor described above that is associated with the scale factor. Thus a spacing of 1.0 means one unit cell edge length independent of the scale factor. As mentioned above, this option can be useful if the spacings LAMMPS computes are inconvenient to use in subsequent commands, which can be the case for non-orthogonal or rotated lattices.

Note that whenever the lattice command is used, the values of the lattice spacings LAMMPS calculates are printed out. Thus their effect in commands that use the spacings should be decipherable.

Example commands for generating a Wurtzite crystal. The lattice constants approximate those of CdSe. The $\sqrt{3} \times 1$ orthorhombic supercell is used with the x, y, and z directions oriented along $[\bar{1}\bar{2}30]$, $[10\bar{1}0]$, and [0001], respectively.

1.50.4 Restrictions

The *a1,a2,a3,basis* keywords can only be used with style *custom*.

1.50.5 Related commands

dimension, *create_atoms*, *region*

1.50.6 Default

```
lattice none 1.0
```

For other lattice styles, the option defaults are origin = 0.0 0.0 0.0, orient = x 1 0 0, orient = y 0 1 0, orient = z 0 0 1, a1 = 1 0 0, a2 = 0 1 0, and a3 = 0 0 1.

1.51 log command

1.51.1 Syntax

```
log file keyword
```

- file = name of new logfile
- keyword = *append* if output should be appended to logfile (optional)

1.51.2 Examples

```
log log.equil
log log.equil append
```

1.51.3 Description

This command closes the current LAMMPS log file, opens a new file with the specified name, and begins logging information to it. If the specified file name is *none*, then no new log file is opened. If the optional keyword *append* is specified, then output will be appended to an existing log file, instead of overwriting it.

If multiple processor partitions are being used, the file name should be a variable, so that different processors do not attempt to write to the same log file.

The file "log.lammps" is the default log file for a LAMMPS run. The name of the initial log file can also be set by the *-log command-line switch*.

1.51.4 Restrictions

none

1.51.5 Related commands

none

1.51.6 Default

The default LAMMPS log file is named log.lammps

1.52 mass command

1.52.1 Syntax

```
mass I value
```

- I = atom type (see asterisk form below), or type label
- value = mass

1.52.2 Examples

```
mass 1 1.0
mass * 62.5
mass 2* 62.5

labelmap atom 1 C
mass C 12.01
```

1.52.3 Description

Set the mass for all atoms of one or more atom types. Per-type mass values can also be set in the *read_data* data file using the "Masses" keyword. See the *units* command for what mass units to use.

The I index can be specified in one of several ways. An explicit numeric value can be used, as in the first example above. Or I can be a type label, which is an alphanumeric string defined by the *labelmap* command or in a section of

a data file read by the *read_data* command, and which converts internally to a numeric type. Or a wild-card asterisk can be used to set the mass for multiple atom types. This takes the form "*" or "*n" or "n*" or "m*n", where m and n are numbers. If N = the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive).

A line in a *data file* that follows the "Masses" keyword specifies mass using the same format as the arguments of the mass command in an input script, except that no wild-card asterisk can be used. For example, under the "Masses" section of a data file, the line that corresponds to the first example above would be listed as

```
1 1.0
```

Note that the mass command can only be used if the *atom style* requires per-type atom mass to be set. Currently, all but the *sphere* and *ellipsoid* and *peri* styles do. They require mass to be set for individual particles, not types. Per-atom masses are defined in the data file read by the *read_data* command, or set to default values by the *create_atoms* command. Per-atom masses can also be set to new values by the *set mass* or *set density* commands.

Also note that *pair_style eam* and *pair_style bop* commands define the masses of atom types in their respective potential files, in which case the mass command is normally not used.

If you define a *hybrid atom style* which includes one (or more) sub-styles which require per-type mass and one (or more) sub-styles which require per-atom mass, then you must define both. However, in this case the per-type mass will be ignored; only the per-atom mass will be used by LAMMPS.

1.52.4 Restrictions

This command must come after the simulation box is defined by a *read_data*, *read_restart*, or *create_box* command.

All masses must be defined before a simulation is run. They must also all be defined before a *velocity* or *fix shake* command is used.

The mass assigned to any type or atom must be > 0.0.

           command "run 5"
mdi connect
mdi exit
```

1.53.3 Description

This command implements operations within LAMMPS to use the MDI Library for coupling to other codes in a client/server protocol.

See the Howto MDI doc page for a discussion of all the different ways 2 or more codes can interact via MDI.

The examples/mdi directory has examples which use LAMMPS in 4 different modes: as a driver using an engine as either a stand-alone code or as a plugin, and as an engine operating as either a stand-alone code or as a plugin. The README file in that directory shows how to launch and couple codes for all the 4 usage modes, and so they communicate via the MDI library using either MPI or sockets.

The scripts in that directory illustrate the use of all the options for this command.

The *engine* option enables LAMMPS to act as an MDI engine (server), responding to requests from an MDI driver (client) code.

The *plugin* option enables LAMMPS to act as an MDI driver (client), and load the MDI engine (server) code as a library plugin. In this case the MDI engine is a library plugin. An MDI engine can also be a stand-alone code, launched separately from LAMMPS, in which case the mdi plugin command is not used.

The *connect* and *exit* options are only used when LAMMPS is acting as an MDI driver. As explained below, these options are normally not needed, except for a specific kind of use case.

The *mdi engine* command is used to make LAMMPS operate as an MDI engine. It is typically used in an input script after LAMMPS has setup the system it is going to model consistent with what the driver code expects. Depending on when the driver code tells the LAMMPS engine to exit, other commands can be executed after this command, but typically it is used at the end of a LAMMPS input script.

To act as an MDI engine operating as an MD code (or surrogate QM code), this is the list of standard MDI commands issued by a driver code which LAMMPS currently recognizes. Using standard commands defined by the MDI library means that a driver code can work interchangeably with LAMMPS or other MD codes or with QM codes which support the MDI standard. See more details about these commands in the MDI library documentation

These commands are valid at the @DEFAULT node defined by MDI. Commands that start with ">" mean the driver is sending information to LAMMPS. Commands that start with "<" are requests by the driver for LAMMPS to send it information. Commands that start with an alphabetic letter perform actions. Commands that start with "@" are MDI "node" commands, which are described further below.

Command name	Action
>CELL or <CELL	Send/request 3 simulation box edge vectors (9 values)
>CELL_DISPL or <CELL_DISPL	Send/request displacement of the simulation box from the origin (3 values)
>CHARGES or <CHARGES	Send/request charge on each atom (N values)
>COORDS or <COORDS	Send/request coordinates of each atom (3N values)
>ELEMENTS	Send elements (atomic numbers) for each atom (N values)
<ENERGY	Request total energy (potential + kinetic) of the system (1 value)
>FORCES or <FORCES	Send/request forces on each atom (3N values)
>+FORCES	Send forces to add to each atom (3N values)
<LABELS	Request string label of each atom (N values)
<MASSES	Request mass of each atom (N values)
MD	Perform an MD simulation for N timesteps (most recent >NSTEPS value)
OPTG	Perform an energy minimization to convergence (most recent >TOLERANCE values)
>NATOMS or <NATOMS	Sends/request number of atoms in the system (1 value)
>NSTEPS	Send number of timesteps for next MD dynamics run via MD command
<PE	Request potential energy of the system (1 value)
<STRESS	Request symmetric stress tensor (virial) of the system (9 values)
>TOLERANCE	Send 4 tolerance parameters for next MD minimization via OPTG command
>TYPES or <TYPES	Send/request the LAMMPS atom type for each atom (N values)
>VELOCITIES or <VELOCITIES	Send/request the velocity of each atom (3N values)
@INIT_MD or @INIT_OPTG	Driver tells LAMMPS to start single-step dynamics or minimization (see below)
EXIT	Driver tells LAMMPS to exit engine mode

Note

The <ENERGY, <FORCES, <PE, and <STRESS commands trigger LAMMPS to compute atomic interactions for the current configuration of atoms and size/shape of the simulation box. I.e. LAMMPS invokes its pair, bond, angle, ..., kspace styles. If the driver is updating the atom coordinates and/or box incrementally (as in an MD simulation which the driver is managing), then the LAMMPS engine will do the same, and only occasionally trigger neighbor list builds. If the change in atom positions is large (since the previous >COORDS command), then LAMMPS will do a more expensive operation to migrate atoms to new processors as needed and re-neighbor. If the >NATOMS or >TYPES or >ELEMENTS commands have been sent (since the previous >COORDS command), then LAMMPS assumes the system is new and re-initializes an entirely new simulation.

Note

The >TYPES or >ELEMENTS commands are how the MDI driver tells the LAMMPS engine which LAMMPS atom type to assign to each atom. If both the MDI driver and the LAMMPS engine are initialized so that atom type values are consistent in both codes, then the >TYPES command can be used. If not, the optional *elements* keyword can be used to specify what element each LAMMPS atom type corresponds to. This is specified by the chemical symbol of the element, e.g. C or Al or Si. A symbol must be specified for each of the ntypes LAMMPS atom types. Each LAMMPS type must map to a unique element; two or more types cannot map to the same element. Ntypes is typically specified via the *create_box* command or in the data file read by the *read_data* command. Once this has been done, the MDI driver can send an >ELEMENTS command to the LAMMPS driver with the atomic number of each atom and the LAMMPS engine will be able to map it to a LAMMPS atom type.

The MD and OPTG commands perform an entire MD simulation or energy minimization (to convergence) with no

communication from the driver until the simulation is complete. By contrast, the @INIT_MD and @INIT_OPTG commands allow the driver to communicate with the engine at each timestep of a dynamics run or iteration of a minimization; see more info below.

The MD command performs a simulation using the most recent >NSTEPS value. The OPTG command performs a minimization using the 4 convergence parameters from the most recent >TOLERANCE command. The 4 parameters sent are those used by the *minimize* command in LAMMPS: etol, ftol, maxiter, and maxeval.

The mdi engine command also implements the following custom MDI commands which are LAMMPS-specific. These commands are also valid at the @DEFAULT node defined by MDI:

- – Command name
  - – Action
- – >NBYTES
  - – Send # of datums in a subsequent command (1 value)
- – >COMMAND
  - – Send a LAMMPS input script command as a string (Nbytes in length)
- – >COMMANDS
  - – Send multiple LAMMPS input script commands as a newline-separated string (Nbytes in length)
- – >INFILE
  - – Send filename of an input script to execute (filename Nbytes in length)
- – <KE
  - – Request kinetic energy of the system (1 value)

Note that other custom commands can easily be added if these are not sufficient to support what a user-written driver code needs. Code to support new commands can be added to the MDI package within LAMMPS, specifically to the src/MDI/mdi_engine.cpp file.

MDI also defines a standard mechanism for the driver to request that an MD engine (LAMMPS) perform a dynamics simulation one step at a time or an energy minimization one iteration at a time. This is so that the driver can (optionally) communicate with LAMMPS at intermediate points of the timestep or iteration by issuing MDI node commands which start with "@".

To tell LAMMPS to run dynamics in single-step mode, the driver sends as @INIT_MD command followed by the these commands. The driver can interact with LAMMPS at 3 node locations within each timestep: @COORDS, @FORCES, @ENDSTEP:

- – Command name
  - – Action
- – @COORDS
  - – Proceed to next @COORDS node = post-integrate location in LAMMPS timestep
- – @FORCES
  - – Proceed to next @FORCES node = post-force location in LAMMPS timestep
- – @ENDSTEP
  - – Proceed to next @ENDSTEP node = end-of-step location in LAMMPS timestep
- – @DEFAULT
  - – Exit MD simulation, return to @DEFAULT node

- – EXIT
  - – Driver tells LAMMPS to exit the MD simulation and engine mode

To tell LAMMPS to run an energy minimization in single-iteration mode. The driver can interact with LAMMPS at 2 node locations within each iteration of the minimizer: @COORDS, @FORCES:

- – Command name
  - – Action
- – @COORDS
  - – Proceed to next @COORDS node = min-pre-force location in LAMMPS min iteration
- – @FORCES
  - – Proceed to next @FORCES node = min-post-force location in LAMMPS min iteration
- – @DEFAULT
  - – Exit minimization, return to @DEFAULT node
- – EXIT
  - – Driver tells LAMMPS to exit the minimization and engine mode

While LAMMPS is at its @COORDS node, the following standard MDI commands are supported, as documented above: >COORDS or <COORDS, @COORDS, @FORCES, @ENDSTEP, @DEFAULT, EXIT.

While LAMMPS is at its @FORCES node, the following standard MDI commands are supported, as documented above: <COORDS, <ENERGY, >FORCES or >+FORCES or <FORCES, <KE, <PE, <STRESS, @COORDS, @FORCES, @ENDSTEP, @DEFAULT, EXIT.

While LAMMPS is at its @ENDSTEP node, the following standard MDI commands are supported, as documented above: <ENERGY, <FORCES, <KE, <PE, <STRESS, @COORDS, @FORCES, @ENDSTEP, @DEFAULT, EXIT.

The *mdi plugin* command is used to make LAMMPS operate as an MDI driver which loads an MDI engine as a plugin library. It is typically used in an input script after LAMMPS has setup the system it is going to model consistent with the engine code.

The *name* argument specifies which plugin library to load. A name like "lammps" is converted to a filename liblammps.so. The path for where this file is located is specified by the -plugin_path switch within the -mdi command-line switch, which is specified when LAMMPS is launched. See the examples/mdi/README files for examples of how this is done.

The *mdi* keyword is required and is used as the -mdi argument passed to the library when it is launched. The -role and -method settings are required. The -name setting can be anything you choose. MDI drivers and engines can query their names to verify they are values they expect.

The *infile* keyword is optional. It sets the name of an input script which the engine will open and process. MDI will pass it as a command-line argument to the library when it is launched. The file typically contains settings that an MD or QM code will use for its calculations.

The *extra* keyword is optional. It contains additional command-line arguments which MDI will pass to the library when it is launched.

The *command* keyword is required. It specifies a LAMMPS input script command (as a single argument in quotes if it is multiple words). Once the plugin library is launched, LAMMPS will execute this command. Other previously-defined commands in the input script, such as the *fix mdi/qm* command, should perform MDI communication with the engine, while the specified *command* executes. Note that if *command* is an *include* command, then it could specify a filename with multiple LAMMPS commands.

Note

When the *command* is complete, LAMMPS will send an MDI EXIT command to the plugin engine and the plugin will be removed. The "mdi plugin" command will then exit and the next command (if any) in the LAMMPS input script will be processed. A subsequent "mdi plugin" command could then load the same or a different MDI plugin if desired.

The *mdi connect* and *mdi exit* commands are only used when LAMMPS is operating as an MDI driver. And when other LAMMPS command(s) which send MDI commands and associated data to/from the MDI engine are not able to initiate and terminate the connection to the engine code.

The only current MDI driver command in LAMMPS is the *fix mdi/qm* command. If it is only used once in an input script then it can initiate and terminate the connection, but if it is being issued multiple times (e.g., in a loop that issues a *clear* command), then it cannot initiate or terminate the connection multiple times. Instead, the *mdi connect* and *mdi exit* commands should be used outside the loop to initiate or terminate the connection.

See the examples/mdi/in.series.driver script for an example of how this is done. The LOOP in that script is reading a series of data file configurations and passing them to an MDI engine (e.g., quantum code) for energy and force evaluation. A *clear* command inside the loop wipes out the current system so a new one can be defined. This operation also destroys all fixes. So the *fix mdi/qm* command is issued once per loop iteration. Note that it includes a "connect no" option which disables the initiate/terminate logic within that fix.

1.53.4 Restrictions

This command is part of the MDI package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

To use LAMMPS in conjunction with other MDI-enabled atomistic codes, the *units* command should be used to specify *real* or *metal* units. This will ensure the correct unit conversions between LAMMPS and MDI units, which the other codes will also perform in their preferred units.

LAMMPS can also be used as an MDI engine in other unit choices it supports (e.g., *lj*), but then no unit conversion is performed.

1.54.1 Syntax

```
min_modify keyword values ...
```

- one or more keyword/value pairs may be listed

```
keyword = dmax or line or norm or alpha_damp or discrete_factor or integrator or␣
→abcfire or tmax
  dmax value = max
    max = maximum distance for line search to move (distance units)
```

```
line value = backtrack or quadratic or forcezero or spin_cubic or spin_none
  backtrack,quadratic,forcezero,spin_cubic,spin_none = style of linesearch to use
norm value = two or inf or max
  two = Euclidean two-norm (length of 3N vector)
  inf = max force component across all 3-vectors
  max = max force norm across all 3-vectors
alpha_damp value = damping
  damping = fictitious magnetic damping for spin minimization (adim)
discrete_factor value = factor
  factor = discretization factor for adaptive spin timestep (adim)
integrator value = eulerimplicit or verlet or leapfrog or eulerexplicit
  time integration scheme for fire minimization
abcfire value = yes or no (default no)
  yes = use ABC-FIRE variant of fire minimization style
  no  = use default FIRE variant of fire minimization style
tmax value = factor
  factor = maximum adaptive timestep for fire minimization (adim)
```

1.54.2 Examples

```
min_modify dmax 0.2
min_modify integrator verlet tmax 4
```

1.54.3 Description

This command sets parameters that affect the energy minimization algorithms selected by the *min_style* command. The various settings may affect the convergence rate and overall number of force evaluations required by a minimization, so users can experiment with these parameters to tune their minimizations.

The *cg* and *sd* minimization styles have an outer iteration and an inner iteration which is steps along a one-dimensional line search in a particular search direction. The *dmax* parameter is how far any atom can move in a single line search in any dimension (x, y, or z). For the *quickmin* and *fire* minimization styles, the *dmax* setting is how far any atom can move in a single iteration (timestep). Thus a value of 0.1 in real *units* means no atom will move further than 0.1 Angstroms in a single outer iteration. This prevents highly overlapped atoms from being moved long distances (e.g. through another atom) due to large forces.

The choice of line search algorithm for the *cg* and *sd* minimization styles can be selected via the *line* keyword. The default *quadratic* line search algorithm starts out using the robust backtracking method described below. However, once the system gets close to a local minimum and the linesearch steps get small, so that the energy is approximately quadratic in the step length, it uses the estimated location of zero gradient as the linesearch step, provided the energy change is downhill. This becomes more efficient than backtracking for highly-converged relaxations. The *forcezero* line search algorithm is similar to *quadratic*. It may be more efficient than *quadratic* on some systems.

The backtracking search is robust and should always find a local energy minimum. However, it will "converge" when it can no longer reduce the energy of the system. Individual atom forces may still be larger than desired at this point, because the energy change is measured as the difference of two large values (energy before and energy after) and that difference may be smaller than machine epsilon even if atoms could move in the gradient direction to reduce forces further.

The choice of a norm can be modified for the min styles *cg*, *sd*, *quickmin*, *fire*, *spin*, *spin/cg*, and *spin/lbfgs* using the *norm* keyword. The default *two* norm computes the 2-norm (Euclidean length) of the global force vector:

$$||\vec{F}||_2 = \sqrt{\vec{F}_1^2 + \cdots + \vec{F}_N^2}$$

The *max* norm computes the length of the 3-vector force for each atom (2-norm), and takes the maximum value of

those across all atoms

$$||\vec{F}||_{max} = \max\left(||\vec{F}_1||, \cdots, ||\vec{F}_N||\right)$$

The *inf* norm takes the maximum component across the forces of all atoms in the system:

$$||\vec{F}||_{inf} = \max\left(|F_1^1|, |F_1^2|, |F_1^3| \cdots, |F_N^1|, |F_N^2|, |F_N^3|\right)$$

For the min styles *spin*, *spin/cg* and *spin/lbfgs*, the force norm is replaced by the spin-torque norm.

Keywords *alpha_damp* and *discrete_factor* only make sense when a *min_spin* command is declared. Keyword *alpha_damp* defines an analog of a magnetic damping. It defines a relaxation rate toward an equilibrium for a given magnetic system. Keyword *discrete_factor* defines a discretization factor for the adaptive timestep used in the *spin* minimization. See *min_spin* for more information about those quantities.

The choice of a line search algorithm for the *spin/cg* and *spin/lbfgs* styles can be specified via the *line* keyword. The *spin_cubic* and *spin_none* keywords only make sense when one of those two minimization styles is declared. The *spin_cubic* performs the line search based on a cubic interpolation of the energy along the search direction. The *spin_none* keyword deactivates the line search procedure. The *spin_none* is a default value for *line* keyword for both *spin/lbfgs* and *spin/cg*. Convergence of *spin/lbfgs* can be more robust if *spin_cubic* line search is used.

The Newton *integrator* used for *fire* minimization can be selected to be either the symplectic Euler (*eulerimplicit*), velocity Verlet (*verlet*), Leapfrog (*leapfrog*) or non-symplectic forward Euler (*eulerexplicit*). The keyword *tmax* defines the maximum value for the adaptive timestep during a *fire* minimization. It is a multiplication factor applied to the current *timestep* (not in time unit). For example, *tmax* = 4.0 with a *timestep* of 2fs, means that the maximum value the timestep can reach during a *fire* minimization is 4fs. Note that parameter defaults has been chosen to be reliable in most cases, but one should consider adjusting *timestep* and *tmax* to optimize the minimization for large or complex systems. Other parameters of the *fire* minimization can be tuned (*tmin*, *delaystep*, *dtgrow*, *dtshrink*, *alpha0*, and *alphashrink*). Please refer to the references describing the *min_style fire*. An additional stopping criteria *vdfmax* is used by *fire* in order to avoid unnecessary looping when it is reasonable to think the system will not be relaxed further. Note that in this case the system will NOT have reached your minimization criteria. This could happen when the system comes to be stuck in a local basin of the phase space. *vdfmax* is the maximum number of consecutive iterations with P(t) < 0.

Added in version 8Feb2023.

The *abcfire* keyword allows to activate the ABC-FIRE variant of the *fire* minimization algorithm. ABC-FIRE introduces an additional factor that modifies the bias and scaling of the velocities of the atoms during the mixing step *(Echeverri Restrepo)*. This can lead to faster convergence of the minimizer.

The *min_style fire* is an optimized implementation. It can behave similarly to the previous version by using the following set of parameters:

```
min_modify integrator eulerexplicit tmax 10.0 tmin 0.0 delaystep 5 &
           dtgrow 1.1 dtshrink 0.5 alpha0 0.1 alphashrink 0.99 &
           vdfmax 100000 halfstepback no initialdelay no
```

1.54.4 Restrictions

For magnetic GNEB calculations, only *spin_none* value for *line* keyword can be used when minimization styles *spin/cg* and *spin/lbfgs* are employed. See *neb/spin* for more explanation.

1.54.5 Related commands

min_style, *minimize*

1.54.6 Default

The option defaults are dmax = 0.1, line = quadratic and norm = two.

For the *spin*, *spin/cg* and *spin/lbfgs* styles, the option defaults are alpha_damp = 1.0, discrete_factor = 10.0, line = spin_none, and norm = euclidean.

For the *fire* style, the option defaults are integrator = eulerimplicit, tmax = 10.0, tmin = 0.02, delaystep = 20, dtgrow = 1.1, dtshrink = 0.5, alpha0 = 0.25, alphashrink = 0.99, vdfmax = 2000, halfstepback = yes and initialdelay = yes.

1.56 min_style spin/cg command

1.57 min_style spin/lbfgs command

1.57.1 Syntax

```
min_style spin
min_style spin/cg
min_style spin/lbfgs
```

1.57.2 Examples

```
min_style  spin/lbfgs
min_modify line spin_cubic discrete_factor 10.0
```

1.57.3 Description

Apply a minimization algorithm to use when a *minimize* command is performed.

Style *spin* defines a damped spin dynamics with an adaptive timestep, according to:

$$\frac{d\vec{s}_i}{dt} = \lambda\, \vec{s}_i \times \left(\vec{\omega}_i \times \vec{s}_i\right)$$

with λ a damping coefficient (similar to a magnetic damping). λ can be defined by setting the *alpha_damp* keyword with the *min_modify* command.

The minimization procedure solves this equation using an adaptive timestep. The value of this timestep is defined by the largest precession frequency that has to be solved in the system:

$$\Delta t_{\max} = \frac{2\pi}{\kappa\, |\vec{\omega}_{\max}|}$$

with $|\vec{\omega}_{\max}|$ the norm of the largest precession frequency in the system (across all processes, and across all replicas if a spin/neb calculation is performed).

κ defines a discretization factor *discrete_factor* for the definition of this timestep. *discrete_factor* can be defined with the *min_modify* command.

Style *spin/cg* defines an orthogonal spin optimization (OSO) combined to a conjugate gradient (CG) algorithm. The *min_modify* command can be used to couple the *spin/cg* to a line search procedure, and to modify the discretization factor *discrete_factor*. By default, style *spin/cg* does not employ the line search procedure and uses the adaptive timestep technique in the same way as style *spin*.

Style *spin/lbfgs* defines an orthogonal spin optimization (OSO) combined to a limited-memory Broyden-Fletcher-Goldfarb-Shanno (L-BFGS) algorithm. By default, style *spin/lbfgs* does not employ line search procedure. If the line search procedure is not used then the discrete factor defines the maximum root mean squared rotation angle of spins by equation *pi/(5*Kappa)*. The default value for Kappa is 10. The *spin_cubic* line search option can improve the convergence of the *spin/lbfgs* algorithm.

The *min_modify* command can be used to activate the line search procedure, and to modify the discretization factor *discrete_factor*.

For more information about styles *spin/cg* and *spin/lbfgs*, see their implementation reported in *(Ivanov)*.

Note

All the *spin* styles replace the force tolerance by a torque tolerance. See *minimize* for more explanation.

Note

The *spin/cg* and *spin/lbfgs* styles can be used for magnetic NEB calculations only if the line search procedure is deactivated. See *neb/spin* for more explanation.

1.57.4 Restrictions

The *spin*, *spin/cg*, and *spin/lbfgps* styles are part of the SPIN package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This minimization procedure is only applied to spin degrees of freedom for a frozen lattice configuration.

```

1.65.3 Description

Choose a minimization algorithm to use when a *minimize* command is performed.

Style *cg* is the Polak-Ribiere version of the conjugate gradient (CG) algorithm. At each iteration the force gradient is combined with the previous iteration information to compute a new search direction perpendicular (conjugate) to the previous search direction. The PR variant affects how the direction is chosen and how the CG method is restarted when it ceases to make progress. The PR variant is thought to be the most effective CG choice for most problems.

Style *hftn* is a Hessian-free truncated Newton algorithm. At each iteration a quadratic model of the energy potential is solved by a conjugate gradient inner iteration. The Hessian (second derivatives) of the energy is not formed directly, but approximated in each conjugate search direction by a finite difference directional derivative. When close to an energy minimum, the algorithm behaves like a Newton method and exhibits a quadratic convergence rate to high accuracy. In most cases the behavior of *hftn* is similar to *cg*, but it offers an alternative if *cg* seems to perform poorly. This style is not affected by the *min_modify* command.

Style *sd* is a steepest descent algorithm. At each iteration, the search direction is set to the downhill direction corresponding to the force vector (negative gradient of energy). Typically, steepest descent will not converge as quickly as CG, but may be more robust in some situations.

Style *quickmin* is a damped dynamics method described in *(Sheppard)*, where the damping parameter is related to the projection of the velocity vector along the current force vector for each atom. The velocity of each atom is initialized to 0.0 by this style, at the beginning of a minimization.

Style *fire* is a damped dynamics method described in *(Bitzek)*, which is similar to *quickmin* but adds a variable timestep and alters the projection operation to maintain components of the velocity non-parallel to the current force vector. The velocity of each atom is initialized to 0.0 by this style, at the beginning of a minimization. This style correspond to an optimized version described in *(Guenole)* that include different time integration schemes and default parameters. The default parameters can be modified with the command *min_modify*.

Style *spin* is a damped spin dynamics with an adaptive timestep.

Style *spin/cg* uses an orthogonal spin optimization (OSO) combined to a conjugate gradient (CG) approach to minimize spin configurations.

Style *spin/lbfgs* uses an orthogonal spin optimization (OSO) combined to a limited-memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) approach to minimize spin configurations.

See the *min/spin* page for more information about the *spin*, *spin/cg* and *spin/lbfgs* styles.

Either the *quickmin* or the *fire* styles are useful in the context of nudged elastic band (NEB) calculations via the *neb* command.

Either the *spin*, *spin/cg*, or *spin/lbfgs* styles are useful in the context of magnetic geodesic nudged elastic band (GNEB) calculations via the *neb/spin* command.

Note

The damped dynamic minimizers use whatever timestep you have defined via the *timestep* command. Often they will converge more quickly if you use a timestep about 10x larger than you would normally use for dynamics simulations. For *fire*, the default timestep is recommended to be equal to the one you would normally use for dynamics simulations.

Note

The *quickmin*, *fire*, *hftn*, *cg/kk*, *quickmin/kk*, and *sd/kk* styles do not yet support the use of the *fix box/relax* command or minimizations involving the electron radius in *eFF* models.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

1.65.4 Restrictions

The *spin*, *spin/cg*, and *spin/lbfgps* styles are part of the SPIN package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

1.66 minimize command

Accelerator Variant: minimize/kk

1.66.1 Syntax

```
minimize etol ftol maxiter maxeval
```

- etol = stopping tolerance for energy (unitless)
- ftol = stopping tolerance for force (force units)
- maxiter = max iterations of minimizer
- maxeval = max number of force/energy evaluations

1.66.2 Examples

```
minimize 1.0e-4 1.0e-6 100 1000
minimize 0.0 1.0e-8 1000 100000
```

1.66.3 Description

Perform an energy minimization of the system, by iteratively adjusting atom coordinates. Iterations are terminated when one of the stopping criteria is satisfied. At that point the configuration will hopefully be in a local potential energy minimum. More precisely, the configuration should approximate a critical point for the objective function (see below), which may or may not be a local minimum.

The minimization algorithm used is set by the *min_style* command. Other options are set by the *min_modify* command. Minimize commands can be interspersed with *run* commands to alternate between relaxation and dynamics. The minimizers bound the distance atoms may move in one iteration, so that you can relax systems with highly overlapped atoms (large energies and forces) by pushing the atoms off of each other.

Neighbor list update settings

The distance that atoms can move during individual minimization steps can be quite large, especially at the beginning of a minimization. Thus *neighbor list settings* of *every* = *1* and *delay* = *0* are **required**. This may be combined with either *check* = *no* (always update the neighbor list) or *check* = *yes* (only update the neighbor list if at least one atom has moved more than half the *neighbor list skin* distance since the last reneighboring). Using *check* = *yes*

is recommended since it avoids unneeded reneighboring steps when the system is closer to the minimum and thus atoms move only small distances. Using *check* = *no* may be required for debugging or when coupling LAMMPS with external codes that require a predictable sequence of neighbor list updates.

If the settings are **not** *every* = *1* and *delay* = *0*, LAMMPS will temporarily apply a *neigh_modify every 1 delay 0 check yes* setting during the minimization and restore the original setting at the end of the minimization. A corresponding message will be printed to the screen and log file, if this happens.

Alternate means of relaxing a system are to run dynamics with a small or *limited timestep*. Or dynamics can be run using *fix viscous* to impose a damping force that slowly drains all kinetic energy from the system. The *pair_style soft* potential can be used to un-overlap atoms while running dynamics.

Note that you can minimize some atoms in the system while holding the coordinates of other atoms fixed by applying *fix setforce 0.0 0.0 0.0* to the other atoms. See a more detailed discussion of *using fixes while minimizing below*.

The *minimization styles* *cg*, *sd*, and *hftn* involves an outer iteration loop which sets the search direction along which atom coordinates are changed. An inner iteration is then performed using a line search algorithm. The line search typically evaluates forces and energies several times to set new coordinates. Currently, a backtracking algorithm is used which may not be optimal in terms of the number of force evaluations performed, but appears to be more robust than previous line searches we have tried. The backtracking method is described in Nocedal and Wright's Numerical Optimization (Procedure 3.1 on p 41).

The *minimization styles* *quickmin* and *fire* perform damped dynamics using an Euler integration step. Thus they require a *timestep* be defined.

Note

The damped dynamic minimizer algorithms will use the timestep you have defined via the *timestep* command or its default value. Often they will converge more quickly if you use a timestep about 10x larger than you would normally use for regular molecular dynamics simulations.

In all cases, the objective function being minimized is the total potential energy of the system as a function of the N atom coordinates:

$$E(r_1, r_2, \ldots, r_N) = \sum_{i,j} E_{pair}(r_i, r_j) + \sum_{ij} E_{bond}(r_i, r_j) + \sum_{ijk} E_{angle}(r_i, r_j, r_k) + \sum_{ijkl} E_{dihedral}(r_i, r_j, r_k, r_l) + \sum_{ijkl} E_{improper}(r_i, r_j, r_k, r_l) + \sum_{i} E_{fix}(r_i)$$

where the first term is the sum of all non-bonded *pairwise interactions* including *long-range Coulombic interactions*, the second through fifth terms are *bond*, *angle*, *dihedral*, and *improper* interactions respectively, and the last term is energy due to *fixes* which can act as constraints or apply force to atoms, such as through interaction with a wall. See the discussion below about how fix commands affect minimization.

The starting point for the minimization is the current configuration of the atoms.

The minimization procedure stops if any of several criteria are met:

- the change in energy between outer iterations is less than *etol*
- the 2-norm (length) of the global force vector is less than the *ftol*
- the line search fails because the step distance backtracks to 0.0
- the number of outer iterations or timesteps exceeds *maxiter*

- the number of total force evaluations exceeds *maxeval*

Note

the *minimization style* *spin*, *spin/cg*, and *spin/lbfgs* replace the force tolerance *ftol* by a torque tolerance. The minimization procedure stops if the 2-norm (length) of the torque vector on atom (defined as the cross product between the atomic spin and its precession vectors omega) is less than *ftol*, or if any of the other criteria are met. Torque have the same units as the energy.

Note

You can also use the *fix halt* command to specify a general criterion for exiting a minimization, that is a calculation performed on the state of the current system, as defined by an *equal-style variable*.

For the first criterion, the specified energy tolerance *etol* is unitless; it is met when the energy change between successive iterations divided by the energy magnitude is less than or equal to the tolerance. For example, a setting of 1.0e-4 for *etol* means an energy tolerance of one part in 10^4. For the damped dynamics minimizers this check is not performed for a few steps after velocities are reset to 0, otherwise the minimizer would prematurely converge.

For the second criterion, the specified force tolerance *ftol* is in force units, since it is the length of the global force vector for all atoms, e.g. a vector of size 3N for N atoms. Since many of the components will be near zero after minimization, you can think of *ftol* as an upper bound on the final force on any component of any atom. For example, a setting of 1.0e-4 for *ftol* means no x, y, or z component of force on any atom will be larger than 1.0e-4 (in force units) after minimization.

Either or both of the *etol* and *ftol* values can be set to 0.0, in which case some other criterion will terminate the minimization.

During a minimization, the outer iteration count is treated as a timestep. Output is triggered by this timestep, e.g. thermodynamic output or dump and restart files.

Using the *thermo_style custom* command with the *fmax* or *fnorm* keywords can be useful for monitoring the progress of the minimization. Note that these outputs will be calculated only from forces on the atoms, and will not include any extra degrees of freedom, such as from the *fix box/relax* command.

Following minimization, a statistical summary is printed that lists which convergence criterion caused the minimizer to stop, as well as information about the energy, force, final line search, and iteration counts. An example is as follows:

```
Minimization stats:
  Stopping criterion = max iterations
  Energy initial, next-to-last, final =
       -0.626828169302     -2.82642039062     -2.82643549739
  Force two-norm initial, final = 2052.1 91.9642
  Force max component initial, final = 346.048 9.78056
  Final line search alpha, max atom move = 2.23899e-06 2.18986e-05
  Iterations, force evaluations = 2000 12724
```

The 3 energy values are for before and after the minimization and on the next-to-last iteration. This is what the *etol* parameter checks.

The two-norm force values are the length of the global force vector before and after minimization. This is what the *ftol* parameter checks.

The max-component force values are the absolute value of the largest component (x,y,z) in the global force vector, i.e. the infinity-norm of the force vector.

The alpha parameter for the line-search, when multiplied by the max force component (on the last iteration), gives the max distance any atom moved during the last iteration. Alpha will be 0.0 if the line search could not reduce the energy. Even if alpha is non-zero, if the "max atom move" distance is tiny compared to typical atom coordinates, then it is possible the last iteration effectively caused no atom movement and thus the evaluated energy did not change and the minimizer terminated. Said another way, even with non-zero forces, it is possibly the effect of those forces to move atoms a distance less than machine precision, so that the energy cannot be further reduced.

The iterations and force evaluation values are what is checked by the *maxiter* and *maxeval* parameters.

Note

There are several force fields in LAMMPS which have discontinuities or other approximations which may prevent you from performing an energy minimization to tight tolerances. For example, you should use a *pair style* that goes to 0.0 at the cutoff distance when performing minimization (even if you later change it when running dynamics). If you do not do this, the total energy of the system will have discontinuities when the relative distance between any pair of atoms changes from cutoff *plus* epsilon to cutoff *minus* epsilon and the minimizer may thus behave poorly. Some of the many-body potentials use splines and other internal cutoffs that inherently have this problem. The *long-range Coulombic styles* (PPPM, Ewald) are approximate to within the user-specified tolerance, which means their energy and forces may not agree to a higher precision than the Kspace-specified tolerance. This agreement is further reduced when using tabulation to speed up the computation of the real-space part of the Coulomb interactions, which is enabled by default. In all these cases, the minimizer may give up and stop before finding a minimum to the specified energy or force tolerance.

Note that a cutoff Lennard-Jones potential (and others) can be shifted so that its energy is 0.0 at the cutoff via the *pair_modify* command. See the doc pages for individual *pair styles* for details. Note that most Coulombic potentials have a cutoff, unless versions with a long-range component are used (e.g. *pair_style lj/cut/coul/long*) or some other damping/smoothing schemes are used. The CHARMM potentials go to 0.0 at the cutoff (e.g. *pair_style lj/charmm/coul/charmm*), as do the GROMACS potentials (e.g. *pair_style lj/gromacs*).

If a soft potential (*pair_style soft*) is used the Astop value is used for the prefactor (no time dependence).

The *fix box/relax* command can be used to apply an external pressure to the simulation box and allow it to shrink/expand during the minimization.

Only a few other fixes (typically those that add forces) are invoked during minimization. See the doc pages for individual *fix* commands to see which ones are relevant. Current examples of fixes that can be used include:

- *fix addforce*
- *fix addtorque/group*
- *fix efield*
- *fix enforce2d*
- *fix indent*
- *fix lineforce*
- *fix planeforce*
- *fix setforce*
- *fix spring*
- *fix spring/self*
- *fix viscous*

- *fix wall*
- *fix wall/region*

Note

Some fixes which are invoked during minimization have an associated potential energy. For that energy to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the *fix_modify energy* option for that fix. The doc pages for individual *fix* commands specify if this should be done.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

1.66.4 Restrictions

Changed in version 15Sep2022.

It used to be an error to use *fix shake* with minimization but this is no longer the case. While the SHAKE constraint equations cannot be applied during minimization, fix shake (and fix rattle) will substitute the constraints with stiff harmonic bonds. This allows some (small) changes in the geometry, but those are usually small enough so that when starting an MD run the constraints can be fulfilled during the first time step. The same effect can be achieved without fix shake by replacing the force constants for the bonds and/or angles that would otherwise be constrained by the SHAKE algorithm.

Fix rigid is not supported during minimization. It does not trigger an error to have it defined, but the energy minimization will not keep the defined body(s) rigid during the minimization. Note that if bonds, angles, etc internal to a rigid body have been turned off (e.g. via *neigh_modify exclude*), they will not contribute to the potential energy which is probably not what is desired. One can approximate a minimization with rigid bodies by performing simulated annealing.

Pair potentials that produce torque on a particle (e.g. *granular potentials* or the *GayBerne potential* for ellipsoidal particles) are not relaxed by a minimization. More specifically, radial relaxations are induced, but no rotations are induced by a minimization, so such a system will not fully relax.

1.66.5 Related commands

min_modify, *min_style*, *run_style*

1.66.6 Default

none

1.67 molecule command

1.67.1 Syntax

```
molecule ID file1 keyword values ... file2 keyword values ... fileN ...
```

- ID = user-assigned name for the molecule template
- file1,file2,... = names of files containing molecule descriptions
- zero or more keyword/value pairs may be appended after each file
- keyword = *offset* or *toff* or *boff* or *aoff* or *doff* or *ioff* or *scale* or *check_labels* or *auto*

```
offset values = Toff Boff Aoff Doff Ioff
  Toff = offset to add to atom types
  Boff = offset to add to bond types
  Aoff = offset to add to angle types
  Doff = offset to add to dihedral types
  Ioff = offset to add to improper types
toff value = Toff
  Toff = offset to add to atom types
boff value = Boff
  Boff = offset to add to bond types
aoff value = Aoff
  Aoff = offset to add to angle types
doff value = Doff
  Doff = offset to add to dihedral types
ioff value = Ioff
  Ioff = offset to add to improper types
scale value = sfactor
  sfactor = scale factor to apply to the size, mass, and dipole of the molecule
check_labels value = string
  string = string containing any of the following characters: 'b', 'a', 'd', or 'i'
auto value = string
  string = string containing any of the following characters:
   'a', 'd', or 'i', which will autogenerate angles, dihedrals, and
   impropers, respectively
```

1.67.2 Examples

```
molecule 1 mymol.txt
molecule water tip3p.json
molecule 1 co2.txt h2o.txt
molecule CO2 co2.txt boff 3 aoff 2
molecule 1 mymol.txt offset 6 9 18 23 14
molecule objects file.1 scale 1.5 file.1 scale 2.0 file.2 scale 1.3
molecule 1 mymol.txt auto ad
```

1.67.3 Description

Define a molecule template that can be used as part of other LAMMPS commands, typically to define a collection of particles as a bonded molecule or a rigid body. Commands that currently use molecule templates include:

- *fix deposit*

- *fix pour*
- *fix rigid/small*
- *fix shake*
- *fix gcmc*
- *fix bond/react*
- *create_atoms*
- *atom_style template*

Changed in version 4Jul2026.

It can also be used to define a collection of line segments (2d) or triangles (3d) which define an object's surface or a boundary condition for granular particles to interact with, via these commands:

- *fix surface/global*
- *fix surface/local*

See the *Howto granular surfaces* doc page for more details on these kinds of models.

The ID of a molecule template can only contain alphanumeric characters and underscores, same as other IDs in LAMMPS.

A single template can contain multiple molecules, listed one per file. Some of the commands listed above currently use only the first molecule in the template, and will issue a warning if the template contains multiple molecules. The *atom_style template* command allows multiple-molecule templates to define a system with more than one templated molecule.

The molecule file can be either in a *native* format or in JSON format. JSON format filenames **must** have the extension ".json". Files with any other name will be assumed to be in the "native" format. The details of the two formats are described below. When referencing multiple molecule files in a single *molecule* command, each of those files may be either format.

Each filename can be followed by optional keywords which are applied only to the molecule in the file as used in this template. This is to make it easy to use the same molecule file in different molecule templates or in different simulations. You can specify the same file multiple times with different optional keywords.

The *offset*, *toff*, *boff*, *aoff*, *doff*, *ioff* keywords add the specified offset values to the atom types, bond types, angle types, dihedral types, and/or improper types as they are read from the molecule file. E.g. if *toff* = 2, and the file uses atom types 1,2,3, then each created molecule will have atom types 3,4,5. For the *offset* keyword, all five offset values must be specified, but individual values will be ignored if the molecule template does not use that attribute (e.g. no bonds).

Note

Offsets are **ignored** on lines using type labels, as the type labels will determine the actual types directly depending on the current *labelmap* settings.

Note

For molecule files defining line segments or triangles, only the *toff* keyword is relevant; the other offset keywords are ignored

The *scale* keyword scales the size of the molecule. This can be useful for modeling polydisperse granular rigid bodies. The scale factor is applied to each of these properties in the molecule file, if they are defined: the individual particle coordinates (Coords or "coords" section), the individual mass of each particle (Masses or "masses" section), the individual diameters of each particle (Diameters or "diameters" section), the per-atom dipoles (Dipoles or "dipoles" section) the total mass of the molecule (header keyword = mass), the center-of-mass of the molecule (header keyword = com), and the moments of inertia of the molecule (header keyword = inertia). For line or tri molecules, the scale factor multiplies the line endpoints or triangle vertices.

Added in version 11Feb2026.

The *check_labels* keyword causes the molecule command to issue a warning if the type label of a bond, angle, dihedral, or improper defined in the molecule template is not consistent with the atom types of its constituent atoms. The *check_labels* value is a single string that should contain one or more of the characters 'b', 'a', 'd', and 'i', which correspond to bonds, angles, dihedrals, and impropers, respectively. For example, the keyword/value pair *check_labels badi* will check all the type labels of all bonded interactions, while *check_labels adi* will only check type labels for angles, dihedrals, and impropers but not for bonds. The *check_labels* keyword requires using a specific convention for *type label* for enabling commands in LAMMPS (like *fix bond/react*) to infer the types of bonded interactions. Bond, angle, dihedral, and improper type labels must contain their constituent atom types delimited by hyphens. That is, for a dihedral that formed by three atoms of type 'c2' and one atom of 'n', the dihedral type label must be 'c2-c2-c2-n' . If the constituent atoms do not have these atom types in the proper order, a warning will be generated when using the *check_labels* keyword. Certain symmetries are considered to account for equivalent ways of writing bonded interactions. Type labels for bonds, angles, and dihedrals are assumed to be equivalent to those written in reverse order. For example, an angle with type label 'c1-c2-n' is equivalent to 'n-c2-c1'. Symmetries for impropers are more complex and are described on the doc page for each improper style in the 'Symmetry convention' section.

Note

The molecule command can be used to define molecules with bonds, angles, dihedrals, impropers, and special bond lists of neighbors within a molecular topology, so that you can later add the molecules to your simulation, via one or more of the commands listed above. Since this topology-related information requires that suitable storage is reserved when LAMMPS creates the simulation box (e.g. when using the *create_box* command or the *read_data* command) suitable space has to be reserved at that step so you do not overflow those pre-allocated data structures when adding molecules later. Both the *create_box* command and the *read_data* command have "extra" options which ensure extra space is allocated for storing topology info for molecules that are added later. This feature is *not* available for the *read_restart command*, thus binary restart files need to be converted to data files first.

Added in version 30Mar2026.

The *auto* keyword allows the molecule command to generate new angles, dihedrals, and/or impropers, and assign their angle types, dihedral types, and/or improper types. New interactions are discovered by traversing the bond graph defined in the *Bonds* section, and new types are inferred using *type label*. Type labels for angle, dihedral, and improper types must already be defined (e.g., by the read_data command), to use the *auto* keyword, and each of the labels must be defined as a list with its constituent atom type labels separated by hyphens, as described for the *check_labels* keyword. The *auto* value is a single string that should contain one or more of the characters 'a', 'd', and 'i', which correspond to angles, dihedrals, and impropers, respectively. For example, the keyword/value pair *auto adi* will generate angle, dihedral, and improper information, while *auto di* will only generate information for dihedrals and impropers but not for angles. Angles are generated from all unique 1-2-3 paths through the bond graph. Dihedrals are generated from all unique 1-2-3-4 paths through the bond graph, as long as there are no duplicate atoms in the dihedral. Impropers are

generated from all atoms bonded to exactly three neighbors. The type assigned to each generated 2-, 3- and 4-body interaction is found by searching the list of type labels for a match, e.g., 'c1-c2-c3' or 'c3-c2-c1' in the case of a 3-atom angle. If a matching type cannot be found, LAMMPS will generate an error.

Note

This command requires *Special Bonds* data to exist, which are generated automatically by default.

1.67.4 Format of a native molecule file

The format of an "native" individual molecule file looks similar but is *different* from that of a data file read by the *read_data* commands. Here is a simple example for a TIP3P water molecule:

```
# Water molecule. TIP3P geometry
# header section:
3 atoms
2 bonds
1 angles

# body section:
Coords

1    0.00000  -0.06556   0.00000
2    0.75695   0.52032   0.00000
3   -0.75695   0.52032   0.00000

Types

1        1   # O
2        2   # H
3        2   # H

Charges

1       -0.834
2        0.417
3        0.417

Bonds

1   1      1      2
2   1      1      3

Angles

1   1      2      1      3
```

A molecule file has a header and a body. The header appears first. The first line of the header and thus of the molecule file is *always* skipped; it typically contains a description of the file or a comment from the software that created the file.

Then lines are read one line at a time. Lines can have a trailing comment starting with '#' that is ignored. There *must* be at least one blank between any valid content and the comment. If the line is blank (i.e. contains only white-space

after comments are deleted), it is skipped. If the line contains a header keyword, the corresponding value(s) is/are read from the line. A line that is *not* blank and does *not* contains a header keyword begins the body of the file.

The body of the file contains zero or more sections. The first line of a section has only a keyword. The next line is skipped. The remaining lines of the section contain values. The number of lines depends on the section keyword as described below. Zero or more blank lines can be used between sections. Sections can appear in any order, with a few exceptions as noted below.

Added in version 4Jul2026: New header keywords *lines* and *tris*

These are the recognized header keywords. Header lines can come in any order. The numeric value(s) are read from the beginning of the line. The keyword should appear at the end of the line. All these settings have default values, as explained below. A line need only appear if the value(s) are different than the default, except when defining a *body* particle, which requires setting the number of *atoms* to 1, and setting the *inertia* in a specific section (see below).

Number(s)	Keyword	Meaning	Default Value
N	atoms	# of atoms N in molecule	keyword is *required*
Nb	bonds	# of bonds Nb in molecule	0
Na	angles	# of angles Na in molecule	0
Nd	dihedrals	# of dihedrals Nd in molecule	0
Ni	impropers	# of impropers Ni in molecule	0
Nf	fragments	# of fragments Nf in molecule	0
Ninteger Ndouble	body	# of integer and floating-point values in *body particle*	0 0
Mtotal	mass	total mass of molecule	computed
Xc Yc Zc	com	coordinates of center-of-mass of molecule	computed
Ixx Iyy Izz Ixy Ixz Iyz	inertia	6 components of inertia tensor of molecule	computed
Nlines	lines	# of lines Nlines in molecule	0
Ntris	triangles	# of triangle Ntris in molecule	0

A molecule file can contain only either the *atoms*, *lines*, or *triangles* keyword. All the other keywords can only be used for a molecule file containing the *atoms* keyword.

For *mass*, *com*, and *inertia*, the default is for LAMMPS to calculate this quantity itself if needed, assuming the molecules consist of a set of point particles or finite-size particles (with a non-zero diameter) that do **not** overlap. If finite-size particles in the molecule **do** overlap, LAMMPS will not account for the overlap effects when calculating any of these 3 quantities, so you should pre-compute them yourself and list the values in the file.

The mass and center-of-mass coordinates (Xc,Yc,Zc) are self-explanatory. The 6 moments of inertia (ixx,iyy,izz,ixy,ixz,iyz) should be the values consistent with the current orientation of the rigid body around its center of mass. The values are with respect to the simulation box XYZ axes, not with respect to the principal axes of the rigid body itself. LAMMPS performs the latter calculation internally.

These are the allowed section keywords for the body of the file.

- *Coords, Types, Molecules, Fragments, Charges, Diameters, Dipoles, Masses* = atom-property sections
- *Bonds, Angles, Dihedrals, Impropers* = molecular topology sections
- *Special Bond Counts, Special Bonds* = special neighbor info
- *Shake Flags, Shake Atoms, Shake Bond Types* = SHAKE info
- *Body Integers, Body Doubles* = body-property sections
- *Lines, Triangles* = corner points of lines or triangles

Similar to the corresponding keywords, a molecule file can only contain either a Coords, Lines, or Triangles section. All of the other sections can only be used in molecule files for atoms.

For the Types, Bonds, Angles, Dihedrals, and Impropers sections, each atom/bond/angle/etc type can be specified either as a number (numeric type) or as an alphanumeric type label. The latter is only allowed if type labels have been defined, either by the *labelmap* command or in data files read by the *read_data* command which have sections for Atom Type Labels, Bond Type Labels, Angle Type Labels, etc. See the *Howto type labels* doc page for the allowed syntax of type labels and a general discussion of how type labels can be used. When using type labels, any values specified as *offset* are ignored.

If a Bonds section is specified then the Special Bond Counts and Special Bonds sections can also be used, if desired, to explicitly list the 1-2, 1-3, 1-4 neighbors within the molecule topology (see details below). This is optional since if these sections are not included, LAMMPS will auto-generate this information. Note that LAMMPS uses this info to properly exclude or weight bonded pairwise interactions between bonded atoms. See the *special_bonds* command for more details. One reason to list the special bond info explicitly is for the *thermalized Drude oscillator model* which treats the bonds between nuclear cores and Drude electrons in a different manner.

Note

Whether a section is required depends on how the molecule template is used by other LAMMPS commands. For example, to add a molecule via the *fix deposit* command, the Coords and Types sections are required. To add a rigid body via the *fix pour* command, the Bonds (Angles, etc) sections are not required, since the molecule will be treated as a rigid body. Some sections are optional. For example, the *fix pour* command can be used to add "molecules" which are clusters of finite-size granular particles. If the Diameters section is not specified, each particle in the molecule will have a default diameter of 1.0. See the doc pages for LAMMPS commands that use molecule templates for more details.

Each section is listed below in alphabetic order. The format of each section is described including the number of lines it must contain and rules (if any) for whether it can appear in the data file. For per- atom sections, entries should be numbered from 1 to Natoms (where Natoms is the number of atoms in the template), indicating which atom (or bond, etc) the entry applies to. Per-atom sections need to include a setting for every atom, but the atoms can be listed in any order.

Coords section:

- one line per atom
- line syntax: ID x y z
- x,y,z = coordinate of atom

Types section:

- one line per atom
- line syntax: ID type
- type = atom type of atom (1-Natomtype, or type label)

Molecules section:

- one line per atom
- line syntax: ID molecule-ID
- molecule-ID = molecule ID of atom

Fragments section:

- one line per fragment
- line syntax: ID a b c d ...
- a,b,c,d,... = IDs of atoms in fragment

The ID of a fragment can only contain alphanumeric characters and underscores. The atom IDs should be values from 1 to Natoms, where Natoms = # of atoms in the molecule.

Charges section:

- one line per atom
- line syntax: ID q
- q = charge on atom

This section is only allowed for *atom styles* that support charge. If this section is not included, the default charge on each atom in the molecule is 0.0.

Diameters section:

- one line per atom
- line syntax: ID diam
- diam = diameter of atom

This section is only allowed for *atom styles* that support finite-size spherical particles, e.g. atom_style sphere. If not listed, the default diameter of each atom in the molecule is 1.0.

Added in version 7Feb2024.

Dipoles section:

- one line per atom
- line syntax: ID mux muy muz
- mux,muy,muz = x-, y-, and z-component of point dipole vector of atom

This section is only allowed for *atom styles* that support particles with point dipoles, e.g. atom_style dipole. If not listed, the default dipole component of each atom in the molecule is set to 0.0.

Masses section:

- one line per atom
- line syntax: ID mass
- mass = mass of atom

This section is only allowed for *atom styles* that support per-atom mass, as opposed to per-type mass. See the *mass* command for details. If this section is not included, the default mass for each atom is derived from its volume (see Diameters section) and a default density of 1.0, in *units* of mass/volume.

Bonds section:

- one line per bond
- line syntax: ID type atom1 atom2
- type = bond type (1-Nbondtype, or type label)
- atom1,atom2 = IDs of atoms in bond

The IDs for the two atoms in each bond should be values from 1 to Natoms, where Natoms = # of atoms in the molecule.

Angles section:

- one line per angle
- line syntax: ID type atom1 atom2 atom3
- type = angle type (1-Nangletype, or type label)
- atom1,atom2,atom3 = IDs of atoms in angle

The IDs for the three atoms in each angle should be values from 1 to Natoms, where Natoms = # of atoms in the molecule. The three atoms are ordered linearly within the angle. Thus the central atom (around which the angle is computed) is the atom2 in the list.

Dihedrals section:

- one line per dihedral
- line syntax: ID type atom1 atom2 atom3 atom4
- type = dihedral type (1-Ndihedraltype, or type label)
- atom1,atom2,atom3,atom4 = IDs of atoms in dihedral

The IDs for the four atoms in each dihedral should be values from 1 to Natoms, where Natoms = # of atoms in the molecule. The 4 atoms are ordered linearly within the dihedral.

Impropers section:

- one line per improper
- line syntax: ID type atom1 atom2 atom3 atom4
- type = improper type (1-Nimpropertype, or type label)
- atom1,atom2,atom3,atom4 = IDs of atoms in improper

The IDs for the four atoms in each improper should be values from 1 to Natoms, where Natoms = # of atoms in the molecule. The ordering of the 4 atoms determines the definition of the improper angle used in the formula for the defined *improper style*. See the doc pages for individual styles for details.

Special Bond Counts section:

- one line per atom
- line syntax: ID N1 N2 N3
- N1 = # of 1-2 bonds
- N2 = # of 1-3 bonds

- N3 = # of 1-4 bonds

N1, N2, N3 are the number of 1-2, 1-3, 1-4 neighbors respectively of this atom within the topology of the molecule. See the *special_bonds* page for more discussion of 1-2, 1-3, 1-4 neighbors. If this section appears, the Special Bonds section must also appear.

As explained above, LAMMPS will auto-generate this information if this section is not specified. If specified, this section will override what would be auto-generated.

Special Bonds section:

- one line per atom
- line syntax: ID a b c d ...
- a,b,c,d,... = IDs of atoms in N1+N2+N3 special bonds

A, b, c, d, etc are the IDs of the n1+n2+n3 atoms that are 1-2, 1-3, 1-4 neighbors of this atom. The IDs should be values from 1 to Natoms, where Natoms = # of atoms in the molecule. The first N1 values should be the 1-2 neighbors, the next N2 should be the 1-3 neighbors, the last N3 should be the 1-4 neighbors. No atom ID should appear more than once. See the *special_bonds* doc page for more discussion of 1-2, 1-3, 1-4 neighbors. If this section appears, the Special Bond Counts section must also appear.

As explained above, LAMMPS will auto-generate this information if this section is not specified. If specified, this section will override what would be auto-generated.

Shake Flags section:

- one line per atom
- line syntax: ID flag
- flag = 0,1,2,3,4

This section is only needed when molecules created using the template will be constrained by SHAKE via the "fix shake" command. The other two Shake sections must also appear in the file, following this one.

The meaning of the flag for each atom is as follows. See the *fix shake* page for a further description of SHAKE clusters.

- 0 = not part of a SHAKE cluster
- 1 = part of a SHAKE angle cluster (two bonds and the angle they form)
- 2 = part of a 2-atom SHAKE cluster with a single bond
- 3 = part of a 3-atom SHAKE cluster with two bonds
- 4 = part of a 4-atom SHAKE cluster with three bonds

Shake Atoms section:

- one line per atom
- line syntax: ID a b c d
- a,b,c,d = IDs of atoms in cluster

This section is only needed when molecules created using the template will be constrained by SHAKE via the "fix shake" command. The other two Shake sections must also appear in the file.

The a,b,c,d values are atom IDs (from 1 to Natoms) for all the atoms in the SHAKE cluster that this atom belongs to. The number of values that must appear is determined by the shake flag for the atom (see the Shake Flags section above). All atoms in a particular cluster should list their a,b,c,d values identically.

If flag = 0, no a,b,c,d values are listed on the line, just the (ignored) ID.

If flag = 1, a,b,c are listed, where a = ID of central atom in the angle, and b,c the other two atoms in the angle.

If flag = 2, a,b are listed, where a = ID of atom in bond with the lowest ID, and b = ID of atom in bond with the highest ID.

If flag = 3, a,b,c are listed, where a = ID of central atom, and b,c = IDs of other two atoms bonded to the central atom.

If flag = 4, a,b,c,d are listed, where a = ID of central atom, and b,c,d = IDs of other three atoms bonded to the central atom.

See the *fix shake* page for a further description of SHAKE clusters.

Shake Bond Types section:

- one line per atom
- line syntax: ID a b c
- a,b,c = bond types (or angle type) of bonds (or angle) in cluster

This section is only needed when molecules created using the template will be constrained by SHAKE via the "fix shake" command. The other two Shake sections must also appear in the file.

The a,b,c values are bond types for all bonds in the SHAKE cluster that this atom belongs to. Bond types may be either numbers (from 1 to Nbondtypes) or bond type labels as defined by the *labelmap* command or a "Bond Type Labels" section of a data file.

The number of values that must appear is determined by the shake flag for the atom (see the Shake Flags section above). All atoms in a particular cluster should list their a,b,c values identically.

If flag = 0, no a,b,c values are listed on the line, just the (ignored) ID.

If flag = 1, a,b,c are listed, where a = bondtype of the bond between the central atom and the first non-central atom (value b in the Shake Atoms section), b = bondtype of the bond between the central atom and the second non-central atom (value c in the Shake Atoms section), and c = the angle type (1 to Nangletypes, or angle type label) of the angle between the three atoms.

If flag = 2, only a is listed, where a = bondtype of the bond between the two atoms in the cluster.

If flag = 3, a,b are listed, where a = bondtype of the bond between the central atom and the first non-central atom (value b in the Shake Atoms section), and b = bondtype of the bond between the central atom and the second non-central atom (value c in the Shake Atoms section).

If flag = 4, a,b,c are listed, where a = bondtype of the bond between the central atom and the first non-central atom (value b in the Shake Atoms section), b = bondtype of the bond between the central atom and the second non-central atom (value c in the Shake Atoms section), and c = bondtype of the bond between the central atom and the third non-central atom (value d in the Shake Atoms section).

See the *fix shake* page for a further description of SHAKE clusters.

Body Integers section:

- one line

- line syntax: N E F
- N = number of sub-particles or number of vertices
- E,F = number of edges and faces

This section is only needed when the molecule is a body particle. the other Body section must also appear in the file.

The total number of values that must appear is determined by the body style, and must be equal to the Ninteger value given in the *body* header.

For *nparticle* and *rounded/polygon*, only the number of sub-particles or vertices N is required, and Ninteger should have a value of 1.

For *rounded/polyhedron*, the number of edges E and faces F is required, and Ninteger should have a value of 3.

See the *Howto body* page for a further description of the file format.

Body Doubles section:

- first line
- line syntax: Ixx Iyy Izz Ixy Ixz Iyz
- Ixx Iyy Izz Ixy Ixz Iyz = 6 components of inertia tensor of body particle
- one line per sub-particle or vertex
- line syntax: x y z
- x, y, z = coordinates of sub-particle or vertex
- one line per edge
- line syntax: N1 N2
- N1, N2 = vertex indices
- one line per face
- line syntax: N1 N2 N3 N4
- N1, N2, N3, N4 = vertex indices
- last line
- line syntax: diam
- diam = rounded diameter that surrounds each vertex

This section is only needed when the molecule is a body particle. the other Body section must also appear in the file.

The total number of values that must appear is determined by the body style, and must be equal to the Ndouble value given in the *body* header. The 6 moments of inertia and the 3N coordinates of the sub-particles or vertices are required for all body styles.

For *rounded/polygon*, the E = 6 + 3*N + 1 edges are automatically determined from the vertices.

For *rounded/polyhedron*, the 2E vertex indices for the end points of the edges and 4F vertex indices defining the faces are required.

See the *Howto body* page for a further description of the file format.

Added in version 4Jul2026.

Lines section:

- one line per line segment
- line syntax: ID molecule-ID type x1 y1 x2 y2
- molecule-ID = molecule-ID of the line segment
- type = type of the line segment
- x1,y1,x2,y2 = coords of two endpoints of line segment

Each line segment is assigned a molecule-ID and type, similar to an atom type. This allows a collection of lines to represent multiple 2d bodies, e.g. a collection of squares. Line-segments in each could have a different molecule-ID, or the left-facing edges could have a unique atom type.

The coords of two different line segments which are connected by a common point should list the exact same coordinates for the common point. This allows a command like *fix surface/local* to infer connectivity of the two line segments.

The ordering of the two points defines the direction of an outward normal for the line segment. This is defined by a right-hand rule. The outward normal N = (0,0,1) x (p2-p1), where p1 and p2 are the 2 points. In other words, a unit z-direction vector is crossed into the vector from p1 to p2 to determine the normal.

It depends on how the line segments are used by other commands in LAMMPS whether the normal direction matters or not.

Added in version 4Jul2026.

Triangles section:

- one line per triangle
- line syntax: ID molecule-ID type x1 y1 z1 x2 y2 z2 x3 y3 z3
- molecule-ID = molecule-ID assigned triangle
- type = type assigned to triangle
- x1,y1,z1,x2,y2,z2,x3,y3,z3 = coords of three corner points of triangle

Each triangle is assigned a molecule-ID and type, similar to an atom type. This allows a collection of triangles to represent multiple 3d objects, e.g. a curved surface on the left and right of the simulation box. Triangles in each could have a different molecule-ID, or the the triangles in the upper half could have a different type than those in the lower half.

The coords of two different triangles which share a common edge (2 points) or corner point (single point) should list the exact same coordinates for the common points. This allows a command like *fix surface/local* to infer connectivity of the two triangles.

The ordering of the three points defines the direction of the outward normal for the triangle. This is defined by a right-hand rule. The outward normal N = (p2-p1) x (p3-p1), where p1, p2, p3 are the 3 points. In other words, the edge from p1 to p2 is crossed into the edge from p1 to p3 to determine the normal.

It depends on how the triangles are used by other commands in LAMMPS whether the normal direction matters or not.

1.67.5 Format of a JSON molecule file

Added in version 12Jun2025.

The format of a JSON format individual molecule file must follow the JSON format, which evolved from the JavaScript programming language as a programming-language-neutral data interchange language. The JSON syntax is independent of its content, and thus the data in the file must follow suitable conventions to be correctly processed. LAMMPS provides a JSON schema file for JSON format molecule files in the *tools/json folder* to represent those conventions. Using the schema file any JSON format molecule files can be validated. Please note that the format requirement for JSON are very strict and the JSON reader in LAMMPS does not accept files with extensions like comments. Validating

a particular JSON format molecule file against this schema ensures that both, the JSON syntax requirement *and* the LAMMPS conventions for molecule template files are followed. LAMMPS should be able to read and parse any JSON file that passes the schema check. This is a formal check only and thus it **cannot** check whether the file contents are consistent or physically meaningful.

Here is a simple example for the same TIP3P water molecule from above in JSON format and also using *type labels* instead of numeric types:

```
{
    "application": "LAMMPS",
    "format": "molecule",
    "revision": 1,
    "title": "Water molecule. TIP3P geometry",
    "schema": "https://download.lammps.org/json/molecule-schema.json",
    "units": "real",
    "coords": {
        "format": ["atom-id", "x", "y", "z"],
        "data": [
            [1,  0.00000, -0.06556,  0.00000],
            [2,  0.75695,  0.52032,  0.00000],
            [3, -0.75695,  0.52032,  0.00000]
        ]
    },
    "types": {
        "format": ["atom-id", "type"],
        "data": [
            [1,  "OW"],
            [2,  "HO1"],
            [3,  "HO1"]
        ]
    },
    "charges": {
        "format": ["atom-id", "charge"],
        "data": [
            [1, -0.834],
            [2,  0.417],
            [3,  0.417]
        ]
    },
    "bonds": {
        "format": ["bond-type", "atom1", "atom2"],
        "data": [
            ["OW-HO1",  1,  2],
            ["OW-HO1",  1,  3]
        ]
    },
    "angles": {
        "format": ["angle-type", "atom1", "atom2", "atom3"],
        "data": [
            ["HO1-OW-HO1",  2,  1,  3]
        ]
    }
}
```

Unlike with the native molecule file format, there are no header or body sections, just a list of keywords with associated

data. JSON format data is read, parsed, and stored in an internal dictionary data structure in one step and thus the order of keywords is not relevant.

Data for keywords is either provided directly following the keyword or as a *data block*. A *data block* is a list that has to include two keywords, "format" and "data", where the former lists keywords of the properties that are stored in the columns of the "data" lists. The names and order of entries in the "format" list (and thus how the data is interpreted) are currently fixed.

Since the length of the various lists can be easily obtained from the internal data structure, several header keywords of the "native" molecule file are not needed. On the other hand, some additional keywords are required to identify the conventions applied to the generic JSON file format. The structure of the data itself mostly follows what is used for the "native" molecule file format.

Keyword	Argument(s)	Required	Description
application	"LAMMPS	yes	indicates a LAMMPS JSON file; files from other applications may be accepted in the future
format	"molecule"	yes	indicates a molecule template file
revision	an integer	yes	currently 1, to facility backward compatibility on changes to the conventions
title	a string	no	information about the template which will echoed to the screen and log
schema	URL as string	no	location of a JSON schema file for validating the molecule file format
units	a string	no	indicates *units settings* for this molecule template
com	list with 3 doubles	no	overrides the auto-computed center-of-mass for the template
masstotal	double	no	overrides the auto-computed total mass for the template
inertia	list with 6 doubles	no	overrides the auto-computed moments of inertia
coords	a data block	no	contains atom positions with the format "atom-id", "x", "y", "z" (same as Coords)
types	a data block	yes	assigns atom types to atoms with the format "atom-id", "type" (same as Types)
molecu	a data block	no	assigns molecule-IDs to atoms with the format "atom-id", "molecule-id" (same as Molecules)
fragments	a data block	no	assigns atom-ids to fragment-IDs with the format "fragment-id", "atom-id-list" (same as Fragments)
charges	a data block	no	assigns charges to atoms with the format "atom-id", "charge" (same as Charges)
dipoles	a data block	no	assigns point dipoles to atoms with the format "atom-id", "mux", "muy", "muz" (same as Dipoles)
diameters	a data block	no	assigns diameters to atoms with the format "atom-id", "diameter" (same as Diameters)
masses	a data block	no	assigns per-atom masses to atoms with the format "atom-id", "mass" (same as Masses)
bonds	a data block	no	defines bonds in the molecule template with the format "bond-type", "atom1", "atom2" (same as Bonds without bond-ID)
angles	a data block	no	defines angles in the molecule template with the format "angle-type", "atom1", "atom2", "atom3" (same as Angles without angle-ID)
dihedrals	a data block	no	defines dihedrals in the molecule template with the format "dihedral-type", "atom1", "atom2", "atom3", "atom4" (same as Dihedrals without dihedral-ID)
impropers	a data block	no	defines impropers in the molecule template with the format "improper-type", "atom1", "atom2", "atom3", "atom4" (same as Impropers without improper-ID)
shake	3 JSON objects	no	contains the sub-sections "flags", "atoms", "bonds" described below
special	2 JSON objects	no	contains the sub-sections "counts" and "bonds" described below
body	2 JSON objects	no	contains the "integers" and "doubles" sub-sections with arrays with the same data as Body Integers and Body Doubles, respectively

The following table describes the sub-sections for the "special" entry from above:

Sub-section	Argument(s)	Required	Description
counts	a data block	yes	contains the counts of 1-2, 1-3, and 1-4 special neighbors with the format "atom-id", "n12", "n13", "n14" (same as Special Bond Counts)
bonds	a data block	yes	contains the lists of special neighbors to atoms with the format "atom-id", "atom-id-list" (same as Special Bonds)

The following table describes the sub-sections for the "shake" entry from above:

Sub-section	Argument(s)	Required	Description
flags	a data block	yes	contains the counts shake flags for atoms with the format "atom-id", "flag" (same as Shake Flags)
atoms	a data block	yes	contains the lists of shake cluster atom-ids for atoms with the format "atom-id", "atom-id-list" (same as Shake Atoms)
bonds	a data block	yes	contains the lists of shake bond or angle types for atoms with the format "atom-id", "type-list" (same as Shake Bonds)

The "special" and "shake" sections are usually not needed, since the data can be auto-generated as soon as the simulation box is defined. Below is an example for what would have to be *added* to the example JSON file above in case the molecule command needs to be issued earlier.

```
"special": {
    "counts": {
        "format": ["atom-id", "n12", "n13", "n14"],
        "data": [
            [1, 2, 0, 0],
            [2, 1, 1, 0],
            [3, 1, 1, 0]
        ]
    },
    "bonds": {
        "format": ["atom-id", "atom-id-list"],
        "data": [
            [1,  [2, 3]],
            [2,  [1, 3]],
            [3,  [1, 2]]
        ]
    }
},
"shake": {
    "flags": {
        "format": ["atom-id", "flag"],
        "data": [
            [1, 1],
            [2, 1],
            [3, 1]
        ]
    },
```

(continues on next page)

(continued from previous page)

```
    "atoms": {
        "format": ["atom-id", "atom-id-list"],
        "data": [
            [1,  [1, 2, 3]],
            [2,  [1, 2, 3]],
            [3,  [1, 2, 3]]
        ]
    },
    "types": {
        "format": ["atom-id", "type-list"],
        "data": [
            [1,  ["OW-HO1",  "OW-HO1", "HO1-OW-HO1"]],
            [2,  ["OW-HO1",  "OW-HO1", "HO1-OW-HO1"]],
            [3,  ["OW-HO1",  "OW-HO1", "HO1-OW-HO1"]]
        ]
    }
}
```

Below is a minimal example of a JSON format molecule template for a body particle for *pair style body/nparticle*. Molecule templates for body particles must contain only one atom:

```
{
    "application": "LAMMPS",
    "format": "molecule",
    "revision": 1,
    "title": "Square body for body/nparticles",
    "schema": "https://download.lammps.org/json/molecule-schema.json",
    "units": "real",
    "coords": {
        "format": ["atom-id", "x", "y", "z"],
        "data": [
            [1,  0.00000,  0.00000,  0.00000]
        ]
    },
    "types": {
        "format": ["atom-id", "type"],
        "data": [
            [1,  1]
        ]
    },
    "masses": {
        "format": ["atom-id", "mass"],
        "data": [
            [1,  1.0]
        ]
    },
    "body": {
        "integers": [4],
        "doubles": [
            1.0, 1.0, 4.0, 0.0, 0.0, 0.0,
            -0.70710678118654752440, -0.70710678118654752440, 0.0,
            -0.70710678118654752440,  0.70710678118654752440, 0.0,
```

(continues on next page)

(continued from previous page)

```
            0.7071067811865475244,  0.7071067811865475244, 0.0,
            0.7071067811865475244, -0.7071067811865475244, 0.0
        ]
    }
}
```

1.67.6 Restrictions

The *lines* and *tris* keywords and corresponding sections are currently not (yet) supported with molecule files in JSON format.

1.67.7 Related commands

write_molecule, *fix deposit*, *fix pour*, *fix gcmc*, *fix bond/react*, *create_atoms*

1.67.8 Default

The default keywords values are offset 0 0 0 0 0 and scale = 1.0.

1.68 neb command

1.68.1 Syntax

```
neb etol ftol N1 N2 Nevery file-style arg keyword values
```

- etol = stopping tolerance for energy (dimensionless)
- ftol = stopping tolerance for force (force units)
- N1 = max # of iterations (timesteps) to run initial NEB
- N2 = max # of iterations (timesteps) to run barrier-climbing NEB
- Nevery = print replica energies and reaction coordinates every this many timesteps
- file-style = *final* or *each* or *none*

```
final arg = filename
  filename = file with initial coords for final replica
    coords for intermediate replicas are linearly interpolated

```

1.68.3 Description

Perform a nudged elastic band (NEB) calculation using multiple replicas of a system. Two or more replicas must be used; the first and last are the end points of the transition path.

NEB is a method for finding both the atomic configurations and height of the energy barrier associated with a transition state, e.g. for an atom to perform a diffusive hop from one energy basin to another in a coordinated fashion with its neighbors. The implementation in LAMMPS follows the discussion in these 4 papers: *(Henkelman1)*, *(Henkelman2)*, *(Nakano2)* and *(Maras)*.

Each replica runs on a partition of one or more processors. Processor partitions are defined at run-time using the *-partition command-line switch*. Note that if you have MPI installed, you can run a multi-replica simulation with more replicas (partitions) than you have physical processors, e.g you can run a 10-replica simulation on just one or two processors. You will simply not get the performance speed-up you would see with one or more physical processors per replica. See the *Howto replica* doc page for further discussion.

Note

As explained below, a NEB calculation performs a damped dynamics minimization across all the replicas. The minimizer uses whatever timestep you have defined in your input script, via the *timestep* command. Often NEB will converge more quickly if you use a timestep about 10x larger than you would normally use for dynamics simulations.

When a NEB calculation is performed, it is assumed that each replica is running the same system, though LAMMPS does not check for this. I.e. the simulation domain, the number of atoms, the interaction potentials, and the starting configuration when the neb command is issued should be the same for every replica.

In a NEB calculation each replica is connected to other replicas by inter-replica nudging forces. These forces are imposed by the *fix neb* command, which must be used in conjunction with the neb command. The group used to define the fix neb command defines the NEB atoms which are the only ones that inter-replica springs are applied to. If the group does not include all atoms, then non-NEB atoms have no inter-replica springs and the forces they feel and their motion is computed in the usual way due only to other atoms within their replica. Conceptually, the non-NEB atoms provide a background force field for the NEB atoms. They can be allowed to move during the NEB minimization procedure (which will typically induce different coordinates for non-NEB atoms in different replicas), or held fixed using other LAMMPS commands such as *fix setforce*. Note that the *partition* command can be used to invoke a command on a subset of the replicas, e.g. if you wish to hold NEB or non-NEB atoms fixed in only the end-point replicas.

The initial atomic configuration for each of the replicas can be specified in different manners via the *file-style* setting, as discussed below. Only atoms whose initial coordinates should differ from the current configuration need be specified.

Conceptually, the initial and final configurations for the first replica should be states on either side of an energy barrier.

As explained below, the initial configurations of intermediate replicas can be atomic coordinates interpolated in a linear fashion between the first and last replicas. This is often adequate for simple transitions. For more complex transitions, it may lead to slow convergence or even bad results if the minimum energy path (MEP, see below) of states over the barrier cannot be correctly converged to from such an initial path. In this case, you will want to generate initial states for the intermediate replicas that are geometrically closer to the MEP and read them in.

For a *file-style* setting of *final*, a filename is specified which contains atomic coordinates for zero or more atoms, in the format described below. For each atom that appears in the file, the new coordinates are assigned to that atom in the final replica. Each intermediate replica also assigns a new position to that atom in an interpolated manner. This is done by using the current position of the atom as the starting point and the read-in position as the final point. The distance between them is calculated, and the new position is assigned to be a fraction of the distance. E.g. if there are 10 replicas, the second replica will assign a position that is 10% of the distance along a line between the starting and final point, and the 9th replica will assign a position that is 90% of the distance along the line. Note that for this procedure to produce consistent coordinates across all the replicas, the current coordinates need to be the same in all replicas. LAMMPS does not check for this, but invalid initial configurations will likely result if it is not the case.

Note

The "distance" between the starting and final point is calculated in a minimum-image sense for a periodic simulation box. This means that if the two positions are on opposite sides of a box (periodic in that dimension), the distance between them will be small, because the periodic image of one of the atoms is close to the other. Similarly, even if the assigned position resulting from the interpolation is outside the periodic box, the atom will be wrapped back into the box when the NEB calculation begins.

For a *file-style* setting of *each*, a filename is specified which is assumed to be unique to each replica. This can be done by using a variable in the filename, e.g.

```
variable i equal part
neb 0.0 0.001 1000 500 50 each coords.initial.$i
```

which in this case will substitute the partition ID (0 to N-1) for the variable I, which is also effectively the replica ID. See the *variable* command for other options, such as using world-, universe-, or uloop-style variables.

Each replica (except the first replica) will read its file, formatted as described below, and for any atom that appears in the file, assign the specified coordinates to its atom. The various files do not need to contain the same set of atoms.

For a *file-style* setting of *none*, no filename is specified. Each replica is assumed to already be in its initial configuration at the time the neb command is issued. This allows each replica to define its own configuration by reading a replica-specific data or restart or dump file, via the *read_data*, *read_restart*, or *read_dump* commands. The replica-specific names of these files can be specified as in the discussion above for the *each* file-style. Also see the section below for how a NEB calculation can produce restart files, so that a long calculation can be restarted if needed.

Note

None of the *file-style* settings change the initial configuration of any atom in the first replica. The first replica must thus be in the correct initial configuration at the time the neb command is issued.

A NEB calculation proceeds in two stages, each of which is a minimization procedure, performed via damped dynamics. To enable this, you must first define a damped dynamics *min_style*, such as *quickmin* or *fire*. The *cg*, *sd*, and *hftn* styles cannot be used, since they perform iterative line searches in their inner loop, which cannot be easily synchronized across multiple replicas.

The minimizer tolerances for energy and force are set by *etol* and *ftol*, the same as for the *minimize* command.

A non-zero *etol* means that the NEB calculation will terminate if the energy criterion is met by every replica. The energies being compared to *etol* do not include any contribution from the inter-replica nudging forces, since these are non-conservative. A non-zero *ftol* means that the NEB calculation will terminate if the force criterion is met by every replica. The forces being compared to *ftol* include the inter-replica nudging forces.

The maximum number of iterations in each stage is set by *N1* and *N2*. These are effectively timestep counts since each iteration of damped dynamics is like a single timestep in a dynamics *run*. During both stages, the potential energy of each replica and its normalized distance along the reaction path (reaction coordinate RD) will be printed to the screen and log file every *Nevery* timesteps. The RD is 0 and 1 for the first and last replica. For intermediate replicas, it is the cumulative distance (normalized by the total cumulative distance) between adjacent replicas, where "distance" is defined as the length of the 3N-vector of differences in atomic coordinates, where N is the number of NEB atoms involved in the transition. These outputs allow you to monitor NEB's progress in finding a good energy barrier. *N1* and *N2* must both be multiples of *Nevery*.

In the first stage of NEB, the set of replicas should converge toward a minimum energy path (MEP) of conformational states that transition over a barrier. The MEP for a transition is defined as a sequence of 3N-dimensional states, each of which has a potential energy gradient parallel to the MEP itself. The configuration of highest energy along a MEP corresponds to a saddle point. The replica states will also be roughly equally spaced along the MEP due to the inter-replica nudging force added by the *fix neb* command.

In the second stage of NEB, the replica with the highest energy is selected and the inter-replica forces on it are converted to a force that drives its atom coordinates to the top or saddle point of the barrier, via the barrier-climbing calculation described in *(Henkelman2)*. As before, the other replicas rearrange themselves along the MEP so as to be roughly equally spaced.

When both stages are complete, if the NEB calculation was successful, the configurations of the replicas should be along (close to) the MEP and the replica with the highest energy should be an atomic configuration at (close to) the saddle point of the transition. The potential energies for the set of replicas represents the energy profile of the transition along the MEP.

A few other settings in your input script are required or advised to perform a NEB calculation. See the NOTE about the choice of timestep at the beginning of this doc page.

An atom map must be defined which it is not by default for *atom_style atomic* problems. The *atom_modify map* command can be used to do this.

The minimizers in LAMMPS operate on all atoms in your system, even non-NEB atoms, as defined above. To prevent non-NEB atoms from moving during the minimization, you should use the *fix setforce* command to set the force on each of those atoms to 0.0. This is not required, and may not even be desired in some cases, but if those atoms move too far (e.g. because the initial state of your system was not well-minimized), it can cause problems for the NEB procedure.

The damped dynamics *minimizers*, such as *quickmin* and *fire*), adjust the position and velocity of the atoms via an Euler integration step. Thus you must define an appropriate *timestep* to use with NEB. As mentioned above, NEB will often converge more quickly if you use a timestep about 10x larger than you would normally use for dynamics simulations.

Each file read by the neb command containing atomic coordinates used to initialize one or more replicas must be formatted as follows.

The file can be ASCII text or a compressed text file (detected by a *supported compression format suffix*). The file can contain initial blank lines or comment lines starting with "#" which are ignored. The first non-blank, non-comment line should list N = the number of lines to follow. The N successive lines contain the following information:

```
ID1 x1 y1 z1
ID2 x2 y2 z2
...
IDN xN yN zN
```

The fields are the atom ID, followed by the x,y,z coordinates. The lines can be listed in any order. Additional trailing information on the line is OK, such as a comment.

Note that for a typical NEB calculation you do not need to specify initial coordinates for very many atoms to produce differing starting and final replicas whose intermediate replicas will converge to the energy barrier. Typically only new coordinates for atoms geometrically near the barrier need be specified.

Also note there is no requirement that the atoms in the file correspond to the NEB atoms in the group defined by the *fix neb* command. Not every NEB atom need be in the file, and non-NEB atoms can be listed in the file.

Four kinds of output can be generated during a NEB calculation: energy barrier statistics, thermodynamic output by each replica, dump files, and restart files.

When running with multiple partitions (each of which is a replica in this case), the print-out to the screen and master log.lammps file contains a line of output, printed once every *Nevery* timesteps. The amount of information printed in this line can be selected with the *verbosity* keyword. Available options are *terse*, *default*, and *verbose*.

With the *terse* setting, it contains the timestep, the maximum force of a replica, the maximum force per atom (in any replica), potential gradients in the initial, final, and climbing replicas, the forward and backward energy barriers, the total reaction coordinate (RDT).

With the *default* setting, additionally the normalized reaction coordinate and potential energy of each replica are printed.

With the *verbose* setting, additional per-replica properties are printed: the "path angle" (pathangle), the angle between the 3N-length tangent vector and the 3N-length force vector at image *i* (angletangrad), the angle between the 3N-length energy gradient vector of replica *i* and that of replica *i*+1 (anglegrad), the norm of the energy gradient (gradV), the the two-norm of the 3N-length force vector (RepForce), and the maximum force component of any atom (MaxAtomForce).

The "maximum force per replica" is the two-norm of the 3N-length force vector for the atoms in each replica, maximized across replicas, which is what the *ftol* setting is checking against. In this case, N is all the atoms in each replica. The "maximum force per atom" is the maximum force component of any atom in any replica. The potential gradients are the two-norm of the 3N-length force vector solely due to the interaction potential i.e. without adding in inter-replica forces.

The "reaction coordinate" (RD) for each replica is the two-norm of the 3N-length vector of distances between its atoms and the preceding replica's atoms, added to the RD of the preceding replica. The RD of the first replica RD1 = 0.0; the RD of the final replica RDN = RDT, the total reaction coordinate. The normalized RDs are divided by RDT, so that they form a monotonically increasing sequence from zero to one. When computing RD, N only includes the atoms being operated on by the fix neb command.

The forward (reverse) energy barrier is the potential energy of the highest replica minus the energy of the first (last) replica.

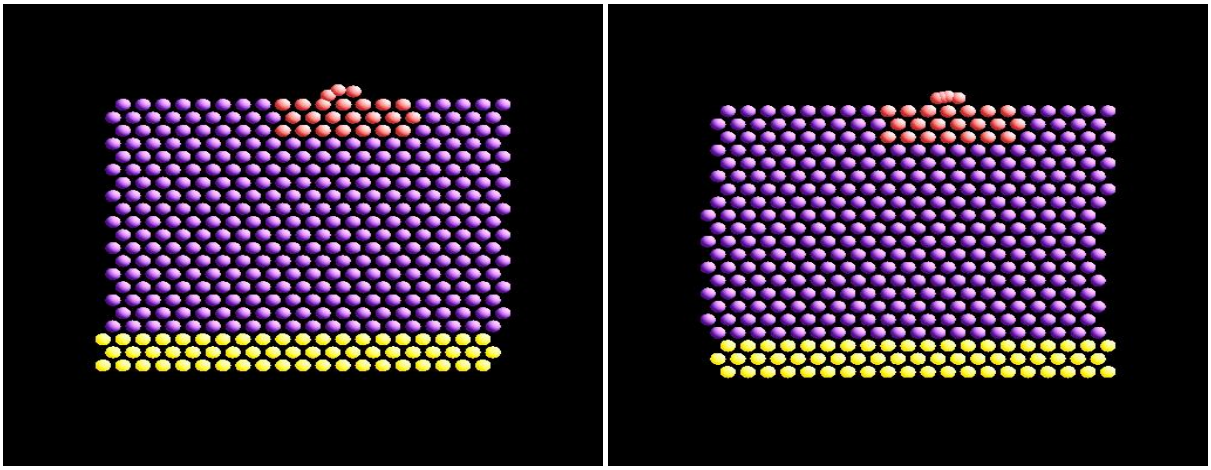
The "path angle" (pathangle) for the replica i which is the angle between the 3N-length vectors $(R_{i-1}-R_i)$ and $(R_{i+1}-R_i)$ (where R_i is the atomic coordinates of replica i). A "path angle" of 180 indicates that replicas i-1, i and i+1 are aligned. "angletangrad" is the angle between the 3N-length tangent vector and the 3N-length force vector at image i. The tangent vector is calculated as in *(Henkelman1)* for all intermediate replicas and at R2 - R1 and RM - RM-1 for the first and last replica, respectively. "anglegrad" is the angle between the 3N-length energy gradient vector of replica i and that of replica i+1. It is not defined for the final replica and reads nan. gradV is the norm of the energy gradient of image i (∇V). ReplicaForce is the two-norm of the 3N-length force vector (including nudging forces) for replica i. MaxAtomForce is the maximum force component of any atom in replica i.

When a NEB calculation does not converge properly, the supplementary information can help understanding what is going wrong. For instance when the path angle becomes acute, the definition of tangent used in the NEB calculation is questionable and the NEB cannot may diverge *(Maras)*.

When running on multiple partitions, LAMMPS produces additional log files for each partition, e.g. log.lammps.0, log.lammps.1, etc. For a NEB calculation, these contain the thermodynamic output for each replica.

If *dump* commands in the input script define a filename that includes a *universe* or *uloop* style *variable*, then one dump file (per dump command) will be created for each replica. At the end of the NEB calculation, the final snapshot in each

file will contain the sequence of snapshots that transition the system over the energy barrier. Earlier snapshots will show the convergence of the replicas to the MEP.



Likewise, *restart* filenames can be specified with a *universe* or *uloop* style *variable*, to generate restart files for each replica. These may be useful if the NEB calculation fails to converge properly to the MEP, and you wish to restart the calculation from an intermediate point with altered parameters.

There are 2 Python scripts provided in the tools/python directory, neb_combine.py and neb_final.py, which are useful in analyzing output from a NEB calculation. Assume a NEB simulation with M replicas, and the NEB atoms labeled with a specific atom type.

The neb_combine.py script extracts atom coords for the NEB atoms from all M dump files and creates a single dump file where each snapshot contains the NEB atoms from all the replicas and one copy of non-NEB atoms from the first replica (presumed to be identical in other replicas). This can be visualized/animated to see how the NEB atoms relax as the NEB calculation proceeds.

The neb_final.py script extracts the final snapshot from each of the M dump files to create a single dump file with M snapshots. This can be visualized to watch the system make its transition over the energy barrier.

To illustrate, here are images from the final snapshot produced by the neb_combine.py script run on the dump files produced by the two example input scripts in examples/neb.

1.68.4 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the *Build package* doc page for more info.

To read compressed files, you must compile LAMMPS with the `-DLAMMPS_GZIP` option. See the *Build settings* doc page for details.

```

1.69.3 Description

Perform a geodesic nudged elastic band (GNEB) calculation using multiple replicas of a system. Two or more replicas must be used; the first and last are the end points of the transition path.

GNEB is a method for finding both the spin configurations and height of the energy barrier associated with a transition state, e.g. spins to perform a collective rotation from one energy basin to another. The implementation in LAMMPS follows the discussion in the following paper: *(Bessarab)*.

Each replica runs on a partition of one or more processors. Processor partitions are defined at run-time using the *-partition command-line switch*. Note that if you have MPI installed, you can run a multi-replica simulation with more replicas (partitions) than you have physical processors, e.g you can run a 10-replica simulation on just one or two

processors. You will simply not get the performance speed-up you would see with one or more physical processors per replica. See the *Howto replica* doc page for further discussion.

Note

As explained below, a GNEB calculation performs a minimization across all the replicas. One of the *spin* style minimizers has to be defined in your input script.

When a GNEB calculation is performed, it is assumed that each replica is running the same system, though LAMMPS does not check for this. I.e. the simulation domain, the number of magnetic atoms, the interaction potentials, and the starting configuration when the neb command is issued should be the same for every replica.

In a GNEB calculation each replica is connected to other replicas by inter-replica nudging forces. These forces are imposed by the *fix neb/spin* command, which must be used in conjunction with the neb command. The group used to define the fix neb/spin command defines the GNEB magnetic atoms which are the only ones that inter-replica springs are applied to. If the group does not include all magnetic atoms, then non-GNEB magnetic atoms have no inter-replica springs and the torques they feel and their precession motion is computed in the usual way due only to other magnetic atoms within their replica. Conceptually, the non-GNEB atoms provide a background force field for the GNEB atoms. Their magnetic spins can be allowed to evolve during the GNEB minimization procedure.

The initial spin configuration for each of the replicas can be specified in different manners via the *file-style* setting, as discussed below. Only atomic spins whose initial coordinates should differ from the current configuration need to be specified.

Conceptually, the initial and final configurations for the first replica should be states on either side of an energy barrier.

As explained below, the initial configurations of intermediate replicas can be spin coordinates interpolated in a linear fashion between the first and last replicas. This is often adequate for simple transitions. For more complex transitions, it may lead to slow convergence or even bad results if the minimum energy path (MEP, see below) of states over the barrier cannot be correctly converged to from such an initial path. In this case, you will want to generate initial states for the intermediate replicas that are geometrically closer to the MEP and read them in.

For a *file-style* setting of *final*, a filename is specified which contains atomic and spin coordinates for zero or more atoms, in the format described below. For each atom that appears in the file, the new coordinates are assigned to that atom in the final replica. Each intermediate replica also assigns a new spin to that atom in an interpolated manner. This is done by using the current direction of the spin at the starting point and the read-in direction as the final point. The "angular distance" between them is calculated, and the new direction is assigned to be a fraction of the angular distance.

Note

The "angular distance" between the starting and final point is evaluated in the geodesic sense, as described in *(Bessarab)*.

Note

The angular interpolation between the starting and final point is achieved using Rodrigues formula:

$$\vec{m}_i^{\,v} = \vec{m}_i^{\,I}\cos(\omega_i^v) + (\vec{k}_i \times \vec{m}_i^{\,I})\sin(\omega_i^v) + (1.0 - \cos(\omega_i^v))\vec{k}_i(\vec{k}_i \cdot \vec{m}_i^{\,I})$$

where $\vec{m}_i^I$ is the initial spin configuration for spin i, ω_i^ν is a rotation angle defined as:

$$\omega_i^\nu = (\nu - 1)\Delta\omega_i \text{ and } \Delta\omega_i = \frac{\omega_i}{Q - 1}$$

with ν the image number, Q the total number of images, and ω_i the total rotation between the initial and final spins. $\vec{k}_i$ defines a rotation axis such as:

$$\vec{k}_i = \frac{\vec{m}_i^I \times \vec{m}_i^F}{|\vec{m}_i^I \times \vec{m}_i^F|}$$

if the initial and final spins are not aligned. If the initial and final spins are aligned, then their cross product is null, and the expression above does not apply. If they point toward the same direction, the intermediate images conserve the same orientation. If the initial and final spins are aligned, but point toward opposite directions, an arbitrary rotation vector belonging to the plane perpendicular to initial and final spins is chosen. In this case, a warning message is displayed.

For a *file-style* setting of *each*, a filename is specified which is assumed to be unique to each replica. See the *neb* documentation page for more information about this option.

For a *file-style* setting of *none*, no filename is specified. Each replica is assumed to already be in its initial configuration at the time the neb command is issued. This allows each replica to define its own configuration by reading a replica-specific data or restart or dump file, via the *read_data*, *read_restart*, or *read_dump* commands. The replica-specific names of these files can be specified as in the discussion above for the *each* file-style. Also see the section below for how a NEB calculation can produce restart files, so that a long calculation can be restarted if needed.

Note

None of the *file-style* settings change the initial configuration of any atom in the first replica. The first replica must thus be in the correct initial configuration at the time the neb command is issued.

A NEB calculation proceeds in two stages, each of which is a minimization procedure. To enable this, you must first define a *min_style*, using either the *spin*, *spin/cg*, or *spin/lbfgs* style (see *min_spin* for more information). The other styles cannot be used, since they relax the lattice degrees of freedom instead of the spins.

The minimizer tolerances for energy and force are set by *etol* and *ttol*, the same as for the *minimize* command.

A non-zero *etol* means that the GNEB calculation will terminate if the energy criterion is met by every replica. The energies being compared to *etol* do not include any contribution from the inter-replica nudging forces, since these are non-conservative. A non-zero *ttol* means that the GNEB calculation will terminate if the torque criterion is met by every replica. The torques being compared to *ttol* include the inter-replica nudging forces.

The maximum number of iterations in each stage is set by *N1* and *N2*. These are effectively timestep counts since each iteration of damped dynamics is like a single timestep in a dynamics *run*. During both stages, the potential energy of each replica and its normalized distance along the reaction path (reaction coordinate RD) will be printed to the screen and log file every *Nevery* timesteps. The RD is 0 and 1 for the first and last replica. For intermediate replicas, it is the cumulative angular distance (normalized by the total cumulative angular distance) between adjacent replicas, where "distance" is defined as the length of the 3N-vector of the geodesic distances in spin coordinates, with N the number of GNEB spins involved (see equation (13) in *(Bessarab)*). These outputs allow you to monitor NEB's progress in finding a good energy barrier. *N1* and *N2* must both be multiples of *Nevery*.

In the first stage of GNEB, the set of replicas should converge toward a minimum energy path (MEP) of conformational states that transition over a barrier. The MEP for a transition is defined as a sequence of 3N-dimensional spin states, each of which has a potential energy gradient parallel to the MEP itself. The configuration of highest energy along a MEP corresponds to a saddle point. The replica states will also be roughly equally spaced along the MEP due to the inter-replica nudging force added by the *fix neb* command.

In the second stage of GNEB, the replica with the highest energy is selected and the inter-replica forces on it are converted to a force that drives its spin coordinates to the top or saddle point of the barrier, via the barrier-climbing calculation described in *(Bessarab)*. As before, the other replicas rearrange themselves along the MEP so as to be roughly equally spaced.

When both stages are complete, if the GNEB calculation was successful, the configurations of the replicas should be along (close to) the MEP and the replica with the highest energy should be a spin configuration at (close to) the saddle point of the transition. The potential energies for the set of replicas represents the energy profile of the transition along the MEP.

An atom map must be defined which it is not by default for *atom_style atomic* problems. The *atom_modify map* command can be used to do this.

An initial value can be defined for the timestep. Although, the *spin* minimization algorithm is an adaptive timestep methodology, so that this timestep is likely to evolve during the calculation.

The minimizers in LAMMPS operate on all spins in your system, even non-GNEB atoms, as defined above.

Each file read by the neb/spin command containing spin coordinates used to initialize one or more replicas must be formatted as follows.

The file can be ASCII text or a gzipped text file (detected by a .gz suffix). The file can contain initial blank lines or comment lines starting with "#" which are ignored. The first non-blank, non-comment line should list N = the number of lines to follow. The N successive lines contain the following information:

```
ID1 g1 x1 y1 z1 sx1 sy1 sz1
ID2 g2 x2 y2 z2 sx2 sy2 sz2
...
IDN gN yN zN sxN syN szN
```

The fields are the atom ID, the norm of the associated magnetic spin, followed by the *x,y,z* coordinates and the *sx,sy,sz* spin coordinates. The lines can be listed in any order. Additional trailing information on the line is OK, such as a comment.

Note that for a typical GNEB calculation you do not need to specify initial spin coordinates for very many atoms to produce differing starting and final replicas whose intermediate replicas will converge to the energy barrier. Typically only new spin coordinates for atoms geometrically near the barrier need be specified.

Also note there is no requirement that the atoms in the file correspond to the GNEB atoms in the group defined by the *fix neb* command. Not every GNEB atom need be in the file, and non-GNEB atoms can be listed in the file.

Four kinds of output can be generated during a GNEB calculation: energy barrier statistics, thermodynamic output by each replica, dump files, and restart files.

When running with multiple partitions (each of which is a replica in this case), the print-out to the screen and master log.lammps file contains a line of output, printed once every *Nevery* timesteps. It contains the timestep, the maximum torque per replica, the maximum torque per atom (in any replica), potential gradients in the initial, final, and climbing replicas, the forward and backward energy barriers, the total reaction coordinate (RDT), and the normalized reaction coordinate and potential energy of each replica.

The "maximum torque per replica" is the two-norm of the 3N-length vector given by the cross product of a spin by its precession vector omega, in each replica, maximized across replicas, which is what the *ttol* setting is checking against. In this case, N is all the atoms in each replica. The "maximum torque per atom" is the maximum torque component of any atom in any replica. The potential gradients are the two-norm of the 3N-length magnetic precession vector

solely due to the interaction potential i.e. without adding in inter-replica forces, and projected along the path tangent (as detailed in Appendix D of *(Bessarab)*).

The "reaction coordinate" (RD) for each replica is the two-norm of the 3N-length vector of geodesic distances between its spins and the preceding replica's spins (see equation (13) of *(Bessarab)*), added to the RD of the preceding replica. The RD of the first replica RD1 = 0.0; the RD of the final replica RDN = RDT, the total reaction coordinate. The normalized RDs are divided by RDT, so that they form a monotonically increasing sequence from zero to one. When computing RD, N only includes the spins being operated on by the fix neb/spin command.

The forward (reverse) energy barrier is the potential energy of the highest replica minus the energy of the first (last) replica.

Supplementary information for all replicas can be printed out to the screen and master log.lammps file by adding the *verbose* keyword. This information include the following. The "GradVidottan" are the projections of the potential gradient for the replica i on its tangent vector (as detailed in Appendix D of *(Bessarab)*). The "DNi" are the non normalized geodesic distances (see equation (13) of *(Bessarab)*), between a replica i and the next replica i+1. For the last replica, this distance is not defined and a "NAN" value is the corresponding output.

When a NEB calculation does not converge properly, the supplementary information can help understanding what is going wrong.

When running on multiple partitions, LAMMPS produces additional log files for each partition, e.g. log.lammps.0, log.lammps.1, etc. For a GNEB calculation, these contain the thermodynamic output for each replica.

If *dump* commands in the input script define a filename that includes a *universe* or *uloop* style *variable*, then one dump file (per dump command) will be created for each replica. At the end of the GNEB calculation, the final snapshot in each file will contain the sequence of snapshots that transition the system over the energy barrier. Earlier snapshots will show the convergence of the replicas to the MEP.

Likewise, *restart* filenames can be specified with a *universe* or *uloop* style *variable*, to generate restart files for each replica. These may be useful if the GNEB calculation fails to converge properly to the MEP, and you wish to restart the calculation from an intermediate point with altered parameters.

A c file script in provided in the tool/spin/interpolate_gneb directory, that interpolates the MEP given the information provided by the *verbose* output option (as detailed in Appendix D of *(Bessarab)*).

1.69.4 Restrictions

This command can only be used if LAMMPS was built with the SPIN package. See the *Build package* doc page for more info.

For magnetic GNEB calculations, only the *spin_none* value for the *line* keyword can be used when minimization styles *spin/cg* and *spin/lbfgs* are employed.

1.70 neigh_modify command

1.70.1 Syntax

```
neigh_modify keyword values ...
```

- one or more keyword/value pairs may be listed

```
keyword = delay or every or check or once or cluster or include or exclude or page␣
↪or one or binsize or collection/type or collection/interval
  delay value = N
    N = delay building neighbor lists until this many steps since last build
  every value = M
    M = consider building neighbor lists every this many steps
  check value = yes or no
    yes = only build if at least one atom has moved half the skin distance or more
    no = always build on 1st step where every and delay are conditions are satisfied
  once value = yes or no
    yes = only build neighbor list once at start of run and never rebuild
    no = rebuild neighbor list according to other settings
  cluster value = yes or no
    yes = check bond,angle,etc neighbor list for nearby clusters
    no = do not check bond,angle,etc neighbor list for nearby clusters
  include value = group-ID
    group-ID = only build pair neighbor lists for atoms in this group
  exclude values:
    type M N
      M,N = exclude if one atom in pair is type M, other is type N (M and N may be␣
↪type labels)
    group group1-ID group2-ID
      group1-ID,group2-ID = exclude if one atom is in 1st group, other in 2nd
    molecule/intra group-ID
      group-ID = exclude if both atoms are in the same molecule and in group
    molecule/inter group-ID
      group-ID = exclude if both atoms are in different molecules and in group
    none
      delete all exclude settings
  page value = N
    N = number of pairs stored in a single neighbor page
  one value = N
    N = max number of neighbors of one atom
  binsize value = size
    size = bin size for neighbor list construction (distance units)
  collection/type values = N arg1 ... argN
    N = number of custom collections
    arg = N separate lists of types (see below)
  collection/interval values = N arg1 ... argN
    N = number of custom collections
    arg = N separate cutoffs for intervals (see below)
  bin/hash value = yes or no
    yes = use a hash table to store atoms in bins
    no = use a linked list to store atoms in bins
```

1.70.2 Examples

```
neigh_modify every 2 delay 10 check yes page 100000

neigh_modify exclude molecule/intra rigid
neigh_modify collection/type 2 1*2,5 3*4
neigh_modify collection/interval 2 1.0 10.0
```

1.70.3 Description

This command sets parameters that affect the building and use of pairwise neighbor lists. Depending on what pair interactions and other commands are defined, a simulation may require one or more neighbor lists.

The *every*, *delay*, *check*, and *once* options affect how often lists are built as a simulation runs. The *delay* setting means never build new lists until at least N steps after the previous build. The *every* setting means attempt to build lists every M steps (after the delay has passed). If the *check* setting is *no*, the lists are built on the first step that satisfies the *delay* and *every* settings. If the *check* setting is *yes*, then the *every* and *delay* settings determine when a build may possibly be performed, but an actual build only occurs if at least one atom has moved more than half the neighbor skin distance (specified in the *neighbor* command) since the last neighbor list build.

Regardless of the *every*, *delay*, *check*, and *once* settings, a neighbor list rebuild is always forced on any timestep when a *restart* file is written, and on timesteps when a fix requests reneighboring (e.g. fixes that create or delete atoms, such as *fix deposit* or *fix evaporate*). This ensures that all atoms are correctly assigned to their owning subdomains before the operation is performed. A consequence is that enabling *restart* output can change the total number of neighbor list builds reported at the end of a run (and thus, as noted below, subtly alter the trajectory) relative to an otherwise identical run without restart output.

Impact of neighbor list settings

The choice of neighbor list settings can have a significant impact on the (parallel) performance of LAMMPS and the correctness of the simulation results. Since building the neighbor lists is time consuming, doing it less frequently can speed up a calculation. If the lists are rebuilt too infrequently, however, interacting pairs may be missing and thus the resulting pairwise interactions incorrect. The optimal settings depend on many factors like the properties of the simulated system (density, geometry, topology, temperature, pressure), the force field parameters and settings, the size of the timestep, neighbor list skin distance and more. The default settings are chosen to be very conservative to guarantee correctness of the simulation. They depend on the *check* flag heuristics to reduce the number of neighbor list rebuilds at a minor expense for executing the check. Determining the correctness of a specific choice of neighbor list settings is complicated by the fact that a neighbor list rebuild changes the order in which pairwise interactions are computed and thus - due to the limitations of floating-point math - the trajectory.

If the *once* setting is yes, then the neighbor list is only built once at the beginning of each run, and never rebuilt, except for the forced rebuilds described above (when a restart file is written or a fix requests reneighboring). This setting should only be made if you are certain atoms will not move far enough that the neighbor list should be rebuilt, e.g. running a simulation of a cold crystal. Note that it is not that expensive to check if neighbor lists should be rebuilt.

When the rRESPA integrator is used (see the *run_style* command), the *every* and *delay* parameters refer to the longest (outermost) timestep.

The *cluster* option does a sanity test every time neighbor lists are built for bond, angle, dihedral, and improper interactions, to check that each set of 2, 3, or 4 atoms is a cluster of nearby atoms. It does this by computing the distance between pairs of atoms in the interaction and ensuring they are not further apart than half the periodic box length. If they are, an error is generated, since the interaction would be computed between far-away atoms instead of their nearby periodic images. The only way this should happen is if the pairwise cutoff is so short that atoms that are part of the

same interaction are not communicated as ghost atoms. This is an unusual model (e.g. no pair interactions at all) and the problem can be fixed by use of the *comm_modify cutoff* command. Note that to save time, the default *cluster* setting is *no*, so that this check is not performed.

The *include* option limits the building of pairwise neighbor lists to atoms in the specified group. This can be useful for models where a large portion of the simulation is particles that do not interact with other particles or with each other via pairwise interactions. The group specified with this option must also be specified via the *atom_modify first* command. Note that specifying "all" as the group-ID effectively turns off the *include* option.

The *exclude* option turns off pairwise interactions between certain pairs of atoms, by not including them in the neighbor list. These are sample scenarios where this is useful:

- In crack simulations, pairwise interactions can be shut off between 2 slabs of atoms to effectively create a crack.
- When a large collection of atoms is treated as frozen, interactions between those atoms can be turned off to save needless computation. E.g. Using the *fix setforce* command to freeze a wall or portion of a bio-molecule.
- When one or more rigid bodies are specified, interactions within each body can be turned off to save needless computation. See the *fix rigid* command for more details.

Changed in version 29Aug2024: Support for type labels was added.

The *exclude type* option turns off the pairwise interaction if one atom is of type M and the other of type N. M can equal N. The *exclude group* option turns off the interaction if one atom is in the first group and the other is the second. Group1-ID can equal group2-ID. The *exclude molecule/intra* option turns off the interaction if both atoms are in the specified group and in the same molecule, as determined by their molecule ID. The *exclude molecule/inter* turns off the interaction between pairs of atoms that have different molecule IDs and are both in the specified group.

Each of the exclude options can be specified multiple times. The *exclude type* option is the most efficient option to use; it requires only a single check, no matter how many times it has been specified. The other exclude options are more expensive if specified multiple times; they require one check for each time they have been specified.

Note that the exclude options only affect pairwise interactions; see the *delete_bonds* command for information on turning off bond interactions.

Note

Excluding pairwise interactions will not work correctly when also using a long-range solver via the *kspace_style* command. LAMMPS will give a warning to this effect. This is because the short-range pairwise interaction needs to subtract off a term from the total energy for pairs whose short-range interaction is excluded, to compensate for how the long-range solver treats the interaction. This is done correctly for pairwise interactions that are excluded (or weighted) via the *special_bonds* command. But it is not done for interactions that are excluded via these neigh_modify exclude options.

The *page* and *one* options affect how memory is allocated for the neighbor lists. For most simulations the default settings for these options are fine, but if a very large problem is being run or a very long cutoff is being used, these parameters can be tuned. The indices of neighboring atoms are stored in "pages", which are allocated one after another as they fill up. The size of each page is set by the *page* value. A new page is allocated when the next atom's neighbors could potentially overflow the list. This threshold is set by the *one* value which tells LAMMPS the maximum number of neighbor's one atom can have.

Note

LAMMPS can crash without an error message if the number of neighbors for a single particle is larger than the *page* setting, which means it is much, much larger than the *one* setting. This is because LAMMPS does not error check these limits for every pairwise interaction (too costly), but only after all the particle's neighbors have been found. This problem usually means something is very wrong with the way you have setup your problem (particle spacing,

cutoff length, neighbor skin distance, etc). If you really expect that many neighbors per particle, then boost the *one* and *page* settings accordingly.

The *binsize* option allows you to specify what size of bins will be used in neighbor list construction to sort and find neighboring atoms. By default, for *neighbor style bin*, LAMMPS uses bins that are 1/2 the size of the maximum pair cutoff. For *neighbor style multi*, the bins are 1/2 the size of the collection interaction cutoff. Typically these are good values for minimizing the time for neighbor list construction. This setting overrides the default. If you make it too big, there is little overhead due to looping over bins, but more atoms are checked. If you make it too small, the optimal number of atoms is checked, but bin overhead goes up. If you set the binsize to 0.0, LAMMPS will use the default binsize of 1/2 the cutoff.

The *collection/type* option allows you to define collections of atom types, used by the *multi* neighbor mode. By grouping atom types with similar physical size or interaction cutoff lengths, one may be able to improve performance by reducing overhead. You must first specify the number of collections N to be defined followed by N lists of types. Each list consists of a series of type ranges separated by commas. The range can be specified as a single numeric value, or a wildcard asterisk can be used to specify a range of values. This takes the form "*" or "*n" or "n*" or "m*n". For example, if M = the number of atom types, then an asterisk with no numeric values means all types from 1 to M. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to M (inclusive). A middle asterisk means all types from m to n (inclusive). Note that all atom types must be included in exactly one of the N collections.

The *collection/interval* option provides a similar capability. This command allows a user to define collections by specifying a series of cutoff intervals. LAMMPS will automatically sort atoms into these intervals based on their type-dependent cutoffs or their finite size. You must first specify the number of collections N to be defined followed by N values representing the upper cutoff of each interval. This command is particularly useful for granular pair styles where the interaction distance of particles depends on their radius and may not depend on their atom type.

Added in version 4Jul2026.

The *bin/hash* option toggles whether the atoms in a bin are stored in a linked list (default) or a hash table where each bin is a key that maps to a set of all atoms contained in that bin. This may be required when the simulation box is too large relative to the size of a neighbor bin (which will cause LAMMPS to error), but will also reduce memory usage and can improve performance in systems with lots of bins that do not contain atoms. For instance, in a binary system with a large disparity in atom sizes/cutoffs. Here, the total number of bins will be determined by the size of the smallest particle. However, almost all bins that lie within the span of the largest particle will be empty. The hash option is only available for the *multi* neighbor mode.

If this option is used to avoid errors regarding the number of bins used to construct neighbor lists, one may need to additionally increase the size of the bin used to sort atoms using the *atom_modify* command. If adjusted, it is recommended to keep the increase conservative such that bins are still reasonably small to preserve performance.

1.70.4 Restrictions

If the *delay* setting is non-zero, then it must be a multiple of the *every* setting.

The *molecule/intra* and *molecule/inter* exclusion options can only be used with atom styles that define molecule IDs.

The value of the *page* setting must be at least 10x larger than the *one* setting. This ensures neighbor pages are not mostly empty space.

The *exclude group* setting is currently not compatible with dynamic groups.

1.70.5 Related commands

neighbor, *delete_bonds*

1.70.6 Default

The option defaults are delay = 0, every = 1, check = yes, once = no, cluster = no, include = all (same as no include option defined), exclude = none, page = 100000, one = 2000, bin/hash no, and binsize = 0.0.

1.71 neighbor command

1.71.1 Syntax

```
neighbor skin style
```

- skin = extra distance beyond force cutoff (distance units)
- style = *bin* or *nsq* or *multi*

1.71.2 Examples

```
neighbor 0.3 bin
neighbor 2.0 nsq
```

1.71.3 Description

This command sets parameters that affect the building of pairwise neighbor lists. All atom pairs within a neighbor cutoff distance equal to the their force cutoff plus the *skin* distance are stored in the list. Typically, the larger the skin distance, the less often neighbor lists need to be built, but more pairs must be checked for possible force interactions every timestep. The default value for *skin* depends on the choice of units for the simulation; see the default values below.

The *skin* distance is also used to determine how often atoms migrate to new processors if the *check* option of the *neigh_modify* command is set to *yes*. Atoms are migrated (communicated) to new processors on the same timestep that neighbor lists are re-built.

The *style* value selects what algorithm is used to build the list. The *bin* style creates the list by binning which is an operation that scales linearly with N/P, the number of atoms per processor where N = total number of atoms and P = number of processors. It is almost always faster than the *nsq* style which scales as (N/P)^2. For unsolvated small molecules in a non-periodic box, the *nsq* choice can sometimes be faster. Either style should give the same answers.

The *multi* style is a modified binning algorithm that is useful for systems with a wide range of cutoff distances, e.g. due to different size particles. For granular pair styles, cutoffs are set to the sum of the maximum atomic radii for each atom type. For the *bin* style, the bin size is set to 1/2 of the largest cutoff distance between any pair of atom types and a single set of bins is defined to search over for all atom types. This can be inefficient if one pair of types has a very long cutoff, but other type pairs have a much shorter cutoff. The *multi* style uses different sized bins for collections of different sized particles, where "size" may mean the physical size of the particle or its cutoff distance for interacting with other particles. Different sets of bins are then used to construct the neighbor lists as as further described by Shire, Hanley, and Stratford *(Shire)* and Monti et al. *(Monti)*. This imposes some extra setup overhead, but the searches themselves may be much faster.

For instance in a dense binary system in d-dimensions with a ratio of the size of the largest to smallest collection bin λ, the computational costs of building a default neighbor list grows as λ^{2d} while the costs for *multi* grows as λ^{d}, equivalent to the cost of force evaluations, as argued in Monti et al. *(Monti)*. In other words, the neighboring costs of *multi* are expected to scale the same as force calculations, such that its relative cost is independent of the particle size ratio. This is not the case for the default style which becomes substantially more expensive with increasing size ratios.

By default in *multi*, each atom type defines a separate collection of particles. For systems where two or more atom types have the same size (either physical size or cutoff distance), the definition of collections can be customized, which

can result in less overhead and faster performance. See the *neigh_modify* command for how to define custom collections. Whether the collection definition is customized or not, also see the *comm_modify mode multi* command for communication options that further improve performance in a manner consistent with neighbor style multi.

Note

If there are multiple sub-styles in a *hybrid/overlay pair style* that cover the same atom types, but have significantly different cutoffs, the *multi* style does not apply. Instead, the *pair_modify neigh/trim* setting applies (which is *yes* by default). Please check the neighbor list summary printed at the beginning of a calculation to verify that the desired set of neighbor list builds is performed.

The *neigh_modify* command has additional options that control how often neighbor lists are built and which pairs are stored in the list.

When a run is finished, counts of the number of neighbors stored in the pairwise list and the number of times neighbor lists were built are printed to the screen and log file. See the *Run output* page for details.

1.72 newton command

1.72.1 Syntax

```
newton flag
newton flag1 flag2
```

- flag = *on* or *off* for both pairwise and bonded interactions
- flag1 = *on* or *off* for pairwise interactions
- flag2 = *on* or *off* for bonded interactions

1.72.2 Examples

```
newton off
newton on off
```

1.72.3 Description

This command turns Newton's third law *on* or *off* for pairwise and bonded interactions. For most problems, setting Newton's third law to *on* means a modest savings in computation at the cost of two times more communication. Whether this is faster depends on problem size, force cutoff lengths, a machine's compute/communication ratio, and how many processors are being used.

Setting the pairwise newton flag to *off* means that if two interacting atoms are on different processors, both processors compute their interaction and the resulting force information is not communicated. Similarly, for bonded interactions, newton *off* means that if a bond, angle, dihedral, or improper interaction contains atoms on 2 or more processors, the interaction is computed by each processor.

LAMMPS should produce the same answers for any newton flag settings, except for round-off issues.

With *run_style* *respa* and only bonded interactions (bond, angle, etc) computed in the innermost timestep, it may be faster to turn newton *off* for bonded interactions, to avoid extra communication in the innermost loop.

1.72.4 Restrictions

The newton bond setting cannot be changed after the simulation box is defined by a *read_data* or *create_box* command.

1.73 next command

1.73.1 Syntax

```
next variables
```

- variables = one or more variable names

1.73.2 Examples

```
next x
next a t x myTemp
```

1.73.3 Description

This command is used with variables defined by the *variable* command. It assigns the next value to the variable from the list of values defined for that variable by the *variable* command. Thus when that variable is subsequently substituted for in an input script command, the new value is used.

See the *variable* command for info on how to define and use different kinds of variables in LAMMPS input scripts. If a variable name is a single lower-case character from "a" to "z", it can be used in an input script command as $a or $z. If it is multiple letters, it can be used as ${myTemp}.

If multiple variables are used as arguments to the *next* command, then all must be of the same variable style: *index*, *loop*, *file*, *universe*, or *uloop*. An exception is that *universe*- and *uloop*-style variables can be mixed in the same *next* command.

All the variables specified with the next command are incremented by one value from their respective list of values. A *file*-style variable reads the next line from its associated file. An *atomfile*-style variable reads the next set of lines (one per atom) from its associated file. *String*- or *atom*- or *equal*- or *world*-style variables cannot be used with the next command, since they only store a single value.

When any of the variables in the next command has no more values, a flag is set that causes the input script to skip the next *jump* command encountered. This enables a loop containing a next command to exit. As explained in the *variable* command, the variable that has exhausted its values is also deleted. This allows it to be used and re-defined later in the input script. *File*-style and *atomfile*-style variables are exhausted when the end-of-file is reached.

When the next command is used with *index*- or *loop*-style variables, the next value is assigned to the variable for all processors. When the next command is used with *file*-style variables, the next line is read from its file and the string assigned to the variable. When the next command is used with *atomfile*-style variables, the next set of per-atom values is read from its file and assigned to the variable.

When the next command is used with *universe*- or *uloop*-style variables, all *universe*- or *uloop*-style variables must be listed in the next command. This is because of the manner in which the incrementing is done, using a single lock file for all variables. The next value (for each variable) is assigned to whichever processor partition executes the command first. All processors in the partition are assigned the same value(s). Running LAMMPS on multiple partitions of processors via the *-partition command-line switch*. *Universe*- and *uloop*-style variables are incremented using the files "tmp.lammps.variable" and "tmp.lammps.variable.lock" which you will see in your directory during and after such a LAMMPS run.

Here is an example of running a series of simulations using the next command with an *index*-style variable. If this input script is named in.polymer, 8 simulations would be run using data files from directories run1 through run8.

```
variable d index run1 run2 run3 run4 run5 run6 run7 run8
shell cd $d
read_data data.polymer
run 10000
shell cd ..
clear
next d
jump in.polymer
```

If the variable "d" were of style *universe*, and the same in.polymer input script were run on 3 partitions of processors, then the first 3 simulations would begin, one on each set of processors. Whichever partition finished first, it would assign variable "d" the fourth value and run another simulation, and so forth until all 8 simulations were finished.

Jump and next commands can also be nested to enable multi-level loops. For example, this script will run 15 simulations in a double loop.

```
variable i loop 3
  variable j loop 5
  clear
  ...
  read_data data.polymer.$i$j
  print Running simulation $i.$j
  run 10000
```

(continues on next page)

(continued from previous page)

```
  next j
  jump in.script
next i
jump in.script
```

Here is an example of a double loop which uses the *if* and *jump* commands to break out of the inner loop when a condition is met, then continues iterating through the outer loop.

```
label       loopa
variable    a loop 5
  label     loopb
  variable  b loop 5
  print     "A,B = $a,$b"
  run       10000
  if        $b > 2 then "jump in.script break"
  next      b
  jump      in.script loopb
label       break
variable    b delete

next        a
jump        in.script loopa
```

1.74.2 Examples

```
package gpu 0
package gpu 0 omp 2 device_type intelgpu
package kokkos neigh half comm device
package omp 0 neigh no
package omp 4
package intel 1
package intel 2 omp 4 mode mixed
```

1.74.3 Description

This command invokes package-specific settings for the various accelerator packages available in LAMMPS. Currently the following packages use settings from this command: GPU, INTEL, KOKKOS, and OPENMP.

If this command is specified in an input script, it must be near the top of the script, before the simulation box has been

defined. This is because it specifies settings that the accelerator packages use in their initialization, before a simulation is defined.

This command can also be specified from the command-line when launching LAMMPS, using the "-pk" *command-line switch*. The syntax is exactly the same as when used in an input script.

Note that all of the accelerator packages require the package command to be specified (except the OPT package), if the package is to be used in a simulation (LAMMPS can be built with an accelerator package without using it in a particular simulation). However, in all cases, a default version of the command is typically invoked by other accelerator settings.

The KOKKOS package requires a "-k on" *command-line switch* respectively, which invokes a "package kokkos" command with default settings.

For the GPU, INTEL, and OPENMP packages, if a "-sf gpu" or "-sf intel" or "-sf omp" *command-line switch* is used to auto-append accelerator suffixes to various styles in the input script, then those switches also invoke a "package gpu", "package intel", or "package omp" command with default settings.

Note

A package command for a particular style can be invoked multiple times when a simulation is setup, e.g. by the *-c on, -k on, -sf, and -pk command-line switches*, and by using this command in an input script. Each time it is used all of the style options are set, either to default values or to specified settings. I.e. settings from previous invocations do not persist across multiple invocations.

See the *Accelerator packages* page for more details about using the various accelerator packages for speeding up LAMMPS simulations.

GPU package settings

The *gpu* style invokes settings associated with the use of the *GPU package*.

The *Ngpu* argument sets the number of GPUs per node. If *Ngpu* is 0 and no other keywords are specified, GPU or accelerator devices are auto-selected. In this process, all platforms are searched for accelerator devices and GPUs are chosen if available. The device with the highest number of compute cores is selected. The number of devices is increased to be the number of matching accelerators with the same number of compute cores. If there are more devices than MPI tasks, the additional devices will be unused. The auto-selection of GPUs/ accelerator devices and platforms can be restricted by specifying a non-zero value for *Ngpu* and / or using the *gpuID*, *platform*, and *device_type* keywords as described below. If there are more MPI tasks (per node) than GPUs, multiple MPI tasks will share each GPU.

Optional keyword/value pairs can also be specified. Each has a default value as listed below.

Changed in version 10Dec2025: Updated description to the current state of the GPU package

The *neigh* keyword specifies where neighbor lists for pair style computation will be built. If *neigh* is *yes*, which is the default, neighbor list building is performed on the GPU. If *neigh* is *no*, neighbor list building is instead performed on the CPU. If *neigh* is *hybrid* the binning step of the neighbor list build is performed on the CPU and the list themselves on the GPU. GPU neighbor list building currently is not fully compatible with a triclinic box; if the behavior is significantly different from the CPU case, use the *neigh no* setting. GPU neighbor lists are not accessible for commands that are not GPU-enabled. When a non-GPU enabled command requires a neighbor list, it will be built on the CPU. In these cases, it can be more efficient to only use CPU neighbor list builds, particularly if the CPU neighbor list is perpetual, i.e. used in every step. If a GPU environment does not support building neighbor lists on the GPU, the default setting it will automatically change to *neigh no*.

The *newton* keyword sets the Newton flags for pairwise (not bonded) interactions to *off* or *on*, the same as the *newton* command allows. If this keyword is not used, the pairwise Newton setting is left unchanged, that is it keeps the value selected by the *newton* command, which is *on* by default. A setting of *off* causes more computation but less communication. Note that the newton setting for bonded interactions is not affected by this keyword.

Changed in version 2Sep2026.

A pairwise Newton setting of *on* is no longer restricted. Previously, combining it with a *split* value of less than 1.0 was an error, because the host/device particle-split load balancing required the setting to be *off*. That load balancing has been removed, so the restriction no longer applies.

The *pair/only* keyword can change how any "gpu" suffix is applied. By default a suffix is applied to all styles for which an accelerated variant is available. However, that is not always the most effective way to use an accelerator w. With *pair/only* set to *on* the suffix will only by applied to supported pair styles, which tend to be the most effective in using an accelerator and their operation can be overlapped with all other computations on the CPU.

The *binsize* keyword sets the size of bins used to bin atoms in neighbor list builds performed on the GPU, if *neigh* = *yes* is set. If *binsize* is set to 0.0 (the default), then the binsize is set automatically using heuristics in the GPU package.

The *split* keyword is deprecated and its value is ignored. The GPU package formerly supported offloading a fraction of pair force calculations to the CPU concurrently with the GPU; this host/device particle-split load-balancing has been removed. All pair force calculations for GPU-accelerated styles are now performed entirely on the GPU. Other computations (*bond*, *angle*, *dihedral*, *improper*, and *long-range*) still run on the CPU concurrently with the GPU pair force calculation, which is the primary source of GPU/CPU overlap performance.

Changed in version 2Sep2026: The *split* keyword is deprecated; its value is ignored.

The *gpuID* keyword is used to specify the first ID for the GPU or other accelerator that LAMMPS will use. For example, if the ID is 1 and *Ngpu* is 3, GPUs 1-3 will be used. Device IDs should be determined from the output of nvc_get_devices, ocl_get_devices, or hip_get_devices as provided in the lib/gpu directory. When using OpenCL with accelerators that have main memory NUMA, the accelerators can be split into smaller virtual accelerators for more efficient use with MPI.

The *tpa* keyword sets the number of GPU vector lanes per atom used to perform force calculations. With a default value of 1, the number of lanes will be chosen based on the pair style, however, the value can be set explicitly with this keyword to fine-tune performance. For large cutoffs or with a small number of particles per GPU, increasing the value can improve performance. The number of lanes per atom must be a power of 2 and currently cannot be greater than the SIMD width for the GPU / accelerator. In the case it exceeds the SIMD width, it will automatically be decreased to meet the restriction.

The *blocksize* keyword allows you to tweak the number of threads used per thread block. This number should be a multiple of 32 (for GPUs) and its maximum depends on the specific GPU hardware. Typical choices are 64, 128, or 256. A larger block size increases occupancy of individual GPU cores, but reduces the total number of thread blocks, thus may lead to load imbalance. On modern hardware, the sensitivity to the blocksize is typically low.

The *Nthreads* value for the *omp* keyword sets the number of OpenMP threads allocated for each MPI task. This setting controls OpenMP parallelism only for routines run on the CPUs. For more details on setting the number of OpenMP threads, see the discussion of the *Nthreads* setting on this page for the "package omp" command. The meaning of *Nthreads* is exactly the same for the GPU, INTEL, and GPU packages.

The *platform* keyword is only used with OpenCL to specify the ID for an OpenCL platform. See the output from ocl_get_devices in the lib/gpu directory. In LAMMPS only one platform can be active at a time and by default (id=-1) the platform is auto-selected to find the GPU with the most compute cores. When *Ngpu* or other keywords are specified, the auto-selection is appropriately restricted. For example, if *Ngpu* is 3, only platforms with at least 3 accelerators are considered. Similar restrictions can be enforced by the *gpuID* and *device_type* keywords.

The *device_type* keyword can be used for OpenCL to specify the type of GPU to use or specify a custom configuration for an accelerator. In most cases this selection will be automatic and there is no need to use the keyword. The *applegpu* type is not specific to a particular GPU vendor, but is separate due to the more restrictive Apple OpenCL implementation. For expert users, to specify a custom configuration, the *custom* keyword followed by the next parameters can be specified:

CONFIG_ID, SIMD_SIZE, MEM_THREADS, SHUFFLE_AVAIL, FAST_MATH, THREADS_PER_ATOM, THREADS_PER_CHARGE, THREADS_PER_THREE, BLOCK_PAIR, BLOCK_BIO_PAIR, BLOCK_ELLIPSE,

PPPM_BLOCK_1D, BLOCK_NBOR_BUILD, BLOCK_CELL_2D, BLOCK_CELL_ID, MAX_SHARED_TYPES, MAX_BIO_SHARED_TYPES, PPPM_MAX_SPLINE, NBOR_PREFETCH.

CONFIG_ID can be 0. SHUFFLE_AVAIL in {0,1} indicates that inline-PTX (NVIDIA) or OpenCL extensions (Intel) should be used for horizontal vector operations. FAST_MATH in {0,1} indicates that OpenCL fast math optimizations are used during the build and hardware-accelerated transcendental functions are used when available. THREADS_PER_* give the default *tpa* values for ellipsoidal models, styles using charge, and any other styles. The BLOCK_* parameters specify the block sizes for various kernel calls and the MAX_*SHARED_* parameters are used to determine the amount of local shared memory to use for storing model parameters.

For OpenCL, the routines are compiled at runtime for the specified GPU or accelerator architecture. The *ocl_args* keyword can be used to specify additional flags for the runtime build.

INTEL package settings

The *intel* style invokes settings associated with the use of the INTEL package.

Removed in version 4Jul2026.

Support for offloading to Intel(R) Xeon Phi(TM) co-processors was removed. The leading numeric argument (formerly the number of co-processors per node) is ignored.

Optional keyword/value pairs can also be specified. Each has a default value as listed below.

The *Nthreads* value for the *omp* keyword sets the number of OpenMP threads allocated for each MPI task. This setting controls OpenMP parallelism only for routines run on the CPUs. For more details on setting the number of OpenMP threads, see the discussion of the *Nthreads* setting on this page for the "package omp" command. The meaning of *Nthreads* is exactly the same for the GPU, INTEL, and GPU packages.

The *mode* keyword determines the precision mode to use for computing pair style forces on the CPU when using a INTEL supported *pair style*. It can take a value of *single*, *mixed* which is the default, or *double*. *Single* means single precision is used for the entire force calculation. *Mixed* means forces between a pair of atoms are computed in single precision, but accumulated and stored in double precision, including storage of forces, torques, energies, and virial quantities. *Double* means double precision is used for the entire force calculation.

The *lrt* keyword can be used to enable "Long Range Thread (LRT)" mode. It can take a value of *yes* to enable and *no* to disable. LRT mode generates an extra thread (in addition to any OpenMP threads specified with the OMP_NUM_THREADS environment variable or the *omp* keyword). The extra thread is dedicated for performing part of the *PPPM solver* computations and communications. This can improve parallel performance on processors supporting Simultaneous Multithreading (SMT) such as Hyper-Threading (HT) on Intel processors. In this mode, one additional thread is generated per MPI process. LAMMPS will generate a warning in the case that more threads are used than available in SMT hardware on a node. If the PPPM solver from the INTEL package is not used, then the LRT setting is ignored and no extra threads are generated. Enabling LRT will replace the *run_style* with the *verlet/lrt/intel* style that is identical to the default *verlet* style aside from supporting the LRT feature. This feature requires setting the pre-processor flag -DLMP_INTEL_USELRT in the makefile when compiling LAMMPS.

Added in version 15Jun2023.

The *pppm_table* keyword with the argument yes allows to use a pre-computed table to efficiently spread the charge to the PPPM grid. This feature is enabled by default but can be turned off using the keyword with the argument *no*.

KOKKOS package settings

The *kokkos* style invokes settings associated with the use of the KOKKOS package.

All of the settings are optional keyword/value pairs. Each has a default value as listed below.

The *neigh* keyword determines how neighbor lists are built. A value of *half* uses a thread-safe variant of half-neighbor lists, the same as used by most pair styles in LAMMPS, which is the default when running on CPUs (i.e. the Kokkos CUDA back end is not enabled).

A value of *full* uses a full neighbor lists and is the default when running on GPUs. This performs twice as much computation as the *half* option, however that is often a win because it is thread-safe and does not require atomic operations in the calculation of pair forces. For that reason, *full* is the default setting for GPUs. However, when running on CPUs, a *half* neighbor list is the default because it are often faster, just as it is for non-accelerated pair styles. Similarly, the *neigh/qeq* keyword determines how neighbor lists are built for *fix qeq/reaxff/kk*.

If the *neigh/thread* keyword is set to *off*, then the KOKKOS package threads only over atoms. However, for small systems, this may not expose enough parallelism to keep a GPU busy. When this keyword is set to *on*, the KOKKOS package threads over both atoms and neighbors of atoms. When using *neigh/thread on*, the *newton pair* setting must be "off". Using *neigh/thread on* may be slower for large systems, so this this option is turned on by default only when running on one or more GPUs and there are 16k atoms or less owned by an MPI rank. Not all KOKKOS-enabled potentials support this keyword yet, and only thread over atoms. Many simple pairwise potentials such as Lennard-Jones do support threading over both atoms and neighbors.

If the *neigh/transpose* keyword is set to *off*, then the KOKKOS package will use the same memory layout for building the neighbor list on GPUs as used for the pair style. When this keyword is set to *on* it will use a different (transposed) memory layout to build the neighbor list on GPUs. This can be faster in some cases (e.g. ReaxFF HNS benchmark) but slower in others (e.g. Lennard Jones benchmark). The copy between different memory layouts is done out of place and therefore doubles the memory overhead of the neighbor list, which can be significant.

The *newton* keyword sets the Newton flags for pairwise and bonded interactions to *off* or *on*, the same as the *newton* command allows. The default for GPUs is *off* because this will almost always give better performance for the KOKKOS package. This means more computation is done, but less communication. However, when running on CPUs a value of *on* is the default since it can often be faster, just as it is for non-accelerated pair styles

The *binsize* keyword sets the size of bins used to bin atoms during neighbor list builds. The same value can be set by the *neigh_modify binsize* command. Making it an option in the package kokkos command allows it to be set from the command-line. The default value for CPUs is 0.0, which means the LAMMPS default will be used, which is bins = 1/2 the size of the pairwise cutoff + neighbor skin distance. This is fine when neighbor lists are built on the CPU. For GPU builds, a 2x larger binsize equal to the pairwise cutoff + neighbor skin is often faster, which is the default. Note that if you use a longer-than-usual pairwise cutoff, e.g. to allow for a smaller fraction of KSpace work with a *long-range Coulombic solver* because the GPU is faster at performing pairwise interactions, then this rule of thumb may give too large a binsize and the default should be overridden with a smaller value.

The *comm* and *comm/exchange* and *comm/forward* and *comm/pair/forward* and *comm/fix/forward* and *comm/compute/forward* and *comm/reverse* and *comm/pair/reverse* and *comm/fix/reverse* keywords determine whether the host or device performs the packing and unpacking of data when communicating per-atom data between processors. "Exchange" communication happens only on timesteps that neighbor lists are rebuilt. The data is only for atoms that migrate to new processors. "Forward" communication happens every timestep. "Reverse" communication happens every timestep if the *newton* option is on. The data is for atom coordinates and any other atom properties that needs to be updated for ghost atoms owned by each processor. "Comm/pair" controls additional communication in pair styles, such as pair_style EAM. "Comm/fix" controls additional communication in fixes, such as fix SHAKE. Similarly, "comm/compute" controls additional communication in computes.

The *comm* keyword is simply a short-cut to set the same value for all the comm keywords.

The value options for the keywords are *no* or *host* or *device*. A value of *no* means to use the standard non-KOKKOS method of packing/unpacking data for the communication. A value of *host* means to use the host, typically a multicore CPU, and perform the packing/unpacking in parallel with threads. A value of *device* means to use the device, typically a GPU, to perform the packing/unpacking operation.

For the *comm/pair/forward* or *comm/fix/forward* or *comm/compute/forward* or *comm/pair/reverse* keywords, if a value of *host* is used it will be automatically be changed to *no* since these keywords don't support *host* mode. The value of *no* will also always be used when running on the CPU, i.e. setting the value to *device* will have no effect if the pair/fix style is running on the CPU. For the *comm/fix/forward* or *comm/compute/forward* or *comm/pair/reverse* or *comm/fix/reverse* keywords, not all styles support *device* mode and in that case will run in *no* mode instead.

The optimal choice for these keywords depends on the input script and the hardware used. The *no* value is useful for

verifying that the Kokkos-based *host* and *device* values are working correctly. It is the default when running on CPUs since it is usually the fastest.

When running on CPUs, the *host* and *device* values work identically. When using GPUs, the *device* value is the default since it will typically be optimal if all of your styles used in your input script are supported by the KOKKOS package. In this case data can stay on the GPU for many timesteps without being moved between the host and GPU, if you use the *device* value. If your script uses styles (e.g. fixes) which are not yet supported by the KOKKOS package, then data has to be moved between the host and device anyway, so it is typically faster to let the host handle communication, by using the *host* value. Using *host* instead of *no* will enable use of multiple threads to pack/unpack communicated data. When running small systems on a GPU, performing the exchange pack/unpack on the host CPU can give speedup since it reduces the number of CUDA kernel launches.

The *sort* keyword determines whether the host or device performs atom sorting, see the *atom_modify sort* command. The value options for the *sort* keyword are *no* or *device* similar to the *comm* keywords above. If a value of *host* is used it will be automatically be changed to *no* since the *sort* keyword does not support *host* mode. Not all fix styles with extra atom data support *device* mode and in that case a warning will be given and atom sorting will run in *no* mode instead.

Added in version 17Apr2024.

The *atom/map* keyword determines whether the host or device builds the atom_map, see the *atom_modify map* command. The value options for the *atom/map* keyword are identical to the *sort* keyword above.

The *gpu/aware* keyword chooses whether GPU-aware MPI will be used. When this keyword is set to *on*, buffers in GPU memory are passed directly through MPI send/receive calls. This reduces overhead of first copying the data to the host CPU. However GPU-aware MPI is not supported on all systems, which can lead to segmentation faults and would require using a value of *off*. If LAMMPS can safely detect that GPU-aware MPI is not available (currently only possible with OpenMPI v2.0.0 or later), then the *gpu/aware* keyword is automatically set to *off* by default. When the *gpu/aware* keyword is set to *off* while any of the *comm* keywords are set to *device*, the value for these *comm* keywords will be automatically changed to *no*. This setting has no effect if not running on GPUs or if using only one MPI rank. GPU-aware MPI is available for OpenMPI 1.8 (or later versions), Mvapich2 1.9 (or later) when the "MV2_USE_CUDA" environment variable is set to "1", CrayMPI, and IBM Spectrum MPI when the "-gpu" flag is used.

The *pair/only* keyword can change how the KOKKOS suffix "kk" is applied when using an accelerator device. By default device acceleration is always used for all available styles. With *pair/only* set to *on* the suffix setting will choose device acceleration only for pair styles and run all other force computations on the host CPU. The *comm* flags, along with the *sort* and *atom/map* keywords will also automatically be changed to *no*. This can result in better performance for certain configurations and system sizes.

The following parameters allow users to tune the overall performance depending on the simulated systems. If not explicitly specified, their values will be set internally by the KOKKOS package.

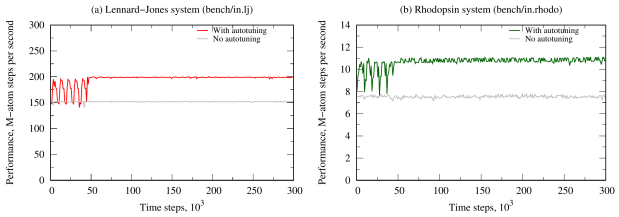
The *threads/per/atom* keyword sets the number of GPU vector lanes per atom used to perform force calculations. This keyword is only applicable when *neigh/thread* is set to *on*. For large cutoffs or with a small number of particles per GPU, increasing the value can improve performance. The number of lanes per atom must be a power of 2 and currently cannot be greater than the SIMD width for the GPU / accelerator. In the case it exceeds the SIMD width, it will automatically be decreased to meet the restriction.

The *pair/team/size* keyword sets the number of threads per block for the pair force compute kernel. This keyword is only applicable when *neigh/thread* is set to *on*. The default value of this parameter is determined based on the GPU architecture at runtime.

The *nbin/atoms/per/bin* keyword sets the number of atoms per bin used for the neighbor list builds on the GPU, which then determines the number of GPU threads per bin. The default value of this parameter is 16.

The *nbor/chunk/size* keyword sets the number of iterations that a work item is scheduled for the neighbor list builds on the GPU using the flat method (i.e., each thread finds the neighbor list of an atom). If not specified, the default value of this parameter is determined based on the GPU architecture at runtime.

The *bond/chunk/size* keyword sets the number of iterations that a work item is scheduled for the bond force kernel on the GPU. The default value of this parameter is determined based on the GPU architecture at runtime.



Added in version 4Jul2026.

The *auto/tuning* keyword enables the auto-tuning feature of the KOKKOS package when using GPUs. The following KOKKOS styles currently support auto-tuning:

- *bond/class2/kk*
- *bond/fene/kk*
- *bond/harmonic/kk*
- *lj/cut/kk*
- *lj/cut/coul/long/kk*
- *lj/charmm/coul/long/kk*
- *lj/cut/dipole/cut/kk*
- *dpd/kk*
- *sw/kk*
- *tersoff/kk*
- *zbl/kk*

These styles serve as templates for incorporating auto-tuners into other KOKKOS styles in the future. To avoid duplicated codes, one possibility is to refactor the tuners so that KOKKOS styles can request and enable them through a consistent API.

It is recommended that auto-tuning is enabled only when the simulated system is in steady state. The performance gain due to auto-tuning typically varies with the KOKKOS styles and the simulated system. For the benchmark systems *bench/in.lj* and *bench/in.rhodo*, the speedup vs without auto-tuning could be 30% and 50%, respectively (figure below).

When enabled, the tuner of the KOKKOS styles in use will scan through the possible values of kernel launch parameters, such as *pair/team/size threads/per/atom* for pair styles, *bond/chunk/size* for bond styles, and *nbin/atoms/per/bin* for neighbor builds. When the scanning completes, the tuner stores the best overall performance (in terms of the number of time steps per second) with the corresponding kernel launch parameter combination.

The tuner then uses the optimal parameter combination to launch the kernels on the GPU and monitors the simulation performance periodically. If the performance repeatedly drops below a certain relative tolerance from the last stored optimal value, the tuner may attempt to find the new optimal parameter combination by rerunning the scanning process.

There could be multiple tuners active in a run, for instance, when *bench/in.rhodo* is run on the GPUs, both *lj/charmm/coul/long/kk* and *bond/harmonic/kk* have their tuners activated. During the run, each tuner writes the current parameter combination and measured performance to a file named *tuning-[style-name].log*.

The following parameters are needed for the auto-tuning process.

> **nevery:** controls the interval used to estimate the overall performance for a combination of these two parameters. *nevery* needs to be large enough to have a stable estimate of the performance, to achieve a

sufficiently large number of kernel calls, while small enough to reduce the time required for scanning over all the combinations. *nevery* = 100 is usually a reasonable value.

nsamples: indicates the number of samples the tuners will collect for each parameter combination. *nsamples* = 5 is usually a reasonable value.

mode: determines how the performance of a collection of samples is *determined: max* means the maximum value, *ave* means the arithmetic *average value, and *median* means the median value.

reltol: sets the relative tolerance for performance degradation compared to the last optimal performance, which may trigger a re-scan of the parameter space. Setting *reltol* to be equal or greater than 1.0 will disable re-scanning.

For example, suppose that *nevery* = 100, *nsamples* = 5, *mode* = median and *reltol* = 0.2. For a typical pair style, the tuner scans over 90 parameter combinations (*pair/team/size*, *threads/per/atom*): 15 values of *pair/team/size* starting from 64 to 512 incremental by 32, and 6 values of *threads/per/atom*. For each parameter combination, the tuner monitors and saves the performance after 100 steps. When a scan over 90 combinations completes (9000 steps in this example), the best performance value is stored as a sample. After *nsamples* = 5 samples are collected, the median value is stored and the optimal parameter combination (*pair/team/size*, *threads/per/atom*) will be used for the next kernel launches. The figures above illustrate the simulation performance over time with auto-tuning using this setting for *bench/in.lj* (left panel) and *bench/in.rhodo* (right panel). The plateau regions correspond to the regime where the kernels are launched with the corresponding optimal parameter combinations.

Suppose that the last stored best performance is 1000 time steps per second. After the optimal parameter combination is locked in, the tuner keeps monitoring the performance every *nevery* = 100 time steps. If the performance drops below (1 - *reltol*) * 1000 = 800 time steps per second by *nsamples* = 5 times (not necessarily consecutively) the tuner will trigger a re-scanning over the parameter combinations to find a new optimal parameter combination.

If *nevery* is 0, auto-tuning is effectively disabled. The 3 parameters *nsamples*, *mode* and *reltol* still need to be specified but have no effect to the run.

One can also use the output in the log files *tuning-[style-name].log* as hints to select a combination of *pair/team/size and *threads/per/atom* to specify at command line arguments without enabling auto-tuning.

Note

Do not use *auto/tuning* in tandem with *pair/team/size* and/or *threads/per/atom* in the same command line because the latter override the scanning process of the tuners.

OPENMP package settings

The *omp* style invokes settings associated with the use of the OPENMP package.

The *Nthreads* argument sets the number of OpenMP threads allocated for each MPI task. For example, if your system has nodes with dual quad-core processors, it has a total of 8 cores per node. You could use two MPI tasks per node (e.g. using the -ppn option of the mpirun command in MPICH or -npernode in OpenMPI), and set *Nthreads* = 4. This would use all 8 cores on each node. Note that the product of MPI tasks * threads/task should not exceed the physical number of cores (on a node), otherwise performance will suffer.

Setting *Nthreads* = 0 instructs LAMMPS to use whatever value is the default for the given OpenMP environment. This is usually determined via the *OMP_NUM_THREADS* environment variable or the compiler runtime. Note that in most cases the default for OpenMP capable compilers is to use one thread for each available CPU core when *OMP_NUM_THREADS* is not explicitly set, which can lead to poor performance.

Here are examples of how to set the environment variable when launching LAMMPS:

```
env OMP_NUM_THREADS=4 lmp_machine -sf omp -in in.script
env OMP_NUM_THREADS=2 mpirun -np 2 lmp_machine -sf omp -in in.script
mpirun -x OMP_NUM_THREADS=2 -np 2 lmp_machine -sf omp -in in.script
```

or you can set it permanently in your shell's start-up script. All three of these examples use a total of 4 CPU cores.

Note that different MPI implementations have different ways of passing the OMP_NUM_THREADS environment variable to all MPI processes. The second example line above is for MPICH; the third example line with -x is for OpenMPI. Check your MPI documentation for additional details.

What combination of threads and MPI tasks gives the best performance is difficult to predict and can depend on many components of your input. Not all features of LAMMPS support OpenMP threading via the OPENMP package and the parallel efficiency can be very different, too.

Note

If you build LAMMPS with the GPU, INTEL, and / or OPENMP packages, be aware these packages all allow setting of the *Nthreads* value via their package commands, but there is only a single global *Nthreads* value used by OpenMP. Thus if multiple package commands are invoked, you should ensure the values are consistent. If they are not, the last one invoked will take precedence, for all packages. Also note that if the *-sf hybrid intel omp command-line switch* is used, it invokes a "package intel" command, followed by a "package omp" command, both with a setting of *Nthreads* = 0. Likewise for a hybrid suffix for gpu and omp. Note that KOKKOS also supports setting the number of OpenMP threads from the command-line using the "-k on" *command-line switch*. The default for KOKKOS is 1 thread per MPI task, so any other number of threads should be explicitly set using the "-k on" command-line switch (and this setting should be consistent with settings from any other packages used).

Optional keyword/value pairs can also be specified. Each has a default value as listed below.

The *neigh* keyword specifies whether neighbor list building will be multi-threaded in addition to force calculations. If *neigh* is set to *no* then neighbor list calculation is performed only by MPI tasks with no OpenMP threading. If *mode* is *yes* (the default), a multi-threaded neighbor list build is used. Using *neigh* = *yes* is almost always faster and should produce identical neighbor lists at the expense of using more memory. Specifically, neighbor list pages are allocated for all threads at the same time and each thread works within its own pages.

1.74.4 Restrictions

This command cannot be used after the simulation box is defined by a *read_data* or *create_box* command.

The *gpu* style of this command can only be invoked if LAMMPS was built with the GPU package. See the *Build package* doc page for more info.

The *intel* style of this command can only be invoked if LAMMPS was built with the INTEL package. See the *Build package* page for more info.

The *kokkos* style of this command can only be invoked if LAMMPS was built with the KOKKOS package. See the *Build package* doc page for more info.

The *omp* style of this command can only be invoked if LAMMPS was built with the OPENMP package. See the *Build package* doc page for more info.

1.74.5 Related commands

suffix, *-pk command-line switch*

1.74.6 Defaults

For the GPU package, the default parameters and settings are:

```
Ngpu = 0, neigh = yes, newton = on, binsize = 0.0, gpuID = 0 to Ngpu-1, tpa = 1, omp = 0,
↪ platform=-1.
```

These settings are made automatically if the "-sf gpu" *command-line switch* is used. If it is not used, you must invoke the package gpu command in your input script or via the "-pk gpu" *command-line switch*.

For the INTEL package, the default parameters and settings are:

```
omp = 0, mode = mixed, lrt = no, pppm_table = yes
```

These settings are made automatically if the "-sf intel" *command-line switch* is used. If it is not used, you must invoke the package intel command in your input script or via the "-pk intel" *command-line switch*.

For the KOKKOS package when using GPUs, the option defaults are:

```
neigh = full, neigh/qeq = full, newton = off, binsize = 2x LAMMPS default value, comm =␣
↪device, sort = device, atom/map = device, neigh/transpose = off, gpu/aware = on, auto/
↪tuning = disabled
```

For GPUs, option neigh/thread = on when there are 16k atoms or less on an MPI rank, otherwise it is "off". When LAMMPS can safely detect that GPU-aware MPI is not available, the default value of gpu/aware becomes "off".

For the KOKKOS package when using CPUs, the option defaults are:

```
neigh = half, neigh/qeq = half, newton = on, binsize = 0.0, comm = no, sort = no, atom/
↪map = no
```

These settings are made automatically by the required "-k on" *command-line switch*. You can change them by using the package kokkos command in your input script or via the *-pk kokkos command-line switch*.

For the OMP package, the defaults are

```
Nthreads = 0, neigh = yes
```

These settings are made automatically if the "-sf omp" *command-line switch* is used. If it is not used, you must invoke the package omp command in your input script or via the "-pk omp" *command-line switch*.

1.75 pair_coeff command

1.75.1 Syntax

```
pair_coeff I J args
```

- I,J = numeric atom types (see asterisk form below), or type labels
- args = coefficients for one or more pairs of atom types

1.75.2 Examples

```
pair_coeff 1 2 1.0 1.0 2.5
pair_coeff 2 * 1.0 1.0
pair_coeff 3* 1*2 1.0 1.0 2.5
pair_coeff * * 1.0 1.0
pair_coeff * * nialhjea 1 1 2
pair_coeff * 3 morse.table ENTRY1
pair_coeff 1 2 lj/cut 1.0 1.0 2.5 # (for pair_style hybrid)

labelmap atom 1 C
labelmap atom 2 H
pair_coeff C H 1.0 1.0 2.5
```

1.75.3 Description

Specify the pairwise force field coefficients for one or more pairs of atom types. The number and meaning of the coefficients depends on the pair style. Pair coefficients can also be set in the data file read by the *read_data* command or in a restart file.

I and J can be specified in one of several ways. Explicit numeric values can be used for each, as in the first example above. Or, one or both of the types in the I,J pair can be a type label, which is an alphanumeric string defined by the *labelmap* command or in a section of a data file read by the *read_data* command, and which converts internally to a numeric type. Internally, LAMMPS will set coefficients for the symmetric J,I interaction to the same values as the I,J interaction.

For numeric values only, a wildcard asterisk can be used in place of or in conjunction with the I,J arguments to set the coefficients for multiple pairs of atom types. This takes the form "*" or "*n" or "n*" or "m*n". If *N* is the number of atom types, then an asterisk with no numeric values means all types from 1 to *N*. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to *N* (inclusive). A middle asterisk means all types from m to n (inclusive). For the asterisk syntax, only type pairs with I <= J are considered; if asterisks imply type pairs where J < I, they are ignored. Again internally, LAMMPS will set the coefficients for the symmetric J,I interactions to the same values as the I <= J interactions.

Note that a pair_coeff command can override a previous setting for the same I,J pair. For example, these commands set the coeffs for all I,J pairs, then overwrite the coeffs for just the I,J = 2,3 pair:

```
pair_coeff * * 1.0 1.0 2.5
pair_coeff 2 3 2.0 1.0 1.12
```

A line in a data file that specifies pair coefficients uses the exact same format as the arguments of the pair_coeff command in an input script, with the exception of the I,J type arguments. In each line of the "Pair Coeffs" section of a data file, only a single type I is specified, which sets the coefficients for type I interacting with type I. This is because the section has exactly *N* lines, where *N* is the number of atom types. For this reason, the wild-card asterisk should also not be used as part of the I argument. Thus in a data file, the line corresponding to the first example above would be listed as

```
2 1.0 1.0 2.5
```

For many potentials, if coefficients for type pairs with I != J are not set explicitly by a pair_coeff command, the values are inferred from the I,I and J,J settings by mixing rules; see the *pair_modify* command for a discussion. Details on this option as it pertains to individual potentials are described on the page for the potential.

Many pair styles, typically for many-body potentials, use tabulated potential files as input, when specifying the pair_coeff command. Potential files provided with LAMMPS are in the potentials directory of the distribution. For some potentials, such as EAM, other archives of suitable files can be found on the Web. They can be used with LAMMPS so long as they are in the format LAMMPS expects, as discussed on the individual doc pages. The first line

of potential files may contain metadata with upper case tags followed their value. These may be parsed and used by LAMMPS. Currently supported are the "DATE:" tag and the `UNITS:` tag. For pair styles that have been programmed to support the metadata, the value of the "DATE:" tag is printed to the screen and logfile so that the version of a potential file can be later identified. The `UNITS:` tag indicates the *units* setting required for this particular potential file. If the potential file was created for a different sets of units, LAMMPS will terminate with an error. If the potential file does not contain the tag, no check will be made and it is the responsibility of the user to determine that the unit style is correct.

In some select cases and for specific combinations of unit styles, LAMMPS is capable of automatically converting potential parameters from a file. In those cases, a warning message signaling that an automatic conversion has happened is printed to the screen.

When a pair_coeff command using a potential file is specified, LAMMPS looks for the potential file in 2 places. First it looks in the location specified. E.g. if the file is specified as "niu3.eam", it is looked for in the current working directory. If it is specified as "../potentials/niu3.eam", then it is looked for in the potentials directory, assuming it is a sister directory of the current working directory. If the file is not found, it is then looked for in one of the directories specified by the `LAMMPS_POTENTIALS` environment variable. Thus if this is set to the potentials directory in the LAMMPS distribution, then you can use those files from anywhere on your system, without copying them into your working directory. Environment variables are set in different ways for different shells. Here are example settings for

csh, tcsh:

```
setenv LAMMPS_POTENTIALS /path/to/lammps/potentials
```

bash:

```
export LAMMPS_POTENTIALS=/path/to/lammps/potentials
```

Windows:

```
set LAMMPS_POTENTIALS="C:\\Path to LAMMPS\\Potentials"
```

The `LAMMPS_POTENTIALS` environment variable may contain paths to multiple folders, if they are separated by ";" on Windows and ":" on all other operating systems, just like the `PATH` and similar environment variables.

The alphabetic list of pair styles defined in LAMMPS is given on the *pair_style* doc page. They are also listed in more compact form on the *Commands pair* doc page.

Click on the style to display the formula it computes and its coefficients as specified by the associated pair_coeff command.

1.75.4 Restrictions

This command must come after the simulation box is defined by a *read_data*, *read_restart*, or *create_box* command.

1.75.5 Related commands

pair_style, *pair_modify*, *read_data*, *read_restart*, *pair_write*

1.75.6 Default

none

1.76 pair_modify command

1.76.1 Syntax

```
pair_modify keyword values ...
```

- one or more keyword/value pairs may be listed
- keyword = *pair* or *shift* or *mix* or *table* or *table/disp* or *tabinner* or *tabinner/disp* or *tail* or *compute* or *nofdotr* or *special* or *compute/tally* or *neigh/trim*

```
pair value = sub-style N
  sub-style = sub-style of pair hybrid
  N = which instance of sub-style (1 to M), only specify if sub-style is used␣
↪multiple times
mix value = geometric or arithmetic or sixthpower

pair_modify pair lj/cut/coul/long special lj 0.0 0.0 0.5 special coul 0.0 0.0 0.8333333
```

1.76.3 Description

Modify the parameters of the currently defined pair style. If the pair style is *hybrid or hybrid/overlay*, then the specified parameters are by default modified for all the hybrid sub-styles.

Note

The behavior for hybrid pair styles can be changed by using the *pair* keyword, which allows selection of a specific sub-style to apply all remaining keywords to. The *special* and *compute/tally* keywords can **only** be used in

conjunction with the *pair* keyword. See further details about these 3 keywords below.

The *mix* keyword affects pair coefficients for interactions between atoms of type I and J, when I != J and the coefficients are not explicitly set in the input script. Note that coefficients for I = J must be set explicitly, either in the input script via the *pair_coeff* command or in the "Pair Coeffs" or "PairIJ Coeffs" sections of the *data file*. For some pair styles it is not necessary to specify coefficients when I != J, since a "mixing" rule will create them from the I,I and J,J settings. The pair_modify *mix* value determines what formulas are used to compute the mixed coefficients. In each case, the cutoff distance is mixed the same way as sigma.

Note that not all pair styles support mixing and some mix options are not available for certain pair styles. Also, there are additional restrictions when using *pair style hybrid or hybrid/overlay*. See the page for individual pair styles for those restrictions. Note also that the *pair_coeff* command also can be used to directly set coefficients for a specific I != J pairing, in which case no mixing is performed. If possible, LAMMPS will print an informational message about how many of the mixed pair coefficients were generated and which mixing rule was applied.

- mix *geometric*

$$\varepsilon_{ij} = \sqrt{\varepsilon_i \varepsilon_j}$$
$$\sigma_{ij} = \sqrt{\sigma_i \sigma_j}$$

- mix *arithmetic*

$$\varepsilon_{ij} = \sqrt{\varepsilon_i \varepsilon_j}$$
$$\sigma_{ij} = \frac{1}{2}(\sigma_i + \sigma_j)$$

- mix *sixthpower*

$$\varepsilon_{ij} = \frac{2\sqrt{\varepsilon_i \varepsilon_j}\sigma_i^3 \sigma_j^3}{\sigma_i^6 + \sigma_j^6}$$
$$\sigma_{ij} = \left(\frac{1}{2}(\sigma_i^6 + \sigma_j^6)\right)^{\frac{1}{6}}$$

The *shift* keyword determines whether a Lennard-Jones potential is shifted at its cutoff to 0.0. If so, this adds an energy term to each pairwise interaction which will be included in the thermodynamic output, but does not affect pair forces or atom trajectories. See the doc page for individual pair styles to see which ones support this option.

The *table* and *table/disp* keywords apply to pair styles with a long-range Coulombic term or long-range dispersion term respectively; see the page for individual styles to see which potentials support these options. If N is non-zero, a table of length 2^N is pre-computed for forces and energies, which can shrink their computational cost by up to a factor of 2. The table is indexed via a bit-mapping technique *(Wolff)* and a linear interpolation is performed between adjacent table values. In our experiments with different table styles (lookup, linear, spline), this method typically gave the best performance in terms of speed and accuracy.

The choice of table length is a tradeoff in accuracy versus speed. A larger N yields more accurate force computations, but requires more memory which can slow down the computation due to cache misses. A reasonable value of N is between 8 and 16. The default value of 12 (table of length 4096) gives approximately the same accuracy as the no-table (N = 0) option. For N = 0, forces and energies are computed directly, using a polynomial fit for the needed erfc() function evaluation, which is what earlier versions of LAMMPS did. Values greater than 16 typically slow down the simulation and will not improve accuracy; values from 1 to 8 give unreliable results.

The *tabinner* and *tabinner/disp* keywords set an inner cutoff above which the pairwise computation is done by table lookup (if tables are invoked), for the corresponding Coulombic and dispersion tables discussed with the *table* and *table/disp* keywords. The smaller the cutoff is set, the less accurate the table becomes (for a given number of table

values), which can require use of larger tables. The default cutoff value is sqrt(2.0) distance units which means nearly all pairwise interactions are computed via table lookup for simulations with "real" units, but some close pairs may be computed directly (non-table) for simulations with "lj" units.

When the *tail* keyword is set to *yes*, certain pair styles will add a long-range VanderWaals tail "correction" to the energy and pressure. These corrections are bookkeeping terms which do not affect dynamics, unless a constant-pressure simulation is being performed. See the page for individual styles to see which support this option. These corrections are included in the calculation and printing of thermodynamic quantities (see the *thermo_style* command). Their effect will also be included in constant NPT or NPH simulations where the pressure influences the simulation box dimensions (e.g. the *fix npt* and *fix nph* commands). The formulas used for the long-range corrections come from equation 5 of *(Sun)*.

Note

The tail correction terms are computed at the beginning of each run, using the current atom counts of each atom type. If atoms are deleted (or lost) or created during a simulation, e.g. via the *fix gcmc* command, the correction factors are not re-computed. If you expect the counts to change dramatically, you can break a run into a series of shorter runs so that the correction factors are re-computed more frequently.

Several additional assumptions are inherent in using tail corrections, including the following:

- The simulated system is a 3d bulk homogeneous liquid. This option should not be used for systems that are non-liquid, 2d, have a slab geometry (only 2d periodic), or inhomogeneous.
- G(r), the radial distribution function (rdf), is unity beyond the cutoff, so a fairly large cutoff should be used (i.e. 2.5 sigma for an LJ fluid), and it is probably a good idea to verify this assumption by checking the rdf. The rdf is not exactly unity beyond the cutoff for each pair of interaction types, so the tail correction is necessarily an approximation.

  The tail corrections are computed at the beginning of each simulation run. If the number of atoms changes during the run, e.g. due to atoms leaving the simulation domain, or use of the *fix gcmc* command, then the corrections are not updated to reflect the changed atom count. If this is a large effect in your simulation, you should break the long run into several short runs, so that the correction factors are re-computed multiple times.
- Thermophysical properties obtained from calculations with this option enabled will not be thermodynamically consistent with the truncated force-field that was used. In other words, atoms do not feel any LJ pair interactions beyond the cutoff, but the energy and pressure reported by the simulation include an estimated contribution from those interactions.

The *compute* keyword allows pairwise computations to be turned off, even though a *pair_style* is defined. This is not useful for running a real simulation, but can be useful for debugging purposes or for performing a *rerun* simulation, when you only wish to compute partial forces that do not include the pairwise contribution.

Two examples are as follows. First, this option allows you to perform a simulation with *pair_style hybrid* with only a subset of the hybrid sub-styles enabled. Second, this option allows you to perform a simulation with only long-range interactions but no short-range pairwise interactions. Doing this by simply not defining a pair style will not work, because the *kspace_style* command requires a Kspace-compatible pair style be defined.

The *nofdotr* keyword allows to disable an optimization that computes the global stress tensor from the total forces and atom positions rather than from summing forces between individual pairs of atoms.

The *pair* keyword can only be used with the *hybrid and hybrid/overlay* pair styles. If used, it must appear first in the list of keywords.

Its meaning is that all the following parameters will only be modified for the specified sub-style. If the sub-style is defined multiple times, then an additional numeric argument *N* must also be specified, which is a number from 1 to M

where M is the number of times the sub-style was listed in the *pair_style hybrid* command. The extra number indicates which instance of the sub-style the remaining keywords will be applied to.

The *special* and *compute/tally* keywords can **only** be used in conjunction with the *pair* keyword and they must directly follow it. I.e. any other keyword, must appear after *pair*, *special*, and *compute/tally*.

The *special* keyword overrides the global *special_bonds* 1-2, 1-3, 1-4 exclusion settings (weights) for the sub-style selected by the *pair* keyword.

Similar to the *special_bonds* command, it takes 4 arguments. The *which* argument can be *lj* to change only the non-Coulomb weights (e.g. Lennard-Jones or Buckingham), *coul* to change only the Coulombic settings, or *lj/coul* to change both to the same values. The *wt1,wt2,wt3* values are numeric weights from 0.0 to 1.0 inclusive, for the 1-2, 1-3, and 1-4 bond topology neighbors, respectively. The *special* keyword can be used multiple times, e.g. to set the *lj* and *coul* settings to different values.

Note

The *special* keyword is not compatible with pair styles from the GPU or the INTEL package and attempting to use it will cause an error.

Note

Weights of exactly 0.0 or 1.0 in the *special_bonds* command have implications on the neighbor list construction, which means that they cannot be overridden by using the *special* keyword. One workaround for this restriction is to use the *special_bonds* command with weights like 1.0e-10 or 0.999999999 instead of 0.0 or 1.0, respectively, which enables to reset each them to any value between 0.0 and 1.0 inclusively. Otherwise you can set **all** global weights to an arbitrary number between 0.0 or 1.0, like 0.5, and then you have to override **all** *special* settings for **all** sub-styles which use the 1-2, 1-3, and 1-4 exclusion weights in their force/energy computation.

The *compute/tally* keyword disables or enables registering *compute */tally* computes for the sub-style specified by the *pair* keyword. Use *no* to disable, or *yes* to enable.

Note

The "pair_modify pair compute/tally" command must be issued **before** the corresponding compute style is defined.

Added in version 3Aug2022.

The *neigh/trim* keyword controls whether an explicit cutoff is set for each neighbor list request issued by individual pair sub-styles when using *pair hybrid/overlay*. When this keyword is set to *no*, then the cutoff of each pair sub-style neighbor list will be set equal to the largest cutoff, even if a shorter cutoff is specified for a particular sub-style. If possible the neighbor list will be copied directly from another list. When this keyword is set to *yes* then the cutoff of the neighbor list will be explicitly set to the value requested by the pair sub-style, and if possible the list will be created by trimming neighbors from another list with a longer cutoff, otherwise a new neighbor list will be created with the specified cutoff. The *yes* option can be faster when there are multiple pair styles with different cutoffs since the number of pair-wise distance checks between neighbors is reduced (but the time required to build the neighbor lists is increased). The *no* option could be faster when two or more neighbor lists have similar (but not exactly the same) cutoffs.

Note

The "pair_modify neigh/trim" command *only* applies when there are multiple pair sub-styles for the same atoms

with different cutoffs, i.e. when using pair style hybrid/overlay. If you have different cutoffs for different pairs for atoms type, the *neighbor style multi* should be used to create optimized neighbor lists.

1.76.4 Restrictions

You cannot use *shift* yes with *tail* yes, since those are conflicting options. You cannot use *tail* yes with 2d simulations. You cannot use *special* with pair styles from the GPU or INTEL package.

1.76.5 Related commands

pair_style, *pair_style hybrid*, *pair_coeff*, *thermo_style*, *compute */tally*, *neighbor multi*

1.76.6 Default

The option defaults are mix = geometric, shift = no, table = 12, tabinner = sqrt(2.0), tail = no, compute = yes, and neigh/trim yes.

Note that some pair styles perform mixing, but only a certain style of mixing. See the doc pages for individual pair styles for details.

(Sun) Sun, J Phys Chem B, 102, 7338-7364 (1998).

1.77 pair_style command

1.77.1 Syntax

```
pair_style style args
```

- style = one of the styles from the list below
- args = arguments used by a particular style

1.77.2 Examples

```
pair_style lj/cut 2.5
pair_style eam/alloy
pair_style hybrid lj/charmm/coul/long 10.0 eam
pair_style table linear 1000
pair_style none
```

1.77.3 Description

Set the formula(s) LAMMPS uses to compute pairwise interactions. In LAMMPS, pair potentials are defined between pairs of atoms that are within a cutoff distance and the set of active interactions typically changes over time. See the *bond_style* command to define potentials between pairs of bonded atoms, which typically remain in place for the duration of a simulation.

In LAMMPS, pairwise force fields encompass a variety of interactions, some of which include many-body effects, e.g. EAM, Stillinger-Weber, Tersoff, REBO potentials. They are still classified as "pairwise" potentials because the set of

interacting atoms changes with time (unlike molecular bonds) and thus a neighbor list is used to find nearby interacting atoms.

Hybrid models where specified pairs of atom types interact via different pair potentials can be setup using the *hybrid* pair style.

The coefficients associated with a pair style are typically set for each pair of atom types, and are specified by the *pair_coeff* command or read from a file by the *read_data* or *read_restart* commands.

The *pair_modify* command sets options for mixing of type I-J interaction coefficients and adding energy offsets or tail corrections to Lennard-Jones potentials. Details on these options as they pertain to individual potentials are described on the doc page for the potential. Likewise, info on whether the potential information is stored in a *restart file* is listed on the potential doc page.

In the formulas listed for each pair style, E is the energy of a pairwise interaction between two atoms separated by a distance r. The force between the atoms is the negative derivative of this expression.

If the pair_style command has a cutoff argument, it sets global cutoffs for all pairs of atom types. The distance(s) can be smaller or larger than the dimensions of the simulation box.

In many cases, the global cutoff value can be overridden for a specific pair of atom types by the *pair_coeff* command.

If a new pair_style command is specified with a new style, all previous *pair_coeff* and *pair_modify* command settings are erased; those commands must be re-specified if necessary.

If a new pair_style command is specified with the same style, then only the global settings in that command are reset. Any previous doc:*pair_coeff* <*pair_coeff*> and *pair_modify* command settings are preserved. The only exception is that if the global cutoff in the pair_style command is changed, it will override the corresponding cutoff in any of the previous *pair_modify* commands.

Two pair styles which do not follow this rule are the pair_style *table* and *hybrid* commands. A new pair_style command for these styles will wipe out all previously specified *pair_coeff* and *pair_modify* settings, including for the sub-styles of the *hybrid* command.

Here is an alphabetic list of pair styles defined in LAMMPS. They are also listed in more compact form on the *Commands pair* doc page.

Click on the style to display the formula it computes, any additional arguments specified in the pair_style command, and coefficients specified by the associated *pair_coeff* command.

There are also additional accelerated pair styles included in the LAMMPS distribution for faster performance on CPUs, GPUs, and KNLs. The individual style names on the *Commands pair* doc page are followed by one or more of (g,i,k,o,t) to indicate which accelerated styles exist.

- *none* - turn off pairwise interactions
- *hybrid* - multiple styles of pairwise interactions
- *hybrid/molecular* - different pair styles for intra- and inter-molecular interactions
- *hybrid/overlay* - multiple styles of superposed pairwise interactions
- *hybrid/scaled* - multiple styles of scaled superposed pairwise interactions
- *zero* - neighbor list but no interactions
- *zero/coul* - like *zero*, but presents itself as a Coulombic pair style
- *adp* - angular dependent potential (ADP) of Mishin
- *aip/water/2dm* - anisotropic interfacial potential for water in 2d geometries
- *airebo* - AIREBO potential of Stuart

- *airebo/bc* - AIREBO with bond-centric P_CC (Hur and Stuart)
- *airebo/morse* - AIREBO with Morse instead of LJ
- *amoeba* -
- *atm* - Axilrod-Teller-Muto potential
- *beck* - Beck potential
- *body/nparticle* - interactions between body particles
- *body/rounded/polygon* - granular-style 2d polygon potential
- *body/rounded/polyhedron* - granular-style 3d polyhedron potential
- *bondval* - Bond-Valence potential
- *bondval/vec* - Bond-Valence vector potential
- *bop* - BOP potential of Pettifor
- *born* - Born-Mayer-Huggins potential
- *born/coul/dsf* - Born with damped-shifted-force model
- *born/coul/dsf/cs* - Born with damped-shifted-force and core/shell model
- *born/coul/long* - Born with long-range Coulomb
- *born/coul/long/cs* - Born with long-range Coulomb and core/shell
- *born/coul/msm* - Born with long-range MSM Coulomb
- *born/coul/wolf* - Born with Wolf potential for Coulomb
- *born/coul/wolf/cs* - Born with Wolf potential for Coulomb and core/shell model
- *born/gauss* - Born-Mayer / Gaussian potential
- *bpm/peri* - short-range contact force for the BPM peridynamics model
- *bpm/spring* - repulsive harmonic force with damping
- *brownian* - Brownian potential for Fast Lubrication Dynamics
- *brownian/poly* - Brownian potential for Fast Lubrication Dynamics with polydispersity
- *buck* - Buckingham potential
- *buck/coul/cut* - Buckingham with cutoff Coulomb
- *buck/coul/long* - Buckingham with long-range Coulomb
- *buck/coul/long/cs* - Buckingham with long-range Coulomb and core/shell
- *buck/coul/msm* - Buckingham with long-range MSM Coulomb
- *buck/long/coul/long* - long-range Buckingham with long-range Coulomb
- *buck/mdf* - Buckingham with a taper function
- *buck6d/coul/gauss/dsf* - dispersion-damped Buckingham with damped-shift-force model
- *buck6d/coul/gauss/long* - dispersion-damped Buckingham with long-range Coulomb
- *colloid* - integrated colloidal potential
- *comb* - charge-optimized many-body (COMB) potential
- *comb3* - charge-optimized many-body (COMB3) potential

- *cosine/squared* - Cooke-Kremer-Deserno membrane model potential
- *coul/ctip* - Charge Transfer Interatomic (Coulomb) Potential
- *coul/cut* - cutoff Coulomb potential
- *coul/cut/dielectric* -
- *coul/cut/global* - cutoff Coulomb potential
- *coul/cut/soft* - Coulomb potential with a soft core
- *coul/cut/soft/gapsys* - Coulomb potential with a soft core with continuous force and first derivative of force
- *coul/debye* - cutoff Coulomb potential with Debye screening
- *coul/diel* - Coulomb potential with dielectric permittivity
- *coul/dsf* - Coulomb with damped-shifted-force model
- *coul/esp* - long-range Coulomb potential for ESP kspace solver
- *coul/exclude* - subtract Coulomb potential for excluded pairs
- *coul/long* - long-range Coulomb potential
- *coul/long/cs* - long-range Coulomb potential and core/shell
- *coul/long/dielectric* -
- *coul/long/soft* - long-range Coulomb potential with a soft core
- *coul/msm* - long-range MSM Coulomb
- *coul/slater/cut* - smeared out Coulomb
- *coul/slater/long* - long-range smeared out Coulomb
- *coul/shield* - Coulomb for boron nitride for use with *ilp/graphene/hbn* potential
- *coul/streitz* - Coulomb via Streitz/Mintmire Slater orbitals
- *coul/tt* - damped charge-dipole Coulomb for Drude dipoles
- *coul/wolf* - Coulomb via Wolf potential
- *coul/wolf/cs* - Coulomb via Wolf potential with core/shell adjustments
- *dispersion/d3* - Dispersion correction for potentials derived from DFT functionals
- *dpd* - dissipative particle dynamics (DPD)
- *dpd/coul/slater/long* - dissipative particle dynamics (DPD) with electrostatic interactions
- *dpd/ext* - generalized force field for DPD
- *dpd/ext/tstat* - pairwise DPD thermostatting with generalized force field
- *dpd/fdt* - DPD for constant temperature and pressure
- *dpd/fdt/energy* - DPD for constant energy and enthalpy
- *dpd/tstat* - pairwise DPD thermostatting
- *dsmc* - Direct Simulation Monte Carlo (DSMC)
- *e3b* - Explicit-three body (E3B) water model
- *drip* - Dihedral-angle-corrected registry-dependent interlayer potential (DRIP)
- *eam* - embedded atom method (EAM)

- *eam/alloy* - alloy EAM
- *eam/cd* - concentration-dependent EAM
- *eam/cd/old* - older two-site model for concentration-dependent EAM
- *eam/fs* - Finnis-Sinclair EAM
- *eam/fs/apip* - *adaptive precision* version of FS EAM, used as fast potential
- *eam/he* - Finnis-Sinclair EAM modified for Helium in metals
- *eam/apip* - *adaptive-precision* version of EAM, used as fast potential
- *edip* - three-body EDIP potential
- *edip/multi* - multi-element EDIP potential
- *edpd* - eDPD particle interactions
- *eff/cut* - electron force field with a cutoff
- *eim* - embedded ion method (EIM)
- *exp6/rx* - reactive DPD potential
- *extep* - extended Tersoff potential
- *gauss* - Gaussian potential
- *gauss/cut* - generalized Gaussian potential
- *gayberne* - Gay-Berne ellipsoidal potential
- *granular* - Generalized granular potential
- *granular/superellipsoid* - Generalized granular potential for superellipsoids
- *gran/hertz/history* - granular potential with Hertzian interactions
- *gran/hooke* - granular potential without history effects
- *gran/hooke/history* - granular potential with history effects
- *gw* - Gao-Weber potential
- *gw/zbl* - Gao-Weber potential with a repulsive ZBL core
- *harmonic/cut* - repulsive-only harmonic potential
- *hbond/dreiding/lj* - DREIDING hydrogen bonding LJ potential
- *hbond/dreiding/lj/angleoffset* - DREIDING hydrogen bonding LJ potential with offset for hbond angle
- *hbond/dreiding/morse* - DREIDING hydrogen bonding Morse potential
- *hbond/dreiding/morse/angleoffset* - DREIDING hydrogen bonding Morse potential with offset for hbond angle
- *hdnnp* - High-dimensional neural network potential
- *hippo* -
- *ilp/graphene/hbn* - registry-dependent interlayer potential (ILP)
- *ilp/tmd* - interlayer potential (ILP) potential for transition metal dichalcogenides (TMD)
- *kim* - interface to potentials provided by KIM project
- *kolmogorov/crespi/full* - Kolmogorov-Crespi (KC) potential with no simplifications
- *kolmogorov/crespi/z* - Kolmogorov-Crespi (KC) potential with normals along z-axis

- *lambda/input/apip* - constant as input for the precision calculation of an *adaptive-precision interatomic potential (APIP)*
- *lambda/input/csp/apip* - CSP as input for the precision calculation of an *adaptive-precision interatomic potential (APIP)*
- *lambda/zone/apip* - transition zone of an *adaptive-precision interatomic potential*
- *lcbop* - long-range bond-order potential (LCBOP)
- *ldd* - Local density and gradient of density interactions (LDD)
- *lebedeva/z* - Lebedeva interlayer potential for graphene with normals along z-axis
- *lennard/mdf* - LJ potential in A/B form with a taper function
- *lepton* - pair potential from evaluating a string
- *lepton/coul* - pair potential from evaluating a string with support for charges
- *lepton/sphere* - pair potential from evaluating a string with support for radii
- *line/lj* - LJ potential between line segments
- *list* - potential between pairs of atoms explicitly listed in an input file
- *lj/charmm/coul/charmm* - CHARMM potential with cutoff Coulomb
- *lj/charmm/coul/charmm/implicit* - CHARMM for implicit solvent
- *lj/charmm/coul/long* - CHARMM with long-range Coulomb
- *lj/charmm/coul/long/soft* - CHARMM with long-range Coulomb and a soft core
- *lj/charmm/coul/msm* - CHARMM with long-range MSM Coulomb
- *lj/charmmfsw/coul/charmmfsh* - CHARMM with force switching and shifting
- *lj/charmmfsw/coul/long* - CHARMM with force switching and long-rnage Coulomb
- *lj/class2* - COMPASS (class 2) force field without Coulomb
- *lj/class2/coul/cut* - COMPASS with cutoff Coulomb
- *lj/class2/coul/cut/soft* - COMPASS with cutoff Coulomb with a soft core
- *lj/class2/coul/long* - COMPASS with long-range Coulomb
- *lj/class2/coul/long/cs* - COMPASS with long-range Coulomb with core/shell adjustments
- *lj/class2/coul/long/soft* - COMPASS with long-range Coulomb with a soft core
- *lj/class2/soft* - COMPASS (class 2) force field with no Coulomb with a soft core
- *lj/cubic* - LJ with cubic after inflection point
- *lj/cut* - cutoff Lennard-Jones potential without Coulomb
- *lj/cut/coul/cut* - LJ with cutoff Coulomb
- *lj/cut/coul/cut/dielectric* -
- *lj/cut/coul/cut/soft* - LJ with cutoff Coulomb with a soft core
- *lj/cut/coul/debye* - LJ with Debye screening added to Coulomb
- *lj/cut/coul/debye/dielectric* -
- *lj/cut/coul/dsf* - LJ with Coulomb via damped shifted forces
- *lj/cut/coul/esp* - LJ with long-range Coulomb for ESP kspace solver

- *lj/cut/coul/long* - LJ with long-range Coulomb
- *lj/cut/coul/long/cs* - LJ with long-range Coulomb with core/shell adjustments
- *lj/cut/coul/long/dielectric* -
- *lj/cut/coul/long/soft* - LJ with long-range Coulomb with a soft core
- *lj/cut/coul/msm* - LJ with long-range MSM Coulomb
- *lj/cut/coul/msm/dielectric* -
- *lj/cut/coul/wolf* - LJ with Coulomb via Wolf potential
- *lj/cut/dipole/cut* - point dipoles with cutoff
- *lj/cut/dipole/long* - point dipoles with long-range Ewald
- *lj/cut/soft* - LJ with a soft core
- *lj/cut/soft/gapsys* - LJ potential with a soft core with continuous force and first derivative of force
- *lj/cut/sphere* - LJ where per-atom radius is used as LJ sigma
- *lj/cut/thole/long* - LJ with Coulomb with thole damping
- *lj/cut/tip4p/cut* - LJ with cutoff Coulomb for TIP4P water
- *lj/cut/tip4p/long* - LJ with long-range Coulomb for TIP4P water
- *lj/cut/tip4p/long/soft* - LJ with cutoff Coulomb for TIP4P water with a soft core
- *lj/expand* - Lennard-Jones for variable size particles
- *lj/expand/coul/long* - Lennard-Jones for variable size particles with long-range Coulomb
- *lj/expand/sphere* - Variable size LJ where per-atom radius is used as delta (size)
- *lj/gromacs* - GROMACS-style Lennard-Jones potential
- *lj/gromacs/coul/gromacs* - GROMACS-style LJ and Coulomb potential
- *lj/long/coul/long* - long-range LJ and long-range Coulomb
- *lj/long/coul/long/dielectric* -
- *lj/long/dipole/long* - long-range LJ and long-range point dipoles
- *lj/long/tip4p/long* - long-range LJ and long-range Coulomb for TIP4P water
- *lj/mdf* - LJ potential with a taper function
- *lj/pirani* - Improved LJ potential
- *lj/relres* - LJ using multiscale Relative Resolution (RelRes) methodology *(Chaimovich)*.
- *lj/spica* - LJ for SPICA coarse-graining
- *lj/spica/coul/long* - LJ for SPICA coarse-graining with long-range Coulomb
- *lj/spica/coul/msm* - LJ for SPICA coarse-graining with long-range Coulomb via MSM
- *lj/sf/dipole/sf* - LJ with dipole interaction with shifted forces
- *lj/smooth* - smoothed Lennard-Jones potential
- *lj/smooth/linear* - linear smoothed LJ potential
- *lj/switch3/coulgauss/long* - smoothed LJ vdW potential with Gaussian electrostatics
- *lj96/cut* - Lennard-Jones 9/6 potential

- *local/density* - Generalized basic local density potential
- *lubricate* - Hydrodynamic lubrication forces
- *lubricate/poly* - Hydrodynamic lubrication forces with polydispersity
- *lubricateU* - Hydrodynamic lubrication forces for Fast Lubrication Dynamics
- *lubricateU/poly* - Hydrodynamic lubrication forces for Fast Lubrication with polydispersity
- *mbx* - Many-Body eXpansion (MBX) potential
- *mdpd* - mDPD particle interactions
- *mdpd/rhosum* - mDPD particle interactions for mass density
- *meam* - Modified embedded atom method (MEAM)
- *meam/ms* - Multi-state modified embedded atom method (MS-MEAM)
- *meam/spline* - Splined version of MEAM
- *meam/sw/spline* - Splined version of MEAM with a Stillinger-Weber term
- *mesocnt* - Mesoscopic vdW potential for (carbon) nanotubes
- *mesocnt/viscous* - Mesoscopic vdW potential for (carbon) nanotubes with friction
- *mgpt* - Simplified model generalized pseudopotential theory (MGPT) potential
- *mie/cut* - Mie potential
- *mliap* - Multiple styles of machine-learning potential
- *mm3/switch3/coulgauss/long* - Smoothed MM3 vdW potential with Gaussian electrostatics
- *momb* - Many-Body Metal-Organic (MOMB) force field
- *morse* - Morse potential
- *morse/smooth/linear* - Linear smoothed Morse potential
- *morse/soft* - Morse potential with a soft core
- *multi/lucy* - DPD potential with density-dependent force
- *multi/lucy/rx* - reactive DPD potential with density-dependent force
- *nb3b/harmonic* - Non-bonded 3-body harmonic potential
- *nb3b/screened* - Non-bonded 3-body screened harmonic potential
- *nm/cut* - N-M potential
- *nm/cut/coul/cut* - N-M potential with cutoff Coulomb
- *nm/cut/coul/long* - N-M potential with long-range Coulomb
- *nm/cut/split* - Split 12-6 Lennard-Jones and N-M potential
- *oxdna/coaxstk* -
- *oxdna/excv* -
- *oxdna/hbond* -
- *oxdna/stk* -
- *oxdna/xstk* -
- *oxdna2/coaxstk* -

- *oxrna2/dh* -
- *oxrna2/excv* -
- *oxrna2/hbond* -
- *oxrna2/stk* -
- *oxrna2/xstk* -
- *pace* - Atomic Cluster Expansion (ACE) machine-learning potential
- *pace/extrapolation* - Atomic Cluster Expansion (ACE) machine-learning potential with extrapolation grades
- *pace/apip* - *adaptive-precision* version of ACE, used as precise potential
- *pace/fast/apip* - *adaptive-precision* version of ACE, used as fast potential
- *pace/precise/apip* - *adaptive-precision* version of ACE, used as precise potential
- *pedone* - Pedone (PMMCS) potential (non-Coulomb part)
- *pod* - Proper orthogonal decomposition (POD) machine-learning potential
- *peri/eps* - Peridynamic EPS potential
- *peri/lps* - Peridynamic LPS potential
- *peri/pmb* - Peridynamic PMB potential
- *peri/ves* - Peridynamic VES potential
- *polymorphic* - Polymorphic 3-body potential
- *python* -
- *quip* -
- *reaxff* - ReaxFF potential
- *rebo* - Second generation REBO potential of Brenner
- *rebomos* - REBOMoS potential for MoS2
- *rheo* - fluid interactions in RHEO package
- *rheo/solid* - solid interactions in RHEO package

- *resquared* - Everaers RE-Squared ellipsoidal potential
- *runner* - high-dimensional neural network potentials ML-RUNNER package
- *saip/metal* - Interlayer potential for hetero-junctions formed with hexagonal 2D materials and metal surfaces
- *saip/metal/tmd* - Interlayer potential for transition-metal dichalcogenide / metal interfaces
- *sdpd/taitwater/isothermal* - Smoothed dissipative particle dynamics for water at isothermal conditions
- *smatb* - Second Moment Approximation to the Tight Binding
- *smatb/single* - Second Moment Approximation to the Tight Binding for single-element systems
- *smd/hertz* -
- *smd/tlsph* -
- *smd/tri_surface* -
- *smd/ulsph* -
- *smtbq* -
- *snap* - SNAP machine-learning potential
- *soft* - Soft (cosine) potential
- *sph/heatconduction* -
- *sph/idealgas* -
- *sph/lj* -
- *sph/rhosum* -
- *sph/taitwater* -
- *sph/taitwater/morris* -
- *spin/dipole/cut* -

- *spin/dmi* -
- *spin/exchange* -
- *spin/exchange/biquadratic* -
- *spin/magelec* -
- *spin/neel* -
- *srp* -
- *srp/react* -
- *surf/granular* - line/triangle interactions with granular spheres
- *sw* - Stillinger-Weber 3-body potential
- *sw/angle/table* - Stillinger-Weber potential with tabulated angular term
- *sw/mod* - modified Stillinger-Weber 3-body potential
- *table* - tabulated pair potential
- *table/rx* -
- *tdpd* - tDPD particle interactions

- *tersoff* - Tersoff 3-body potential
- *tersoff/mod* - modified Tersoff 3-body potential
- *tersoff/mod/c* -
- *tersoff/table* -
- *tersoff/zbl* - Tersoff/ZBL 3-body potential
- *thole* - Coulomb interactions with thole damping
- *threebody/table* - generic tabulated three-body potential
- *tip4p/cut* - Coulomb for TIP4P water w/out LJ
- *tip4p/long* - long-range Coulomb for TIP4P water w/out LJ
- *tip4p/long/soft* -
- *tracker* - monitor information about pairwise interactions
- *tri/lj* - LJ potential between triangles
- *ufm* -
- *uf3* - UF3 machine-learning potential
- *vashishta* - Vashishta 2-body and 3-body potential
- *vashishta/table* -
- *wf/cut* - Wang-Frenkel Potential for short-ranged interactions
- *ylz* - Yuan-Li-Zhang Potential for anisotropic interactions
- *yukawa* - Yukawa potential
- *yukawa/colloid* - screened Yukawa potential for finite-size particles
- *zbl* - Ziegler-Biersack-Littmark potential

1.77.4 Restrictions

This command must be used before any coefficients are set by the *pair_coeff*, *read_data*, or *read_restart* commands.

Some pair styles are part of specific packages. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info. The doc pages for individual pair potentials tell if it is part of a package.

1.77.5 Related commands

pair_coeff, *read_data*, *pair_modify*, *kspace_style*, *dielectric*, *pair_write*

1.77.6 Default

```
pair_style none
```

1.78 pair_write command

1.78.1 Syntax

```
pair_write itype jtype N style inner outer file keyword Qi Qj
```

- itype,jtype = 2 atom types (numeric or type label)
- N = # of values
- style = *r* or *rsq* or *bitmap*
- inner,outer = inner and outer cutoff (distance units)
- file = name of file to write values to
- keyword = section name in file for this set of tabulated values
- Qi,Qj = 2 atom charges (charge units) (optional)

1.78.2 Examples

```
pair_write 1 3 500 r 1.0 10.0 table.txt LJ
pair_write 1 1 1000 rsq 2.0 8.0 table.txt Yukawa_1_1 -0.5 0.5

labelmap atom 1 C 2 H
pair_write C H 500 r 1.0 10.0 table.txt LJ
```

1.78.3 Description

Write energy and force values to a file as a function of distance for the currently defined pair potential. This is useful for plotting the potential function or otherwise debugging its values. If the file already exists, the table of values is appended to the end of the file to allow multiple tables of energy and force to be included in one file. In case a new file is created, the first line will be a comment containing a "DATE:" and "UNITS:" tag with the current date and the current *units* setting as argument. For subsequent invocations of the pair_write command, the current units setting is compared against the entry in the file, if present, and pair_write will refuse to add a table if the units are not the same.

The energy and force values are computed at distances from inner to outer for 2 interacting atoms of type *itype* and *jtype*, using the appropriate *pair_coeff* coefficients. If the style is *r*, then N distances are used, evenly spaced in r; if the style is *rsq*, N distances are used, evenly spaced in r^2.

For example, for N = 7, style = *r*, inner = 1.0, and outer = 4.0, values are computed at r = 1.0, 1.5, 2.0, 2.5, 3.0, 3.5, 4.0.

If the style is *bitmap*, then 2^N values are written to the file in a format and order consistent with how they are read in by the *pair_coeff* command for pair style *table*. For reasonable accuracy in a bitmapped table, choose N >= 12, an *inner* value that is smaller than the distance of closest approach of 2 atoms, and an *outer* value <= cutoff of the potential.

If the pair potential is computed between charged atoms, the charges of the pair of interacting atoms can optionally be specified. If not specified, values of Qi = Qj = 1.0 are used.

The file is written in the format used as input for the *pair_style table* option with *keyword* as the section name. Each line written to the file lists an index number (1-N), a distance (in distance units), an energy (in energy units), and a force (in force units).

1.78.4 Restrictions

All force field coefficients for pair and other kinds of interactions must be set before this command can be invoked.

Due to how the pairwise force is computed, an inner value > 0.0 must be specified even if the potential has a finite value at r = 0.0.

The *pair_write* command can only be used for pairwise additive interactions for which a *Pair::single()* function can be and has been implemented. This excludes for example manybody potentials or TIP4P coulomb styles.

1.78.5 Related commands

pair_style table, *pair_style*, *pair_coeff*

1.78.6 Default

none

1.79 partition command

1.79.1 Syntax

```
partition style N command ...
```

- style = *yes* or *no*
- N = partition number (see asterisk form below)
- command = any LAMMPS command

1.79.2 Examples

```
partition yes 1 processors 4 10 6
partition no 5 print "Active partition"
partition yes *5 fix all nve
partition yes 6* fix all nvt temp 1.0 1.0 0.1
```

1.79.3 Description

This command invokes the specified command on a subset of the partitions of MPI processes you have defined via the *-partition command-line switch*.

Normally, every input script command in your script is invoked by every partition. This behavior can be modified by defining world- or universe-style *variables* that have different values for each partition. This mechanism can be used to cause your script to jump to different input script files on different partitions, if such a variable is used in a *jump* command.

The "partition" command is another mechanism for having as input script operate differently on different partitions. It is basically a prefix on any LAMMPS command. The command will only be invoked on the partition(s) specified by the *style* and *N* arguments.

If the *style* is *yes*, the command will be invoked on any partition which matches the *N* argument. If the *style* is *no* the command will be invoked on all the partitions which do not match the *Np* argument.

Partitions are numbered from 1 to *Np*, where *Np* is the number of partitions specified by the *-partition command-line switch*.

N can be specified in one of two ways. An explicit numeric value can be used, as in the first example above. Or a wild-card asterisk can be used to span a range of partition numbers. This takes the form "*" or "*n" or "n*" or "m*n". An asterisk with no numeric values means all partitions from 1 to *Np*. A leading asterisk means all partitions from 1 to n (inclusive). A trailing asterisk means all partitions from n to *Np* (inclusive). A middle asterisk means all partitions from m to n (inclusive).

This command can be useful for the "run_style verlet/split" command which imposed requirements on how the *processors* command lays out a 3d grid of MPI processes in each of 2 partitions.

1.80 plugin command

1.80.1 Syntax

```
plugin command args
```

- command = *load* or *unload* or *list* or *clear* or *restore*
- args = list of arguments for a particular plugin command

```
load file = load plugin(s) from shared object in file
unload style name = unload plugin name of style style
    style = pair or bond or angle or dihedral or improper or kspace or compute or␣
↪fix or region or command or run or min
list = print a list of currently loaded plugins
clear = unload all currently loaded plugins
restore = restore all loaded plugins
```

1.80.2 Examples

```
plugin load morse2plugin.so
plugin unload pair morse2/omp
plugin unload command hello
plugin list
plugin clear
plugin restore
```

1.80.3 Description

The plugin command allows to load (and unload) additional styles and commands into a LAMMPS binary from so-called dynamic shared object (DSO) files. This enables to add new functionality to an existing LAMMPS binary without having to recompile and link the entire executable.

Plugins are a global, per-executable property

Unlike most settings in LAMMPS, plugins are a per-executable global property. Loading a plugin means that it is not only available for the current LAMMPS instance but for all *future* LAMMPS instances.

Loaded plugins are kept in a process-global style registry, so they remain available after a *clear* command and do not need to be loaded again.

When using the library interface or the Python or Fortran module to create multiple concurrent LAMMPS instances, a plugin loaded by any instance is immediately available to all other LAMMPS instances in the same process.

The *load* command will load and initialize all plugins contained in the plugin DSO with the given filename. A message with information about the plugin style and name and more will be printed. Individual DSO files may contain multiple plugins. If a plugin is already loaded it will be skipped. More details about how to write and compile the plugin DSO is given in programmer's guide part of the manual under *Writing plugins*.

The *unload* command will remove the given style or the given name from the list of available styles. If the plugin style is currently in use, that style instance will be deleted and replaced by the default setting for that style.

The *list* command will print a list of the loaded plugins and their styles and names.

The *clear* command will unload all currently loaded plugins.

Added in version 12Jun2025.

Changed in version 2Sep2026.

The *restore* command is no longer required and does nothing: loaded plugins are now kept in a process-global style registry that persists across the *clear* command and is shared by all LAMMPS instances in the same process. The command is retained for backward compatibility.

Automatic loading of plugins

Added in version 4May2022.

When the environment variable `LAMMPS_PLUGIN_PATH` is set, then LAMMPS will search the directory (or directories) listed in this path for files with names that end in `plugin.so` (e.g. `helloplugin.so`) and will try to load the contained plugins automatically at start-up.

1.80.4 Restrictions

The *plugin* command is part of the PLUGIN package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

If plugins access functions or classes from a package, LAMMPS must have been compiled with that package included.

Plugins are dependent on the LAMMPS binary interface (ABI) and particularly the MPI library used. So they are not guaranteed to work when the plugin was compiled with a different MPI library or different compilation settings or a different LAMMPS version. There are no checks, so if there is a mismatch the plugin object will either not load or data corruption and crashes may happen.

1.81 prd command

1.81.1 Syntax

```
prd N t_event n_dephase t_dephase t_correlate compute-ID seed keyword value ...
```

- N = # of timesteps to run (not including dephasing/quenching)
- t_event = timestep interval between event checks
- n_dephase = number of velocity randomizations to perform in each dephase run
- t_dephase = number of timesteps to run dynamics after each velocity randomization during dephase
- t_correlate = number of timesteps within which 2 consecutive events are considered to be correlated
- compute-ID = ID of the compute used for event detection
- random_seed = random # seed (positive integer)
- zero or more keyword/value pairs may be appended
- keyword = *min* or *temp* or *vel* or *time*

```
min values = etol ftol maxiter maxeval
  etol = stopping tolerance for energy, used in quenching
  ftol = stopping tolerance for force, used in quenching
  maxiter = max iterations of minimize, used in quenching
  maxeval = max number of force/energy evaluations, used in quenching
temp value = Tdephase
  Tdephase = target temperature for velocity randomization, used in dephasing
vel values = loop dist
  loop = all or local or geom, used in dephasing
  dist = uniform or gaussian, used in dephasing
time value = steps or clock
  steps = simulation runs for N timesteps on each replica (default)
  clock = simulation runs for N timesteps across all replicas
```

prd 5000 100 10 10 100 1 54982 min 0.1 0.1 100 200
```

1.81.3 Description

Run a parallel replica dynamics (PRD) simulation using multiple replicas of a system. One or more replicas can be used. The total number of steps *N* to run can be interpreted in one of two ways; see discussion of the *time* keyword below.

PRD is described in *(Voter1998)* by Art Voter. Similar to global or local hyperdynamics (HD), PRD is a method for performing accelerated dynamics that is suitable for infrequent-event systems that obey first-order kinetics. A good overview of accelerated dynamics methods (AMD) for such systems in given in this review paper *(Voter2002)* from Art's group. To quote from the paper: "The dynamical evolution is characterized by vibrational excursions within a

potential basin, punctuated by occasional transitions between basins. The transition probability is characterized by p(t) = k*exp(-kt) where k is the rate constant."

Both PRD and HD produce a time-accurate trajectory that effectively extends the timescale over which a system can be simulated, but they do it differently. PRD creates Nr replicas of the system and runs dynamics on each independently with a normal unbiased potential until an event occurs in one of the replicas. The time between events is reduced by a factor of Nr replicas. HD uses a single replica of the system and accelerates time by biasing the interaction potential in a manner such that each timestep is effectively longer. For both methods, per CPU second, more physical time elapses and more events occur. See the *hyper* page for more info about HD.

In PRD, each replica runs on a partition of one or more processors. Processor partitions are defined at run-time using the *-partition command-line switch*. Note that if you have MPI installed, you can run a multi-replica simulation with more replicas (partitions) than you have physical processors, e.g you can run a 10-replica simulation on one or two processors. However for PRD, this makes little sense, since running a replica on virtual instead of physical processors,offers no effective parallel speed-up in searching for infrequent events. See the *Howto replica* doc page for further discussion.

When a PRD simulation is performed, it is assumed that each replica is running the same model, though LAMMPS does not check for this. I.e. the simulation domain, the number of atoms, the interaction potentials, etc should be the same for every replica.

A PRD run has several stages, which are repeated each time an "event" occurs in one of the replicas, as explained below. The logic for a PRD run is as follows:

```
while (time remains):
  dephase for n_dephase*t_dephase steps
  until (event occurs on some replica):
    run dynamics for t_event steps
    quench
    check for uncorrelated event on any replica
  until (no correlated event occurs):
    run dynamics for t_correlate steps
    quench
    check for correlated event on this replica
  event replica shares state with all replicas
```

Before this loop begins, the state of the system on replica 0 is shared with all replicas, so that all replicas begin from the same initial state. The first potential energy basin is identified by quenching (an energy minimization, see below) the initial state and storing the resulting coordinates for reference.

In the first stage, dephasing is performed by each replica independently to eliminate correlations between replicas. This is done by choosing a random set of velocities, based on the *random_seed* that is specified, and running *t_dephase* timesteps of dynamics. This is repeated *n_dephase* times. At each of the *n_dephase* stages, if an event occurs during the *t_dephase* steps of dynamics for a particular replica, the replica repeats the stage until no event occurs.

If the *temp* keyword is not specified, the target temperature for velocity randomization for each replica is the current temperature of that replica. Otherwise, it is the specified *Tdephase* temperature. The style of velocity randomization is controlled using the keyword *vel* with arguments that have the same meaning as their counterparts in the *velocity* command.

In the second stage, each replica runs dynamics continuously, stopping every *t_event* steps to check if a transition event has occurred. This check is performed by quenching the system and comparing the resulting atom coordinates to the coordinates from the previous basin. The first time through the PRD loop, the "previous basin" is the set of quenched coordinates from the initial state of the system.

A quench is an energy minimization and is performed by whichever algorithm has been defined by the *min_style* command. Minimization parameters may be set via the *min_modify* command and by the *min* keyword of the PRD command. The latter are the settings that would be used with the *minimize* command. Note that typically, you do not need to perform a highly-converged minimization to detect a transition event, though you may need to in order to prevent a set of atoms in the system from relaxing to a saddle point.

The event check is performed by a compute with the specified *compute-ID*. Currently there is only one compute that works with the PRD command, which is the *compute event/displace* command. Other event-checking computes may be added. *Compute event/displace* checks whether any atom in the compute group has moved further than a specified threshold distance. If so, an "event" has occurred.

In the third stage, the replica on which the event occurred (event replica) continues to run dynamics to search for correlated events. This is done by running dynamics for *t_correlate* steps, quenching every *t_event* steps, and checking if another event has occurred.

The first time no correlated event occurs, the final state of the event replica is shared with all replicas, the new basin reference coordinates are updated with the quenched state, and the outer loop begins again. While the replica event is searching for correlated events, all the other replicas also run dynamics and event checking with the same schedule, but the final states are always overwritten by the state of the event replica.

The outer loop of the pseudocode above continues until *N* steps of dynamics have been performed. Note that *N* only includes the dynamics of stages 2 and 3, not the steps taken during dephasing or the minimization iterations of quenching. The specified *N* is interpreted in one of two ways, depending on the *time* keyword. If the *time* value is *steps*, which is the default, then each replica runs for *N* timesteps. If the *time* value is *clock*, then the simulation runs until *N* aggregate timesteps across all replicas have elapsed. This aggregate time is the "clock" time defined below, which typically advances nearly M times faster than the timestepping on a single replica, where M is the number of replicas.

Four kinds of output can be generated during a PRD run: event statistics, thermodynamic output by each replica, dump files, and restart files.

When running with multiple partitions (each of which is a replica in this case), the print-out to the screen and master log.lammps file is limited to event statistics. Note that if a PRD run is performed on only a single replica then the event statistics will be intermixed with the usual thermodynamic output discussed below.

The quantities printed each time an event occurs are the timestep, CPU time, clock, event number, a correlation flag, the number of coincident events, and the replica number of the chosen event.

The timestep is the usual LAMMPS timestep, except that time does not advance during dephasing or quenches, but only during dynamics. Note that are two kinds of dynamics in the PRD loop listed above that contribute to this timestepping. The first is when all replicas are performing independent dynamics, waiting for an event to occur. The second is when correlated events are being searched for, but only one replica is running dynamics.

The CPU time is the total elapsed time on each processor, since the start of the PRD run.

The clock is the same as the timestep except that it advances by M steps per timestep during the first kind of dynamics when the M replicas are running independently. The clock advances by only 1 step per timestep during the second kind of dynamics, when only a single replica is checking for a correlated event. Thus "clock" time represents the aggregate time (in steps) that has effectively elapsed during a PRD simulation on M replicas. If most of the PRD run is spent in the second stage of the loop above, searching for infrequent events, then the clock will advance nearly M times faster than it would if a single replica was running. Note the clock time between successive events should be drawn from p(t).

The event number is a counter that increments with each event, whether it is uncorrelated or correlated.

The correlation flag will be 0 when an uncorrelated event occurs during the second stage of the loop listed above, i.e. when all replicas are running independently. The correlation flag will be 1 when a correlated event occurs during the third stage of the loop listed above, i.e. when only one replica is running dynamics.

When more than one replica detects an event at the end of the same event check (every *t_event* steps) during the second stage, then one of them is chosen at random. The number of coincident events is the number of replicas that detected an event. Normally, this value should be 1. If it is often greater than 1, then either the number of replicas is too large, or *t_event* is too large.

The replica number is the ID of the replica (from 0 to M-1) in which the event occurred.

When running on multiple partitions, LAMMPS produces additional log files for each partition, e.g. log.lammps.0, log.lammps.1, etc. For the PRD command, these contain the thermodynamic output for each replica. You will see short runs and minimizations corresponding to the dynamics and quench operations of the loop listed above. The timestep will be reset appropriately depending on whether the operation advances time or not.

After the PRD command completes, timing statistics for the PRD run are printed in each replica's log file, giving a breakdown of how much CPU time was spent in each stage (dephasing, dynamics, quenching, etc).

Any *dump files* defined in the input script, will be written to during a PRD run at timesteps corresponding to both uncorrelated and correlated events. This means the requested dump frequency in the *dump* command is ignored. There will be one dump file (per dump command) created for all partitions.

The atom coordinates of the dump snapshot are those of the minimum energy configuration resulting from quenching following a transition event. The timesteps written into the dump files correspond to the timestep at which the event occurred and NOT the clock. A dump snapshot corresponding to the initial minimum state used for event detection is written to the dump file at the beginning of each PRD run.

If the *restart* command is used, a single restart file for all the partitions is generated, which allows a PRD run to be continued by a new input script in the usual manner.

The restart file is generated at the end of the loop listed above. If no correlated events are found, this means it contains a snapshot of the system at time T + *t_correlate*, where T is the time at which the uncorrelated event occurred. If correlated events were found, then it contains a snapshot of the system at time T + *t_correlate*, where T is the time of the last correlated event.

The restart frequency specified in the *restart* command is interpreted differently when performing a PRD run. It does not mean the timestep interval between restart files. Instead it means an event interval for uncorrelated events. Thus a frequency of 1 means write a restart file every time an uncorrelated event occurs. A frequency of 10 means write a restart file every 10th uncorrelated event.

When an input script reads a restart file from a previous PRD run, the new script can be run on a different number of replicas or processors. However, it is assumed that *t_correlate* in the new PRD command is the same as it was previously. If not, the calculation of the "clock" value for the first event in the new run will be slightly off.

1.81.4 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the *Build package* doc page for more info.

The *N* and *t_correlate* settings must be integer multiples of *t_event*.

Runs restarted from restart file written during a PRD run will not produce identical results due to changes in the random numbers used for dephasing.

This command cannot be used when any fixes are defined that keep track of elapsed time to perform time-dependent operations. Examples include the "ave" fixes such as *fix ave/chunk*. Also *fix dt/reset* and *fix deposit*.

1.81.5 Related commands

1.81.6 Default

The option defaults are min = 0.1 0.1 40 50, no temp setting, vel = geom gaussian, and time = steps.

(Voter1998) Voter, Phys Rev B, 57, 13985 (1998).

(Voter2002) Voter, Montalenti, Germann, Annual Review of Materials Research 32, 321 (2002).

1.82 print command

1.82.1 Syntax

```
print string keyword value
```

- string = text string to print, which may contain variables
- zero or more keyword/value pairs may be appended
- keyword = *file* or *append* or *screen* or *universe*

  file value = filename
  append value = filename
  screen value = *yes* or *no*
  universe value = *yes* or *no*

1.82.2 Examples

```
print "Done with equilibration" file info.dat
print Vol=$v append info.dat screen no
print "The system volume is now $v"
print 'The system volume is now $v'
print "NEB calculation 1 complete" screen no universe yes
print """
System volume = $v
System temperature = $t
"""
```

1.82.3 Description

Print a text string to the screen and logfile. The text string must be a single argument, so if it is one line but more than one word, it should be enclosed in single or double quotes. To generate multiple lines of output, the string can be enclosed in triple quotes, as in the last example above. If the text string contains variables, they will be evaluated and their current values printed.

Added in version 15Jun2023: support for vector style variables

See the *variable* command for a description of *equal* and *vector* style variables which are typically the most useful ones to use with the print command. Equal- and vector-style variables can calculate formulas involving mathematical operations, atom properties, group properties, thermodynamic properties, global values calculated by a *compute* or *fix*, or references to other *variables*. Vector-style variables are printed in a bracketed, comma-separated format, e.g. [1,2,3,4] or [12.5,2,4.6,10.1].

Note

As discussed on the *Commands parse* doc page, the text string can use "immediate" variables, specified as $(formula) with parenthesis, where the numeric formula has the same syntax as equal-style variables described on the *variable* doc page. This is a convenient way to evaluate a formula immediately without using the variable command to define a named variable and then use that variable in the text string. The formula can include a trailing colon and format string which determines the precision with which the numeric value is output. This is also explained on the *Commands parse* doc page.

If you want the print command to be executed multiple times (with changing variable values), there are 3 options. First, consider using the *fix print* command, which will print a string periodically during a simulation. Second, the print command can be used as an argument to the *every* option of the *run* command. Third, the print command could appear in a section of the input script that is looped over (see the *jump* and *next* commands).

If the *file* or *append* keyword is used, a filename is specified to which the output will be written. If *file* is used, then the filename is overwritten if it already exists. If *append* is used, then the filename is appended to if it already exists, or created if it does not exist.

If the *screen* keyword is used, output to the screen and logfile can be turned on or off as desired.

If the *universe* keyword is used, output to the global screen and logfile can be turned on or off as desired. In multi-partition calculations, the *screen* option and the corresponding output only apply to the screen and logfile of the individual partition.

1.82.4 Restrictions

none

processors * * * part 1 2 multiple
```

1.83.3 Description

Specify how MPI processes are mapped as a regular 3d grid to the global simulation box. The mapping involves 2 steps. First if there are P MPI processes, it means choosing a factorization $P = Px$ by Py by Pz so that there are Px MPI processes in the x dimension, and similarly for the y and z dimensions. Second, the P MPI processes are mapped to the regular 3d grid. The arguments to this command control each of these 2 steps.

The Px, Py, Pz parameters affect the factorization. Any of the 3 parameters can be specified with an asterisk "*", which means LAMMPS will choose the number of MPI processes in that dimension of the grid. It will do this based on the size and shape of the global simulation box so as to minimize the surface-to-volume ratio of each MPI rank's subdomain.

Choosing explicit values for Px or Py or Pz can be used to override the default manner in which LAMMPS will create the regular 3d grid of MPI processes, if it is known to be sub-optimal for a particular problem. E.g. a problem where the extent of atoms will change dramatically in a particular dimension over the course of the simulation.

The product of Px, Py, Pz must equal P, the total # of MPI processes LAMMPS is running on. For a *2d simulation*, Pz must equal 1.

Note that if you run on a prime number of MPI processes P, then a grid such as 1 x P x 1 will be required, which may incur extra communication costs due to the high surface area of each processor's subdomain.

Also note that if multiple partitions are being used then P is the number of MPI processes in this partition; see the *-partition command-line switch* page for details. Also note that you can prefix the *processors* command with the *partition* command to easily specify different Px, Py, Pz values for different partitions.

You can use the *partition* command to specify different processor grids for different partitions, e.g.

```
partition yes 1 processors 4 4 4
partition yes 2 processors 2 3 2
```

Note

This command only affects the initial regular 3d grid created when the simulation box is first specified via a *create_box* or *read_data* or *read_restart* command. Or if the simulation box is re-created via the *replicate* command. The same regular grid is initially created, regardless of which *comm_style* command is in effect.

If load-balancing is never invoked via the *balance* or *fix balance* commands, then the initial regular grid will persist for all simulations. If balancing is performed, some of the methods invoked by those commands retain the logical topology of the initial 3d grid, and the mapping of MPI processes to the grid specified by the *processors* command. However the grid spacings in different dimensions may change, so that MPI processes would own subdomains of different sizes. If the *comm_style tiled* command is used, methods invoked by the balancing commands may discard the 3d grid of MPI processes and tile the simulation domain with subdomains of different sizes and shapes which no longer have a logical 3d connectivity. If that occurs, all the information specified by the *processors* command is ignored.

The *grid* keyword affects the factorization of P into Px, Py, Pz and it can also affect how the P MPI ranks are mapped to the 3d grid of MPI processes.

The *onelevel* style creates a 3d grid that is compatible with the Px, Py, Pz settings, and which minimizes the surface-to-volume ratio of each processor's subdomain, as described above. The mapping of MPI processes to the grid is determined by the *map* keyword setting.

The *twolevel* style can be used on machines with multicore nodes to minimize off-node communication. It ensures that contiguous subsections of the 3d grid are assigned to all the cores of a node. For example if Nc is 4, then 2x2x1 or 2x1x2 or 1x2x2 subsections of the 3d grid will correspond to the cores of each node. This affects both the factorization and mapping steps.

The Cx, Cy, Cz settings are similar to the Px, Py, Pz settings, only their product should equal Nc. Any of the 3 parameters can be specified with an asterisk "*", which means LAMMPS will choose the number of cores in that dimension of the node's sub-grid. As with Px, Py, Pz, it will do this based on the size and shape of the global simulation box so as to minimize the surface-to-volume ratio of each processor's subdomain.

Note

For the *twolevel* style to work correctly, it assumes the ranks of the MPI processes that LAMMPS is running on are ordered by core and then by node. E.g. if you are running on 2 quad-core nodes, for a total of 8 MPI processes, then it assumes ranks 0, 1, 2, and 3 are on node 1, and ranks 4, 5, 6, and 7 are on node 2. This is the default rank ordering for most MPI implementations, but some MPI libraries provide options for customizing this ordering, e.g. via environment variable settings.

The *numa* style operates similar to the *twolevel* keyword except that it auto-detects which cores are running on which nodes. It will also subdivide the cores into NUMA domains. Currently, the number of NUMA domains is not auto-detected and must be specified using the *numa_nodes* keyword. Otherwise, the default value is used. The *numa* style uses a different algorithm than the *twolevel* keyword for doing the two-level factorization of the simulation box into a 3d processor grid to minimize off-node communication and communication across NUMA domains. It does its own MPI-based mapping of nodes and cores to the regular 3d grid. Thus it may produce a different layout of the MPI ranks than the *twolevel* options.

The *numa* style will give an error if the number of MPI processes is not divisible by the number of cores used per node, or any of the Px or Py or Pz values is greater than 1.

Note

Unlike the *twolevel* style, the *numa* style does not require any particular ordering of MPI ranks in order to work correctly. This is because it auto-detects which processes are running on which nodes. However, it assumes that the lowest ranks are in the first NUMA domain, and so forth. MPI rank orderings that do not preserve this property might result in more intra-node communication between CPUs.

The *custom* style uses the file *infile* to define both the 3d factorization and the mapping of processors to the grid.

The file should have the following format. Any number of initial blank or comment lines (starting with a "#" character) can be present. The first non-blank, non-comment line should have 3 values:

```
Px Py Pz
```

These must be compatible with the total number of processors and the *Px*, *Py*, *Pz* settings of the processors command.

This line should be immediately followed by P = *Px* * *Py* * *Pz* lines of the form:

```
ID I J K
```

where ID is an MPI process rank (from 0 to P-1) and *I*, *J*, *K* are the MPI rank's location in the 3d grid. *I* must be a number from 1 to *Px* (inclusive) and similarly for *J* and *Py* or *K* and *Pz*. The *P* lines can be listed in any order, but no MPI rank should appear more than once.

The *numa_nodes* keyword is used to specify the number of NUMA domains per node. It is currently only used by the *numa* style for two-level factorization to reduce the amount of MPI communications between CPUs. A good setting for this will typically be equal to the number of CPU sockets per node.

The *map* keyword affects how the *P* MPI process ranks (from 0 to P-1) are mapped to the 3d grid of MPI processes. It is only used by the *onelevel* and *twolevel* grid settings.

The *cart* style uses the family of MPI Cartesian functions to perform the mapping, namely MPI_Cart_create(), MPI_Cart_get(), MPI_Cart_shift(), and MPI_Cart_rank(). It invokes the MPI_Cart_create() function with its reorder flag = 0, so that MPI is not free to reorder the processors.

The *cart/reorder* style does the same thing as the *cart* style except it sets the reorder flag to 1, so that MPI can reorder processors if it desires.

The *xyz*, *xzy*, *yxz*, *yzx*, *zxy*, and *zyx* styles are all similar. If the style is IJK, then it maps the *P* processors to the grid so that the MPI ranks in the *I* direction varies fastest, the MPI ranks in the *J* direction varies next fastest, and the MPI rank in the *K* direction varies slowest. For example, if you select style *xyz* and you have a 2x2x2 grid of 8 processors, the assignments of the 8 octants of the simulation domain will be:

```
proc 0 = lo x, lo y, lo z octant
proc 1 = hi x, lo y, lo z octant
proc 2 = lo x, hi y, lo z octant
proc 3 = hi x, hi y, lo z octant
proc 4 = lo x, lo y, hi z octant
proc 5 = hi x, lo y, hi z octant
proc 6 = lo x, hi y, hi z octant
proc 7 = hi x, hi y, hi z octant
```

Note that, in principle, an MPI implementation on a particular machine should be aware of both the machine's network topology and the specific subset of processors and nodes that were assigned to your simulation. Thus its `MPI_Cart_xxx()` calls can optimize the assignment of MPI processes to the 3d grid to minimize communication costs. In practice, however, few if any MPI implementations actually do this. So it is likely that the *cart* and *cart/reorder* styles simply give the same result as one of the *IJK* styles.

Also note, that for the *twolevel* grid style, the *map* setting is used to first map the nodes to the 3d grid, then again to the cores within each node. For the latter step, the *cart* and *cart/reorder* styles are not supported, so an *xyz* style is used in their place.

The *part* keyword affects the factorization of *P* into *Px*, *Py*, *Pz*.

It can be useful when running in multi-partition mode, e.g. with the *run_style verlet/split* command. It specifies a dependency between a sending partition *Psend* and a receiving partition *Precv* which is enforced when each is setting up their own mapping of their processors to the simulation box. Each of *Psend* and *Precv* must be integers from 1 to *Np*, where *Np* is the number of partitions you have defined via the *-partition command-line switch*.

A "dependency" means that the sending partition will create its regular 3d grid as *Px* by *Py* by *Pz* and after it has done this, it will send the *Px*, *Py*, *Pz* values to the receiving partition. The receiving partition will wait to receive these values before creating its own regular 3d grid and will use the sender's *Px*, *Py*, *Pz* values as a constraint. The nature of the constraint is determined by the *cstyle* argument.

For a *cstyle* of *multiple*, each dimension of the sender's processor grid is required to be an integer multiple of the corresponding dimension in the receiver's processor grid. This is a requirement of the *run_style verlet/split* command.

For example, assume the sending partition creates a 4x6x10 grid = 240 processor grid. If the receiving partition is running on 80 processors, it could create a 4x2x10 grid, but it will not create a 2x4x10 grid, since in the y-dimension, 6 is not an integer multiple of 4.

Note

If you use the *partition* command to invoke different "processors" commands on different partitions, and you also use the *part* keyword, then you must ensure that both the sending and receiving partitions invoke the "processors" command that connects the 2 partitions via the *part* keyword. LAMMPS cannot easily check for this, but your simulation will likely hang in its setup phase if this error has been made.

The *file* keyword writes the mapping of the factorization of *P* MPI processes and their mapping to the 3d grid to the specified file *outfile*. This is useful to check that you assigned physical processors in the manner you desired, which can be tricky to figure out, especially when running on multiple partitions or on, a multicore machine or when the MPI ranks were reordered by use of the *-reorder command-line switch* or due to use of MPI-specific launch options such as a config file.

If you have multiple partitions you should ensure that each one writes to a different file, e.g. using a *world-style variable* for the filename. The file has a self-explanatory header, followed by one-line per processor in this format:

world-ID universe-ID original-ID: I J K: name

The IDs are the MPI ranks in this simulation (the world), the universe (of multiple simulations), and the original MPI communicator used to instantiate LAMMPS, respectively. The world and universe IDs will only be different if you are running on more than one partition; see the *-partition command-line switch*. The universe and original IDs will only be different if you used the *-reorder command-line switch* to reorder the MPI processes differently than their rank in the original communicator LAMMPS was instantiated with.

I, *J*, *K* are the indices of the processor in the regular 3d grid, each from 1 to *Nd*, where *Nd* is the number of MPI processes in that dimension of the grid.

The *name* is what is returned by a call to MPI_Get_processor_name() and should represent an identifier relevant to the physical processors in your machine. Note that depending on the MPI implementation, multiple cores can have the same *name*.

1.83.4 Restrictions

This command cannot be used *after* the simulation box is defined by a *read_data* or *create_box* command. It can be used *before* a restart file is read to change the 3d processor grid from what is specified in the restart file.

The *grid numa* keyword only currently works with the *map cart* option.

The *part* keyword (for the receiving partition) only works with the *grid onelevel* or *grid twolevel* options.

1.83.5 Related commands

partition, *-reorder command-line switch*

1.83.6 Default

The option defaults are *Px Py Pz* = * * *, grid = onelevel, map = cart, and numa_nodes = 2.

1.84 python command

1.84.1 Syntax

```
python mode keyword args ...
```

- mode = *source* or *name* of Python function

  if mode is *source*:

  ```
  keyword = here or name of a Python file
    here arg = inline
      inline = one or more lines of Python code which will be executed immediately
               must be a single argument, typically enclosed between triple quotes
    Python file = name of a file with Python code which will be executed immediately
  ```

- if *mode* is *name* of a Python function:

  ```
  one or more keywords with/without arguments must be appended
  keyword = invoke or input or return or format or length or file or here or exists
    invoke arg = logreturn (optional)
      invoke the previously-defined Python function
      if logreturn is specified, print the return value of the invoked function to␣
  ↪the screen and logfile
    input args = N i1 i2 ... iN
      N = # of inputs to function
      i1,...,iN = value, SELF, or LAMMPS variable name
        value = integer number, floating point number, or string
        SELF = reference to LAMMPS itself which can then be accessed by Python␣
  ↪function
        variable = v_name, where name = name of a LAMMPS variable, e.g. v_abc
        internal variable = iv_name, where name = name of a LAMMPS internal-style␣
  ↪variable, e.g. iv_xyz
    return arg = varReturn
  ```

```
    varReturn = v_name  = LAMMPS variable name which the return value of the Python␣
↪function will be assigned to
  format arg = fstring with M characters
    M = N if no return value, where N = # of inputs
    M = N+1 if there is a return value
    fstring = each character (i,f,s,p) corresponds (in order) to an input or return␣
↪value
      'i' = integer, 'f' = floating point, 's' = string, 'p' = SELF
  length arg = Nlen
    Nlen = max length of string returned from Python function
  file arg = filename
    filename = file of Python code, which defines the Python function
  here arg = inline
    inline = one or more lines of Python code which defines the Python function
             must be a single argument, typically enclosed between triple quotes
  exists arg = none = Python code has been loaded by previous python command
```

1.84.2 Examples

```
python pForce input 2 v_x 20.0 return v_f format fff file force.py
python pForce invoke logreturn

python factorial input 1 myN return v_fac format ii here """
def factorial(n):
  if n == 1: return n
  return n * factorial(n-1)
 """

python loop input 1 SELF return v_value format pf here """
def loop(lmpptr,N,cut0):
  from lammps import lammps
  lmp = lammps(ptr=lmpptr)

  # loop N times, increasing cutoff each time

  for i in range(N):
    cut = cut0 + i*0.1
    lmp.set_variable("cut",cut)               # set a variable in LAMMPS
    lmp.command("pair_style lj/cut ${cut}")   # LAMMPS commands
    lmp.command("pair_coeff * * 1.0 1.0")
    lmp.command("run 100")
"""

python source funcdef.py

python source here "from lammps import lammps"
```

1.84.3 Description

The *python* command interfaces LAMMPS with an embedded Python interpreter and enables executing arbitrary python code in that interpreter. This can be done immediately, by using *mode* = *source*. Or execution can be deferred, by registering a Python function for later execution, by using *mode* = *name* of a Python function.

Later execution can be triggered in one of two ways. One is to use the python command again with its *invoke* keyword.

The other is to trigger the evaluation of a python-style, equal-style, vector-style, or atom-style variable. A python-style variable invokes its associated Python function; its return value becomes the value of the python-style variable. Equal-, vector-, and atom-style variables can use a Python function wrapper in their formulas which encodes the python-style variable name, and specifies arguments (which themselves can be numeric formulas) to pass to the Python function associated with the python-style variable.

As explained on the *variable* doc page, the definition of a python-style variable associates a Python function name with the variable. Its specification must match the *mode* argument of the *python* command for the Python function name. For example these two commands would be consistent:

```
variable foo python myMultiply
python myMultiply return v_foo format f file funcs.py
```

The two commands can appear in either order in the input script so long as both are specified before the Python function is invoked for the first time.

Note that python-style, equal-style, vector-style, and atom-style variables can be used in many different ways within LAMMPS. They can be evaluated directly in an input script, effectively replacing the variable with its value. Or they can be passed to various commands as arguments, so that the variable is evaluated multiple times during a simulation run. See the *variable* command doc page for more details on variable styles which enable Python function evaluation.

The Python code for a Python function can be included directly in the input script or in a separate Python file. The function can be standard Python code or it can make "callbacks" to LAMMPS through its library interface to query or set internal values within LAMMPS. This is a powerful mechanism for performing complex operations in a LAMMPS input script that are not possible with the simple input script and variable syntax which LAMMPS defines. Thus your input script can operate more like a true programming language.

Use of this command requires building LAMMPS with the PYTHON package which links to the Python library so that the Python interpreter is embedded in LAMMPS. More details about this process are given below.

A broader overview of how Python can be used with LAMMPS is given in the *Use Python with LAMMPS* section of the documentation. There is also an `examples/python` directory which illustrates use of the python command.

The first argument to the *python* command is the *mode* setting, which is either *source* or the *name* of a Python function.

Changed in version 22Dec2022.

If *source* is used, it is followed by either the *here* keyword or a file name containing Python code. The *here* keyword is followed by a single *inline* argument which is a string containing one or more python commands. The string can either be on the same line as the *python* command, enclosed in quotes, or it can be multiple lines enclosed in triple quotes.

In either case, the in-line code or the file contents are passed to the python interpreter and executed immediately. The code will be loaded into and run in the "main" module of the Python interpreter. This allows running arbitrary Python code at any time while processing the LAMMPS input file. This can be used to pre-load Python modules, initialize global variables, define functions or classes, or perform operations using the Python programming language. The Python code will be executed in parallel on all the MPI processes being used to run LAMMPS. Note that no arguments can be passed to the executed Python code.

If the *mode* setting is the *name* of a Python function, then it will be registered with LAMMPS for future execution (or can already be defined, see the *exists* keyword). One or more keywords must follow the *mode* function name. One of the keywords must be *invoke*, *file*, *here*, or *exists*, which specifies what Python code to load into the Python interpreter. Note that only one of those 4 keywords is allowed since their operations are mutually exclusive.

If the *invoke* keyword is used, no other keywords can be used. A previous *python* command must have registered the Python function referenced by this command, which can then be invoked multiple times in an input script via the *invoke* keyword. Each invocation passes current values for arguments to the Python function. A return value of the Python

function will be ignored unless the Python function is linked to a *python style variable* with the *return* keyword. This return value can be logged to the screen and logfile by adding the optional *logreturn* argument to the *invoke* keyword. In that case a message with the name of the python command and the return value is printed. Note that return values of python functions are otherwise *only* accessible when the function is invoked indirectly by evaluating its associated *python style variable*, as described below.

The *file* keyword gives the name of a file containing Python code, which should end with a ".py" suffix. The code will be immediately loaded into and run in the "main" module of the Python interpreter. The Python code will be executed in parallel on all MPI processes. Note that Python code which contains a function definition does NOT "execute" the function when it is run; it simply defines the function so that it can be invoked later.

The *here* keyword does the same thing, except that the Python code follows as a single argument to the *here* keyword. This can be done using triple quotes as delimiters, as in the examples above and below. This allows Python code to be listed verbatim in your input script, with proper indentation, blank lines, and comments, as desired. See the *Commands parse* doc page, for an explanation of how triple quotes can be used as part of input script syntax.

The *exists* keyword takes no argument. It simply means that Python code containing the needed Python function has already been loaded into the LAMMPS Python interpreter, for example by previous *python source* command or in a file that was loaded previously with the *file* keyword. This allows use of a single file of Python code which contains multiple functions, any of which can be used in the same (or different) input scripts (see below).

Note that the Python code that is loaded and run by the *file* or *here* keyword must contain a function with the specified function *name*. To operate properly when the function is later invoked, the code for the function must match the *input* and *return* and *format* keywords specified by the python command. Otherwise Python will generate an error.

The other keywords which can be used with the *python* command are *input*, *return*, *format*, and *length*.

The *input* keyword defines how many arguments *N* the Python function expects. If it takes no arguments, then the *input* keyword should not be used. Each argument can be specified directly as a value, e.g. '6' or '3.14159' or 'abc' (a string of characters). The type of each argument is specified by the *format* keyword as explained below, so that Python will know how to interpret the value. If the word SELF is used for an argument it has a special meaning. A pointer is passed to the Python function which it can convert into a reference to LAMMPS itself using the *LAMMPS Python module*. This enables the function to call back to LAMMPS through its library interface as explained below. This allows the Python function to query or set values internal to LAMMPS which can affect the subsequent execution of the input script.

A LAMMPS variable can also be used as an *input* argument, specified as v_name, where "name" is the name of the variable defined in the input script. Any style of LAMMPS variable returning a scalar or a string can be used, as defined by the *variable* command. The style of variable must be consistent with the *format* keyword specification for the type of data that is passed to Python. Each time the Python function is invoked, the LAMMPS variable is evaluated and its value is passed as an argument to the Python function. Note that a python-style variable can be used as an argument, which means that the a Python function can use arguments which invoke other Python functions.

A LAMMPS internal-style variable can also be used as an *input* argument, specified as iv_name, where "name" is the name of the internal-style variable. The internal-style variable does not have to be defined in the input script (though it can be); if it is not defined, this command creates an *internal-style variable* with the specified name.

An internal-style variable must be used when an equal-style, vector-style, or atom-style variable triggers the invocation of the Python function defined by this command, by including a Python function wrapper with arguments in its formula. Each of the arguments must be specified as an internal-style variable via the *input* keyword.

In brief, the syntax for a Python function wrapper in a variable formula is `py_varname(arg1,arg2,...argN)`, where "varname" is the name of a python-style variable associated with a Python function defined by this command. One or more arguments to the function wrapper can themselves be sub-formulas which the variable command will evaluate and pass as arguments to the Python function. This is done by assigning the numeric result for each argument to an internal-style variable; thus the *input* keyword must specify the arguments as internal-style variables and their format (see below) as "f" for floating point. This is because LAMMPS variable formulas are calculated with floating point

arithmetic (any integer values are converted to floating point). Note that the Python function can also have additional inputs, also specified by the *input* keyword, which are NOT arguments in the Python function wrapper. See the example below for the `mixedargs` Python function.

See the *variable* command doc page for full details on formula syntax including for Python function wrappers. Examples using Python function wrappers are shown below. Note that as explained above with python-style variables, Python function wrappers can be nested; a sub-formula for an argument can contain its own Python function wrapper which invokes another Python function.

The *return* keyword is only needed if the Python function returns a value. The specified *varReturn* is of the form v_name, where "name" is the name of a python-style LAMMPS variable, defined by the *variable* command. The Python function can return a numeric or string value, as specified by the *format* keyword. This return value is *only* accessible when its associated python-style variable is evaluated. When the *invoke* keyword is used, the return value of the python function is ignored unless the optional *logreturn* argument is specified.

The *format* keyword must be used if the *input* or *return* keywords are used. It defines an *fstring* with M characters, where M = sum of number of inputs and outputs. The order of characters corresponds to the N inputs, followed by the return value (if it exists). Each character must be one of the following: "i" for integer, "f" for floating point, "s" for string, or "p" for SELF. Each character defines the type of the corresponding input or output value of the Python function and affects the type conversion that is performed internally as data is passed back and forth between LAMMPS and Python. Note that it is permissible to use a *python-style variable* in a LAMMPS command that allows for an equal-style variable as an argument, but only if the output of the Python function is flagged as a numeric value ("i" or "f") via the *format* keyword.

If the *return* keyword is used and the *format* keyword specifies the output as a string, then the default maximum length of that string is 63 characters (64-1 for the string terminator). If you want to return a longer string, the *length* keyword can be specified with its *Nlen* value set to a larger number. LAMMPS will then allocate Nlen+1 space to include the string terminator. If the Python function generates a string longer than the default 63 or the specified *Nlen*, it will be truncated.

This section describes how Python code can be written to work with LAMMPS.

Whether you load Python code from a file or directly from your input script, via the *file* and *here* keywords, the code can be identical. It must be indented properly as Python requires. It can contain comments or blank lines. If the code is in your input script, it cannot however contain triple-quoted Python strings, since that will conflict with the triple-quote parsing that the LAMMPS input script performs.

All the Python code you specify via one or more python commands is loaded into the Python "main" module, i.e. `__name__ == '__main__'`. The code can define global variables, define global functions, define classes or execute statements that are outside of function definitions. It can contain multiple functions, only one of which matches the *func* setting in the python command. This means you can use the *file* keyword once to load several functions, and the *exists* keyword thereafter in subsequent python commands to register the other functions that were previously loaded with LAMMPS.

A Python function you define (or more generally, the code you load) can import other Python modules or classes, it can make calls to other system functions or functions you define, and it can access or modify global variables (in the "main" module) which will persist between successive function calls. The latter can be useful, for example, to prevent a function from being invoke multiple times per timestep by different commands in a LAMMPS input script that access the returned python-style variable associated with the function. For example, consider this function loaded with two global variables defined outside the function:

```
nsteplast = -1
nvaluelast = 0

def expensive(nstep):
  global nsteplast,nvaluelast
```

(continues on next page)

(continued from previous page)

```
  if nstep == nsteplast: return nvaluelast
  nsteplast = nstep
  # perform complicated calculation
  nvalue = ...
  nvaluelast = nvalue
  return nvalue
```

The variable 'nsteplast' stores the previous timestep the function was invoked (passed as an argument to the function). The variable 'nvaluelast' stores the return value computed on the last function invocation. If the function is invoked again on the same timestep, the previous value is simply returned, without re-computing it. The "global" statement inside the Python function allows it to overwrite the global variables from within the local context of the function.

Also note that if you load Python code multiple times (via multiple python commands), you can overwrite previously loaded variables and functions if you are not careful. E.g. if the code above were loaded twice, the global variables would be re-initialized, which might not be what you want. Likewise, if a function with the same name exists in two chunks of Python code you load, the function loaded second will override the function loaded first.

It's important to realize that if you are running LAMMPS in parallel, each MPI task will load the Python interpreter and execute a local copy of the Python function(s) you define. There is no connection between the Python interpreters running on different processors. This implies three important things.

First, if you put a print or other statement creating output to the screen in your Python function, you will see P copies of the output, when running on P processors. If the prints occur at (nearly) the same time, the P copies of the output may be mixed together.

It is possible to avoid this issue, by passing the pointer to the current LAMMPS class instance to the Python function via the {input} SELF argument described above. The Python function can then use the Python interface to the LAMMPS library interface, and determine the MPI rank of the current process. The Python code can then ensure output will only appear on MPI rank 0. The following LAMMPS input demonstrates how this could be done. The text 'Hello, LAMPS!' should be printed only once, even when running LAMMPS in parallel.

```
python python_hello input 1 SELF format p here """
def python_hello(handle):
    from lammps import lammps
    lmp = lammps(ptr=handle)
    me = lmp.extract_setting('world_rank')
    if me == 0:
        print('Hello, LAMMPS!')
"""

python python_hello invoke
```

Second, if your Python code loads Python modules that are not pre-loaded by the Python library, then it will load the module from disk. This may be a bottleneck if 1000s of processors try to load a module at the same time. On some large supercomputers, loading of modules from disk by Python may be disabled. In this case you would need to pre-build a Python library that has the required modules pre-loaded and link LAMMPS with that library.

Third, if your Python code calls back to LAMMPS (discussed in the next section) and causes LAMMPS to perform an MPI operation requires global communication (e.g. via MPI_Allreduce), such as computing the global temperature of the system, then you must ensure all your Python functions (running independently on different processors) call back to LAMMPS. Otherwise the code may hang.

As mentioned above, a Python function can "call back" to LAMMPS through its library interface, if the SELF input is used to pass Python a pointer to LAMMPS. The mechanism for doing this is as follows:

```
def foo(handle,...):
  from lammps import lammps
  lmp = lammps(ptr=handle)
  lmp.command('print "Hello from inside Python"')
  ...
```

The function definition must include a variable ('handle' in this case) which corresponds to SELF in the *python* command. The first line of the function imports the *"lammps" Python module*. The second line creates a Python object `lmp` which wraps the instance of LAMMPS that called the function. The 'ptr=handle' argument is what makes that happen. The third line invokes the command() function in the LAMMPS library interface. It takes a single string argument which is a LAMMPS input script command for LAMMPS to execute, the same as if it appeared in your input script. In this case, LAMMPS should output

```
Hello from inside Python
```

to the screen and log file. Note that since the LAMMPS print command itself takes a string in quotes as its argument, the Python string must be delimited with a different style of quotes.

The *Use Python with LAMMPS* page describes the syntax for how Python wraps the various functions included in the LAMMPS library interface.

A more interesting example is in the `examples/python/in.python` script which loads and runs the following function from `examples/python/funcs.py`:

```
def loop(N,cut0,thresh,lmpptr):
  print("LOOP ARGS", N, cut0, thresh, lmpptr)
  from lammps import lammps
  lmp = lammps(ptr=lmpptr)
  natoms = lmp.get_natoms()

  for i in range(N):
    cut = cut0 + i*0.1

    lmp.set_variable("cut",cut)                 # set a variable in LAMMPS
    lmp.command("pair_style lj/cut ${cut}")     # LAMMPS command
    #lmp.command("pair_style lj/cut %d" % cut)  # alternate form of LAMMPS command

    lmp.command("pair_coeff * * 1.0 1.0")       # ditto
    lmp.command("run 10")                       # ditto
    pe = lmp.extract_compute("thermo_pe",0,0)   # extract total PE from LAMMPS
    print("PE", pe/natoms, thresh)
    if pe/natoms < thresh: return
```

with these input script commands:

```
python          loop input 4 10 1.0 -4.0 SELF format iffp file funcs.py
python          loop invoke
```

This has the effect of looping over a series of 10 short runs (10 timesteps each) where the pair style cutoff is increased from a value of 1.0 in distance units, in increments of 0.1. The looping stops when the per-atom potential energy falls below a threshold of -4.0 in energy units. More generally, Python can be used to implement a loop with complex logic, much more so than can be created using the LAMMPS *jump* and *if* commands.

Several LAMMPS library functions are called from the loop function. Get_natoms() returns the number of atoms in the simulation, so that it can be used to normalize the potential energy that is returned by extract_compute() for the "thermo_pe" compute that is defined by default for LAMMPS thermodynamic output. Set_variable() sets the value of

a string variable defined in LAMMPS. This library function is a useful way for a Python function to return multiple values to LAMMPS, more than the single value that can be passed back via a return statement. This cutoff value in the "cut" variable is then substituted (by LAMMPS) in the pair_style command that is executed next. Alternatively, the "alternate form of LAMMPS command" line could be used in place of the 2 preceding lines, to have Python insert the value into the LAMMPS command string.

Note

When using the callback mechanism just described, recognize that there are some operations you should not attempt because LAMMPS cannot execute them correctly. If the Python function is invoked between runs in the LAMMPS input script, then it should be OK to invoke any LAMMPS input script command via the library interface command() or file() functions, so long as the command would work if it were executed in the LAMMPS input script directly at the same point.

As noted above, a Python function can be invoked during a run, whenever an associated python-style variable it is assigned to is evaluated.

If the variable is an input argument to another LAMMPS command (e.g. *fix setforce*), then the Python function will be invoked inside the class for that command, possibly in one of its methods that is invoked in the middle of a timestep. You cannot execute arbitrary input script commands from the Python function (again, via the command() or file() functions) at that point in the run and expect it to work. Other library functions such as those that invoke computes or other variables may have hidden side effects as well. In these cases, LAMMPS has no simple way to check that something illogical is being attempted.

The same constraints apply to Python functions called during a simulation run at each time step using the *fix python/invoke* command.

As noted above, a Python function can also be invoked within the formula for an equal-style, vector-style, or atom-style variable. This means the Python function will be invoked whenever that variable is invoked. In the case of a vector-style variable, the Python function can be invoked once per element of the global vector. In the case of an atom-style variable, the Python function can be invoked once per atom.

Here are three simple examples using equal-, vector-, and atom-style variables to trigger execution of a Python function:

```
variable        foo python truncate
python          truncate return v_foo input 1 iv_arg format fi here """
def truncate(x):
  return int(x)
"""
variable        ptrunc equal py_foo(press)
print           "TRUNCATED pressure = ${ptrunc}"
```

The Python `truncate` function simply converts a floating-point value to an integer value. When the LAMMPS print command evaluates the equal-style `ptrunc` variable, the current thermodynamic pressure is passed to the Python function. The truncated value is output to the screen and logfile by the print command. Note that the *input* keyword for the *python* command, specifies an internal-style variable named "arg" as iv_arg which is required to invoke the Python function from a Python function wrapper.

The last 2 lines can be replaced by these to define a vector-style variable which invokes the same Python `truncate` function:

```
compute         ke all temp
variable        ke vector c_ke
variable        ketrunc vector py_foo(v_ke)
thermo_style    custom step temp epair v_ketrunc[*6]
```

The vector-style variable `ketrunc` invokes the Python `truncate` function on each of the 6 components of the global kinetic energy tensor calculated by the *compute ke* command. The 6 truncated values will be printed with thermo output to the screen and log file.

Or the last 2 lines of the equal-style variable example can be replaced by these to define atom-style variables which invoke the same Python `truncate` function:

```
variable        xtrunc atom py_foo(x)
variable        ytrunc atom py_foo(y)
variable        ztrunc atom py_foo(z)
dump            1 all custom 100 tmp.dump id x y z v_xtrunc v_ytrunc v_ztrunc
```

When the dump command invokes the 3 atom-style variables, their arguments x,y,z to the Python function wrapper are the current per-atom coordinates of each atom. The Python `truncate` function is thus invoked 3 times for each atom, and the truncated coordinate values for each atom are written to the dump file.

Note that when using a Python function wrapper in a variable, arguments can be passed to the Python function either from the variable formula or by *input* keyword to the *python command*. For example, consider these (made up) commands:

```
variable        foo python mixedargs
python          mixedargs return v_foo input 6 7.5 v_myValue iv_arg1 iv_argy iv_argz v_
↪flag &
                format fffffsf here """
def mixedargs(a,b,x,y,z,flag):
  ...
  return result
"""
variable        flag string optionABC
variable        myValue equal "2.0*temp*c_pe"
compute         pe all pe
compute         peatom all pe/atom
variable        field atom py_foo(x+3.0,sqrt(y),(z-zlo)*c_peatom)
```

They define a Python `mixedargs` function with 6 arguments. Three of them are internal-style variables, which the variable formula calculates as numeric values for each atom and passes to the function. In this example, these arguments are themselves small formulas containing the x,y,z coordinates of each atom as well as a per-atom compute (c_peratom) and thermodynamic keyword (zlo).

The other three arguments `(7.5,v_myValue,v_flag)` are defined by the *python* command. The first and last are constant values ("7.5" and the `optionABC` string). The second argument (`myValue`) is the result of an equal-style variable formula which accesses the system temperature and potential energy.

The "result" returned by each invocation of the Python `mixedargs` function becomes the per-atom value in the atom-style "field" variable, which could be output to a dump file or used elsewhere in the input script.

If you run Python code directly on your workstation, either interactively or by using Python to launch a Python script stored in a file, and your code has an error, you will typically see informative error messages. That is not the case when you run Python code from LAMMPS using an embedded Python interpreter. The code will typically fail silently. LAMMPS will catch some errors but cannot tell you where in the Python code the problem occurred. For example, if

the Python code cannot be loaded and run because it has syntax or other logic errors, you may get an error from Python pointing to the offending line, or you may get one of these generic errors from LAMMPS:

```
Could not process Python file
Could not process Python string
```

When the Python function is invoked, if it does not return properly, you will typically get this generic error from LAMMPS:

```
Python function evaluation failed
```

Here are three suggestions for debugging your Python code while running it under LAMMPS.

First, don't run it under LAMMPS, at least to start with! Debug it using plain Python. Load and invoke your function, pass it arguments, check return values, etc.

Second, add Python print statements to the function to check how far it gets and intermediate values it calculates. See the discussion above about printing from Python when running in parallel.

Third, use Python exception handling. For example, say this statement in your Python function is failing, because you have not initialized the variable foo:

```
foo += 1
```

If you put one (or more) statements inside a "try" statement, like this:

```
import exceptions
print("Inside simple function")
try:
  foo += 1      # one or more statements here
except Exception as e:
  print("FOO error:", e)
```

then you will get this message printed to the screen:

```
FOO error: local variable 'foo' referenced before assignment
```

If there is no error in the try statements, then nothing is printed. Either way the function continues on (unless you put a return or sys.exit() in the except clause).

1.84.4 Restrictions

This command is part of the PYTHON package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

If you use Python code which calls back to LAMMPS, via the SELF input argument explained above, there is an extra step required when building LAMMPS. LAMMPS must also be built as a shared library and your Python function must be able to load the *"lammps" Python module* that wraps the LAMMPS library interface.

These are the same steps required to use Python by itself to wrap LAMMPS. Details on these steps are explained on the *Python* doc page. Note that it is important that the stand-alone LAMMPS executable and the LAMMPS shared library be consistent (built from the same source code files) in order for this to work. If the two have been built at different times using different source files, problems may occur.

Another limitation of calling back to Python from the LAMMPS module using the *python* command in a LAMMPS input is that both, the Python interpreter and LAMMPS, must be linked to the same Python runtime as a shared library.

If the Python interpreter is linked to Python statically (which seems to happen with Conda) then loading the shared LAMMPS library will create a second python "main" module that hides the one from the Python interpreter and all previous defined function and global variables will become invisible.

shell, *variable*, *fix python/invoke*

1.84.6 Default

none

1.85 quit command

1.85.1 Syntax

```
quit status
```

status = numerical exit status (optional)

1.85.2 Examples

```
quit
if "$n > 10000" then "quit 1"
```

1.85.3 Description

This command causes LAMMPS to exit, after shutting down all output cleanly.

It can be used as a debug statement in an input script, to terminate the script at some intermediate point.

It can also be used as an invoked command inside the "then" or "else" portion of an *if* command.

The optional status argument is an integer which signals the return status to a program calling LAMMPS. A return status of 0 usually indicates success. A status != 0 is failure, where the specified value can be used to distinguish the kind of error, e.g. where in the input script the quit was invoked. If not specified, a status of 0 is returned.

1.86 read_data command

1.86.1 Syntax

```
read_data file keyword args ...
```

- file = name of data file to read in
- zero or more keyword/arg pairs may be appended
- keyword = *add* or *offset* or *shift* or *extra/atom/types* or *extra/bond/types* or *extra/angle/types* or *extra/dihedral/types* or *extra/improper/types* or *extra/bond/per/atom* or *extra/angle/per/atom* or *extra/dihedral/per/atom* or *extra/improper/per/atom* or *extra/special/per/atom* or *group* or *nocoeff* or *fix*

```
  add arg = append or IDoffset or IDoffset MOLoffset or merge
    append = add new atoms with atom IDs appended to current IDs
    IDoffset = add new atoms with atom IDs having IDoffset added
    MOLoffset = add new atoms with molecule IDs having MOLoffset added (only when␣
  ↪molecule IDs are enabled)
    merge = add new atoms with their atom IDs (and molecule IDs) unchanged
  offset args = toff boff aoff doff ioff
    toff = offset to add to atom types
    boff = offset to add to bond types
    aoff = offset to add to angle types
    doff = offset to add to dihedral types
    ioff = offset to add to improper types
  shift args = Sx Sy Sz
    Sx,Sy,Sz = distance to shift atoms when adding to system (distance units)
  extra/atom/types arg = # of extra atom types
  extra/bond/types arg = # of extra bond types
  extra/angle/types arg = # of extra angle types
  extra/dihedral/types arg = # of extra dihedral types
  extra/improper/types arg = # of extra improper types
  extra/bond/per/atom arg = leave space for this many new bonds per atom
  extra/angle/per/atom arg = leave space for this many new angles per atom
  extra/dihedral/per/atom arg = leave space for this many new dihedrals per atom
  extra/improper/per/atom arg = leave space for this many new impropers per atom
  extra/special/per/atom arg = leave space for extra 1-2,1-3,1-4 interactions per atom
  group args = groupID
    groupID = add atoms in data file to this group
  nocoeff = ignore force field parameters
  fix args = fix-ID header-string section-string
    fix-ID = ID of fix to process header lines and sections of data file
    header-string = header lines containing this string will be passed to fix
    section-string = section names with this string will be passed to fix
```

1.86.2 Examples

```
read_data data.lj
read_data ../run7/data.polymer.gz
read_data data.protein fix mycmap crossterm CMAP
read_data data.water add append offset 3 1 1 1 1 shift 0.0 0.0 50.0
read_data data.water add merge group solvent
```

1.86.3 Description

Read in a data file containing information LAMMPS needs to run a simulation. The file can be ASCII text or a compressed text file (detected by its suffix) if LAMMPS has been compiled with support for *compression commands*.

This is one of 3 ways to specify the simulation box: see the *create_box* and *read_restart* and commands for alternative methods. It is also one of 3 ways to specify initial atom coordinates: see the *create_atoms* and *read_restart* and commands for alternative methods. Also see the explanation of the *-restart command-line switch* which can convert a restart file to a data file.

This command can be used multiple times to add new atoms and their properties to an existing system by using the *add*, *offset*, and *shift* keywords. However, it is important to understand that several system parameters, like the number of types of different kinds and per atom settings are **locked in** after the first *read_data* command, which means that no type ID (including its offset) may have a larger value when processing additional data files than what is set by the first data file and the corresponding *read_data* command options. See more details on this situation below, which includes the use case for the *extra* keywords.

The *group* keyword adds all the atoms in the data file to the specified group-ID. The group will be created if it does not already exist. This is useful if you are reading multiple data files and wish to put sets of atoms into different groups so they can be operated on later. E.g. a group of added atoms can be moved to new positions via the *displace_atoms* command. Note that atoms read from the data file are also always added to the "all" group. The *group* command discusses atom groups, as used in LAMMPS.

The *nocoeff* keyword tells read_data to ignore force field parameters. The various Coeff sections are still read and have to have the correct number of lines, but they are not applied. This also allows to read a data file without having any pair, bond, angle, dihedral or improper styles defined, or to read a data file for a different force field.

The use of the *fix* keyword is discussed below.

1.86.4 Reading multiple data files

The read_data command can be used multiple times with the same or different data files to build up a complex system from components contained in individual data files. For example one data file could contain fluid in a confined domain; a second could contain wall atoms, and the second file could be read a third time to create a wall on the other side of the fluid. The third set of atoms could be rotated to an opposing direction using the *displace_atoms* command, after the third read_data command is used.

The *add*, *offset*, *shift*, *extra*, and *group* keywords are useful in this context.

If a simulation box does not yet exist, the *add* keyword cannot be used; the read_data command is being used for the first time. If a simulation box does exist, due to using the *create_box* command, or a previous read_data command, then the *add* keyword must be used.

Note

If the first read_data command defined an orthogonal or restricted triclinic or general triclinic simulation box (see the sub-section below on header keywords), then subsequent data files must define the same kind of simulation box. For orthogonal boxes, the new box can be a different size; see the next Note. For a restricted triclinic box, the 3 new tilt factors ("xy xz yz" keyword) must have the same values as in the original data file. For a general triclinic box, the new avec, bvec, cvec, and "abc origin" keywords must have the same values in the original data file. files. Also the *shift* keyword cannot be used in subsequent read_data commands for a general triclinic box.

Note

For orthogonal boxes, the simulation box size in the new data file will be merged with the existing simulation box to create a large enough box in each dimension to contain both the existing and new atoms. Each box dimension never shrinks due to this merge operation, it only stays the same or grows. Care must be used if you are growing the existing simulation box in a periodic dimension. If there are existing atoms with bonds that straddle that periodic boundary, then the atoms may become far apart if the box size grows. This will separate the atoms in the bond, which can lead to "lost" bond atoms or bad dynamics.

The three choices for the *add* argument affect how the atom IDs and molecule IDs of atoms in the data file are treated.

If *append* is specified, atoms in the data file are added to the current system, with their atom IDs reset so that an atom-ID = M in the data file becomes atom-ID = N+M, where N is the largest atom ID in the current system. This rule is applied to all occurrences of atom IDs in the data file, e.g. in the Velocity or Bonds section. This is also done for molecule IDs, if the atom style does support molecule IDs or they are enabled via fix property/atom.

If *IDoffset* is specified, then *IDoffset* is a numeric value is given, e.g. 1000, so that an atom-ID = M in the data file becomes atom-ID = 1000+M. For systems with enabled molecule IDs, another numerical argument *MOLoffset* is required representing the equivalent offset for molecule IDs.

If *merge* is specified, the data file atoms are added to the current system without changing their IDs. They are assumed to merge (without duplication) with the currently defined atoms. It is up to you to ensure there are no multiply defined atom IDs, as LAMMPS only performs an incomplete check that this is the case by ensuring the resulting max atom-ID >= the number of atoms. For molecule IDs, there is no check done at all.

The *offset* and *shift* keywords can only be used if the *add* keyword is also specified.

The *offset* keyword adds the specified offset values to the atom types, bond types, angle types, dihedral types, and improper types as they are read from the data file. E.g. if *toff* = 2, and the file uses atom types 1,2,3, then the added atoms will have atom types 3,4,5. These offsets apply to all occurrences of types in the data file, e.g. for the Atoms or Masses or Pair Coeffs or Bond Coeffs sections. This makes it easy to use atoms and molecules and their attributes from a data file in different simulations, where you want their types (atom, bond, angle, etc) to be different depending on what other types already exist. All five offset values must be specified, but individual values will be ignored if the data file does not use that attribute (e.g. no bonds).

Note

Offsets are **ignored** on lines using type labels, as the type labels will determine the actual types directly depending on the current *labelmap* settings.

The *shift* keyword can be used to specify an (Sx, Sy, Sz) displacement applied to the coordinates of each atom. Sz must be 0.0 for a 2d simulation. This is a mechanism for adding structured collections of atoms at different locations within the simulation box, to build up a complex geometry. It is up to you to ensure atoms do not end up overlapping unphysically which would lead to bad dynamics. Note that the *displace_atoms* command can be used to move a subset of atoms after they have been read from a data file. Likewise, the *delete_atoms* command can be used to remove overlapping atoms. Note that the shift values (Sx, Sy, Sz) are also added to the simulation box information (xlo, xhi, ylo, yhi, zlo, zhi) in the data file to shift its boundaries. E.g. xlo_new = xlo + Sx, xhi_new = xhi + Sx.

The *extra* keywords can only be used the first time the read_data command is used. They are useful if you intend to add new atom, bond, angle, etc types later with additional read_data commands. This is because the maximum number of allowed atom, bond, angle, etc types is set by LAMMPS when the system is first initialized. If you do not use the *extra* keywords, then the number of these types will be limited to what appears in the first data file you read. For example, if the first data file is a solid substrate of Si, it will likely specify a single atom type. If you read a second data file with a different material (water molecules) that sit on top of the substrate, you will want to use different atom types for those atoms. You can only do this if you set the *extra/atom/types* keyword to a sufficiently large value when reading

the substrate data file. Note that use of the *extra* keywords also allows each data file to contain sections like Masses or Pair Coeffs or Bond Coeffs which are sized appropriately for the number of types in that data file. If the *offset* keyword is used appropriately when each data file is read, the values in those sections will be stored correctly in the larger data structures allocated by the use of the *extra* keywords. E.g. the substrate file can list mass and pair coefficients for type 1 silicon atoms. The water file can list mass and pair coefficients for type 1 and type 2 hydrogen and oxygen atoms. Use of the *extra* and *offset* keywords will store those mass and pair coefficient values appropriately in data structures that allow for 3 atom types (Si, H, O). Of course, you would still need to specify coefficients for H/Si and O/Si interactions in your input script to have a complete pairwise interaction model.

An alternative to using the *extra* keywords with the read_data command, is to use the *create_box* command to initialize the simulation box and all the various type limits you need via its *extra* keywords. Then use the read_data command one or more times to populate the system with atoms, bonds, angles, etc, using the *offset* keyword if desired to alter types used in the various data files you read.

1.86.5 Format of a data file

The structure of the data file is important, though many settings and sections are optional or can come in any order. See the examples directory for sample data files for different problems.

The file will be read line by line, but there is a limit of 254 characters per line and characters beyond that limit will be ignored.

A data file has a header and a body. The header appears first. The first line of the header and thus of the data file is *always* skipped; it typically contains a description of the file or a comment from the software that created the file.

Then lines are read one line at a time. Lines can have a trailing comment starting with '#' that is ignored. There *must* be at least one blank between any valid content and the comment. If a line is blank (i.e. contains only white-space after comments are deleted), it is skipped. If the line contains a header keyword, the corresponding value(s) is/are read from the line. A line that is *not* blank and does *not* contain a header keyword begins the body of the file.

The body of the file contains zero or more sections. The first line of a section has only a keyword. This line can have a trailing comment starting with '#' that is either ignored or can be used to check for a style match, as described below. There must be a blank between the keyword and any comment. The *next* line is *always* skipped. The remaining lines of the section contain values. The number of lines depends on the section keyword as described below. Zero or more blank lines can be used *between* sections. Sections can appear in any order, with a few exceptions as noted below.

The keyword *fix* can be used one or more times. Each usage specifies a fix that will be used to process a specific portion of the data file. Any header line containing *header-string* and any section that is an exact match to *section-string* will be passed to the specified fix. See the *fix property/atom* command for an example of a fix that operates in this manner. The doc page for the fix defines the syntax of the header line(s) and section that it reads from the data file. Note that the *header-string* can be specified as NULL, in which case no header lines are passed to the fix. This means the fix can infer the length of its Section from standard header settings, such as the number of atoms. Also the *section-string* may be specified as NULL, and in that case the fix ID is used as section name.

The formatting of individual lines in the data file (indentation, spacing between words and numbers) is not important except that header and section keywords (e.g. atoms, xlo xhi, Masses, Bond Coeffs) must be capitalized as shown and cannot have extra white-space between their words - e.g. two spaces or a tab between the 2 words in "xlo xhi" or the 2 words in "Bond Coeffs", is not valid.

1.86.6 Format of the header of a data file

These are the recognized header keywords. Header lines can come in any order. Each keyword takes a single value unless noted in this list. The value(s) are read from the beginning of the line. Thus the keyword *atoms* should be in a line like "1000 atoms"; the keyword *ylo yhi* should be in a line like "-10.0 10.0 ylo yhi"; the keyword *xy xz yz* should be in a line like "0.0 5.0 6.0 xy xz yz".

All these settings have a default value of 0, except for the simulation box size settings; their defaults are explained below. A keyword line need only appear if its value is different than the default.

- *atoms* = # of atoms in system
- *bonds* = # of bonds in system
- *angles* = # of angles in system
- *dihedrals* = # of dihedrals in system
- *impropers* = # of impropers in system
- *atom types* = # of atom types in system
- *bond types* = # of bond types in system
- *angle types* = # of angle types in system
- *dihedral types* = # of dihedral types in system
- *improper types* = # of improper types in system
- *extra bond per atom* = leave space for this many new bonds per atom (deprecated, use extra/bond/per/atom keyword)
- *extra angle per atom* = leave space for this many new angles per atom (deprecated, use extra/angle/per/atom keyword)
- *extra dihedral per atom* = leave space for this many new dihedrals per atom (deprecated, use extra/dihedral/per/atom keyword)
- *extra improper per atom* = leave space for this many new impropers per atom (deprecated, use extra/improper/per/atom keyword)
- *extra special per atom* = leave space for this many new special bonds per atom (deprecated, use extra/special/per/atom keyword)
- *ellipsoids* = # of ellipsoids in system
- *lines* = # of line segments in system
- *triangles* = # of triangles in system
- *bodies* = # of bodies in system
- *xlo xhi* = simulation box boundaries in x dimension (2 values)
- *ylo yhi* = simulation box boundaries in y dimension (2 values)
- *zlo zhi* = simulation box boundaries in z dimension (2 values)
- *xy xz yz* = simulation box tilt factors for triclinic system (3 values)
- *avec* = first edge vector of a general triclinic simulation box (3 values)
- *bvec* = second edge vector of a general triclinic simulation box (3 values)
- *cvec* = third edge vector of a general triclinic simulation box (3 values)
- *abc origin* = origin of a general triclinic simulation box (3 values)

1.86.7 Header specification of the simulation box size and shape

The last 8 keywords in the list of header keywords are for simulation boxes of 3 kinds which LAMMPS supports:

- orthogonal box = faces are perpendicular to the xyz coordinate axes
- restricted triclinic box = a parallelepiped defined by 3 edge vectors oriented in a constrained manner
- general triclinic box = a parallelepiped defined by 3 arbitrary edge vectors

For restricted and general triclinic boxes, see the *Howto_triclinic* doc page for a fuller description than is given here.

The units of the values for all 8 keywords in in distance units; see the *units* command for details.

For all 3 kinds of simulation boxes, the system may be periodic or non-periodic in any dimension; see the *boundary* command for details.

When the simulation box is created by the read_data command, it is also partitioned into a regular 3d grid of subdomains, one per processor, based on the number of processors being used and the settings of the *processors* command. For each kind of simulation box the subdomains have the same shape as the simulation box, i.e. smaller orthogonal bricks for orthogonal boxes, smaller parallelepipeds for triclinic boxes. The partitioning can later be changed by the *balance* or *fix balance* commands.

For an orthogonal box, only the *xlo xhi*, *ylo yhi*, *zlo zhi* keywords are used. They define the extent of the simulation box in each dimension so that the resulting edge vectors of an orthogonal box are:

- **A** = (xhi-xlo,0,0)
- **B** = (0,yhi-ylo,0)
- **C** = (0,0,zhi-zlo)

The origin (lower left corner) of the orthogonal box is at (xlo,ylo,zlo). The default values for these 3 keywords are -0.5 and 0.5 for each lo/hi pair. For a 2d simulation, the zlo and zhi values must straddle zero. The default zlo/zhi values do this, so that keyword is not needed in 2d.

For a restricted triclinic box, the *xy xz yz* keyword is used in addition to the *xlo xhi*, *ylo yhi*, *zlo zhi* keywords. The three *xy,xz,yz* values can be 0.0 or positive or negative, and are called "tilt factors" because they are the amount of displacement applied to edges of faces of an orthogonal box to transform it into a restricted triclinic parallelepiped.

The *Howto_triclinic* doc page discusses the tilt factors in detail and explains that the resulting edge vectors of a restricted triclinic box are:

- **A** = (xhi-xlo,0,0)
- **B** = (xy,yhi-ylo,0)
- **C** = (xz,yz,zhi-zlo)

This restricted form of edge vectors requires that **A** be in the direction of the x-axis, **B** be in the xy plane with its y-component in the +y direction, and **C** have its z-component in the +z direction. The origin (lower left corner) of the restricted triclinic box is at (xlo,ylo,zlo).

For a 2d simulation, the zlo and zhi values must straddle zero. The default zlo/zhi values do this, so that keyword is not needed in 2d. The xz and yz values must also be zero in 2d. The shape of the 2d restricted triclinic simulation box is effectively a parallelogram.

Note

When a restricted triclinic box is used, the simulation domain should normally be periodic in any dimensions that tilt is applied to, which is given by the second dimension of the tilt factor (e.g. y for xy tilt). This is so that pairs of atoms interacting across that boundary will have one of them shifted by the tilt factor. Periodicity is set by the *boundary* command which also describes the shifting by the tilt factor. For example, if the xy tilt factor is non-zero,

then the y dimension should be periodic. Similarly, the z dimension should be periodic if xz or yz is non-zero. LAMMPS does not require this periodicity, but you may lose atoms if this is not the case.

Note

Normally, the specified tilt factors (xy,xz,yz) should not skew the simulation box by more than half the distance of the corresponding parallel box length for computational efficiency. For example, if x_{lo} = 2 and x_{hi} = 12, then the x box length is 10 and the xy tilt factor should be between −5 and 5. LAMMPS will issue a warning if this is not the case. See the last sub-section of the *Howto_triclinic* doc page for more details.

Note

If a simulation box is initially orthogonal, but will tilt during a simulation, e.g. via the *fix deform* command, then the box should be defined as restricted triclinic with all 3 tilt factors = 0.0. Alternatively, the *change box* command can be used to convert an orthogonal box to a restricted triclinic box.

For a general triclinic box, the *avec*, *bvec*, *cvec*, and *abc origin* keywords are used. The *xlo xhi*, *ylo yhi*, *zlo zhi*, and *xy xz yz* keywords are NOT used. The first 3 keywords define the 3 edge vectors **A**, **B**, **C** of the general triclinic box. They can be arbitrary vectors so long as they are distinct, non-zero, and not co-planar. They must also define a right-handed system such that (**A** x **B**) points in the direction of **C**. Note that a left-handed system can be converted to a right-handed system by simply swapping the order of any pair of the **A**, **B**, **C** vectors. The origin of the box (origin of the 3 edge vectors) is set by the *abc origin* keyword.

The default values for these 4 keywords are as follows:

- avec = (1,0,0)
- bvec = (0,1,0)
- cvec = (0,0,1)
- abc origin = (0,0,0) for 3d, (0,0,-0.5) for 2d

For 2d simulations, *cvec* = (0,0,1) is required, and the 3rd value of *abc origin* must be -0.5. These are the default values, so the *cvec* keyword is not needed in 2d.

Note

LAMMPS allows specification of general triclinic simulation boxes as a convenience for users who may be converting data from solid-state crystallographic representations or from DFT codes for input to LAMMPS. However, as explained on the *Howto_triclinic* doc page, internally, LAMMPS only uses restricted triclinic simulation boxes. This means the box and per-atom information (e.g. coordinates, velocities) in the data file are converted (rotated) from general to restricted triclinic form when the file is read. Other sections of the data file must also list their per-atom data appropriately if vector quantities are specified. This requirement is explained below for the relevant sections. The *Howto_triclinic* doc page also discusses other LAMMPS commands which can input/output general triclinic representations of the simulation box and per-atom data.

The following explanations apply to all 3 kinds of simulation boxes: orthogonal, restricted triclinic, and general triclinic.

If the system is periodic (in a dimension), then atom coordinates can be outside the bounds (in that dimension); they will be remapped (in a periodic sense) back inside the box. For triclinic boxes, periodicity in x,y,z refers to the faces

of the parallelepiped defined by the **A**,**B**,**C** edge vectors of the simulation box. See the *boundary* command doc page for a fuller discussion.

Note that if the *add* option is being used to add atoms to a simulation box that already exists, this periodic remapping will be performed using simulation box bounds that are the union of the existing box and the box boundaries in the new data file.

If the system is non-periodic (in a dimension), then an image flag for that direction has no meaning, since there cannot be periodic images without periodicity and the data file is therefore - technically speaking - invalid. This situation would happen when a data file was written with periodic boundaries and then read back for non-periodic boundaries. Accepting a non-zero image flag can lead to unexpected results for any operations and computations in LAMMPS that internally use unwrapped coordinates (for example computing the center of mass of a group of atoms). Thus all non-zero image flags for non-periodic dimensions will be be reset to zero on reading the data file and LAMMPS will print a warning message, if that happens. This is equivalent to wrapping atoms individually back into the principal unit cell in that direction. This operation is equivalent to the behavior of the *change_box command* when used to change periodicity.

If those atoms with non-zero image flags are involved in bonded interactions, this reset can lead to undesired changes, when the image flag values differ between the atoms, i.e. the bonded interaction straddles domain boundaries. For example a bond can become stretched across the unit cell if one of its atoms is wrapped to one side of the cell and the second atom to the other. In those cases the data file needs to be pre-processed externally to become valid again. This can be done by first unwrapping coordinates and then wrapping entire molecules instead of individual atoms back into the principal simulation cell and finally expanding the cell dimensions in the non-periodic direction as needed, so that the image flag would be zero.

Note

If the system is non-periodic (in a dimension), then all atoms in the data file must have coordinates (in that dimension) that are "greater than or equal to" the lo value and "less than or equal to" the hi value. If the non-periodic dimension is of style "fixed" (see the *boundary* command), then the atom coords must be strictly "less than" the hi value, due to the way LAMMPS assign atoms to processors. Note that you should not make the lo/hi values radically smaller/larger than the extent of the atoms. For example, if atoms extend from 0 to 50, you should not specify the box bounds as -10000 and 10000 unless you also use the *processors command*. This is because LAMMPS uses the specified box size to layout the 3d grid of processors. A huge (mostly empty) box will be sub-optimal for performance when using "fixed" boundary conditions (see the *boundary* command). When using "shrink-wrap" boundary conditions (see the *boundary* command), a huge (mostly empty) box may cause a parallel simulation to lose atoms when LAMMPS shrink-wraps the box around the atoms. The read_data command will generate an error in this case.

1.86.8 Meaning of other header keywords

The "extra bond per atom" setting (angle, dihedral, improper) is only needed if new bonds (angles, dihedrals, impropers) will be added to the system when a simulation runs, e.g. by using the *fix bond/create* command. Using this header flag is deprecated; please use the *extra/bond/per/atom* keyword (and correspondingly for angles, dihedrals and impropers) in the read_data command instead. Either will pre-allocate space in LAMMPS data structures for storing the new bonds (angles, dihedrals, impropers).

The "extra special per atom" setting is typically only needed if new bonds/angles/etc will be added to the system, e.g. by using the *fix bond/create* command. Or if entire new molecules will be added to the system, e.g. by using the *fix deposit* or *fix pour* commands, which will have more special 1-2,1-3,1-4 neighbors than any other molecules defined in the data file. Using this header flag is deprecated; please use the *extra/special/per/atom* keyword instead. Using this setting will pre-allocate space in the LAMMPS data structures for storing these neighbors. See the *special_bonds* and *molecule* doc pages for more discussion of 1-2,1-3,1-4 neighbors.

Note

All of the "extra" settings are only applied in the first data file read and when no simulation box has yet been created; as soon as the simulation box is created (and read_data implies that), these settings are *locked* and cannot be changed anymore. Please see the description of the *add* keyword above for reading multiple data files. If they appear in later data files, they are ignored.

The "ellipsoids" and "lines" and "triangles" and "bodies" settings are only used with *atom_style ellipsoid or line or tri or body* and specify how many of the atoms are finite-size ellipsoids or lines or triangles or bodies; the remainder are point particles. See the discussion of ellipsoidflag and the *Ellipsoids* section below. See the discussion of lineflag and the *Lines* section below. See the discussion of triangleflag and the *Triangles* section below. See the discussion of bodyflag and the *Bodies* section below.

Note

For *atom_style template*, the molecular topology (bonds,angles,etc) is contained in the molecule templates read-in by the *molecule* command. This means you cannot set the *bonds*, *angles*, etc header keywords in the data file, nor can you define *Bonds*, *Angles*, etc sections as discussed below. You can set the *bond types*, *angle types*, etc header keywords, though it is not necessary. If specified, they must match the maximum values defined in any of the template molecules.

1.86.9 Format of the body of a data file

These are the section keywords for the body of the file.

- *Atoms, Velocities, Masses, Ellipsoids, Lines, Triangles, Bodies* = atom-property sections
- *Bonds, Angles, Dihedrals, Impropers* = molecular topology sections
- *Atom Type Labels, Bond Type Labels, Angle Type Labels, Dihedral Type Labels, Improper Type Labels* = type label maps
- *Pair Coeffs, PairIJ Coeffs, Bond Coeffs, Angle Coeffs, Dihedral Coeffs, Improper Coeffs* = force field sections
- *BondBond Coeffs, BondAngle Coeffs, MiddleBondTorsion Coeffs, EndBondTorsion Coeffs, AngleTorsion Coeffs, AngleAngleTorsion Coeffs, BondBond13 Coeffs, AngleAngle Coeffs* = class 2 force field sections

These keywords will check an appended comment for a match with the currently defined style:

- *Atoms, Pair Coeffs, PairIJ Coeffs, Bond Coeffs, Angle Coeffs, Dihedral Coeffs, Improper Coeffs*

For example, these lines:

```
Atoms # sphere
Pair Coeffs # lj/cut
```

will check if the currently-defined *atom_style* is *sphere*, and the current *pair_style* is *lj/cut*. If not, LAMMPS will issue a warning to indicate that the data file section likely does not contain the correct number or type of parameters expected for the currently-defined style.

Each section is listed below in alphabetic order. The format of each section is described including the number of lines it must contain and rules (if any) for where it can appear in the data file.

Any individual line in the various sections can have a trailing comment starting with "#" for annotation purposes. There must be at least one blank between valid content and the comment. E.g. in the Atoms section:

```
10 1 17 -1.0 10.0 5.0 6.0   # salt ion
```

Angle Coeffs section:

- one line per angle type
- line syntax: ID coeffs

```
ID = angle type (1-N)
coeffs = list of coeffs
```

- example:

```
6 70 108.5 0 0
```

The number and meaning of the coefficients are specific to the defined angle style. See the *angle_style* and *angle_coeff* commands for details. Coefficients can also be set via the *angle_coeff* command in the input script.

Angle Type Labels section:

- one line per angle type
- line syntax: ID label

```
ID = angle type (1-N)
label = alphanumeric type label
```

Define alphanumeric type labels for each numeric angle type. These can be used in the Angles section in place of a numeric type, but only if the this section appears before the Angles section.

See the *Howto type labels* doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

AngleAngle Coeffs section:

- one line per improper type
- line syntax: ID coeffs

```
ID = improper type (1-N)
coeffs = list of coeffs (see improper_coeff)
```

AngleAngleTorsion Coeffs section:

- one line per dihedral type
- line syntax: ID coeffs

```
ID = dihedral type (1-N)
coeffs = list of coeffs (see dihedral_coeff)
```

Angles section:

- one line per angle

- line syntax: ID type atom1 atom2 atom3

```
ID = number of angle (1-Nangles)
type = angle type (1-Nangletype, or type label)
atom1,atom2,atom3 = IDs of 1st,2nd,3rd atom in angle
```

example:

```
2 2 17 29 430
```

The three atoms are ordered linearly within the angle. Thus the central atom (around which the angle is computed) is the atom2 in the list. E.g. H,O,H for a water molecule. The *Angles* section must appear after the *Atoms* section.

All values in this section must be integers (1, not 1.0). However, the type can be a numeric value or an alphanumeric label. The latter is only allowed if the type label has been defined by the *labelmap* command or an Angle Type Labels section earlier in the data file. See the *Howto type labels* doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

AngleTorsion Coeffs section:

- one line per dihedral type
- line syntax: ID coeffs

  ```
  ID = dihedral type (1-N)
  coeffs = list of coeffs (see dihedral_coeff)
  ```

Atom Type Labels section:

- one line per atom type
- line syntax: ID label

```
ID = numeric atom type (1-N)
label = alphanumeric type label
```

Define alphanumeric type labels for each numeric atom type. These can be used in the Atoms section in place of a numeric type, but only if the Atom Type Labels section appears before the Atoms section.

See the *Howto type labels* doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

Atoms section:

- one line per atom
- line syntax: depends on atom style

An *Atoms* section must appear in the data file if natoms > 0 in the header section. The atoms can be listed in any order. These are the line formats for each *atom style* in LAMMPS. As discussed below, each line can optionally have 3 flags (nx,ny,nz) appended to it, which indicate which image of a periodic simulation box the atom is in. These may be important to include for some kinds of analysis.

Note

For orthogonal and restricted and general triclinic simulation boxes, the atom coordinates (x,y,z) listed in this section should be inside the corresponding simulation box. For restricted triclinic boxes that means the parallelepiped defined by the *xlo xhi*, *ylo yhi*, *zlo zhi*, and *xy xz yz*, keywords. For general triclinic boxes that means the parallelepiped defined by the 3 edge vectors and origin specified by the *avec*, *bvec*, *cvec*, and *abc origin* header keywords. See the discussion in the header section above about how atom coordinates outside the simulation box are (or are not) remapped to be inside the box.

angle	atom-ID molecule-ID atom-type x y z
atomic	atom-ID atom-type x y z
body	atom-ID atom-type bodyflag mass x y z
bond	atom-ID molecule-ID atom-type x y z
bpm/sphere	atom-ID molecule-ID atom-type diameter density x y z

hybrid	atom-ID atom-type x y z sub-style1 sub-style2 ...

The per-atom values have these meanings and units, listed alphabetically:

- atom-ID = integer ID of atom
- atom-type = type of atom (1-Ntype, or type label)
- bodyflag = 1 for body particles, 0 for point particles
- ccN = chemical concentration for tDPD particles for each species (mole/volume units)
- cradius = contact radius for SMD particles (distance units)
- cv = heat capacity (need units) for SPH particles
- density = density of particle (mass/distance^3 or mass/distance^2 or mass/distance units, depending on dimensionality of particle)
- diameter = diameter of spherical atom (distance units)

- edpd_temp = temperature for eDPD particles (temperature units)
- edpd_cv = volumetric heat capacity for eDPD particles (energy/temperature/volume units)
- ellipsoidflag = 1 for ellipsoidal particles, 0 for point particles
- eradius = electron radius (or fixed-core radius)
- esph = energy (need units) for SPH particles
- espin = electron spin (+1/-1), 0 = nuclei, 2 = fixed-core, 3 = pseudo-cores (i.e. ECP)
- kradius = kernel radius for SMD particles (distance units)
- lineflag = 1 for line segment particles, 0 for point or spherical particles
- mass = mass of particle (mass units)
- molecule-ID = integer ID of molecule the atom belongs to
- mux,muy,muz = components of dipole moment of atom (dipole units) (see general triclinic note below)
- q = charge on atom (charge units)
- rho = density (need units) for SPH particles
- sp = magnitude of magnetic spin of atom (Bohr magnetons)
- spx,spy,spz = components of magnetic spin of atom (unit vector) (see general triclinic note below)
- template-atom = which atom within a template molecule the atom is
- template-index = which molecule within the molecule template the atom is part of
- theta = internal temperature of a DPD particle
- triangleflag = 1 for triangular particles, 0 for point or spherical particles
- volume = volume of Peridynamic particle (distance^3 units)
- x,y,z = coordinates of atom (distance units)
- x0,y0,z0 = original (strain-free) coordinates of atom (distance units) (see general triclinic note below)

The units for these quantities depend on the unit style; see the *units* command for details.

For 2d simulations, the atom coordinate z must be specified as 0.0. If the data file is created by another program, then z values for a 2d simulation can be within epsilon of 0.0, and LAMMPS will force them to zero.

Note

If the data file defines a general triclinic box, then the following per-atom values in the list above are per-atom vectors which imply an orientation: (mux,muy,muz) and (spx,spy,spz). This means they should be specified consistent with the general triclinic box and its orientation relative to the standard x,y,z coordinate axes. For example a dipole moment vector which will be in the +x direction once LAMMPS converts from a general to restricted triclinic box, should be specified in the data file in the direction of the **A** edge vector. Likewise the (x0,y0,z0) per-atom strain-free coordinates should be inside the general triclinic simulation box as explained in the note above. See the *Howto triclinic* doc page for more details.

The atom-ID is used to identify the atom throughout the simulation and in dump files. Normally, it is a unique value from 1 to Natoms for each atom. Unique values larger than Natoms can be used, but they will cause extra memory to be allocated on each processor, if an atom map array is used, but not if an atom map hash is used; see the *atom_modify* command for details. If an atom map is not used (e.g. an atomic system with no bonds), and you don't care if unique atom IDs appear in dump files, then the atom-IDs can all be set to 0.

The atom-type can be a numeric value or an alphanumeric label. The latter is only allowed if the type label has been defined by the *labelmap* command or an Atom Type Labels section earlier in the data file. See the *Howto type labels* doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

The molecule ID is a second identifier attached to an atom. Normally, it is a number from 1 to N, identifying which molecule the atom belongs to. It can be 0 if it is a non-bonded atom or if you don't care to keep track of molecule assignments.

The diameter specifies the size of a finite-size spherical particle. It can be set to 0.0, which means that atom is a point particle.

The ellipsoidflag, lineflag, triangleflag, and bodyflag determine whether the particle is a finite-size ellipsoid or line or triangle or body of finite size, or whether the particle is a point particle. Additional attributes must be defined for each ellipsoid, line, triangle, or body in the corresponding *Ellipsoids*, *Lines*, *Triangles*, or *Bodies* section.

The *template-index* and *template-atom* are only defined used by *atom_style template*. In this case the *molecule* command is used to define a molecule template which contains one or more molecules (as separate files). If an atom belongs to one of those molecules, its *template-index* and *template-atom* are both set to positive integers; if not the values are both 0. The *template-index* is which molecule (1 to Nmols) the atom belongs to. The *template-atom* is which atom (1 to Natoms) within the molecule the atom is.

Some pair styles and fixes and computes that operate on finite-size particles allow for a mixture of finite-size and point particles. See the doc pages of individual commands for details.

For finite-size particles, the density is used in conjunction with the particle volume to set the mass of each particle as mass = density * volume. In this context, volume can be a 3d quantity (for spheres or ellipsoids), a 2d quantity (for triangles), or a 1d quantity (for line segments). If the volume is 0.0, meaning a point particle, then the density value is used as the mass. One exception is for the body atom style, in which case the mass of each particle (body or point particle) is specified explicitly. This is because the volume of the body is unknown.

Note that for 2d simulations of spheres, this command will treat them as spheres when converting density to mass. However, they can also be modeled as 2d discs (circles) if the *set density/disc* command is used to reset their mass after the read_data command is used. A *disc* keyword can also be used with time integration fixes, such as *fix nve/sphere* and *fix nvt/sphere* to time integrate their motion as 2d discs (not 3d spheres), by changing their moment of inertia.

For atom_style hybrid, following the 5 initial values (ID,type,x,y,z), specific values for each sub-style must be listed. The order of the sub-styles is the same as they were listed in the *atom_style* command. The specific values for each sub-style are those that are not the 5 standard ones (ID,type,x,y,z). For example, for the "charge" sub-style, a "q" value would appear. For the "full" sub-style, a "molecule-ID" and "q" would appear. These are listed in the same order they appear as listed above. Thus if

```
atom_style hybrid charge sphere
```

were used in the input script, each atom line would have these fields:

```
atom-ID atom-type x y z q diameter density
```

Note that if a non-standard value is defined by multiple sub-styles, it only appears once in the atom line. E.g. the atom line for atom_style hybrid dipole full would list "q" only once, with the dipole sub-style fields; "q" does not appear with the full sub-style fields.

```
atom-ID atom-type x y z q mux muy myz molecule-ID
```

Atom lines specify the (x,y,z) coordinates of atoms. These can be inside or outside the simulation box. When the data file is read, LAMMPS wraps coordinates outside the box back into the box for dimensions that are periodic. As discussed above, if an atom is outside the box in a non-periodic dimension, it will be lost.

LAMMPS always stores atom coordinates as values which are inside the simulation box. It also stores 3 flags which indicate which image of the simulation box (in each dimension) the atom would be in if its coordinates were unwrapped

across periodic boundaries. An image flag of 0 means the atom is still inside the box when unwrapped. A value of 2 means add 2 box lengths to get the unwrapped coordinate. A value of -1 means subtract 1 box length to get the unwrapped coordinate. LAMMPS updates these flags as atoms cross periodic boundaries during the simulation. The *dump* command can output atom coordinates in wrapped or unwrapped form, as well as the 3 image flags.

In the data file, atom lines (all lines or none of them) can optionally list 3 trailing integer values (nx,ny,nz), which are used to initialize the atom's image flags. If nx,ny,nz values are not listed in the data file, LAMMPS initializes them to 0. Note that the image flags are immediately updated if an atom's coordinates need to wrapped back into the simulation box.

It is only important to set image flags correctly in a data file if a simulation model relies on unwrapped coordinates for some calculation; otherwise they can be left unspecified. Examples of LAMMPS commands that use unwrapped coordinates internally are as follows:

- Atoms in a rigid body (see *fix rigid*, *fix rigid/small*) must have consistent image flags, so that when the atoms are unwrapped, they are near each other, i.e. as a single body.
- If the *replicate* command is used to generate a larger system, image flags must be consistent for bonded atoms when the bond crosses a periodic boundary. I.e. the values of the image flags should be different by 1 (in the appropriate dimension) for the two atoms in such a bond.
- If you plan to *dump* image flags and perform post-analysis that will unwrap atom coordinates, it may be important that a continued run (restarted from a data file) begins with image flags that are consistent with the previous run.

Note

If your system is an infinite periodic crystal with bonds then it is impossible to have fully consistent image flags. This is because some bonds will cross periodic boundaries and connect two atoms with the same image flag.

Atom velocities and other atom quantities not defined above are set to 0.0 when the *Atoms* section is read. Velocities can be set later by a *Velocities* section in the data file or by a *velocity* or *set* command in the input script.

Bodies section:

- one or more lines per body
- first line syntax: atom-ID Ninteger Ndouble

```
Ninteger = # of integer quantities for this particle
Ndouble = # of floating-point quantities for this particle
```

- 0 or more integer lines with total of Ninteger values
- 0 or more double lines with total of Ndouble values
- example:

```
12 3 6
2 3 2
1.0 2.0 3.0 1.0 2.0 4.0
```

- example:

```
12 0 14
1.0 2.0 3.0 1.0 2.0 4.0 1.0
2.0 3.0 1.0 2.0 4.0 4.0 2.0
```

The *Bodies* section must appear if *atom_style body* is used and any atoms listed in the *Atoms* section have a bodyflag = 1. The number of bodies should be specified in the header section via the "bodies" keyword.

Each body can have a variable number of integer and/or floating-point values. The number and meaning of the values is defined by the body style, as described in the *Howto body* doc page. The body style is given as an argument to the *atom_style body* command.

The Ninteger and Ndouble values determine how many integer and floating-point values are specified for this particle. Ninteger and Ndouble can be as large as needed and can be different for every body. Integer values are then listed next on subsequent lines. Lines are read one at a time until Ninteger values are read. Floating-point values follow on subsequent lines, Again lines are read one at a time until Ndouble values are read. Note that if there are no values of a particular type, no lines appear for that type.

The *Bodies* section must appear after the *Atoms* section.

Bond Coeffs section:

- one line per bond type
- line syntax: ID coeffs

```
ID = bond type (1-N)
coeffs = list of coeffs
```

- example:

```
4 250 1.49
```

The number and meaning of the coefficients are specific to the defined bond style. See the *bond_style* and *bond_coeff* commands for details. Coefficients can also be set via the *bond_coeff* command in the input script.

Bond Type Labels section:

- one line per bond type
- line syntax: ID label

```
ID = bond type (1-N)
label = alphanumeric type label
```

Define alphanumeric type labels for each numeric bond type. These can be used in the Bonds section in place of a numeric type, but only if the this section appears before the Angles section.

See the *Howto type labels* doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

BondAngle Coeffs section:

- one line per angle type
- line syntax: ID coeffs

```
ID = angle type (1-N)
coeffs = list of coeffs (see class 2 section of angle_coeff)
```

BondBond Coeffs section:

- one line per angle type
- line syntax: ID coeffs

```
ID = angle type (1-N)
coeffs = list of coeffs (see class 2 section of angle_coeff)
```

BondBond13 Coeffs section:

- one line per dihedral type
- line syntax: ID coeffs

```
ID = dihedral type (1-N)
coeffs = list of coeffs (see class 2 section of dihedral_coeff)
```

Bonds section:

- one line per bond
- line syntax: ID type atom1 atom2

```
ID = bond number (1-Nbonds)
type = bond type (1-Nbondtype, or type label)
atom1,atom2 = IDs of 1st,2nd atom in bond
```

- example:

```
12 3 17 29
```

The *Bonds* section must appear after the *Atoms* section.

All values in this section must be integers (1, not 1.0). However, the type can be a numeric value or an alphanumeric label. The latter is only allowed if the type label has been defined by the *labelmap* command or a Bond Type Labels section earlier in the data file. See the *Howto type labels* doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

Dihedral Coeffs section:

- one line per dihedral type
- line syntax: ID coeffs

```
ID = dihedral type (1-N)
coeffs = list of coeffs
```

- example:

```
3 0.6 1 0 1
```

The number and meaning of the coefficients are specific to the defined dihedral style. See the *dihedral_style* and *dihedral_coeff* commands for details. Coefficients can also be set via the *dihedral_coeff* command in the input script.

Dihedral Type Labels section:

- one line per dihedral type

- line syntax: ID label

```
ID = dihedral type (1-N)
label = alphanumeric type label
```

Define alphanumeric type labels for each numeric dihedral type. These can be used in the Dihedrals section in place of a numeric type, but only if the this section appears before the Dihedrals section.

See the *Howto type labels* doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

Dihedrals section:

- one line per dihedral
- line syntax: ID type atom1 atom2 atom3 atom4

```
ID = number of dihedral (1-Ndihedrals)
type = dihedral type (1-Ndihedraltype, or type label)
atom1,atom2,atom3,atom4 = IDs of 1st,2nd,3rd,4th atom in dihedral
```

- example:

```
12 4 17 29 30 21
```

The 4 atoms are ordered linearly within the dihedral. The *Dihedrals* section must appear after the *Atoms* section.

All values in this section must be integers (1, not 1.0). However, the type can be a numeric value or an alphanumeric label. The latter is only allowed if the type label has been defined by the *labelmap* command or a Dihedral Type Labels section earlier in the data file. See the *Howto type labels* doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

Ellipsoids section:

- one line per ellipsoid
- line syntax: atom-ID shapex shapey shapez quatw quati quatj quatk
- line syntax (*superellipsoids*): atom-ID shapex shapey shapez quatw quati quatj quatk block1 block2

```
atom-ID = ID of atom which is an ellipsoid
shapex,shapey,shapez = 3 diameters of ellipsoid (distance units)
quatw,quati,quatj,quatk = quaternion components for orientation of atom
block1,block2 = 2 blockiness parameters (for superellipsoids only)
```

- examples:

```
12 1 2 1 1 0 0 0
12 1 2 1 1 0 0 0 2 2
```

The *Ellipsoids* section must appear if *atom_style ellipsoid* is used and any atoms are listed in the *Atoms* section with an ellipsoidflag = 1. The number of ellipsoids should be specified in the header section via the "ellipsoids" keyword.

The 3 shape values specify the 3 diameters or aspect ratios of a finite-size ellipsoidal particle, when it is oriented along the 3 coordinate axes. They must all be non-zero values.

The values *quatw*, *quati*, *quatj*, and *quatk* set the orientation of the atom as a quaternion (4-vector). Note that the shape attributes specify the aspect ratios of an ellipsoidal particle, which is oriented by default with its x-axis along

the simulation box's x-axis, and similarly for y and z. If this body is rotated (via the right-hand rule) by an angle theta around a unit vector (a,b,c), then the quaternion that represents its new orientation is given by (cos(theta/2), a*sin(theta/2), b*sin(theta/2), c*sin(theta/2)). These 4 components are quatw, quati, quatj, and quatk as specified above. LAMMPS normalizes each atom's quaternion in case (a,b,c) is not specified as a unit vector.

Added in version 30Mar2026.

The blockiness values *block1*, *block2* generalize the geometry to a super ellipsoid for use in granular simulations. Sections through the center and parallel to the z-axis are superellipses with squareness *block1* and sections in the x-y plane are superellipses with squareness *block2*. These parameters are optional and default to a value of 2, recovering ellipsoid geometry. When specified, both values must be greater than or equal to 2.

If the data file defines a general triclinic box, then the quaternion for each ellipsoid should be specified for its orientation relative to the standard x,y,z coordinate axes. When the system is converted to a restricted triclinic box, the ellipsoid quaternions will be altered to reflect the new orientation of the ellipsoid.

The *Ellipsoids* section must appear after the *Atoms* section.

EndBondTorsion Coeffs section:

- one line per dihedral type
- line syntax: ID coeffs

```
ID = dihedral type (1-N)
coeffs = list of coeffs (see class 2 section of dihedral_coeff)
```

Improper Coeffs section:

- one line per improper type
- line syntax: ID coeffs

```
ID = improper type (1-N)
coeffs = list of coeffs
```

- example:

```
2 20 0.0548311
```

The number and meaning of the coefficients are specific to the defined improper style. See the *improper_style* and *improper_coeff* commands for details. Coefficients can also be set via the *improper_coeff* command in the input script.

Improper Type Labels section:

- one line per improper type
- line syntax: ID label

```
ID = improper type (1-N)
label = alphanumeric type label
```

Define alphanumeric type labels for each numeric improper type. These can be used in the Impropers section in place of a numeric type, but only if the this section appears before the Impropers section.

See the *Howto type labels* doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

Impropers section:

- one line per improper
- line syntax: ID type atom1 atom2 atom3 atom4

```
ID = number of improper (1-Nimpropers)
type = improper type (1-Nimpropertype, or type label)
atom1,atom2,atom3,atom4 = IDs of 1st,2nd,3rd,4th atom in improper
```

- example:

```
12 3 17 29 13 100
```

The ordering of the 4 atoms determines the definition of the improper angle used in the formula for each *improper style*. See the doc pages for individual styles for details.

The *Impropers* section must appear after the *Atoms* section.

All values in this section must be integers (1, not 1.0). However, the type can be a numeric value or an alphanumeric label. The latter is only allowed if the type label has been defined by the *labelmap* command or a Improper Type Labels section earlier in the data file. See the *Howto type labels* doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

Lines section:

- one line per line segment
- line syntax: atom-ID x1 y1 x2 y2

```
atom-ID = ID of atom which is a line segment
x1,y1 = 1st end point
x2,y2 = 2nd end point
```

- example:

```
12 1.0 0.0 2.0 0.0
```

The *Lines* section must appear if *atom_style line* is used and any atoms are listed in the *Atoms* section with a lineflag = 1. The number of lines should be specified in the header section via the "lines" keyword.

The 2 end points are the end points of the line segment. They should be values close to the center point of the line segment specified in the Atoms section of the data file, even if individual end points are outside the simulation box.

The ordering of the 2 points should be such that using a right-hand rule to cross the line segment with a unit vector in the +z direction, gives an "outward" normal vector perpendicular to the line segment. I.e. normal = (c2-c1) x (0,0,1). This orientation may be important for defining some interactions.

If the data file defines a general triclinic box, then the x1,y1 and x2,y2 values for each line segment should be specified for its orientation relative to the standard x,y,z coordinate axes. When the system is converted to a restricted triclinic box, the x1,y1,x2,y2 values will be altered to reflect the new orientation of the line segment.

The *Lines* section must appear after the *Atoms* section.

Masses section:

- one line per atom type
- line syntax: ID mass

```
ID = atom type (1-N or atom type label)
mass = mass value
```

- example:

```
3 1.01
```

This defines the mass of each atom type. This can also be set via the *mass* command in the input script. This section cannot be used for atom styles that define a mass for individual atoms - e.g. *atom_style sphere*.

Using type labels instead of atom type numbers is only allowed if the type label has been defined by the *labelmap* command or a Atom Type Labels section earlier in the data file. See the *Howto type labels* doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

MiddleBondTorsion Coeffs section:

- one line per dihedral type
- line syntax: ID coeffs

```
ID = dihedral type (1-N)
coeffs = list of coeffs (see class 2 section of dihedral_coeff)
```

Pair Coeffs section:

- one line per atom type
- line syntax: ID coeffs

```
ID = atom type (1-N)
coeffs = list of coeffs
```

- example:

```
3 0.022 2.35197 0.022 2.35197
```

The number and meaning of the coefficients are specific to the defined pair style. See the *pair_style* and *pair_coeff* commands for details. Since pair coefficients for types I != J are not specified, these will be generated automatically by the pair style's mixing rule. See the individual pair_style doc pages and the *pair_modify mix* command for details. Pair coefficients can also be set via the *pair_coeff* command in the input script.

PairIJ Coeffs section:

- one line per pair of atom types for all I,J with I <= J
- line syntax: ID1 ID2 coeffs

```
ID1 = atom type I = 1-N
ID2 = atom type J = I-N, with I <= J
coeffs = list of coeffs
```

- examples:

```
3 3 0.022 2.35197 0.022 2.35197
3 5 0.022 2.35197 0.022 2.35197
```

This section must have N*(N+1)/2 lines where N = # of atom types. The number and meaning of the coefficients are specific to the defined pair style. See the *pair_style* and *pair_coeff* commands for details. Since pair coefficients for types I != J are all specified, these values will turn off the default mixing rule defined by the pair style. See the individual pair_style doc pages and the *pair_modify mix* command for details. Pair coefficients can also be set via the *pair_coeff* command in the input script.

Triangles section:

- one line per triangle
- line syntax: atom-ID x1 y1 z1 x2 y2 z2 x3 y3 z3

```
atom-ID = ID of atom which is a line segment
x1,y1,z1 = 1st corner point
x2,y2,z2 = 2nd corner point
x3,y3,z3 = 3rd corner point
```

- example:

```
12 0.0 0.0 0.0 2.0 0.0 1.0 0.0 2.0 1.0
```

The *Triangles* section must appear if *atom_style tri* is used and any atoms are listed in the *Atoms* section with a triangleflag = 1. The number of lines should be specified in the header section via the "triangles" keyword.

The 3 corner points are the corner points of the triangle. They should be values close to the center point of the triangle specified in the Atoms section of the data file, even if individual corner points are outside the simulation box.

The ordering of the 3 points should be such that using a right-hand rule to go from point1 to point2 to point3 gives an "outward" normal vector to the face of the triangle. I.e. normal = (c2-c1) x (c3-c1). This orientation may be important for defining some interactions.

If the data file defines a general triclinic box, then the x1,y1,z1 and x2,y2,z2 and x3,y3,z3 values for each triangle should be specified for its orientation relative to the standard x,y,z coordinate axes. When the system is converted to a restricted triclinic box, the x1,y1,z1,x2,y2,z2,x3,y3,z3 values will be altered to reflect the new orientation of the triangle.

The *Triangles* section must appear after the *Atoms* section.

Velocities section:

- one line per atom
- line syntax: depends on atom style

all styles except those listed	atom-ID vx vy vz
electron	atom-ID vx vy vz ervel
ellipsoid	atom-ID vx vy vz lx ly lz
sphere	atom-ID vx vy vz wx wy wz
hybrid	atom-ID vx vy vz sub-style1 sub-style2 ...

where the keywords have these meanings:

```
vx,vy,vz = translational velocity of atom
lx,ly,lz = angular momentum of aspherical atom
wx,wy,wz = angular velocity of spherical atom
ervel = electron radial velocity (0 for fixed-core)
```

The velocity lines can appear in any order. This section can only be used after an *Atoms* section. This is because the *Atoms* section must have assigned a unique atom ID to each atom so that velocities can be assigned to them.

Vx, vy, vz, and ervel are in *units* of velocity. Lx, ly, lz are in units of angular momentum (distance-velocity-mass). Wx, Wy, Wz are in units of angular velocity (radians/time).

If the data file defines a general triclinic box, then each of the 3 vectors (translational velocity, angular momentum, angular velocity) should be specified for the rotated coordinate axes of the general triclinic box. See the *Howto triclinic* doc page for more details.

For atom_style hybrid, following the 4 initial values (ID,vx,vy,vz), specific values for each sub-style must be listed. The order of the sub-styles is the same as they were listed in the *atom_style* command. The sub-style specific values are those that are not the 5 standard ones (ID,vx,vy,vz). For example, for the "sphere" sub-style, "wx", "wy", "wz" values would appear. These are listed in the same order they appear as listed above. Thus if

```
atom_style hybrid electron sphere
```

were used in the input script, each velocity line would have these fields:

```
atom-ID vx vy vz ervel wx wy wz
```

Translational velocities can also be (re)set by the *velocity* command in the input script.

1.86.10 Restrictions

To read compressed data files, you must compile LAMMPS with the `-DLAMMPS_GZIP` option. See the *Build settings* doc page for details.

Label maps are currently not supported when using the KOKKOS package.

1.86.11 Related commands

read_dump, *read_restart*, *create_atoms*, *write_data*, *labelmap*

1.86.12 Default

The default for all the *extra* keywords is 0.

1.87 read_dump command

1.87.1 Syntax

```
read_dump file Nstep field1 field2 ... keyword values ...
```

- file = name of dump file to read
- Nstep = snapshot timestep to read from file
- one or more fields may be appended

field = *x* or *y* or *z* or *vx* or *vy* or *vz* or *q* or *mol* or *ix* or *iy* or *iz* or *fx* or *fy* or *fz* or *apip_lambda*
x,*y*,*z* = atom coordinates
vx,*vy*,*vz* = velocity components
q = charge
mol = molecule ID
ix,*iy*,*iz* = image flags in each dimension
fx,*fy*,*fz* = force components
apip_lambda = switching parameter of an *adaptive-precision interatomic potential*

- zero or more keyword/value pairs may be appended
- keyword = *nfile* or *box* or *timestep* or *replace* or *purge* or *trim* or *add* or *label* or *scaled* or *wrapped* or *format*

nfile value = Nfiles = how many parallel dump files exist
box value = *yes* or *no* = replace simulation box with dump box
timestep value = *yes* or *no* = reset simulation timestep with dump timestep
replace value = *yes* or *no* = overwrite atoms with dump atoms
purge value = *yes* or *no* = delete all atoms before adding dump atoms
trim value = *yes* or *no* = trim atoms not in dump snapshot
add value = *yes* or *keep* or *no* = add new dump atoms to system
label value = field column
  field = one of the listed fields or *id* or *type*
  column = label on corresponding column in dump file
scaled value = *yes* or *no* = coords in dump file are scaled/unscaled
wrapped value = *yes* or *no* = coords in dump file are wrapped/unwrapped
format values = format of dump file, must be last keyword if used
  native = native LAMMPS dump file
  xyz = XYZ file
  adios [*timeout* value] = dump file written by the *dump adios* command
    timeout = specify waiting time for the arrival of the timestep when running concurrently.
                The value is a float number and is interpreted in seconds.
  molfile style path = VMD molfile plugin interface
    style = *dcd* or *xyz* or others supported by molfile plugins
    path = optional path for location of molfile plugins

1.87.2 Examples

```
read_dump dump.file 5000 x y z
read_dump dump.xyz 5 x y z box no format xyz
read_dump dump.xyz 10 x y z box no format molfile xyz "../plugins"
read_dump dump.dcd 0 x y z box yes format molfile dcd
read_dump dump.file 1000 x y z vx vy vz box yes format molfile lammpstrj /usr/local/lib/
↪vmd/plugins/LINUXAMD64/plugins/molfile
read_dump dump.file 5000 x y vx vy trim yes
read_dump dump.file 5000 x y vx vy add yes box no timestep no
read_dump ../run7/dump.file.gz 10000 x y z box yes
read_dump dump.xyz 10 x y z box no format molfile xyz ../plugins
read_dump dump.dcd 0 x y z format molfile dcd
read_dump dump.file 1000 x y z vx vy vz format molfile lammpstrj /usr/local/lib/vmd/
↪plugins/LINUXAMD64/plugins/molfile
read_dump dump.bp 5000 x y z vx vy vz format adios
read_dump dump.bp 5000 x y z vx vy vz format adios timeout 60.0
```

1.87.3 Description

Read atom information from a dump file to overwrite the current atom coordinates, and optionally the atom velocities and image flags, the simulation timestep, and the simulation box dimensions. This is useful for restarting a run from a particular snapshot in a dump file. See the *read_restart* and *read_data* commands for alternative methods to do this. Also see the *rerun* command for a means of reading multiple snapshots from a dump file.

Note that a simulation box must already be defined before using the read_dump command. This can be done by the *create_box*, *read_data*, or *read_restart* commands. The read_dump command can reset the simulation box dimensions, as explained below.

Also note that reading per-atom information from a dump snapshot is limited to the atom coordinates, velocities and image flags, as explained below. Other atom properties, which may be necessary to run a valid simulation, such as atom charge, or bond topology information for a molecular system, are not read from (or may not even be contained in) dump files. Thus this auxiliary information should be defined in the usual way, e.g. in a data file read in by a *read_data* command, before using the read_dump command, or by the *set* command, after the dump snapshot is read.

If the dump filename specified as *file* ends with ".gz", the dump file is read in gzipped format.

You can read dump files that were written (in parallel) to multiple files via the "%" wild-card character in the dump file name. If any specified dump file name contains a "%", they must all contain it. See the *dump* command for details. The "%" wild-card character is only supported by the *native* format for dump files, described next.

If reading parallel dump files, you must also use the *nfile* keyword to tell LAMMPS how many parallel files exist, via its specified *Nfiles* value.

The format of the dump file is selected through the *format* keyword. If specified, it must be the last keyword used, since all remaining arguments are passed on to the dump reader. The *native* format is for native LAMMPS dump files, written with a *dump atom* or *dump custom* command. The *xyz* format is for generic XYZ formatted dump files (see details below). These formats take no additional values.

The *molfile* format supports reading data through using the VMD molfile plugin interface. This dump reader format is only available, if the MOLFILE package has been installed when compiling LAMMPS.

The *molfile* format takes one or two additional values. The *style* value determines the file format to be used and can be any format that the molfile plugins support, such as DCD or XYZ. Note that DCD dump files can be written by LAMMPS via the *dump dcd* command. The *path* value specifies a list of directories which LAMMPS will search for the molfile plugins appropriate to the specified *style*. The syntax of the *path* value is like other search paths: it can contain multiple directories separated by a colon (or semicolon on windows). The *path* keyword is optional and defaults to ".", i.e. the current directory.

The *adios* format supports reading data that was written by the *dump adios* command. The entire dump is read in parallel across all the processes, dividing the atoms evenly among the processes. The number of writers that has written the dump file does not matter. Using the adios style for dump and read_dump is a convenient way to dump all atoms from *N* writers and read it back by *M* readers. If one is running two LAMMPS instances concurrently where one dumps data and the other is reading it with the rerun command, the timeout option can be specified to wait on the reader side for the arrival of the requested step.

Support for other dump format readers may be added in the future.

Global information is first read from the dump file, namely timestep and box information.

The dump file is scanned for a snapshot with a timestamp that matches the specified *Nstep*. This means the LAMMPS timestep the dump file snapshot was written on for the *native* or *adios* formats.

The list of timestamps available in an adios .bp file is stored in the variable *ntimestep*:

```
console

$ bpls dump.bp -d ntimestep
  uint64_t  ntimestep  5*scalar
    (0)    0 50 100 150 200
```

Note that the *xyz* and *molfile* formats do not store the timestep. For these formats, timesteps are numbered logically, in a sequential manner, starting from 0. Thus to access the 10th snapshot in an *xyz* or *mofile* formatted dump file, use *Nstep* = 9.

The dimensions of the simulation box for the selected snapshot are also read; see the *box* keyword discussion below. For the *native* format, an error is generated if the snapshot is for a triclinic box and the current simulation box is orthogonal or vice versa. A warning will be generated if the snapshot box boundary conditions (periodic, shrink-wrapped, etc) do not match the current simulation boundary conditions, but the boundary condition information in the snapshot is otherwise ignored. See the "boundary" command for more details. The *adios* reader does the same as the *native* format reader.

For the *xyz* format, no information about the box is available, so you must set the *box* flag to *no*. See details below.

For the *molfile* format, reading simulation box information is typically supported, but the location of the simulation box origin is lost and no explicit information about periodicity or orthogonal/triclinic box shape is available. The MOLFILE package makes a best effort to guess based on heuristics, but this may not always work perfectly.

Per-atom information from the dump file snapshot is then read from the dump file snapshot. This corresponds to the specified *fields* listed in the read_dump command. It is an error to specify a z-dimension field, namely *z*, *vz*, or *iz*, for a 2d simulation.

For dump files in *native* format, each column of per-atom data has a text label listed in the file. A matching label for each field must appear, e.g. the label "vy" for the field *vy*. For the *x*, *y*, *z* fields any of the following labels are considered a match:

```
x, xs, xu, xsu for field x
y, ys, yu, ysu for field y
z, zs, zu, zsu for field z
```

The meaning of xs (scaled), xu (unwrapped), and xsu (scaled and unwrapped) is explained on the *dump* command doc page. These labels are searched for in the list of column labels in the dump file, in order, until a match is found.

The dump file must also contain atom IDs, with a column label of "id".

If the *add* keyword is specified with a value of *yes* or *keep*, as discussed below, the dump file must contain atom types, with a column label of "type".

If a column label you want to read from the dump file is not a match to a specified field, the *label* keyword can be used to specify the specific column label from the dump file to associate with that field. An example is if a time-averaged coordinate is written to the dump file via the *fix ave/atom* command. The column will then have a label corresponding to the fix-ID rather than "x" or "xs". The *label* keyword can also be used to specify new column labels for fields *id* and *type*.

For dump files in *xyz* format, only the *type*, *x*, *y*, and *z* fields are supported. There are many variants of the XYZ file format. LAMMPS will read the number of atoms from the first line of each frame, ignore the second (title) line, and then read one line for each atom in the format:

```
<label> <x coordinate>  <y coordinate> <z coordinate>
```

If the atom label is a numeric integer (like with XYZ files created by created with default settings by *dump style xyz*), that number will be used as the atom type. If the atom label is a string, then a type map must be created using the

labelmap command. This map needs to associate each (numeric) atom type with a string label. The numeric atom type is stored internally.

The xyz format dump file does not store atom IDs, so these are assigned consecutively to the atoms as they appear in the dump file, starting from 1. Thus you should ensure that the order of atoms is consistent from snapshot to snapshot in the XYZ dump file. See the *dump_modify sort* command if the XYZ dump file was written by LAMMPS.

For dump files in *molfile* format, the *x*, *y*, *z*, *vx*, *vy*, and *vz* fields can be specified. However, not all molfile formats store velocities, or their respective plugins may not support reading of velocities. The molfile dump files do not store atom IDs, so these are assigned consecutively to the atoms as they appear in the dump file, starting from 1. Thus you should ensure that the order of atoms are consistent from snapshot to snapshot in the molfile dump file. See the *dump_modify sort* command if the dump file was written by LAMMPS.

The *adios* format supports all fields that the *native* format supports except for the *q* charge field. The list of fields stored in an adios .bp file is recorded in the attributes *columns* (array of short strings) and *columnstr* (space-separated single string).

```
console

$ bpls -la dump.bp column*
  string    columns           attr   = {"id", "type", "x", "y", "z", "vx", "vy", "vz"}
  string    columnstr         attr   = "id type x y z vx vy vz "
```

Information from the dump file snapshot is used to overwrite or replace properties of the current system. There are various options for how this is done, determined by the specified fields and optional keywords.

Changed in version 3Aug2022.

The timestep of the snapshot becomes the current timestep for the simulation unless the *timestep* keyword is specified with a *no* value (default setting is *yes*). See the *reset_timestep* command if you wish to change this to a different value after the dump snapshot is read.

If the *box* keyword is specified with a *yes* value, then the current simulation box dimensions are replaced by the dump snapshot box dimensions. If the *box* keyword is specified with a *no* value, the current simulation box is unchanged.

If the *purge* keyword is specified with a *yes* value, then all current atoms in the system are deleted before any of the operations invoked by the *replace*, *trim*, or *add* keywords take place.

If the *replace* keyword is specified with a *yes* value, then atoms with IDs that are in both the current system and the dump snapshot have their properties overwritten by field values. If the *replace* keyword is specified with a *no* value, atoms with IDs that are in both the current system and the dump snapshot are not modified.

If the *trim* keyword is specified with a *yes* value, then atoms with IDs that are in the current system but not in the dump snapshot are deleted. These atoms are unaffected if the *trim* keyword is specified with a *no* value.

If the *add* keyword is specified with a *no* value (default), then dump file atoms with IDs that are not in the current system are not added to the system. They are simply ignored.

If a *yes* value is specified, the atoms with new IDs are added to the system but their atom IDs are not preserved. Instead, after all the atoms are added, new IDs are assigned to them in the same manner as is described for the *create_atoms* command. Basically the largest existing atom ID in the system is identified, and all the added atoms are assigned IDs that consecutively follow the largest ID.

If a *keep* value is specified, the atoms with new IDs are added to the system and their atom IDs are preserved. This may lead to non-contiguous IDs for the combined system.

Note that atoms added via the *add* keyword will only have the attributes read from the dump file due to the *field* arguments. For example, if *x* or *y* or *z* or *q* is not specified as a field, a value of 0.0 is used for added atoms. Added atoms must have an atom type, so this value must appear in the dump file.

Any other attributes (e.g. charge or particle diameter for spherical particles) will be set to default values, the same as if the *create_atoms* command were used.

Atom coordinates read from the dump file are first converted into unscaled coordinates, relative to the box dimensions of the snapshot. These coordinates are then be assigned to an existing or new atom in the current simulation. The coordinates will then be remapped to the simulation box, whether it is the original box or the dump snapshot box. If periodic boundary conditions apply, this means the atom will be remapped back into the simulation box if necessary. If shrink-wrap boundary conditions apply, the new coordinates may change the simulation box dimensions. If fixed boundary conditions apply, the atom will be lost if it is outside the simulation box.

For *native* format dump files, the 3 xyz image flags for an atom in the dump file are set to the corresponding values appearing in the dump file if the *ix*, *iy*, *iz* fields are specified. If not specified, the image flags for replaced atoms are not changed and image flags for new atoms are set to default values. If coordinates read from the dump file are in unwrapped format (e.g. *xu*) then the image flags for read-in atoms are also set to default values. The remapping procedure described in the previous paragraph will then change images flags for all atoms (old and new) if periodic boundary conditions are applied to remap an atom back into the simulation box.

Note

If you get a warning about inconsistent image flags after reading in a dump snapshot, it means one or more pairs of bonded atoms now have inconsistent image flags. As discussed on the *Errors common* page this may or may not cause problems for subsequent simulations. One way this can happen is if you read image flag fields from the dump file but do not also use the dump file box parameters.

LAMMPS knows how to compute unscaled and remapped coordinates for the snapshot column labels discussed above, e.g. *x*, *xs*, *xu*, *xsu*. If another column label is assigned to the *x* or *y* or *z* field via the *label* keyword, e.g. for coordinates output by the *fix ave/atom* command, then LAMMPS needs to know whether the coordinate information in the dump file is scaled and/or wrapped. This can be set via the *scaled* and *wrapped* keywords. Note that the value of the *scaled* and *wrapped* keywords is ignored for fields *x* or *y* or *z* if the *label* keyword is not used to assign a column label to that field.

The scaled/unscaled and wrapped/unwrapped setting must be identical for any of the *x*, *y*, *z* fields that are specified. Thus you cannot read *xs* and *yu* from the dump file. Also, if the dump file coordinates are scaled and the simulation box is triclinic, then all 3 of the *x*, *y*, *z* fields must be specified, since they are all needed to generate absolute, unscaled coordinates.

1.87.4 Restrictions

To read gzipped dump files, you must compile LAMMPS with the -DLAMMPS_GZIP option. See the *Build settings* doc page for details.

The *molfile* dump file formats are part of the MOLFILE package. They are only enabled if LAMMPS was built with that packages. See the *Build package* page for more info.

To write and read adios .bp files, you must compile LAMMPS with the *ADIOS* package.

1.88 read_restart command

1.88.1 Syntax

```
read_restart file
```

- file = name of binary restart file to read in

1.88.2 Examples

```
read_restart save.10000
read_restart restart.*
```

1.88.3 Description

Read in a previously saved system configuration from a restart file. This allows continuation of a previous run. Details about what information is stored (and not stored) in a restart file is given below. Basically this operation will re-create the simulation box with all its atoms and their attributes as well as some related global settings, at the point in time it was written to the restart file by a previous simulation. The simulation box will be partitioned into a regular 3d grid of rectangular bricks, one per processor, based on the number of processors in the current simulation and the settings of the *processors* command. The partitioning can later be changed by the *balance* or *fix balance* commands.

Removed in version 23Jun2022.

Atom coordinates that are found to be outside the simulation box when reading the restart will be remapped back into the box and their image flags updated accordingly. This previously required specifying the *remap* option, but that is no longer required.

Restart files are saved in binary format to enable exact restarts, meaning that the trajectories of a restarted run will precisely match those produced by the original run had it continued on.

Some information about a restart file can be gathered directly from the command-line when using LAMMPS with the *-restart2info* command-line flag. On Unix-like operating systems (like Linux or macOS), one can also *configure the "file" command-line program* to display basic information about a restart file

The binary restart file format was not designed with backward, forward, or cross-platform compatibility in mind, so the files are only expected to be read correctly by the same LAMMPS executable on the same platform. Changes to the architecture, compilation settings, or LAMMPS version can render a restart file unreadable or it may read the data incorrectly. If you want a more portable format, you can use the data file format as created by the *write_data* command. Binary restart files can also be converted into a data file from the command-line by the LAMMPS executable that wrote them using the *-restart2data* command-line flag.

Several things can prevent exact restarts due to round-off effects, in which case the trajectories in the 2 runs will slowly diverge. These include running on a different number of processors or changing certain settings such as those set by the *newton* or *processors* commands. LAMMPS will issue a warning in these cases.

Certain fixes will not restart exactly, though they should provide statistically similar results. These include *fix shake* and *fix langevin*.

Certain pair styles will not restart exactly, though they should provide statistically similar results. This is because the forces they compute depend on atom velocities, which are used at half-step values every timestep when forces are

computed. When a run restarts, forces are initially evaluated with a full-step velocity, which is different than if the run had continued. These pair styles include *granular pair styles*, *pair dpd*, and *pair lubricate*.

If a restarted run is immediately different than the run which produced the restart file, it could be a LAMMPS bug, so consider *reporting it* if you think the behavior is a bug.

Because restart files are binary, they may not be portable to other machines. In this case, you can use the *-restart command-line switch* to convert a restart file to a data file.

Similar to how restart files are written (see the *write_restart* and *restart* commands), the restart filename can contain two wild-card characters. If a "*" appears in the filename, the directory is searched for all filenames that match the pattern where "*" is replaced with a timestep value. The file with the largest timestep value is read in. Thus, this effectively means, read the latest restart file. It's useful if you want your script to continue a run from where it left off. See the *run* command and its "upto" option for how to specify the run command so it does not need to be changed either.

If a "%" character appears in the restart filename, LAMMPS expects a set of multiple files to exist. The *restart* and *write_restart* commands explain how such sets are created. Read_restart will first read a filename where "%" is replaced by "base". This file tells LAMMPS how many processors created the set and how many files are in it. Read_restart then reads the additional files. For example, if the restart file was specified as save.% when it was written, then read_restart reads the files save.base, save.0, save.1, ... save.P-1, where P is the number of processors that created the restart file.

Note that P could be the total number of processors in the previous simulation, or some subset of those processors, if the *fileper* or *nfile* options were used when the restart file was written; see the *restart* and *write_restart* commands for details. The processors in the current LAMMPS simulation share the work of reading these files; each reads a roughly equal subset of the files. The number of processors which created the set can be different the number of processors in the current LAMMPS simulation. This can be a fast mode of input on parallel machines that support parallel I/O.

Here is the list of information included in a restart file, which means these quantities do not need to be re-specified in the input script that reads the restart file, though you can redefine many of these settings after the restart file is read.

- *units*
- *newton bond* (see discussion of newton command below)
- *atom style* and *atom_modify* settings id, map, sort
- *comm style* and *comm_modify* settings mode, cutoff, vel
- *timestep size* and *timestep number*
- simulation box size and shape and *boundary* settings
- atom *group* definitions
- per-type atom settings such as *mass*
- per-atom attributes including their group assignments and molecular topology attributes (bonds, angles, etc)
- force field styles (*pair*, *bond*, *angle*, etc)
- force field coefficients (*pair*, *bond*, *angle*, etc) in some cases (see below)
- *pair_modify* settings, except the compute option
- *special_bonds* settings

Here is a list of information not stored in a restart file, which means you must re-issue these commands in your input script, after reading the restart file.

- *newton pair* (see discussion of newton command below)
- *fix* commands (see below)

- *compute* commands (see below)
- *variable* commands
- *region* commands
- *neighbor list* criteria including *neigh_modify* settings
- *kspace_style* and *kspace_modify* settings
- info for *thermodynamic*, *dump*, or *restart* output

The *newton* command has two settings, one for pairwise interactions, the other for bonded. Both settings are stored in the restart file. For the bond setting, the value in the file will overwrite the current value (at the time the read_restart command is issued) and warn if the two values are not the same and the current value is not the default. For the pair setting, the value in the file will not overwrite the current value (so that you can override the previous run's value), but a warning is issued if the two values are not the same and the current value is not the default.

Note that some force field styles (pair, bond, angle, etc) do not store their coefficient info in restart files. Typically these are many-body or tabulated potentials which read their parameters from separate files. In these cases you will need to re-specify the *pair_coeff*, *bond_coeff*, etc commands in your restart input script. The doc pages for individual force field styles mention if this is the case. This is also true of *pair_style hybrid* (bond hybrid, angle hybrid, etc) commands; they do not store coefficient info.

As indicated in the above list, the *fixes* used for a simulation are not stored in the restart file. This means the new input script should specify all fixes it will use. However, note that some fixes store an internal "state" which is written to the restart file. This allows the fix to continue on with its calculations in a restarted simulation. To re-enable such a fix, the fix command in the new input script must be of the same style and use the same fix-ID as was used in the input script that wrote the restart file.

If a match is found, LAMMPS prints a message indicating that the fix is being re-enabled. If no match is found before the first run or minimization is performed by the new script, the "state" information for the saved fix is discarded. At the time the discard occurs, LAMMPS will also print a list of fixes for which the information is being discarded. See the doc pages for individual fixes for info on which ones can be restarted in this manner. Note that fixes which are created internally by other LAMMPS commands (computes, fixes, etc) will have style names which are all-capitalized, and IDs which are generated internally.

Likewise, the *computes* used for a simulation are not stored in the restart file. This means the new input script should specify all computes it will use. However, some computes create a fix internally to store "state" information that persists from timestep to timestep. An example is the *compute msd* command which uses a fix to store a reference coordinate for each atom, so that a displacement can be calculated at any later time. If the compute command in the new input script uses the same compute-ID and group-ID as was used in the input script that wrote the restart file, then it will create the same fix in the restarted run. This means the re-created fix will be re-enabled with the stored state information as described in the previous paragraph, so that the compute can continue its calculations in a consistent manner.

Note

There are a handful of commands which can be used before or between runs which may require a system initialization. Examples include the "balance", "displace_atoms", "delete_atoms", "set" (some options), and "velocity" (some options) commands. This is because they can migrate atoms to new processors. Thus they will also discard unused "state" information from fixes. You will know the discard has occurred because a list of discarded fixes will be printed to the screen and log file, as explained above. This means that if you wish to retain that info in a restarted run, you must re-specify the relevant fixes and computes (which create fixes) before those commands are used.

Some pair styles, like the *granular pair styles*, also use a fix to store "state" information that persists from timestep to timestep. In the case of granular potentials, it is contact information between pairs of touching particles. This info will also be re-enabled in the restart script, assuming you reuse the same granular pair style.

LAMMPS allows bond interactions (angle, etc) to be turned off or deleted in various ways, which can affect how their info is stored in a restart file.

If bonds (angles, etc) have been turned off by the *fix shake* or *delete_bonds* command, their info will be written to a restart file as if they are turned on. This means they will need to be turned off again in a new run after the restart file is read.

Bonds that are broken (e.g. by a bond-breaking potential) are written to the restart file as broken bonds with a type of 0. Thus these bonds will still be broken when the restart file is read.

Bonds that have been broken by the *fix bond/break* command have disappeared from the system. No information about these bonds is written to the restart file.

```

1.89.3 Description

This command defines a geometric region of space. Various other commands use regions. For example, the region can be filled with atoms via the *create_atoms* command. Or a bounding box around the region, can be used to define the simulation box via the *create_box* command. Or the atoms in the region can be identified as a group via the *group* command, or deleted via the *delete_atoms* command. Or the surface of the region can be used as a boundary wall via the *fix wall/region* command.

Commands which use regions typically test whether an atom's position is contained in the region or not. For this purpose, coordinates exactly on the region boundary are considered to be interior to the region. This means, for example, for a spherical region, an atom on the sphere surface would be part of the region if the sphere were defined with the *side in* keyword, but would not be part of the region if it were defined using the *side out* keyword. See more details on the *side* keyword below.

Normally, regions in LAMMPS are "static", meaning their geometric extent does not change with time unless their geometry is defined using references to *equal style variables* where the value changes over time. See below for more details on "variable shapes". If the *move* or *rotate* keyword is used, as described below, the region becomes "dynamic", meaning its location or orientation can change with time. This may be useful, for example, when thermostatting a region, via the compute temp/region command, or when the fix wall/region command uses a region surface as a bounding wall on particle motion, i.e. a rotating container.

The *delete* style removes the named region. Since there is little overhead to defining extra regions, there is normally no need to do this, unless you are defining and discarding large numbers of regions in your input script.

The lo/hi values for *block* or *cone* or *cylinder* or *prism* styles can be specified as EDGE or INF. EDGE means they extend all the way to the global simulation box boundary. Note that this is the current box boundary; if the box changes size during a simulation, the region does not. INF means a large negative or positive number (1.0e20), so it should encompass the simulation box even if it changes size. If a region is defined before the simulation box has been created (via *create_box* or *read_data* or *read_restart* commands), then an EDGE or INF parameter cannot be used. For a *prism* region, a non-zero tilt factor in any pair of dimensions cannot be used if both the lo/hi values in either of those dimensions are INF. E.g. if the xy tilt is non-zero, then xlo and xhi cannot both be INF, nor can ylo and yhi.

Note

Regions in LAMMPS do not get wrapped across periodic boundaries, as specified by the *boundary* command. For example, a spherical region that is defined so that it overlaps a periodic boundary is not treated as 2 half-spheres, one on either side of the simulation box.

Note

Regions in LAMMPS are always 3d geometric objects, regardless of whether the *dimension* of a simulation is 2d or 3d. Thus when using regions in a 2d simulation, you should be careful to define the region so that its intersection with the 2d x-y plane of the simulation has the 2d geometric extent you want.

For style *cone*, an axis-aligned cone is defined which is like a *cylinder* except that two different radii (one at each end) can be defined. Either of the radii (but not both) can be 0.0.

For style *cone* and *cylinder*, the c1,c2 params are coordinates in the 2 other dimensions besides the cylinder axis dimension. For dim = x, c1/c2 = y/z; for dim = y, c1/c2 = x/z; for dim = z, c1/c2 = x/y. Thus the third example above specifies a cylinder with its axis in the y-direction located at x = 2.0 and z = 3.0, with a radius of 5.0, and extending in the y-direction from -5.0 to the upper box boundary.

Added in version 4May2022.

For style *ellipsoid*, an axis-aligned ellipsoid is defined. The ellipsoid has its center at (x,y,z) and is defined by 3 axis-aligned vectors given by A = (a,0,0); B = (0,b,0); C = (0,0,c). Note that although the ellipsoid is specified as axis-aligned

it can be rotated via the optional *rotate* keyword.

For style *plane*, a plane is defined which contain the point (px,py,pz) and has a normal vector (nx,ny,nz). The normal vector does not have to be of unit length. The "inside" of the plane is the half-space in the direction of the normal vector; see the discussion of the *side* option below.

For style *prism*, a parallelepiped is defined (it is too hard to spell parallelepiped in an input script!). The parallelepiped has its "origin" at (xlo,ylo,zlo) and is defined by 3 edge vectors starting from the origin given by A = (xhi-xlo,0,0); B = (xy,yhi-ylo,0); C = (xz,yz,zhi-zlo). *Xy,xz,yz* can be 0.0 or positive or negative values and are called "tilt factors" because they are the amount of displacement applied to faces of an originally orthogonal box to transform it into the parallelepiped.

A prism region that will be used with the *create_box* command to define a triclinic simulation box must have tilt factors (xy,xz,yz) that do not skew the box more than half the distance of corresponding the parallel box length. For example, if xlo = 2 and xhi = 12, then the x box length is 10 and the xy tilt factor must be between -5 and 5. Similarly, both xz and yz must be between -(xhi-xlo)/2 and +(yhi-ylo)/2. Note that this is not a limitation, since if the maximum tilt factor is 5 (as in this example), then configurations with tilt = . . . , -15, -5, 5, 15, 25, . . . are all geometrically equivalent.

For style *sphere*, a sphere is defined with its center at (x,y,z) and with radius as its radius.

The *radius* value for styles *sphere* and *cylinder*, and the parameters a,b,c for style *ellipsoid*, can each be specified as an equal-style *variable*. Likewise, for style *sphere* and *ellipsoid* the x-, y-, and z- coordinates of the center of the sphere/ellipsoid can be specified as an equal-style variable. And for style *cylinder* the two center positions c1 and c2 for the location of the cylinder axes can be specified as a equal-style variable. For styles *block*, *cone*, *prism*, and *plane* all properties can be defined via equal-style variables. For style *plane*, the components of the direction vector normal to plane should be either all constants or all defined by equal-style variables.

If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the radius of the region.

Equal-style variables can specify formulas with various mathematical functions, and include *thermo_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent radius or have a time dependent position of the sphere or cylinder region.

Note

Whenever a region property, such as a coordinate or an upper/lower bound, is defined via an equal-style variable, the variable should not cause any of the region boundaries to move too far within a single timestep. Otherwise, bad dynamics will occur. "Too far" means a small fraction of the approximate distance of closest approach between two particles, which for the case of Lennard-Jones particles is the distance of the energy minimum while for granular particles it is their diameter. An example is a rapidly varying direction vector in region plane since a small change in the normal to plane will shift the region surface far away from the region point by a large displacement. Similarly, bad dynamics can also occur for fast changing variables employed in the move/rotate options.

See the *Howto tricilinc* page for a geometric description of triclinic boxes, as defined by LAMMPS, and how to transform these parameters to and from other commonly used triclinic representations.

The *union* style creates a region consisting of the volume of all the listed regions combined. The *intersect* style creates a region consisting of the volume that is common to all the listed regions.

Note

The *union* and *intersect* regions operate by invoking methods from their list of sub-regions. Thus you cannot delete the sub-regions after defining a *union* or *intersection* region.

The *side* keyword determines whether the region is considered to be inside or outside of the specified geometry. Using this keyword in conjunction with *union* and *intersect* regions, complex geometries can be built up. For example, if the interior of two spheres were each defined as regions, and a *union* style with *side* = out was constructed listing the region-IDs of the 2 spheres, the resulting region would be all the volume in the simulation box that was outside both of the spheres.

The *units* keyword determines the meaning of the distance units used to define the region for any argument above listed as having distance units. It also affects the scaling of the velocity vector specified with the *vel* keyword, the amplitude vector specified with the *wiggle* keyword, and the rotation point specified with the *rotate* keyword, since they each involve a distance metric.

A *box* value selects standard distance units as defined by the *units* command, e.g. Angstroms for units = real or metal. A *lattice* value means the distance units are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacings which are used as follows:

- For style *block*, the lattice spacing in dimension x is applied to xlo and xhi, similarly the spacings in dimensions y,z are applied to ylo/yhi and zlo/zhi.
- For style *cone*, the lattice spacing in argument *dim* is applied to lo and hi. The spacings in the two radial dimensions are applied to c1 and c2. The two cone radii are scaled by the lattice spacing in the dimension corresponding to c1.
- For style *cylinder*, the lattice spacing in argument *dim* is applied to lo and hi. The spacings in the two radial dimensions are applied to c1 and c2. The cylinder radius is scaled by the lattice spacing in the dimension corresponding to c1.
- For style *ellipsoid*, the lattice spacing in dimensions x,y,z are applied to the ellipsoid center x,y,z. The spacing in dimensions x,y,z are applied to the ellipsoid radii a,b,c respectively.
- For style *plane*, the lattice spacing in dimension x is applied to px and nx, similarly the spacings in dimensions y,z are applied to py/ny and pz/nz.
- For style *prism*, the lattice spacing in dimension x is applied to xlo and xhi, similarly for ylo/yhi and zlo/zhi. The lattice spacing in dimension x is applied to xy and xz, and the spacing in dimension y to yz.
- For style *sphere*, the lattice spacing in dimensions x,y,z are applied to the sphere center x,y,z. The spacing in dimension x is applied to the sphere radius.

If the *move* or *rotate* keywords are used, the region is "dynamic", meaning its location or orientation changes with time. These keywords cannot be used with a *union* or *intersect* style region. Instead, the keywords should be used to make the individual sub-regions of the *union* or *intersect* region dynamic.

The *move* keyword allows one or more *equal-style variables* to be used to specify the x,y,z displacement of the region, typically as a function of time. A variable is specified as v_name, where name is the variable name. Any of the three variables can be specified as NULL, in which case no displacement is calculated in that dimension.

Note that equal-style variables can specify formulas with various mathematical functions, and include *thermo_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a region displacement that change as a function of time or spans consecutive runs in a continuous fashion. For the latter, see the *start* and *stop* keywords of the *run* command and the *elaplong* keyword of *thermo_style custom* for details.

For example, these commands would displace a region from its initial position, in the positive x direction, effectively at a constant velocity:

```
variable dx equal ramp(0,10)
region 2 sphere 10.0 10.0 0.0 5 move v_dx NULL NULL
```

Note that the initial displacement is 0.0, though that is not required.

Either of these variables would "wiggle" the region back and forth in the y direction:

```
variable dy equal swiggle(0,5,100)
variable dysame equal 5*sin(2*PI*elaplong*dt/100)
region 2 sphere 10.0 10.0 0.0 5 move NULL v_dy NULL
```

The *rotate* keyword rotates the region around a rotation axis *R* = (Rx,Ry,Rz) that goes through a point *P* = (Px,Py,Pz). The rotation angle is calculated, presumably as a function of time, by a variable specified as v_theta, where theta is the variable name. The variable should generate its result in radians. The direction of rotation for the region around the rotation axis is consistent with the right-hand rule: if your right-hand thumb points along *R*, then your fingers wrap around the axis in the direction of rotation.

The *move* and *rotate* keywords can be used together. In this case, the displacement specified by the *move* keyword is applied to the *P* point of the *rotate* keyword which is equivalent to applying the rotation *first* and then the translation.

The *open* keyword can be used (multiple times) to indicate that one or more faces of the region are ignored for purposes of particle/wall interactions. This keyword is only relevant for regions used by the *fix wall/region* and *fix wall/gran/region* commands. It can be used to create "open" containers where only some of the region faces are walls. For example, a funnel can be created with a *cone* style region that has an open face at the smaller radius for particles to flow out, or at the larger radius for pouring particles into the cone, or both.

Note that using the *open* keyword partly overrides the *side* keyword, since both exterior and interior surfaces of an open region are tested for particle contacts. The exception to this is a *union* or *intersect* region which includes an open sub-region. In that case the *side* keyword is still used to define the union/intersect region volume, and the *open* settings are only applied to the individual sub-regions that use them.

The indices specified as part of the *open* keyword have the following meanings:

For style *block*, indices 1-6 correspond to the xlo, xhi, ylo, yhi, zlo, zhi surfaces of the block. I.e. 1 is the yz plane at x = xlo, 2 is the yz-plane at x = xhi, 3 is the xz plane at y = ylo, 4 is the xz plane at y = yhi, 5 is the xy plane at z = zlo, 6 is the xy plane at z = zhi). In the second-to-last example above, the region is a box open at both xy planes.

For style *prism*, values 1-6 have the same mapping as for style *block*. I.e. in an untilted *prism*, *open* indices correspond to the xlo, xhi, ylo, yhi, zlo, zhi surfaces.

For style *cylinder*, index 1 corresponds to the flat end cap at the low coordinate along the cylinder axis, index 2 corresponds to the high-coordinate flat end cap along the cylinder axis, and index 3 is the curved cylinder surface. For example, a *cylinder* region with *open 1 open 2* keywords will be open at both ends (e.g. a section of pipe), regardless of the cylinder orientation.

For style *cone*, the mapping is the same as for style *cylinder*. Index 1 is the low-coordinate flat end cap, index 2 is the high-coordinate flat end cap, and index 3 is the curved cone surface. In the last example above, a *cone* region is defined along the z-axis that is open at the zlo value (e.g. for use as a funnel).

For all other styles, the *open* keyword is ignored. As indicated above, this includes the *intersect* and *union* regions, though their sub-regions can be defined with the *open* keyword.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

Note

Currently, only *block* and *sphere* style regions are supported by KOKKOS. The code using the region (such as a fix or compute) must also be supported by KOKKOS or no acceleration will occur.

1.89.4 Restrictions

A prism cannot be of 0.0 thickness in any dimension; use a small z thickness for 2d simulations. For 2d simulations, the xz and yz parameters must be 0.0.

1.89.5 Related commands

lattice, *create_atoms*, *delete_atoms*, *group*

1.89.6 Default

The option defaults are side = in, units = lattice, and no move or rotation.

1.90 region2vmd command

1.90.1 Syntax

```
region2vmd filename keyword arg ...
```

- filename = name of file to write VMD script commands to
- zero or more keyword/arg pairs may be appended
- keyword = *region* or *color* or *material* or *command*

  region region-ID = name of region to translate to VMD graphics
  color color-name = set color for following visualized objects
  material material-name = set material for following visualized objects
  command string = string with custom VMD script command (in quotes)

1.90.2 Examples

```
region2vmd regions.vmd material Opaque color red region c1 color green region c2
region2vmd vizbox.vmd command "mol new system.lammpstrj waitfor all" region box
region2vmd regdefs.vmd region upper region lower region hole
```

1.90.3 Description

Added in version 2Apr2025.

Write a VMD Tcl script file with commands that aim to create a visualization of *regions*. There may be multiple region visualizations stored in a single file.

The visualization is implemented by creating a new (and empty) "VMD molecule" and then assigning a sequence of VMD graphics primitives to represent the region in VMD. Each region will be stored in a separate "VMD molecule" with the name "LAMMPS region <region ID>".

Visualization of regions with *dump image*

Regions can also be directly visualized within LAMMPS using the *dump image* command. For more information, see *Visualize LAMMPS snapshots*.

The *region2vmd* command is followed by the filename for the resulting VMD script and an arbitrary number of keyword argument pairs to either write out a new *region* visualization, change the *color* or *material* setting, or to insert arbitrary VMD script *command*s. The keywords and arguments are processed in sequence.

The *region* keyword must be followed by a previously defined LAMMPS *region*. Only a limited set region styles and region settings are currently supported. See **Restrictions** below. Unsupported region styles or regions with unsupported settings will be skipped and a corresponding message is printed.

The *color* keyword must be followed by a color name that is defined in VMD. This color will be used by all following region visualizations. The default setting is 'silver'. VMD has the following colors pre-defined:

blue	red	gray	orange	yellow	tan	silver	green	white	pink	cyan
purple	lime	mauve	ochre	iceblue	black	yellow2	yellow3	green2	green3	cyan2
cyan3	blue2	blue3	violet	violet2	magenta	magenta2	red2	red3	orange2	orange3

The *material* keyword must be followed by a material name that is defined in VMD. This material will be used by all following visualizations. The default setting is 'Transparent'. VMD has the following materials pre-defined:

Opaque	Transparent	BrushedMetal	Diffuse	Ghost	Glass1	Glass2	Glass3
Glossy	HardPlastic	MetallicPastel	Steel	Translucent	Edgy	EdgyShiny	EdgyGlass
Goodsell	AOShiny	AOChalky	AOEdgy	BlownGlass	GlassBubble	RTChrome	

The *command* keyword must be followed by a VMD script command as a single string in quotes. This VMD command will be directly inserted into the created VMD script.

The created file can be loaded into VMD either from the command line with the '-e' flag, or from the command prompt with 'play <script file>', or from the File menu via "Load VMD visualization state".

Setting the "top" molecule in VMD

It is usually desirable to have the "molecule" with the LAMMPS trajectory set at "top" molecule in VMD and not one of the "region molecules". The VMD script generated by this region2vmd assumes that this molecule is already loaded and set as the current "top" molecule. Thus at the beginning of the script the index of the top molecule is stored in the VMD variable 'oldtop' and at the end of the script, that "top" molecule is restored. If no molecule is loaded, this can be inserted into the script with a custom command. The molecule index to this new molecules should be assigned to the oldtop variable. This can be done with e.g. `set oldtop [mol new {regions.vmd} waitfor all]`

1.90.4 Restrictions

Changed in version 11Feb2026.

This command is part of the GRAPHICS package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

Only the following region styles are currently supported: *block*, *cone*, *cylinder*, *ellipsoid*, *prism*, and *sphere*. Regions formed from unions or intersections of other regions are not supported.

Rotating regions are currently not supported.

1.90.5 Related commands

region, *dump image*

1.90.6 Defaults

color = silver, *material* = Transparent

1.91 replicate command

1.91.1 Syntax

```
replicate nx ny nz keyword ...
```

nx,ny,nz = replication factors in each dimension

- zero or more keywords may be appended
- keyword = *bbox* or *bond/periodic*

  bbox = use a bounding-box algorithm which is faster for large proc counts
  bond/periodic = use an algorithm that correctly replicates periodic bond loops

1.91.2 Examples

For examples of replicating simple linear polymer chains (periodic or non-periodic) or periodic carbon nanotubes, see examples/replicate.

```
replicate 2 3 2
replicate 2 3 2 bbox
replicate 2 3 2 bond/periodic
```

1.91.3 Description

Replicate the current system one or more times in each dimension. For example, replication factors of 2,2,2 will create a simulation with 8x as many atoms by doubling the size of the simulation box in each dimension. A replication factor of 1 leaves the simulation domain unchanged in that dimension.

When the new simulation box is created it is partitioned into a regular 3d grid of rectangular bricks, one per processor, based on the number of processors being used and the settings of the *processors* command. The partitioning can be changed by subsequent *balance* or *fix balance* commands.

All properties of each atom are replicated (except per-atom fix data, see the Restrictions section below). This includes their velocities, which may or may not be desirable. New atom IDs are assigned to new atoms, as are new molecule IDs. Bonds and other topology interactions are created between pairs of new atoms as well as between old and new atoms.

Note

The bond discussion which follows only refers to models with permanent covalent bonds typically defined in LAMMPS via a data file. It is not relevant to systems modeled with many-body potentials which can define bonds on-the-fly, based on the current positions of nearby atoms, e.g. models using the *AIREBO* or *ReaxFF* potentials.

If the *bond/periodic* keyword is not specified, bond replication is done by using the image flag for each atom to "unwrap" it out of the periodic box before replicating it. After replication is performed, atoms outside the new periodic box are wrapped back into it. This assigns correct images flags to all atoms in the system. For this to work, all original atoms in the original simulation box must have consistent image flags. This means that if two atoms have a bond between them which crosses a periodic boundary, their respective image flags will differ by 1 in that dimension.

Image flag consistency is not possible if a system has a periodic bond loop, meaning there is a chain of bonds which crosses an entire dimension and re-connects to itself across a periodic boundary. In this case you MUST use the *bond/periodic* keyword to correctly replicate the system. This option zeroes the image flags for all atoms and uses a different algorithm to find new (nearby) bond neighbors in the replicated system. In the final replicated system all image flags are zero (in each dimension).

Note

LAMMPS does not check for image flag consistency before performing the replication (it does issue a warning about this before a simulation is run). If the original image flags are inconsistent, the replicated system will also have inconsistent image flags, but will otherwise be correctly replicated. This is NOT the case if there is a periodic bond loop. See the next note.

Note

LAMMPS does not check for periodic bond loops. If you use the *bond/periodic* keyword for a system without periodic bond loops, the system will be correctly replicated, but image flag information will be lost (which may or may not be important to your model). If you do not use the *bond/periodic* keyword for a system with periodic bond loops, the replicated system will have invalid bonds (typically very long), resulting in bad dynamics.

If possible, the *bbox* keyword should be used when running on a large number of processors, as it can result in a substantial speed-up for the replication operation. It uses a bounding box to only check atoms in replicas that overlap with each processor's new subdomain when assigning atoms to processors. It also preserves image flag information. The only drawback to the *bbox* option is that it requires a temporary use of more memory. Each processor must be able to store all atoms (and their per-atom data) in the original system, before it is replicated.

Note

The algorithm used by the *bond/periodic* keyword builds on the algorithm used by the *bbox* keyword and thus has the same memory requirements. If you specify only the *bond/peridoic* keyword it will internally set the *bbox* keyword as well.

1.91.4 Restrictions

A 2d simulation cannot be replicated in the z dimension.

If a simulation is non-periodic in a dimension, care should be used when replicating it in that dimension, as it may generate atoms nearly on top of each other.

If the current simulation was read in from a restart file (before a run is performed), there must not be any fix information stored in the file for individual atoms. Similarly, no fixes can be defined at the time the replicate command is used that require vectors of atom information to be stored. This is because the replicate command does not know how to replicate that information for new atoms it creates.

To work around this restriction two options are possible. (1) Fixes which use the stored data in the restart file can be defined before replication and then deleted via the *unfix* command and re-defined after it. Or (2) the restart file can be converted to a data file (which deletes the stored fix information) and fixes defined after the replicate command. In both these scenarios, the per-atom fix information in the restart file is lost.

1.91.5 Related commands

none

1.91.6 Default

No settings for using the *bbox* or *bond/periodic* algorithms.

1.92 rerun command

1.92.1 Syntax

```
rerun file1 file2 ... keyword args ...
```

- file1,file2,... = dump file(s) to read
- one or more keywords may be appended, keyword *dump* must appear and be last

```
keyword = first or last or every or skip or start or stop or post or dump
  first args = Nfirst
    Nfirst = dump timestep to start on
  last args = Nlast
    Nlast = dumptimestep to stop on
  every args = Nevery
    Nevery = read snapshots matching every this many timesteps
  skip args = Nskip
    Nskip = read one out of every Nskip snapshots
  start args = Nstart
    Nstart = timestep on which pseudo run will start
  stop args = Nstop
    Nstop = timestep to which pseudo run will end
  post value = yes or no
  dump args = same as read_dump command starting with its field arguments
```

1.92.2 Examples

```
rerun dump.file dump x y z vx vy vz
rerun dump1.txt dump2.txt first 10000 every 1000 dump x y z
rerun dump.vels dump x y z vx vy vz box yes format molfile lammpstrj
rerun dump.dcd dump x y z box no format molfile dcd
rerun ../run7/dump.file.gz skip 2 dump x y z box yes
rerun dump.bp dump x y z box no format adios
rerun dump.bp dump x y z vx vy vz format adios timeout 10.0
```

1.92.3 Description

Perform a pseudo simulation run where atom information is read one snapshot at a time from a dump file(s), and energies and forces are computed on the snapshot to produce thermodynamic or other output.

This can be useful in the following kinds of scenarios, after an initial simulation produced the dump file:

- Compute the energy and forces of snapshots using a different potential.
- Calculate one or more diagnostic quantities on the snapshots that were not computed in the initial run. These can also be computed with settings not used in the initial run, e.g. computing an RDF via the *compute rdf* command with a longer cutoff than was used initially.
- Calculate the portion of per-atom forces resulting from a subset of the potential. E.g. compute only Coulombic forces. This can be done by only defining only a Coulombic pair style in the rerun script. Doing this in the original script would result in different (bad) dynamics.

Conceptually, using the rerun command is like running an input script that has a loop in it (see the *next* and *jump* commands). Each iteration of the loop reads one snapshot from the dump file via the *read_dump* command, sets the timestep to the appropriate value, and then invokes a *run* command for zero timesteps to simply compute energy and forces, and any other *thermodynamic output* or diagnostic info you have defined. This computation also invokes any fixes you have defined that apply constraints to the system, such as *fix shake* or *fix indent*.

Note that a simulation box must already be defined before using the rerun command. This can be done by the *create_box*, *read_data*, or *read_restart* commands.

Also note that reading per-atom information from dump snapshots is limited to the atom coordinates, velocities and image flags as explained in the *read_dump* command. Other atom properties, which may be necessary to compute energies and forces, such as atom charge, or bond topology information for a molecular system, are not read from (or even contained in) dump files. Thus this auxiliary information should be defined in the usual way, e.g. in a data file read in by a *read_data* command, before using the rerun command.

Also note that the frequency of thermodynamic or dump output from the rerun simulation will depend on settings made in the rerun script, the same as for output from any LAMMPS simulation. See further info below as to what that means if the timesteps for snapshots read from dump files do not match the specified output frequency.

If more than one dump file is specified, the dump files are read one after the other in the order specified. It is assumed that snapshot timesteps will be in ascending order. If a snapshot is encountered that is not in ascending order, it will skip the snapshot until it reads one that is. This allows skipping of a duplicate snapshot (same timestep), e.g. that appeared at the end of one file and beginning of the next. However if you specify a series of dump files in an incorrect order (with respect to the timesteps they contain), you may skip large numbers of snapshots.

Note that the dump files specified as part of the *dump* keyword can be parallel files, i.e. written as multiple files either per processor and/or per snapshot. If that is the case they will also be read in parallel which can make the rerun command operate dramatically faster for large systems. See the page for the *read_dump* and *dump* commands which describe how to read and write parallel dump files.

The *first*, *last*, *every*, *skip* keywords determine which snapshots are read from the dump file(s). Snapshots are skipped until they have a timestep >= *Nfirst*. When a snapshot with a timestep > *Nlast* is encountered, the rerun command finishes. Note that the defaults for *first* and *last* are to read all snapshots. If the *every* keyword is set to a value > 0, then only snapshots with timesteps that are a multiple of *Nevery* are read (the first snapshot is always read). If *Nevery* = 0, then this criterion is ignored, i.e. every snapshot is read that meets the other criteria. If the *skip* keyword is used, then after the first snapshot is read, every Nth snapshot is read, where N = *Nskip*. E.g. if *Nskip* = 3, then only 1 out of every 3 snapshots is read, assuming the snapshot timestep is also consistent with the other criteria.

Note

Not all dump formats contain the timestep and not all dump readers support reading it. In that case individual snapshots are assigned consecutive timestep numbers starting at 1.

The *start* and *stop* keywords do not affect which snapshots are read from the dump file(s). Rather, they have the same meaning that they do for the *run* command. They only need to be defined if (a) you are using a *fix* command that changes some value over time, and (b) you want the reference point for elapsed time (from start to stop) to be different than the *first* and *last* settings. See the page for individual fixes to see which ones can be used with the *start/stop* keywords. Note that if you define neither of the *start*/*stop* or *first*/*last* keywords, then LAMMPS treats the pseudo run as going from 0 to a huge value (effectively infinity). This means that any quantity that a fix scales as a fraction of elapsed time in the run, will essentially remain at its initial value. Also note that an error will occur if you read a snapshot from the dump file with a timestep value larger than the *stop* setting you have specified.

The *post* keyword can be used to minimize the output to the screen that happens after a *rerun* command, similar to the post keyword of the *run command*. It is set to *no* by default.

The *dump* keyword is required and must be the last keyword specified. Its arguments are passed internally to the *read_dump* command. The first argument following the *dump* keyword should be the *field1* argument of the *read_dump* command. See the *read_dump* page for details on the various options it allows for extracting information from the dump file snapshots, and for using that information to alter the LAMMPS simulation.

In general, a LAMMPS input script that uses a rerun command can include and perform all the usual operations of an input script that uses the *run* command. There are a few exceptions and points to consider, as discussed here.

Fixes that perform time integration, such as *fix nve* or *fix npt* are not invoked, since no time integration is performed. Fixes that perturb or constrain the forces on atoms will be invoked, just as they would during a normal run. Examples are *fix indent* and *fix langevin*. So you should think carefully as to whether that makes sense for the manner in which you are reprocessing the dump snapshots.

If you only want the rerun script to perform an analysis that does not involve pair interactions, such as use compute msd to calculated displacements over time, you do not need to define a *pair style*, which may also mean neighbor lists will not need to be calculated which saves time. The *comm_modify cutoff* command can also be used to ensure ghost atoms are acquired from far enough away for operations like bond and angle evaluations, if no pair style is being used.

Every time a snapshot is read, the timestep for the simulation is reset, as if the *reset_timestep* command were used. This command has some restrictions as to what fixes can be defined. See its documentation page for details. For example, the *fix deposit* and *fix dt/reset* fixes are in this category. They also make no sense to use with a rerun command.

If time-averaging fixes like *fix ave/time* are used, they are invoked on timesteps that are a function of their *Nevery*, *Nrepeat*, and *Nfreq* settings. As an example, see the *fix ave/time* page for details. You must ensure those settings are consistent with the snapshot timestamps that are read from the dump file(s). If an averaging fix is not invoked on a timestep it expects to be, LAMMPS will flag an error.

The various forms of LAMMPS output, as defined by the *thermo_style*, *thermo*, *dump*, and *restart* commands occur with specified frequency, e.g. every N steps. If the timestep for a dump snapshot is not a multiple of N, then it will be read and processed, but no output will be produced. If you want output for every dump snapshot, you can simply use N=1 for an output frequency, e.g. for thermodynamic output or new dump file output.

1.92.4 Restrictions

The *rerun* command is subject to all restrictions of the *read_dump* command.

1.92.5 Related commands

read_dump

1.92.6 Default

The option defaults are first = 0, last = a huge value (effectively infinity), start = same as first, stop = same as last, every = 0, skip = 1, post = no;

1.93 reset_atoms command

1.93.1 Syntax

```
reset_atoms property arguments ...
```

- property = *id* or *image* or *mol*
- additional arguments depend on the property

```
reset_atoms id keyword value ...
```

  - zero or more keyword/value pairs can be appended
  - keyword = *sort*

    sort value = *yes* or *no*

```
reset_atoms image group-ID
```

  - group-ID = ID of group of atoms whose image flags will be reset

```
reset_atoms mol group-ID keyword value ...
```

  - group-ID = ID of group of atoms whose molecule IDs will be reset
  - zero or more keyword/value pairs can be appended
  - keyword = *compress* or *offset* or *single*

    compress value = *yes* or *no*
    offset value = *Noffset* >= -1
    single value = *yes* or *no* to treat single atoms (no bonds) as molecules

1.93.2 Examples

```
reset_atoms id
reset_atoms id sort yes
reset_atoms image all
reset_atoms image mobile
reset_atoms mol all
reset_atoms mol all offset 10 single yes
reset_atoms mol solvent compress yes offset 100
reset_atoms mol solvent compress no
```

1.93.3 Description

Added in version 22Dec2022.

The *reset_atoms* command resets the values of a specified atom property. In contrast to the *set* command, it does this in a collective manner which resets the values for many atoms in a self-consistent way. This command is often useful when the simulated system has undergone significant modifications like adding or removing atoms or molecules, joining data files, changing bonds, or large-scale diffusion.

The new values can be thought of as a *reset*, similar to values atoms would have if a new data file were being read or a new simulation performed. Note that the *set* command also resets atom properties to new values, but it treats each atom independently.

The *property* setting can be *id* or *image* or *mol*. For *id*, the IDs of all the atoms are reset to contiguous values. For *image*, the image flags of atoms in the specified *group-ID* are reset so that at least one atom in each molecule is in the simulation box (image flag = 0). For *mol*, the molecule IDs of all atoms are reset to contiguous values.

More details on these operations and their arguments or optional keyword/value settings are given below.

Property: *id*

Reset atom IDs for the entire system, including all the global IDs stored for bond, angle, dihedral, improper topology data. This will create a set of IDs that are numbered contiguously from 1 to N for a N atoms system.

This can be useful to do after performing a "delete_atoms" command for a molecular system. The delete_atoms compress yes option will not perform this operation due to the existence of bond topology. It can also be useful to do after any simulation which has lost atoms, e.g. due to atoms moving outside a simulation box with fixed boundaries (see the "boundary command"), or due to evaporation (see the "fix evaporate" command).

If the *sort* keyword is used with a setting of *yes*, then the assignment of new atom IDs will be the same no matter how many processors LAMMPS is running on. This is done by first doing a spatial sort of all the atoms into bins and sorting them within each bin. Because the set of bins is independent of the number of processors, this enables a consistent assignment of new IDs to each atom.

This can be useful to do after using the "create_atoms" command and/or "replicate" command. In general those commands do not guarantee assignment of the same atom ID to the same physical atom when LAMMPS is run on different numbers of processors. Enforcing consistent IDs can be useful for debugging or comparing output from two different runs.

Note that the spatial sort requires communication of atom IDs and coordinates between processors in an all-to-all manner. This is done efficiently in LAMMPS, but it is more expensive than how atom IDs are reset without sorting.

Note that whether sorting or not, the resetting of IDs is not a compression, where gaps in atom IDs are removed by decrementing atom IDs that are larger. Instead the IDs for all atoms are erased, and new IDs are assigned so that the atoms owned by an individual processor have consecutive IDs, as the *create_atoms* command explains.

Note

If this command is used before a *pair style* is defined, an error about bond topology atom IDs not being found may result. This is because the cutoff distance for ghost atom communication was not sufficient to find atoms in bonds, angles, etc that are owned by other processors. The *comm_modify cutoff* command can be used to correct this issue. Or you can define a pair style before using this command. If you do the former, you should unset the *comm_modify cutoff* after using *reset atoms id* so that subsequent communication is not inefficient.

Property: *image*

Reset the image flags of atoms so that at least one atom in each molecule has an image flag of 0. Molecular topology is respected so that if the molecule straddles a periodic simulation box boundary, the images flags of all atoms in the molecule will be consistent. This avoids inconsistent image flags that could result from resetting all image flags to zero with the *set* command.

Note

If the system has no bonds, there is no reason to use this command, since image flags for different atoms do not need to be consistent. Use the *set* command with its *image* keyword instead.

Only image flags for atoms in the specified *group-ID* are reset; all others remain unchanged. No check is made for whether the group covers complete molecule fragments and thus whether the command will result in inconsistent image flags.

Molecular fragments are identified by the algorithm used by the *compute fragment/atom* command. For each fragment the average of the largest and the smallest image flag in each direction across all atoms in the fragment is computed and subtracted from the current image flag in the same direction.

This can be a useful operation to perform after running longer equilibration runs of mobile systems where molecules would pass through the system multiple times and thus produce non-zero image flags.

Note

Same as explained for the *compute fragment/atom* command, molecules are identified using the current bond topology. This will **not** account for bonds broken by the *bond_style quartic* command, because this bond style does not perform a full update of the bond topology data structures within LAMMPS. In that case, using the *delete_bonds all bond 0 remove* will permanently delete such broken bonds and should thus be used first.

Property: *mol*

Reset molecule IDs for a specified group of atoms based on current bond connectivity. This will typically create a new set of molecule IDs for atoms in the group. Only molecule IDs for atoms in the specified *group-ID* are reset; molecule IDs for atoms not in the group are not changed.

For purposes of this operation, molecules are identified by the current bond connectivity in the system, which may or may not be consistent with the current molecule IDs. A molecule in this context is a set of atoms connected to each other with explicit bonds. The specific algorithm used is the one of *compute fragment/atom*. Once the molecules are identified and a new molecule ID computed for each, this command will update the current molecule ID for all atoms in the group with the new molecule ID. Note that if the group excludes atoms within molecules, one (physical) molecule may become two or more (logical) molecules. For example if the group excludes atoms in the middle of a linear chain, then each end of the chain is considered an independent molecule and will be assigned a different molecule ID.

This can be a useful operation to perform after running reactive molecular dynamics run with *fix bond/react*, *fix bond/create*, or *fix bond/break*, all of which can change molecule topologies. It can also be useful after molecules have been deleted with the *delete_atoms* command or after a simulation which has lost molecules, e.g. via the *fix evaporate* command.

The *compress* keyword determines how new molecule IDs are computed. If the setting is *yes* (the default) and there are N molecules in the group, the new molecule IDs will be a set of N contiguous values. See the *offset* keyword for details on selecting the range of these values. If the setting is *no*, the molecule ID of every atom in the molecule will be set to the smallest atom ID of any atom in the molecule.

The *single* keyword determines whether single atoms (not bonded to another atom) are treated as one-atom molecules or not, based on the *yes* or *no* setting. If the setting is *no* (the default), their molecule IDs are set to 0. This setting can

be important if the new molecule IDs will be used as input to other commands such as *compute chunk/atom molecule* or *fix rigid molecule*.

The *offset* keyword is only used if the *compress* setting is *yes*. Its default value is *Noffset* = -1. In that case, if the specified group is *all*, then the new compressed molecule IDs will range from 1 to N. If the specified group is not *all* and the largest molecule ID of atoms outside that group is M, then the new compressed molecule IDs will range from M+1 to M+N, to avoid collision with existing molecule IDs. If an *Noffset* >= 0 is specified, then the new compressed molecule IDs will range from *Noffset*+1 to *Noffset*+N. If the group is not *all* there may be collisions with the molecule IDs of other atoms.

Note

Same as explained for the *compute fragment/atom* command, molecules are identified using the current bond topology. This will **not** account for bonds broken by the *bond_style quartic* command, because this bond style does not perform a full update of the bond topology data structures within LAMMPS. In that case, using the *delete_bonds all bond 0 remove* will permanently delete such broken bonds and should thus be used first.

1.93.4 Restrictions

The *image* property can only be used when the atom style supports bonds.

1.93.5 Related commands

compute fragment/atom, *fix bond/react*, *fix bond/create*, *fix bond/break*, *fix evaporate*, *delete_atoms*, *delete_bonds*

1.93.6 Defaults

For property *id*, the default keyword setting is sort = no.

For property *mol*, the default keyword settings are compress = yes, single = no, and offset = -1.

1.94 reset_timestep command

1.94.1 Syntax

```
reset_timestep N keyword values ...
```

- N = timestep number
- zero or more keyword/value pairs may be appended
- keyword = *time*

  time value = atime
    atime = accumulated simulation time

1.94.2 Examples

```
reset_timestep 0
reset_timestep 4000000
reset_timestep 1000 time 100.0
```

1.94.3 Description

Set the timestep counter to the specified value. This command usually comes after the timestep has been set by reading a restart file via the *read_restart* command, or a previous simulation run or minimization advanced the timestep.

The optional *time* keyword allows to also set the accumulated simulation time. This is usually the number of timesteps times the size of the timestep, but when using variable size timesteps with *fix dt/reset* it can differ.

The *read_data* and *create_box* commands set the timestep to 0; the *read_restart* command sets the timestep to the value it had when the restart file was written. The same applies to the accumulated simulation time.

1.94.4 Restrictions

This command cannot be used when any fixes are defined that keep track of elapsed time to perform certain kinds of time-dependent operations. Examples are the *fix deposit* and *fix dt/reset* commands. The former adds atoms on specific timesteps. The latter keeps track of accumulated time.

Various fixes use the current timestep to calculate related quantities. If the timestep is reset, this may produce unexpected behavior, but LAMMPS allows the fixes to be defined even if the timestep is reset. For example, commands which thermostat the system, e.g. *fix nvt*, allow you to specify a target temperature which ramps from Tstart to Tstop which may persist over several runs. If you change the timestep, you may induce an instantaneous change in the target temperature.

Resetting the timestep clears flags for *computes* that may have calculated some quantity from a previous run. This means these quantity cannot be accessed by a variable in between runs until a new run is performed. See the *variable* command for more details.

1.95 restart command

1.95.1 Syntax

```
restart 0
restart N root keyword value ...
restart N file1 file2 keyword value ...
```

- N = write a restart file on timesteps which are multiples of N
- N can be a variable (see below)
- root = filename to which timestep # is appended
- file1,file2 = two full filenames, toggle between them when writing file
- zero or more keyword/value pairs may be appended
- keyword = *fileper* or *nfile*

```
fileper arg = Np
  Np = write one file for every this many processors
nfile arg = Nf
  Nf = write this many files, one from each of Nf processors
```

1.95.2 Examples

```
restart 0
restart 1000 poly.restart
restart 1000 restart.*.equil
restart 10000 poly.%.1 poly.%.2 nfile 10
restart v_mystep poly.restart
```

1.95.3 Description

Write out a binary restart file with the current state of the simulation on timesteps which are a multiple of N. A value of N = 0 means do not write out any restart files, which is the default. Restart files are written in one (or both) of two modes as a run proceeds. If one filename is specified, a series of filenames will be created which include the timestep in the filename. If two filenames are specified, only 2 restart files will be created, with those names. LAMMPS will toggle between the 2 names as it writes successive restart files.

Note that you can specify the restart command twice, once with a single filename and once with two filenames. This would allow you, for example, to write out archival restart files every 100000 steps using a single filename, and more frequent temporary restart files every 1000 steps, using two filenames. Using restart 0 will turn off both modes of output.

Similar to *dump* files, the restart filename(s) can contain two wild-card characters.

If a "*" appears in the single filename, it is replaced with the current timestep value. This is only recognized when a single filename is used (not when toggling back and forth). Thus, the third example above creates restart files as follows: restart.1000.equil, restart.2000.equil, etc. If a single filename is used with no "*", then the timestep value is appended. E.g. the second example above creates restart files as follows: poly.restart.1000, poly.restart.2000, etc.

If a "%" character appears in the restart filename(s), then one file is written for each processor and the "%" character is replaced with the processor ID from 0 to P-1. An additional file with the "%" replaced by "base" is also written, which contains global information. For example, the files written on step 1000 for filename restart.% would be restart.base.1000, restart.0.1000, restart.1.1000, ..., restart.P-1.1000. This creates smaller files and can be a fast mode of output and subsequent input on parallel machines that support parallel I/O. The optional *fileper* and *nfile* keywords discussed below can alter the number of files written.

Restart files are written on timesteps that are a multiple of N but not on the first timestep of a run or minimization. You can use the *write_restart* command to write a restart file before a run begins. A restart file is not written on the last timestep of a run unless it is a multiple of N. A restart file is written on the last timestep of a minimization if N > 0 and the minimization converges.

Enabling or disabling restarts may change the trajectory

Writing a restart file forces a neighbor list rebuild on that timestep, so that all atoms are correctly assigned to their owning subdomains before the file is written. This rebuild happens regardless of the *neigh_modify* *every*, *delay*, and *check* settings. As a result, enabling restart output can change the number of neighbor list builds reported at the end of a run. And because changing when neighbor lists are rebuilt changes the order in which pairwise interactions are summed, it can also lead to small differences in the trajectory (due to the limitations of floating-point math) compared to an otherwise identical run without restart output.

To obtain the *same* number of neighbor list builds (and thus an identical trajectory) whether or not restart output is enabled, use *neigh_modify* with *check* set to *no* and *every* set to a value <*num*> that evenly divides the restart frequency N (with the default *delay* of 0). The neighbor lists are then rebuilt on a fixed schedule that already includes every restart-write step, so the forced rebuild coincides with a rebuild that would have happened anyway and no extra builds are added.

Instead of a numeric value, N can be specified as an *equal-style variable*, which should be specified as v_name, where

name is the variable name. In this case, the variable is evaluated at the beginning of a run to determine the next timestep at which a restart file will be written out. On that timestep, the variable will be evaluated again to determine the next timestep, etc. Thus the variable should return timestep values. See the stagger() and logfreq() and stride() math functions for *equal-style variables*, as examples of useful functions to use in this context. Other similar math functions could easily be added as options for *equal-style variables*.

For example, the following commands will write restart files every step from 1100 to 1200, and could be useful for debugging a simulation where something goes wrong at step 1163:

```
variable       s equal stride(1100,1200,1)
restart        v_s tmp.restart
```

See the *read_restart* command for information about what is stored in a restart file.

Restart files can be read by a *read_restart* command to restart a simulation from a particular state. Because the file is binary (to enable exact restarts), it may not be readable on another machine. In this case, you can use the *-r command-line switch* to convert a restart file to a data file.

Note

Although the purpose of restart files is to enable restarting a simulation from where it left off, not all information about a simulation is stored in the file. For example, the list of fixes that were specified during the initial run is not stored, which means the new input script must specify any fixes you want to use. Even when restart information is stored in the file, as it is for some fixes, commands may need to be re-specified in the new input script, in order to reuse that information. See the *read_restart* command for information about what is stored in a restart file.

The optional *nfile* or *fileper* keywords can be used in conjunction with the "%" wildcard character in the specified restart file name(s). As explained above, the "%" character causes the restart file to be written in pieces, one piece for each of P processors. By default P = the number of processors the simulation is running on. The *nfile* or *fileper* keyword can be used to set P to a smaller value, which can be more efficient when running on a large number of processors.

The *nfile* keyword sets P to the specified Nf value. For example, if Nf = 4, and the simulation is running on 100 processors, 4 files will be written, by processors 0,25,50,75. Each will collect information from itself and the next 24 processors and write it to a restart file.

For the *fileper* keyword, the specified value of Np means write one file for every Np processors. For example, if Np = 4, every fourth processor (0,4,8,12,etc) will collect information from itself and the next 3 processors and write it to a restart file.

1.95.4 Restrictions

none

1.95.5 Related commands

write_restart, *read_restart*

1.95.6 Default

```
restart 0
```

1.96 run command

1.96.1 Syntax

```
run N keyword values ...
```

- N = # of timesteps
- zero or more keyword/value pairs may be appended
- keyword = *upto* or *start* or *stop* or *pre* or *post* or *every*

```
upto value = none
start value = N1
  N1 = timestep at which 1st run started
stop value = N2
  N2 = timestep at which last run will end
pre value = no or yes
post value = no or yes
every values = M c1 c2 ...
  M = break the run into M-timestep segments and invoke one or more commands␣
↪between each segment
  c1,c2,...,cN = one or more LAMMPS commands, each enclosed in quotes
  c1 = NULL means no command will be invoked
```

1.96.2 Examples

```
run 10000
run 1000000 upto
run 100 start 0 stop 1000
run 1000 pre no post yes
run 100000 start 0 stop 1000000 every 1000 "print 'Protein Rg = $r'"
run 100000 every 1000 NULL
```

1.96.3 Description

Run or continue dynamics for a specified number of timesteps.

When the *run style* is *respa*, N refers to outer loop (largest) timesteps.

A value of N = 0 is acceptable; only the thermodynamics of the system are computed and printed without taking a timestep.

The *upto* keyword means to perform a run starting at the current timestep up to the specified timestep. E.g. if the current timestep is 10,000 and "run 100000 upto" is used, then an additional 90,000 timesteps will be run. This can be useful for very long runs on a machine that allocates chunks of time and terminate your job when time is exceeded. If you need to restart your script multiple times (reading in the last restart file), you can keep restarting your script with the same run command until the simulation finally completes.

The *start* or *stop* keywords can be used if multiple runs are being performed and you want a *fix* command that changes some value over time (e.g. temperature) to make the change across the entire set of runs and not just a single run. See the page for individual fixes to see which ones can be used with the *start/stop* keywords.

For example, consider this fix followed by 10 run commands:

```
fix         1 all nvt 200.0 300.0 1.0
run         1000 start 0 stop 10000
run         1000 start 0 stop 10000
...
run         1000 start 0 stop 10000
```

The NVT fix ramps the target temperature from 200.0 to 300.0 during a run. If the run commands did not have the start/stop keywords (just "run 1000"), then the temperature would ramp from 200.0 to 300.0 during the 1000 steps of each run. With the start/stop keywords, the ramping takes place over the 10000 steps of all runs together.

The *pre* and *post* keywords can be used to streamline the setup, clean-up, and associated output to the screen that happens before and after a run. This can be useful if you wish to do many short runs in succession (e.g. LAMMPS is being called as a library which is doing other computations between successive short LAMMPS runs).

By default (pre and post = yes), LAMMPS creates neighbor lists, computes forces, and imposes fix constraints before every run. And after every run it gathers and prints timings statistics. If a run is just a continuation of a previous run (i.e. no settings are changed), the initial computation is not necessary; the old neighbor list is still valid as are the forces. So if *pre* is specified as "no" then the initial setup is skipped, except for printing thermodynamic info. Note that if *pre* is set to "no" for the very first run LAMMPS performs, then it is overridden, since the initial setup computations must be done.

Note

If your input script "changes" the system between 2 runs, then the initial setup typically needs to be performed to ensure the change is recognized by all parts of the code that are affected. Examples are adding a *fix* or *dump* or *compute*, changing a *neighbor* list parameter, using the *set* command, or writing a restart file via the *write_restart* command, which can migrate atoms between processors. LAMMPS has no easy way to check if this has happened, but it is an error to use the *pre no* option in these cases.

If *post* is specified as "no", the full timing summary is skipped; only a one-line summary timing is printed.

The *every* keyword provides a means of breaking a LAMMPS run into a series of shorter runs. Optionally, one or more LAMMPS commands (c1, c2, ..., cN) will be executed in between the short runs. If used, the *every* keyword must be the last keyword, since it has a variable number of arguments. Each of the trailing arguments is a single LAMMPS command, and each command should be enclosed in quotes, so that the entire command will be treated as a single argument. This will also prevent any variables in the command from being evaluated until it is executed multiple times during the run. Note that if a command itself needs one of its arguments quoted (e.g. the *print* command), then you can use a combination of single and double quotes, as in the example above or below.

The *every* keyword is a means to avoid listing a long series of runs and interleaving commands in your input script. For example, a *print* command could be invoked or a *fix* could be redefined, e.g. to reset a thermostat temperature. Or this could be useful for invoking a command you have added to LAMMPS that wraps some other code (e.g. as a library) to perform a computation periodically during a long LAMMPS run. See the *Modify* doc page for info about how to add new commands to LAMMPS. See the *Howto couple* page for ideas about how to couple LAMMPS to other codes.

With the *every* option, N total steps are simulated, in shorter runs of M steps each. After each M-length run, the specified commands are invoked. If only a single command is specified as NULL, then no command is invoked. Thus these lines:

```
variable q equal x[100]
run 6000 every 2000 "print 'Coord = $q'"
```

are the equivalent of:

```
variable q equal x[100]
run 2000
print "Coord = $q"
run 2000
print "Coord = $q"
run 2000
print "Coord = $q"
```

which does 3 runs of 2000 steps and prints the x-coordinate of a particular atom between runs. Note that the variable "$q" will be evaluated afresh each time the print command is executed.

Note that by using the line continuation character "&", the run every command can be spread across many lines, though it is still a single command:

```
run 100000 every 1000 &
  "print 'Minimum value = $a'" &
  "print 'Maximum value = $b'" &
  "print 'Temp = $c'" &
  "print 'Press = $d'"
```

If the *pre* and *post* options are set to "no" when used with the *every* keyword, then the first run will do the full setup and the last run will print the full timing summary, but these operations will be skipped for intermediate runs.

Note

You might wish to specify a command that exits the run by jumping out of the loop, e.g.

```
variable t equal temp
run 10000 every 100 "if '$t < 300.0' then 'jump SELF afterrun'"
```

However, this will not work. The run command simply executes each command one at a time each time it pauses, then continues the run.

Instead, you should use the *fix halt* command, which has additional options for how to exit the run.

1.96.4 Restrictions

When not using the *upto* keyword, the number of specified timesteps N must fit in a signed 32-bit integer, so you are limited to slightly more than 2 billion steps (2^31) in a single run. When using *upto*, N can be larger than a signed 32-bit integer, however the difference between N and the current timestep must still be no larger than 2^31 steps.

However, with or without the *upto* keyword, you can perform successive runs to run a simulation for any number of steps (ok, up to 2^63 total steps). I.e. the timestep counter within LAMMPS is a 64-bit signed integer.

1.96.5 Related commands

minimize, *run_style*, *temper*, *fix halt*

1.96.6 Default

The option defaults are start = the current timestep, stop = current timestep + N, pre = yes, and post = yes.

1.97 run_style command

1.97.1 Syntax

```
run_style style args
```

- style = *verlet* or *verlet/split* or *verlet/split/rk* or *respa* or *respa/omp*

```
verlet args = none
verlet/split args = none
verlet/split/rk args = none
respa args = N n1 n2 ... keyword values ...
  N = # of levels of rRESPA
  n1, n2, ... = loop factors between rRESPA levels (N-1 values)
  zero or more keyword/value pairings may be appended to the loop factors
  keyword = bond or angle or dihedral or improper or
            pair or inner or middle or outer or hybrid or kspace
    bond value = M
      M = which level (1-N) to compute bond forces in
    angle value = M
      M = which level (1-N) to compute angle forces in
    dihedral value = M
      M = which level (1-N) to compute dihedral forces in
    improper value = M
      M = which level (1-N) to compute improper forces in
    pair value = M
      M = which level (1-N) to compute pair forces in
    inner values = M cut1 cut2
      M = which level (1-N) to compute pair inner forces in
      cut1 = inner cutoff between pair inner and
             pair middle or outer  (distance units)
      cut2 = outer cutoff between pair inner and
             pair middle or outer  (distance units)
    middle values = M cut1 cut2
      M = which level (1-N) to compute pair middle forces in
      cut1 = inner cutoff between pair middle and pair outer (distance units)
      cut2 = outer cutoff between pair middle and pair outer (distance units)
    outer value = M
      M = which level (1-N) to compute pair outer forces in
    hybrid values = M1 M2 ... (as many values as there are hybrid sub-styles
      M1 = which level (1-N) to compute the first pair_style hybrid sub-style in
      M2 = which level (1-N) to compute the second pair_style hybrid sub-style in
      M3,etc
    kspace value = M
      M = which level (1-N) to compute kspace forces in
```

run_style respa 3 4 2 bond 1 hybrid 2 2 1 kspace 3
```

1.97.3 Description

Choose the style of time integrator used for molecular dynamics simulations performed by LAMMPS.

The *verlet* style is the velocity form of the Stoermer-Verlet time integration algorithm (velocity-Verlet)

The *verlet/split* style is also a velocity-Verlet integrator, but it splits the force calculation within each timestep over 2 partitions of processors. See the *-partition command-line switch* for info on how to run LAMMPS with multiple partitions.

Specifically, this style performs all computation except the *kspace_style* portion of the force field on the first partition. This include the *pair style*, *bond style*, *neighbor list building*, *fixes* including time integration, and output. The *kspace_style* portion of the calculation is performed on the second partition.

This can lead to a significant speedup, if the number of processors can be easily increased and the fraction of time is spent in computing Kspace interactions is significant, too. The two partitions may have a different number of processors. This is most useful for the PPPM kspace_style when its performance on a large number of processors degrades due to the cost of communication in its 3d FFTs. In this scenario, splitting your P total processors into 2 subsets of processors, P1 in the first partition and P2 in the second partition, can enable your simulation to run faster. This is because the long-range forces in PPPM can be calculated at the same time as pairwise and bonded forces are being calculated *and* the parallel 3d FFTs can be faster to compute when running on fewer processors. Please note that the scenario of using fewer MPI processes to reduce communication overhead can also be implemented through using MPI with OpenMP threads via the INTEL, KOKKOS, or OPENMP package. This alternative option is typically more effective in case of a fixed number of available processors and less complex to execute.

To use the *verlet/split* style, you must define 2 partitions with the *-partition command-line switch*, where partition P1 is either the same size or an integer multiple of the size of the partition P2. Typically having P1 be 3x larger than P2 is a good choice, since the (serial) performance of LAMMPS is often best if the time spent in the `Pair` computation versus `Kspace` is a 3:1 split. The 3d processor layouts in each partition must overlay in the following sense. If P1 is a Px1 by Py1 by Pz1 grid, and P2 = Px2 by Py2 by Pz2, then Px1 must be an integer multiple of Px2, and similarly for Py1 a multiple of Py2, and Pz1 a multiple of Pz2.

Typically the best way to do this is to let the first partition choose its own optimal layout, then require the second partition's layout to match the integer multiple constraint. See the *processors* command with its *part* keyword for a way to control this, e.g.

```
processors * * * part 1 2 multiple
```

You can also use the *partition* command to explicitly specify the processor layout on each partition. E.g. for 2 partitions of 60 and 15 processors each:

```
partition yes 1 processors 3 4 5
partition yes 2 processors 3 1 5
```

When you run in 2-partition mode with the *verlet/split* style, the thermodynamic data for the entire simulation will be output to the log and screen file of the first partition, which are log.lammps.0 and screen.0 by default; see the *-plog and -pscreen command-line switches* to change this. The log and screen file for the second partition will not contain thermodynamic output beyond the first timestep of the run.

See the *Accelerator packages* page for performance details of the speed-up offered by the *verlet/split* style. One important performance consideration is the assignment of logical processors in the 2 partitions to the physical cores of a parallel machine. The *processors* command has options to support this, and strategies are discussed in *Section 5* of the manual.

Added in version 4Jul2026.

The requirements for the run style *verlet/split/rk* are similar to that of *verlet/split*, and much of what was written above about the latter applies to the former, including the partition requirements. Note that the use of run style *verlet/split/rk* must be paired with the use of kspace style *pppm/rk*.

The main difference is that for *verlet/split/rk*, the work of the K space processes is restricted to the solution of the Poisson equations for computing the long-range forces via pppm. By contrast, the R space processes carry out the other long-range force computations that the K space processes would have done for *verlet/split*. There are two rationales for considering the use of *verlet/split/rk*.

- *Rationale 1*: One of the most significant bottlenecks to parallel scalability is due to the communication overhead for the 3d FFTs in solving the Poisson equation. The other steps (such as accumulating the charge densities and interpolating the long-range forces) have better parallel scaling, and so their reallocation to the R space processes may result in improved parallel speedup at large enough node counts where the speedup for solving the Poisson equation lags behind the speedup of the other computations (thus the Poisson equation solution is a bottleneck in parallel execution).
- *Rationale 2*: The approach *verlet/split/rk* avoids having to communicate atom-specific information between the R space and K space processes. Thus, re-neighboring, for example, stays confined to the R space processes and does not require inter-R/K communication, and so the communication overhead is reduced.

The implementation of *verlet/split/rk* requires the parallel partitioning to occur in the computation of the long-range forces. Consequently, the use of *verlet/split/rk* requires the use of an */rk* type kspace style like *pppm/rk*.

This approach is based on the enhanced baseline decomposition of *(Dandurand)* and works cited within.

The *respa* style implements the rRESPA multi-timescale integrator *(Tuckerman4)* with N hierarchical levels, where level 1 is the innermost loop (shortest timestep) and level N is the outermost loop (largest timestep). The loop factor arguments specify what the looping factor is between levels. N1 specifies the number of iterations of level 1 for a single iteration of level 2, N2 is the iterations of level 2 per iteration of level 3, etc. N-1 looping parameters must be specified.

Thus with a 4-level respa setting of "2 2 2" for the 3 loop factors, you could choose to have bond interactions computed 8x per large timestep, angle interactions computed 4x, pair interactions computed 2x, and long-range interactions once per large timestep.

The *timestep* command sets the large timestep for the outermost rRESPA level. Thus if the 3 loop factors are "2 2 2" for 4-level rRESPA, and the outer timestep is set to 4.0 fs, then the inner timestep would be 8x smaller or 0.5 fs. All other LAMMPS commands that specify number of timesteps (e.g. *thermo* for thermo output every N steps, *neigh_modify delay/every* parameters, *dump* every N steps, etc) refer to the outermost timesteps.

The rRESPA keywords enable you to specify at what level of the hierarchy various forces will be computed. If not specified, the defaults are that bond forces are computed at level 1 (innermost loop), angle forces are computed where bond forces are, dihedral forces are computed where angle forces are, improper forces are computed where dihedral forces are, pair forces are computed at the outermost level, and kspace forces are computed where pair forces are. The inner, middle, outer forces have no defaults.

For fixes that support it, the rRESPA level at which a given fix is active, can be selected through the *fix_modify* command.

The *inner* and *middle* keywords take additional arguments for cutoffs that are used by the pairwise force computations. If the 2 cutoffs for *inner* are 5.0 and 6.0, this means that all pairs up to 6.0 apart are computed by the inner force. Those between 5.0 and 6.0 have their force go ramped to 0.0 so the overlap with the next regime (middle or outer) is smooth. The next regime (middle or outer) will compute forces for all pairs from 5.0 outward, with those from 5.0 to 6.0 having their value ramped in an inverse manner.

Note that you can use *inner* and *outer* without using *middle* to split the pairwise computations into two portions instead of three. Unless you are using a very long pairwise cutoff, a 2-way split is often faster than a 3-way split, since it avoids too much duplicate computation of pairwise interactions near the intermediate cutoffs.

Also note that only a few pair potentials support the use of the *inner* and *middle* and *outer* keywords. If not, only the *pair* keyword can be used with that pair style, meaning all pairwise forces are computed at the same rRESPA level. See the doc pages for individual pair styles for details.

Another option for using pair potentials with rRESPA is with the *hybrid* keyword, which requires the use of the *pair_style hybrid or hybrid/overlay* command. In this scenario, different sub-styles of the hybrid pair style are evaluated at different rRESPA levels. This can be useful, for example, to set different timesteps for hybrid coarse-grained/all-atom models. The *hybrid* keyword requires as many level assignments as there are hybrid sub-styles, which assigns each sub-style to a rRESPA level, following their order of definition in the pair_style command. Since the *hybrid* keyword operates on pair style computations, it is mutually exclusive with either the *pair* or the *inner/middle/outer* keywords.

When using rRESPA (or for any MD simulation) care must be taken to choose a timestep size(s) that ensures the Hamiltonian for the chosen ensemble is conserved. For the constant NVE ensemble, total energy must be conserved. Unfortunately, it is difficult to know *a priori* how well energy will be conserved, and a fairly long test simulation (~10 ps) is usually necessary in order to verify that no long-term drift in energy occurs with the trial set of parameters.

With that caveat, a few rules-of-thumb may be useful in selecting *respa* settings. The following applies mostly to biomolecular simulations using the CHARMM or a similar all-atom force field, but the concepts are adaptable to other problems. Without SHAKE, bonds involving hydrogen atoms exhibit high-frequency vibrations and require a timestep on the order of 0.5 fs in order to conserve energy. The relatively inexpensive force computations for the bonds, angles, impropers, and dihedrals can be computed on this innermost 0.5 fs step. The outermost timestep cannot be greater than 4.0 fs without risking energy drift. Smooth switching of forces between the levels of the rRESPA hierarchy is also necessary to avoid drift, and a 1-2 Angstrom "healing distance" (the distance between the outer and inner cutoffs) works reasonably well. We thus recommend the following settings for use of the *respa* style without SHAKE in biomolecular simulations:

```
timestep  4.0
run_style respa 4 2 2 2 inner 2 4.5 6.0 middle 3 8.0 10.0 outer 4
```

With these settings, users can expect good energy conservation and roughly a 2.5 fold speedup over the *verlet* style with a 0.5 fs timestep.

If SHAKE is used with the *respa* style, time reversibility is lost, but substantially longer time steps can be achieved. For biomolecular simulations using the CHARMM or similar all-atom force field, bonds involving hydrogen atoms exhibit high frequency vibrations and require a time step on the order of 0.5 fs in order to conserve energy. These high frequency modes also limit the outer time step sizes since the modes are coupled. It is therefore desirable to use SHAKE with respa in order to freeze out these high frequency motions and increase the size of the time steps in the respa hierarchy. The following settings can be used for biomolecular simulations with SHAKE and rRESPA:

```
fix             2 all shake 0.000001 500 0 m 1.0 a 1
timestep        4.0
run_style       respa 2 2 inner 1 4.0 5.0 outer 2
```

With these settings, users can expect good energy conservation and roughly a 1.5 fold speedup over the *verlet* style with SHAKE and a 2.0 fs timestep.

For non-biomolecular simulations, the *respa* style can be advantageous if there is a clear separation of time scales - fast and slow modes in the simulation. For example, a system of slowly-moving charged polymer chains could be setup as follows:

```
timestep 4.0
run_style respa 2 8
```

This is two-level rRESPA with an 8x difference between the short and long timesteps. The bonds, angles, dihedrals will be computed every 0.5 fs (assuming real units), while the pair and kspace interactions will be computed once every 4 fs. These are the default settings for each kind of interaction, so no additional keywords are necessary.

Even a LJ system can benefit from rRESPA if the interactions are divided by the inner, middle and outer keywords. A 2-fold or more speedup can be obtained while maintaining good energy conservation. In real units, for a pure LJ fluid at liquid density, with a sigma of 3.0 Angstroms, and epsilon of 0.1 kcal/mol, the following settings seem to work well:

```
timestep  36.0
run_style respa 3 3 4 inner 1 3.0 4.0 middle 2 6.0 7.0 outer 3
```

The *respa/omp* style is a variant of *respa* adapted for use with pair, bond, angle, dihedral, improper, or kspace styles with an *omp* suffix. It is functionally equivalent to *respa* but performs additional operations required for managing *omp* styles. For more on *omp* styles see the *Speed omp* doc page. Accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

You can specify *respa/omp* explicitly in your input script, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

1.97.4 Restrictions

The *verlet/split* style can only be used if LAMMPS was built with the REPLICA package. Correspondingly the *respa/omp* style is available only if the OPENMP package was included. See the *Build package* page for more info.

The *respa* style cannot be used with the KOKKOS package when any style runs on a GPU or other device, or when the package's atom communication, sorting, or atom map run on the device (the defaults of the *package kokkos* command on a GPU). It keeps a copy of the forces of each level and clears and sums those through the plain LAMMPS arrays, and it calls the force computations without the transfers between the host and the device that the *verlet* style performs for KOKKOS. On a device this gives wrong forces with no indication that anything is amiss, so the combination is refused. It can be used when everything stays on the host: a KOKKOS build without a device back end, or a device build with the */kk/host* suffix on every style and *comm host*, *sort no*, and *atom/map no* package settings.

Run style *verlet/split* is not compatible with kspace styles from the INTEL package and it is not compatible with any tip4p, dipole, or spin kspace styles.

Whenever using rRESPA, the user should experiment with trade-offs in speed and accuracy for their system, and verify that they are conserving energy to adequate precision.

timestep, *run*

1.97.6 Default

```
run_style verlet
```

For run_style respa, the default assignment of interactions to rRESPA levels is as follows:

- bond forces = level 1 (innermost loop)
- angle forces = same level as bond forces
- dihedral forces = same level as angle forces
- improper forces = same level as dihedral forces
- pair forces = level N (outermost level)
- kspace forces = same level as pair forces

- inner, middle, outer forces = no default

set atom * d2_Sxyz[1] 6.4
```

1.98.3 Description

Set one or more properties of one or more atoms. Since atom properties are initially assigned by the *read_data*, *read_restart* or *create_atoms* commands, this command changes those assignments. This can be useful for overriding the default values assigned by the *create_atoms* command (e.g. charge = 0.0). It can be useful for altering pairwise and molecular force interactions, since force-field coefficients are defined in terms of types. It can be used to change the labeling of atoms by atom type or molecule ID when they are output in *dump* files. It can also be useful for debugging purposes; i.e. positioning an atom at a precise location to compute subsequent forces or energy.

Note that the *style* and *ID* arguments determine which atoms have their properties reset. The remaining keywords specify which properties to reset and what the new values are. Some strings like *type* or *mol* can be used as a style and/or a keyword.

The *fix set* command can be used with similar syntax to this command to reset atom properties once every *N* steps during a simulation using via atom-style variables.

This section describes how to select which atoms to change the properties of, via the *style* and *ID* arguments.

Changed in version 28Mar2023: Support for type labels was added for selecting atoms by type

The style *atom* selects all the atoms in a range of atom IDs.

The style *type* selects all the atoms in a range of types or type labels. The style *type* selects atoms in one of two ways. A range of numeric atom types can be specified. Or a single atom type label can be specified, e.g. "C". The style *mol* selects all the atoms in a range of molecule IDs.

In each of the range cases, the range can be specified as a single numeric value, or with a wildcard asterisk to specify a range of values. This takes the form "*" or "*n" or "n*" or "m*n". For example, for the style *type*, if N = the number

of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive). For all the styles except *mol*, the lowest value for the wildcard is 1; for *mol* it is 0.

The style *group* selects all the atoms in the specified group. The style *region* selects all the atoms in the specified geometric region. See the *group* and *region* commands for details of how to specify a group or region.

The next section describes the keyword options for which properties to change, for the selected atoms.

Note that except where explicitly prohibited below, all of the keywords allow an *atom-style or atomfile-style variable* to be used as the specified value(s). If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated, and its resulting per-atom value used to determine the value assigned to each selected atom. Note that the per-atom value from the variable will be ignored for atoms that are not selected via the *style* and *ID* settings explained above. A simple way to use per-atom values from the variable to reset a property for all atoms is to use style *atom* with *ID* = "*"; this selects all atom IDs.

Atom-style variables can specify formulas with various mathematical functions, and include *thermo_style* command keywords for the simulation box parameters and timestep and elapsed time. They can also include per-atom values, such as atom coordinates. Thus it is easy to specify a time-dependent or spatially-dependent set of per-atom values. As explained on the *variable* doc page, atomfile-style variables can be used in place of atom-style variables, and thus as arguments to the set command. Atomfile-style variables read their per-atoms values from a file.

Note

Atom-style and atomfile-style variables return floating point per-atom values. If the values are assigned to an integer variable, such as the molecule ID, then the floating point value is truncated to its integer portion, e.g. a value of 2.6 would become 2.

Changed in version 28Mar2023: Support for type labels was added for setting angle types

Keyword *angle* sets the angle type of all angles of selected atoms to the specified value. The value can be a numeric type from 1 to nangletypes. Or it can be a angle type label. See the *Howto type labels* doc page for the allowed syntax of type labels and a general discussion of how type labels can be used. All atoms in a particular angle must be selected atoms in order for the change to be made. The value of nangletypes was set by the *angle types* field in the header of the data file read by the *read_data* command. This keyword does NOT allow use of an atom-style variable.

Keyword *angmom* sets the angular momentum of selected atoms. The particles must be ellipsoids as defined by the *atom_style ellipsoid* command or triangles as defined by the *atom_style tri* command. The angular momentum vector of the particles is set to the 3 specified components.

Changed in version 28Mar2023: Support for type labels was added for setting bond types

Keyword *bond* sets the bond type of all bonds of selected atoms to the specified value. The value can be a numeric type from 1 to nbondtypes. Or it can be a bond type label. See the *Howto type labels* doc page for the allowed syntax of type labels and a general discussion of how type labels can be used. All atoms in a particular bond must be selected atoms in order for the change to be made. The value of nbondtypes was set by the *bond types* field in the header of the data file read by the *read_data* command. This keyword does NOT allow use of an atom-style variable.

Keyword *cc* sets the chemical concentration of a tDPD particle for a specified species as defined by the DPD-MESO package. Currently, only *atom_style tdpd* defines particles with this attribute. An integer for "index" selects a chemical species (1 to Nspecies) where Nspecies is set by the atom_style command. The value for the chemical concentration must be >= 0.0.

Keyword *charge* set the charge of all selected atoms. The *atom style* being used must support the use of atomic charge.

Keyword *density* or *density/disc* also sets the mass of all selected particles, but in a different way. The particles must have a per-atom mass attribute, as defined by the *atom_style* command. If the atom has a radius attribute (see *atom_style sphere*) and its radius is non-zero, its mass is set from the density and particle volume for 3d systems (the input density is assumed to be in mass/distance^3 units). For 2d, the default is for LAMMPS to model particles with a radius attribute as spheres. However, if the *density/disc* keyword is used, then they can be modeled as 2d discs (circles). Their mass is set from the density and particle area (the input density is assumed to be in mass/distance^2 units).

If the atom has a shape attribute (see *atom_style ellipsoid*) and its 3 shape parameters are non-zero, then its mass is set from the density and particle volume (the input density is assumed to be in mass/distance^3 units). The *density/disc* keyword has no effect; it does not (yet) treat 3d ellipsoids as 2d ellipses.

If the atom has a length attribute (see *atom_style line*) and its length is non-zero, then its mass is set from the density and line segment length (the input density is assumed to be in mass/distance units). If the atom has an area attribute (see *atom_style tri*) and its area is non-zero, then its mass is set from the density and triangle area (the input density is assumed to be in mass/distance^2 units).

If none of these cases are valid, then the mass is set to the density value directly (the input density is assumed to be in mass units).

Keyword *diameter* sets the size of the selected atoms. The particles must be finite-size spheres as defined by the *atom_style sphere* command. The diameter of a particle can be set to 0.0, which means they will be treated as point particles. Note that this command does not adjust the particle mass, even if it was defined with a density, e.g. via the *read_data* command.

Changed in version 28Mar2023: Support for type labels was added for setting dihedral types

Keyword *dihedral* sets the dihedral type of all dihedrals of selected atoms to the specified value. The value can be a numeric type from 1 to ndihedraltypes. Or it can be a dihedral type label. See the *Howto type labels* doc page for the allowed syntax of type labels and a general discussion of how type labels can be used. All atoms in a particular dihedral must be selected atoms in order for the change to be made. The value of ndihedraltypes was set by the *dihedral types* field in the header of the data file read by the *read_data* command. This keyword does NOT allow use of an atom-style variable.

Keyword *dipole* uses the specified x,y,z values as components of a vector to set as the orientation of the dipole moment vectors of the selected atoms. The magnitude of the dipole moment is set by the length of this orientation vector.

Keyword *dipole/random* randomizes the orientation of the dipole moment vectors for the selected atoms and sets the magnitude of each to the specified *Dlen* value. For 2d systems, the z component of the orientation is set to 0.0. Random numbers are used in such a way that the orientation of a particular atom is the same, regardless of how many processors are being used. This keyword does NOT allow use of an atom-style variable.

Keyword *dpd/theta* sets the internal temperature of a DPD particle as defined by the DPD-REACT package. If the specified value is a number it must be >= 0.0. If the specified value is NULL, then the kinetic temperature Tkin of each particle is computed as 3/2 k Tkin = KE = 1/2 m v^2 = 1/2 m (vx*vx+vy*vy+vz*vz). Each particle's internal temperature is set to Tkin. If the specified value is an atom-style variable, then the variable is evaluated for each particle. If a value >= 0.0, the internal temperature is set to that value. If it is < 0.0, the computation of Tkin is performed and the internal temperature is set to that value.

Keywords *edpd/temp* and *edpd/cv* set the temperature and volumetric heat capacity of an eDPD particle as defined by the DPD-MESO package. Currently, only *atom_style edpd* defines particles with these attributes. The values for the temperature and heat capacity must be positive.

Keyword *epsilon* sets the dielectric constant of a particle to be that of the medium where the particle resides as defined by the DIELECTRIC package. Currently, only *atom_style dielectric* defines particles with this attribute. The value for the dielectric constant must be >= 0.0. Note that the set command with this keyword will rescale the particle charge accordingly so that the real charge (e.g., as read from a data file) stays intact. To change the real charges, one needs to use the set command with the *charge* keyword. Care must be taken to ensure that the real and scaled charges and the dielectric constants are consistent.

Keyword *image* sets which image of the simulation box the atom is considered to be in. An image of 0 means it is inside the box as defined. A value of 2 means add 2 box lengths to get the true value. A value of -1 means subtract 1 box length to get the true value. LAMMPS updates these flags as atoms cross periodic boundaries during the simulation. The flags can be output with atom snapshots via the *dump* command. If a value of NULL is specified for any of nx,ny,nz, then the current image value for that dimension is unchanged. For non-periodic dimensions only a value of 0 can be specified. This command can be useful after a system has been equilibrated and atoms have diffused one or more box lengths in various directions. This command can then reset the image values for atoms so that they are effectively inside the simulation box, e.g if a diffusion coefficient is about to be measured via the *compute msd* command. Care should be taken not to reset the image flags of two atoms in a bond to the same value if the bond straddles a periodic boundary (rather they should be different by +/- 1). This will not affect the dynamics of a simulation, but may mess up analysis of the trajectories if a LAMMPS diagnostic or your own analysis relies on the image flags to unwrap a molecule which straddles the periodic box.

Changed in version 28Mar2023: Support for type labels was added for setting improper types

Keyword *improper* sets the improper type of all impropers of selected atoms to the specified value. The value can be a numeric type from 1 to nimpropertypes. Or it can be a improper type label. See the *Howto type labels* doc page for the allowed syntax of type labels and a general discussion of how type labels can be used. All atoms in a particular improper must be selected atoms in order for the change to be made. The value of nimpropertypes was set by the *improper types* field in the header of the data file read by the *read_data* command. This keyword does NOT allow use of an atom-style variable.

Keyword *length* sets the length of selected atoms. The particles must be line segments as defined by the *atom_style line* command. If the specified value is non-zero the line segment is (re)set to a length = the specified value, centered around the particle position, with an orientation along the x-axis. If the specified value is 0.0, the particle will become a point particle. Note that this command does not adjust the particle mass, even if it was defined with a density, e.g. via the *read_data* command.

Keyword *mass* sets the mass of all selected particles. The particles must have a per-atom mass attribute, as defined by the *atom_style* command. See the "mass" command for how to set mass values on a per-type basis.

Keyword *mol* sets the molecule ID for all selected atoms. The *atom style* being used must support the use of molecule IDs.

Keyword *omega* sets the angular velocity of selected atoms. The particles must be spheres as defined by the *atom_style sphere* command. The angular velocity vector of the particles is set to the 3 specified components.

Keyword *quat* uses the specified values to create a quaternion (4-vector) that represents the orientation of the selected atoms. The particles must define a quaternion for their orientation (e.g. ellipsoids, triangles, body particles) as defined by the *atom_style* command. Note that particles defined by *atom_style ellipsoid* have 3 shape parameters. The 3 values must be non-zero for each particle set by this command. They are used to specify the aspect ratios of an ellipsoidal particle, which is oriented by default with its x-axis along the simulation box's x-axis, and similarly for y and z. If this body is rotated (via the right-hand rule) by an angle theta around a unit rotation vector (a,b,c), then the quaternion that represents its new orientation is given by (cos(theta/2), a*sin(theta/2), b*sin(theta/2), c*sin(theta/2)). The theta and a,b,c values are the arguments to the *quat* keyword. LAMMPS normalizes the quaternion in case (a,b,c) was not specified as a unit vector. For 2d systems, the a,b,c values are ignored, since a rotation vector of (0,0,1) is the only valid choice.

Keyword *quat/random* randomizes the orientation of the quaternion for the selected atoms. The particles must define a quaternion for their orientation (e.g. ellipsoids, triangles, body particles) as defined by the *atom_style* command. Random numbers are used in such a way that the orientation of a particular atom is the same, regardless of how many processors are being used. For 2d systems, only orientations in the xy plane are generated. As with keyword *quat*, for ellipsoidal particles, the 3 shape values must be non-zero for each particle set by this command. This keyword does NOT allow use of an atom-style variable.

Added in version 15Sep2022.

Keyword *radius/electron* uses the specified value to set the radius of electrons or fixed cores.

Keywords *rheo/rho* and *rheo/status* set the density and the status of rheo particles. In particular, one can only set the phase in the status as described by the *RHEO howto page*.

Keyword *shape* sets the size and shape of the selected atoms. The particles must be ellipsoids as defined by the *atom_style ellipsoid* command. The *Sx*, *Sy*, *Sz* settings are the 3 diameters of the ellipsoid in each direction. All 3 can be set to the same value, which means the ellipsoid is effectively a sphere. They can also all be set to 0.0 which means the particle will be treated as a point particle. Note that this command does not adjust the particle mass, even if it was defined with a density, e.g. via the *read_data* command.

Keyword *smd/contact/radius* only applies to simulations with the Smooth Mach Dynamics package MACHDYN. Itsets an interaction radius for computing short-range interactions, e.g. repulsive forces to prevent different individual physical bodies from penetrating each other. Note that the SPH smoothing kernel diameter used for computing long range, nonlocal interactions, is set using the *diameter* keyword.

Added in version 30Mar2026.

Keyword *block* sets the blockiness of the selected atoms. The particles must be ellipsoids as defined by the *atom_style ellipsoid* command. This command is used to define superellipsoid particle shapes for use in granular simulations. The *block1*, *block2* settings are the 2 exponents of the superellipsoid in the vertical and horizontal directions. Vertical sections through the center are superellipses with squareness *block1* and horizontal sections are superellipses with squareness *block2*. If both parameters are set to a value of 2 (the default), the atom is a regular ellipsoid. The keyword *block* should be used together with the keyword *shape* to give the particle the desired shape. If the keyword *block* is given alone, and the *shape* has not been defined, e.g., in a previous *set* command, the 3 diameters would be set to a value of 1 internally. Note that this command does not adjust the particle mass, even if it was defined with a density, e.g. via the *read_data* command.

Keyword *smd/mass/density* sets the mass of all selected particles, but it is only applicable to the Smooth Mach Dynamics package MACHDYN. It assumes that the particle volume has already been correctly set and calculates particle mass from the provided mass density value.

Keywords *sph/cv*, *sph/e*, and *sph/rho* set the heat capacity, energy, and density of smoothed particle hydrodynamics (SPH) particles. See this PDF guide to using SPH in LAMMPS.

Note

Note that the SPH PDF guide file has not been updated for many years and thus does not reflect the current *syntax* of the SPH package commands. For that, please refer to the LAMMPS manual.

Changed in version 15Sep2022.

Keyword *spin/atom* uses the specified g value to set the magnitude of the magnetic spin vectors, and the x,y,z values as components of a vector to set as the orientation of the magnetic spin vectors of the selected atoms. This keyword was previously called *spin*.

Changed in version 15Sep2022.

Keyword *spin/atom/random* randomizes the orientation of the magnetic spin vectors for the selected atoms and sets the magnitude of each to the specified *Dlen* value. This keyword does NOT allow use of an atom-style variable. This keyword was previously called *spin/random*.

Added in version 15Sep2022.

Keyword *spin/electron* sets the spin of an electron (+/- 1) or indicates nuclei (=0), fixed-cores (=2), or pseudo-cores (= 3).

Keyword *temperature* sets the temperature of a finite-size particle. Currently, only the GRANULAR package supports this attribute. The temperature must be added using an instance of *fix property/atom* The values for the temperature must be positive.

Keyword *theta* sets the orientation of selected atoms. The particles must be line segments as defined by the *atom_style line* command. The specified value is used to set the orientation angle of the line segments with respect to the x axis.

Keyword *theta/random* randomizes the orientation of theta for the selected atoms. The particles must be line segments as defined by the *atom_style line* command. Random numbers are used in such a way that the orientation of a particular atom is the same, regardless of how many processors are being used. This keyword does NOT allow use of an atom-style variable.

Keyword *tri* sets the size of selected atoms. The particles must be triangles as defined by the *atom_style tri* command. If the specified value is non-zero the triangle is (re)set to be an equilateral triangle in the xy plane with side length = the specified value, with a centroid at the particle position, with its base parallel to the x axis, and the y-axis running from the center of the base to the top point of the triangle. If the specified value is 0.0, the particle will become a point particle. Note that this command does not adjust the particle mass, even if it was defined with a density, e.g. via the *read_data* command.

Changed in version 28Mar2023: Support for type labels was added for setting atom types

Keyword *type* sets the atom type for all selected atoms. A specified value can be either a numeric atom type or an atom type label. When using a numeric type, the specified value must be from 1 to ntypes, where ntypes was set by the *create_box* command or the *atom types* field in the header of the data file read by the *read_data* command. When using a type label it must have been defined previously. See the *Howto type labels* doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

Keyword *type/fraction* sets the atom type for a fraction of the selected atoms. The actual number of atoms changed is not guaranteed to be exactly the specified fraction (0 <= *fraction* <= 1), but should be statistically close. Random numbers are used in such a way that a particular atom is changed or not changed, regardless of how many processors are being used. This keyword does NOT allow use of an atom-style variable.

Keywords *type/ratio* and *type/subset* also set the atom type for a fraction of the selected atoms. The actual number of atoms changed will be exactly the requested number. For *type/ratio* the specified fraction (0 <= *fraction* <= 1) determines the number. For *type/subset*, the specified *Nsubset* is the number. An iterative algorithm is used which ensures the correct number of atoms are selected, in a perfectly random fashion. Which atoms are selected will change with the number of processors used. These keywords do not allow use of an atom-style variable.

Keyword *volume* sets the volume of all selected particles. Currently, only the *atom_style peri* command defines particles with a volume attribute. Note that this command does not adjust the particle mass.

Keywords *vx*, *vy*, and *vz* set the velocities of all selected atoms.

Keywords *x*, *y*, *z* set the coordinates of all selected atoms.

Keyword *apip/lambda* sets the switching parameter of an adaptive-precision interatomic potential (*APIP*). The precise potential is used for an atom when its switching parameter λ is 0. The fast potential is used for an atom when its switching parameter λ is 1. Both potentials are partially used for $\lambda \in (0, 1)$.

Keywords *i_name*, *d_name*, *i2_name*, *d2_name* refer to custom per-atom integer and floating-point vectors or arrays that have been added via the *fix property/atom* command. When that command is used specific names are given to each attribute which are the "name" portion of these keywords. For arrays *i2_name* and *d2_name*, the column of the array to set must also be included following the name in brackets: e.g. d2_xyz[2] or i2_mySpin[3].

1.98.4 Restrictions

You cannot set an atom attribute (e.g. *mol* or *q* or *volume*) if the *atom_style* does not have that attribute.

This command requires inter-processor communication to coordinate the setting of bond types (angle types, etc). This means that the system must be ready to perform a simulation before using one of these keywords (force fields set, atom mass set, etc). This is not necessary for other keywords.

Using the *region* style with the bond (angle, etc) keywords can give unpredictable results if there are bonds (angles, etc) that straddle periodic boundaries. This is because the region may only extend up to the boundary and partner atoms in the bond (angle, etc) may have coordinates outside the simulation box if they are ghost atoms.

1.99 shell command

1.99.1 Syntax

```
shell command args
```

- command = *cd* or *mkdir* or *mv* or *rm* or *rmdir* or *putenv* or arbitrary command

```
cd arg = dir
  dir = directory to change to
mkdir args = dir1 dir2 ...
  dir1,dir2 = one or more directories to create
mv args = old new
  old = old filename
  new = new filename or destination folder
rm args = [-f] file1 file2 ...
  -f = turn off warnings (optional)
  file1,file2 = one or more filenames to delete
rmdir args = dir1 dir2 ...
  dir1,dir2 = one or more directories to delete
putenv args = var1=value1 var2=value2
  var=value = one of more definitions of environment variables
anything else is passed as a command to the shell for direct execution
```

1.99.2 Examples

```
shell cd sub1
shell cd ..
shell mkdir tmp1 tmp2/tmp3
shell rmdir tmp1 tmp2
shell mv log.lammps hold/log.1
shell rm TMP/file1 TMP/file2
shell putenv LAMMPS_POTENTIALS=../../potentials
shell my_setup file1 10 file2
shell my_post_process 100 dump.out
```

1.99.3 Description

Execute a shell command. A few simple file-based shell commands are supported directly, in Unix-style syntax. Any command not listed above is passed as-is to the C-library system() call, which invokes the command in a shell. To use the external executable instead of the built-in version one needs to use a full path, for example */bin/rm* instead of *rm*. The built-in commands will also work on operating systems, that do not - by default - provide the corresponding external executables (like *mkdir* on Windows).

This command provides a ways to invoke custom commands or executables from your input script. For example, you can move files around in preparation for the next section of the input script. Or you can run a program that pre-processes data for input into LAMMPS. Or you can run a program that post-processes LAMMPS output data.

With the exception of *cd*, all commands, including ones invoked via a system() call, are executed by only a single processor, so that files/directories are not being manipulated by multiple processors concurrently which may result in unexpected errors or corrupted files.

The *cd* command changes the current working directory similar to the `cd` command. All subsequent LAMMPS commands that read/write files will use the new directory. All processors execute this command.

The *mkdir* command creates directories similar to the Unix `mkdir -p` command. That is, it will attempt to create the entire path of subdirectories if they do not exist yet.

The *mv* command renames a file and/or moves it to a new directory. It cannot rename files across filesystem boundaries or between drives.

The *rm* command deletes file similar to the Unix `rm` command.

The *rmdir* command deletes directories similar to Unix `rmdir` command. If a directory is not empty, its contents are also removed recursively similar to the Unix `rm -r` command.

The *putenv* command defines or updates an environment variable directly. Since this command does not pass through the shell, no shell variable expansion or globbing is performed, only the usual substitution for LAMMPS variables defined with the *variable* command is performed. The resulting string is then used literally.

Any other command is passed as-is to the shell along with its arguments as one string, invoked by the C-library system() call. For example, these lines in your input script:

```
variable n equal 10
variable foo string file2
shell my_setup file1 $n ${foo}
```

would be the same as invoking

```
my_setup file1 10 file2
```

from a command-line prompt. The executable program "my_setup" is run with 3 arguments: file1 10 file2.

1.99.4 Restrictions

LAMMPS will do a best effort to detect errors and print suitable warnings, but due to the nature of delegating commands to the C-library system() call, this is not always reliable.

```

1.100.3 Description

Set weighting coefficients for pairwise energy and force contributions between pairs of atoms that are also permanently bonded to each other, either directly or via one or two intermediate bonds. These weighting factors are used by nearly all *pair styles* in LAMMPS that compute simple pairwise interactions. Permanent bonds between atoms are specified by defining the bond topology in the data file read by the *read_data* command. Typically a *bond_style* command is also used to define a bond potential. The rationale for using these weighting factors is that the interaction between a pair of bonded atoms is all (or mostly) specified by the bond, angle, dihedral potentials, and thus the non-bonded Lennard-Jones or Coulombic interaction between the pair of atoms should be excluded (or reduced by a weighting factor).

Note

These weighting factors are NOT used by *pair styles* that compute many-body interactions, since the "bonds" that result from such interactions are not permanent, but are created and broken dynamically as atom conformations change. Examples of pair styles in this category are EAM, MEAM, Stillinger-Weber, Tersoff, COMB, AIREBO, and ReaxFF. In fact, it generally makes no sense to define permanent bonds between atoms that interact via these potentials, though such bonds may exist elsewhere in your system, e.g. when using the *pair_style hybrid* command. Thus LAMMPS ignores special_bonds settings when many-body potentials are calculated. Please note, that the existence of explicit bonds for atoms that are described by a many-body potential will alter the neighbor list and thus can render the computation of those interactions invalid, since those pairs are not only used to determine direct pairwise interactions but also neighbors of neighbors and more. The recommended course of action is to remove such bonds, or - if that is not possible - use a special bonds setting of 1.0 1.0 1.0.

Note

Unlike some commands in LAMMPS, you cannot use this command multiple times in an incremental fashion: e.g. to first set the LJ settings and then the Coulombic ones. Each time you use this command it sets all the coefficients

to default values and only overrides the one you specify, so you should set all the options you need each time you use it. See more details at the bottom of this page.

The Coulomb factors are applied to any Coulomb (charge interaction) term that the potential calculates. The LJ factors are applied to the remaining terms that the potential calculates, whether they represent LJ interactions or not. The weighting factors are a scaling prefactor on the energy and force between the pair of atoms.

A value of 1.0 means include the full interaction without flagging the pair as a "special pair"; a value of 0.0 means exclude the pair completely from the neighbor list, except for pair styles that require a *kspace style* and pair styles *amoeba*, *hippo*, *thole*, *coul/exclude*, and pair styles that include "coul/dsf" or "coul/wolf".

Note

To include pairs that would otherwise be excluded (so they are included in the neighbor list for certain analysis compute styles), you can use a very small but non-zero value like 1.0e-100 instead of 0.0. Due to using floating-point math, the computed force, energy, and virial contributions from the pairs will be too small to cause differences.

The first of the 3 coefficients (LJ or Coulombic) is the weighting factor on 1-2 atom pairs, which are pairs of atoms directly bonded to each other. The second coefficient is the weighting factor on 1-3 atom pairs which are those separated by 2 bonds (e.g. the two H atoms in a water molecule). The third coefficient is the weighting factor on 1-4 atom pairs which are those separated by 3 bonds (e.g. the first and fourth atoms in a dihedral interaction). Thus if the 1-2 coefficient is set to 0.0, then the pairwise interaction is effectively turned off for all pairs of atoms bonded to each other. If it is set to 1.0, then that interaction will be at full strength.

Note

For purposes of computing weighted pairwise interactions, 1-3 and 1-4 interactions are not defined from the list of angles or dihedrals used by the simulation. Rather, they are inferred topologically from the set of bonds specified when the simulation is defined from a data or restart file (see *read_data* or *read_restart* commands). Thus the set of 1-2,1-3,1-4 interactions that the weights apply to is the same whether angle and dihedral potentials are computed or not, and remains the same even if bonds are constrained, or turned off, or removed during a simulation.

The two exceptions to this rule are (a) if the *angle* or *dihedral* keywords are set to *yes* (see below), or (b) if the *delete_bonds* command is used with the *special* option that re-computes the 1-2,1-3,1-4 topologies after bonds are deleted; see the *delete_bonds* command for more details.

The *amber* keyword sets the 3 coefficients to 0.0, 0.0, 0.5 for LJ interactions and to 0.0, 0.0, 0.8333 for Coulombic interactions, which is the default for a commonly used version of the AMBER force field, where the last value is really 5/6. See *(Cornell)* for a description of the AMBER force field.

The *charmm* keyword sets the 3 coefficients to 0.0, 0.0, 0.0 for both LJ and Coulombic interactions, which is the default for a commonly used version of the CHARMM force field. Note that in pair styles *lj/charmm/coul/charmm* and *lj/charmm/coul/long* the 1-4 coefficients are defined explicitly, and these pairwise contributions are computed as part of the charmm dihedral style - see the *pair_coeff* and *dihedral_style* commands for more information. See *(MacKerell)* for a description of the CHARMM force field.

The *dreiding* keyword sets the 3 coefficients to 0.0, 0.0, 1.0 for both LJ and Coulombic interactions, which is the default for the Dreiding force field, as discussed in *(Mayo)*.

The *fene* keyword sets the 3 coefficients to 0.0, 1.0, 1.0 for both LJ and Coulombic interactions, which is consistent with a coarse-grained polymer model with *FENE bonds*. See *(Kremer)* for a description of FENE bonds.

The *lj/coul*, *lj*, and *coul* keywords allow the 3 coefficients to be set explicitly. The *lj/coul* keyword sets both the LJ and Coulombic coefficients to the same 3 values. The *lj* and *coul* keywords only set either the LJ or Coulombic coefficients.

Use both of them if you wish to set the LJ coefficients to different values than the Coulombic coefficients.

The *angle* keyword allows the 1-3 weighting factor to be ignored for individual atom pairs if they are not listed as the first and last atoms in any angle defined in the simulation or as 1,3 or 2,4 atoms in any dihedral defined in the simulation. For example, imagine the 1-3 weighting factor is set to 0.5 and you have a linear molecule with 4 atoms and bonds as follows: 1-2-3-4. If your data file defines 1-2-3 as an angle, but does not define 2-3-4 as an angle or 1-2-3-4 as a dihedral, then the pairwise interaction between atoms 1 and 3 will always be weighted by 0.5, but different force fields use different rules for weighting the pairwise interaction between atoms 2 and 4. If the *angle* keyword is specified as *yes*, then the pairwise interaction between atoms 2 and 4 will be unaffected (full weighting of 1.0). If the *angle* keyword is specified as *no* which is the default, then the 2,4 interaction will also be weighted by 0.5.

The *dihedral* keyword allows the 1-4 weighting factor to be ignored for individual atom pairs if they are not listed as the first and last atoms in any dihedral defined in the simulation. For example, imagine the 1-4 weighting factor is set to 0.5 and you have a linear molecule with 5 atoms and bonds as follows: 1-2-3-4-5. If your data file defines 1-2-3-4 as a dihedral, but does not define 2-3-4-5 as a dihedral, then the pairwise interaction between atoms 1 and 4 will always be weighted by 0.5, but different force fields use different rules for weighting the pairwise interaction between atoms 2 and 5. If the *dihedral* keyword is specified as *yes*, then the pairwise interaction between atoms 2 and 5 will be unaffected (full weighting of 1.0). If the *dihedral* keyword is specified as *no* which is the default, then the 2,5 interaction will also be weighted by 0.5.

The *one/five* keyword enable calculation and storage of a list of 1-5 neighbors in the molecular topology for each atom. It is required by some pair styles, such as *pair_style amoeba* and *pair_style hippo*.

Note

LAMMPS stores and maintains a data structure with a list of the first, second, and third neighbors of each atom (within the bond topology of the system). If new bonds are created (or molecules added containing atoms with more special neighbors), the size of this list needs to grow. Note that adding a single bond always adds a new first neighbor but may also induce *many* new second and third neighbors, depending on the molecular topology of your system. Using the *extra/special/per/atom* keyword to either *read_data* or *create_box* reserves empty space in the list for this N additional first, second, or third neighbors to be added. If you do not do this, you may get an error when bonds (or molecules) are added.

Note

If you reuse this command in an input script, you should set all the options you need each time. This command cannot be used a second time incrementally. E.g. these two commands:

```
special_bonds lj 0.0 1.0 1.0
special_bonds coul 0.0 0.0 1.0
```

are not the same as

```
special_bonds lj 0.0 1.0 1.0 coul 0.0 0.0 1.0
```

In the first case you end up with (after the second command):

```
LJ: 0.0 0.0 0.0
Coul: 0.0 0.0 1.0
```

while only in the second case do you get the desired settings of:

```
LJ: 0.0 1.0 1.0
Coul: 0.0 0.0 1.0
```

This happens because the LJ (and Coul) settings are reset to their default values before modifying them, each time the *special_bonds* command is issued.

1.101 suffix command

1.101.1 Syntax

```
suffix style args
```

- style = *off* or *on* or *gpu* or *intel* or *kk* or *omp* or *opt* or *hybrid*
- args = for hybrid style, default suffix to be used and alternative suffix

1.101.2 Examples

```
suffix off
suffix on
suffix gpu
suffix intel
suffix hybrid intel omp
suffix kk
```

1.101.3 Description

This command allows you to use variants of various styles if they exist. In that respect it operates the same as the *-suffix command-line switch*. It also has options to turn off or back on any suffix setting made via the command-line.

The specified style can be *gpu*, *intel*, *kk*, *omp*, *opt* or *hybrid*. These refer to optional packages that LAMMPS can be built with, as described on the *Build package* doc page. The "gpu" style corresponds to the GPU package, the "intel" style to the INTEL package, the "kk" style to the KOKKOS package, the "omp" style to the OPENMP package, and the "opt" style to the OPT package.

These are the variants these packages provide:

- GPU = a handful of pair styles and the PPPM kspace_style, optimized to run on one or more GPUs or multicore CPU/GPU nodes
- INTEL = a collection of pair styles and neighbor routines optimized to run in single, mixed, or double precision on CPUs.
- KOKKOS = a collection of atom, pair, and fix styles optimized to run using the Kokkos library on various kinds of hardware, including GPUs via CUDA and many-core chips via OpenMP or threading.
- OPENMP = a collection of pair, bond, angle, dihedral, improper, kspace, compute, and fix styles with support for OpenMP multi-threading
- OPT = a handful of pair styles, cache-optimized for faster CPU performance
- HYBRID = a combination of two packages can be specified (see below)

As an example, all of the packages provide a *pair_style lj/cut* variant, with style names lj/cut/opt, lj/cut/omp, lj/cut/gpu, lj/cut/intel, or lj/cut/kk. A variant styles can be specified explicitly in your input script, e.g. pair_style lj/cut/gpu. If the suffix command is used with the appropriate style, you do not need to modify your input script. The specified suffix (opt,omp,gpu,intel,kk) is automatically appended whenever your input script command creates a new *atom*, *pair*, *bond*, *angle*, *dihedral*, *improper*, *kspace*, *fix*, *compute*, or *run* style. If the variant version does not exist, the standard version is created.

For "hybrid", two packages are specified. The first is used whenever available. If a style with the first suffix is not available, the style with the suffix for the second package will be used if available. For example, "hybrid intel omp" will use styles from the INTEL package as a first choice and styles from the OPENMP package as a second choice if no INTEL variant is available.

If the specified style is *off*, then any previously specified suffix is temporarily disabled, whether it was specified by a command-line switch or a previous suffix command. If the specified style is *on*, a disabled suffix is turned back on. The use of these 2 commands lets your input script use a standard LAMMPS style (i.e. a non-accelerated variant), which can be useful for testing or benchmarking purposes. Of course this is also possible by not using any suffix commands, and explicitly appending or not appending the suffix to the relevant commands in your input script.

Note

The default *run_style* verlet is invoked prior to reading the input script and is therefore not affected by a suffix command in the input script. The KOKKOS package requires "run_style verlet/kk", so when using the KOKKOS package it is necessary to either use the command line "-sf kk" command or add an explicit "run_style verlet" command to the input script.

    neb_log log.neb
```

1.102.3 Description

Run a temperature accelerated dynamics (TAD) simulation. This method requires two or more partitions to perform NEB transition state searches.

TAD is described in *this paper* by Art Voter. It is a method that uses accelerated dynamics at an elevated temperature to generate results at a specified lower temperature. A good overview of accelerated dynamics methods (AMD) for such systems is given in *this review paper* from the same group. To quote from the review paper: "The dynamical evolution is characterized by vibrational excursions within a potential basin, punctuated by occasional transitions between basins. The transition probability is characterized by p(t) = k*exp(-kt) where k is the rate constant."

TAD is a suitable AMD method for infrequent-event systems, where in addition, the transition kinetics are well-approximated by harmonic transition state theory (hTST). In hTST, the temperature dependence of transition rates follows the Arrhenius relation. As a consequence a set of event times generated in a high-temperature simulation can be mapped to a set of much longer estimated times in the low-temperature system. However, because this mapping involves the energy barrier of the transition event, which is different for each event, the first event at the high temperature may not be the earliest event at the low temperature. TAD handles this by first generating a set of possible events from the current basin. After each event, the simulation is reflected backwards into the current basin. This is repeated until the stopping criterion is satisfied, at which point the event with the earliest low-temperature occurrence time is selected. The stopping criterion is that the confidence measure be greater than 1-*delta*. The confidence measure is the probability that no earlier low-temperature event will occur at some later time in the high-temperature simulation. hTST provides an lower bound for this probability, based on the user-specified minimum pre-exponential factor (reciprocal of *tmax*).

In order to estimate the energy barrier for each event, the TAD method invokes the *NEB* method. Each NEB replica runs on a partition of processors. The current NEB implementation in LAMMPS restricts you to having exactly one processor per replica. For more information, see the documentation for the *neb* command. In the current LAMMPS implementation of TAD, all the non-NEB TAD operations are performed on the first partition, while the other partitions remain idle. See the *Howto replica* doc page for further discussion of multi-replica simulations.

A TAD run has several stages, which are repeated each time an event is performed. The logic for a TAD run is as follows:

```
while (time remains):
  while (time < tstop):
    until (event occurs):
      run dynamics for t_event steps
      quench
    run neb calculation using all replicas
    compute tlo from energy barrier
    update earliest event
    update tstop
    reflect back into current basin
  execute earliest event
```

Before this outer loop begins, the initial potential energy basin is identified by quenching (an energy minimization, see below) the initial state and storing the resulting coordinates for reference.

Inside the inner loop, dynamics is run continuously according to whatever integrator has been specified by the user, stopping every *t_event* steps to check if a transition event has occurred. This check is performed by quenching the system and comparing the resulting atom coordinates to the coordinates from the previous basin.

A quench is an energy minimization and is performed by whichever algorithm has been defined by the *min_style* command; its default is the CG minimizer. The tolerances and limits for each quench can be set by the *min* keyword. Note that typically, you do not need to perform a highly-converged minimization to detect a transition event.

The event check is performed by a compute with the specified *compute-ID*. Currently there is only one compute that works with the TAD command, which is the *compute event/displace* command. Other event-checking computes may

be added. *Compute event/displace* checks whether any atom in the compute group has moved further than a specified threshold distance. If so, an "event" has occurred.

The NEB calculation is similar to that invoked by the *neb* command, except that the final state is generated internally, instead of being read in from a file. The style of minimization performed by NEB is determined by the *neb_style* keyword and must be a damped dynamics minimizer. The tolerances and limits for each NEB calculation can be set by the *neb* keyword. As discussed on the *neb*, it is often advantageous to use a larger timestep for NEB than for normal dynamics. Since the size of the timestep set by the *timestep* command is used by TAD for performing dynamics, there is a *neb_step* keyword which can be used to set a larger timestep for each NEB calculation if desired.

A key aspect of the TAD method is setting the stopping criterion appropriately. If this criterion is too conservative, then many events must be generated before one is finally executed. Conversely, if this criterion is too aggressive, high-entropy high-barrier events will be over-sampled, while low-entropy low-barrier events will be under-sampled. If the lowest pre-exponential factor is known fairly accurately, then it can be used to estimate *tmax*, and the value of *delta* can be set to the desired confidence level e.g. *delta* = 0.05 corresponds to 95% confidence. However, for systems where the dynamics are not well characterized (the most common case), it will be necessary to experiment with the values of *delta* and *tmax* to get a good trade-off between accuracy and performance.

A second key aspect is the choice of *t_hi*. A larger value greatly increases the rate at which new events are generated. However, too large a value introduces errors due to anharmonicity (not accounted for within hTST). Once again, for any given system, experimentation is necessary to determine the best value of *t_hi*.

Five kinds of output can be generated during a TAD run: event statistics, NEB statistics, thermodynamic output by each replica, dump files, and restart files.

Event statistics are printed to the screen and master log.lammps file each time an event is executed. The quantities are the timestep, CPU time, global event number *N*, local event number *M*, event status, energy barrier, time margin, *t_lo* and *delt_lo*. The timestep is the usual LAMMPS timestep, which corresponds to the high-temperature time at which the event was detected, in units of timestep. The CPU time is the total processor time since the start of the TAD run. The global event number *N* is a counter that increments with each executed event. The local event number *M* is a counter that resets to zero upon entering each new basin. The event status is *E* when an event is executed, and is *D* for an event that is detected, while *DF* is for a detected event that is also the earliest (first) event at the low temperature.

The time margin is the ratio of the high temperature time in the current basin to the stopping time. This last number can be used to judge whether the stopping time is too short or too long (see above).

t_lo is the low-temperature event time when the current basin was entered, in units of timestep. del*t_lo* is the time of each detected event, measured relative to *t_lo*. *delt_lo* is equal to the high-temperature time since entering the current basin, scaled by an exponential factor that depends on the hi/lo temperature ratio and the energy barrier for that event.

On lines for executed events, with status *E*, the global event number is incremented by one, the local event number and time margin are reset to zero, while the global event number, energy barrier, and *delt_lo* match the last event with status *DF* in the immediately preceding block of detected events. The low-temperature event time *t_lo* is incremented by *delt_lo*.

NEB statistics are written to the file specified by the *neb_log* keyword. If the keyword value is "none", then no NEB statistics are printed out. The statistics are written every *Nevery* timesteps. See the *neb* command for a full description of the NEB statistics. When invoked from TAD, NEB statistics are never printed to the screen.

Because the NEB calculation must run on multiple partitions, LAMMPS produces additional screen and log files for each partition, e.g. log.lammps.0, log.lammps.1, etc. For the TAD command, these contain the thermodynamic output of each NEB replica. In addition, the log file for the first partition, log.lammps.0, will contain thermodynamic output from short runs and minimizations corresponding to the dynamics and quench operations, as well as a line for each new detected event, as described above.

After the TAD command completes, timing statistics for the TAD run are printed in each replica's log file, giving a breakdown of how much CPU time was spent in each stage (NEB, dynamics, quenching, etc).

Any *dump files* defined in the input script will be written to during a TAD run at timesteps when an event is executed. This means the requested dump frequency in the *dump* command is ignored. There will be one dump file (per dump command) created for all partitions. The atom coordinates of the dump snapshot are those of the minimum energy configuration resulting from quenching following the executed event. The timesteps written into the dump files correspond to the timestep at which the event occurred and NOT the clock. A dump snapshot corresponding to the initial minimum state used for event detection is written to the dump file at the beginning of each TAD run.

If the *restart* command is used, a single restart file for all the partitions is generated, which allows a TAD run to be continued by a new input script in the usual manner. The restart file is generated after an event is executed. The restart file contains a snapshot of the system in the new quenched state, including the event number and the low-temperature time. The restart frequency specified in the *restart* command is interpreted differently when performing a TAD run. It does not mean the timestep interval between restart files. Instead it means an event interval for executed events. Thus a frequency of 1 means write a restart file every time an event is executed. A frequency of 10 means write a restart file every 10th executed event. When an input script reads a restart file from a previous TAD run, the new script can be run on a different number of replicas or processors.

Note that within a single state, the dynamics will typically temporarily continue beyond the event that is ultimately chosen, until the stopping criterion is satisfied. When the event is eventually executed, the timestep counter is reset to the value when the event was detected. Similarly, after each quench and NEB minimization, the timestep counter is reset to the value at the start of the minimization. This means that the timesteps listed in the replica log files do not always increase monotonically. However, the timestep values printed to the master log file, dump files, and restart files are always monotonically increasing.

1.102.4 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the *Build package* doc page for more info.

N setting must be integer multiple of *t_event*.

Runs restarted from restart files written during a TAD run will only produce identical results if the user-specified integrator supports exact restarts. So *fix nvt* will produce an exact restart, but *fix langevin* will not.

This command cannot be used when any fixes are defined that keep track of elapsed time to perform time-dependent operations. Examples include the "ave" fixes such as *fix ave/chunk*. Also *fix dt/reset* and *fix deposit*.

1.102.5 Related commands

compute event/displace, *min_modify*, *min_style*, *run_style*, *minimize*, *temper*, *neb*, *prd*

1.102.6 Default

The option defaults are *min* = 0.1 0.1 40 50, *neb* = 0.01 100 100 10, *neb_style* = *quickmin*, *neb_step* = the same timestep set by the *timestep* command, and *neb_log* = "none".

(Voter2002) Voter, Montalenti, Germann, Annual Review of Materials Research 32, 321 (2002).

1.103 temper command

1.103.1 Syntax

```
temper Nsteps Nevery temp fix-ID seed1 seed2 index
```

- Nsteps = total # of timesteps to run
- Nevery = attempt a tempering swap every this many steps
- temp = initial temperature for this ensemble
- fix-ID = ID of the fix that will control temperature during the run
- seed1 = random # seed used to decide on adjacent temperature to partner with
- seed2 = random # seed for Boltzmann factor in Metropolis swap
- index = which temperature (0 to N-1) I am simulating (optional)

1.103.2 Examples

```
temper 100000 100 $t tempfix 0 58728
temper 40000 100 $t tempfix 0 32285 $w
```

1.103.3 Description

Run a parallel tempering or replica exchange simulation using multiple replicas (ensembles) of a system. Two or more replicas must be used.

Each replica runs on a partition of one or more MPI processes. Processor partitions are defined at run-time using the *-partition command-line switch*. Note that if you have MPI installed, you can run a multi-replica simulation with more replicas (partitions) than you have physical processors, e.g you can run a 10-replica simulation on one or two processors. You will simply not get the performance speed-up you would see with one or more physical processors per replica. See the *Howto replica* doc page for further discussion.

Each replica's temperature is controlled at a different value by a fix with *fix-ID* that controls temperature. Most thermostat fix styles (with and without included time integration) are supported. The command will print an error message and abort, if the chosen fix is unsupported. The desired temperature is specified by *temp*, which is typically a variable previously set in the input script, so that each partition is assigned a different temperature. See the *variable* command for more details. For example:

```
variable t world 300.0 310.0 320.0 330.0
fix myfix all nvt temp $t $t 100.0
temper 100000 100 $t myfix 3847 58382
```

would define 4 temperatures, and assign one of them to the thermostat used by each replica, and to the temper command.

As the tempering simulation runs for *Nsteps* timesteps, a temperature swap between adjacent ensembles will be attempted every *Nevery* timesteps. If *seed1* is 0, then the swap attempts will alternate between odd and even pairings. If *seed1* is non-zero then it is used as a seed in a random number generator to randomly choose an odd or even pairing each time. Each attempted swap of temperatures is either accepted or rejected based on a Boltzmann-weighted Metropolis criterion which uses *seed2* in the random number generator.

As a tempering run proceeds, multiple log files and screen output files are created, one per replica. By default these files are named `log.lammps.M` and `screen.M` where M is the replica number from 0 to N-1, with N = # of replicas. See the *-log and -screen command-line switches* for info on how to change these names.

The main screen and log file (`log.lammps`) will list information about which temperature is assigned to each replica at each thermodynamic output timestep. E.g. for a simulation with 16 replicas:

```
Running on 16 partitions of processors
Step T0 T1 T2 T3 T4 T5 T6 T7 T8 T9 T10 T11 T12 T13 T14 T15
0    0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15
500  1 0 3 2 5 4 6 7 8 9 10 11 12 13 14 15
1000 2 0 4 1 5 3 6 7 8 9 10 11 12 14 13 15
1500 2 1 4 0 5 3 6 7 9 8 10 11 12 14 13 15
2000 2 1 3 0 6 4 5 7 10 8 9 11 12 14 13 15
2500 2 1 3 0 6 4 5 7 11 8 9 10 12 14 13 15
...
```

The column headings *T0* to *TN-1* mean which temperature is currently assigned to the replica 0 to *N*-1. Thus the columns represent replicas and the value in each column is its temperature (also numbered 0 to N-1). For example, a 0 in the fourth column (column *T3*, step 2500) means that the fourth replica is assigned temperature 0, i.e. the lowest temperature. You can verify this time sequence of temperature assignments for the *N*th replica by comparing the *N*th column of screen output to the thermodynamic data in the corresponding `log.lammps.N` or `screen.N` files as time proceeds.

You can have each replica create its own dump file in the following manner:

```
variable rep world 0 1 2 3 4 5 6 7
dump 1 all atom 1000 dump.temper.${rep}
```

Note

Each replica's dump file will contain a continuous trajectory for its atoms where the temperature varies over time as swaps take place involving that replica. If you want a series of dump files, each with snapshots (from all replicas) that are all at a single temperature, then you will need to post-process the dump files using the information from the log.lammps file. E.g. you could produce one dump file with snapshots at 300K (from all replicas), another with snapshots at 310K, etc. Note that these new dump files will not contain "continuous trajectories" for individual atoms, because two successive snapshots (in time) may be from different replicas. The reorder_remd_traj python script can do the reordering for you (and additionally also calculates configurational log-weights of trajectory snapshots in the canonical ensemble). The script can be found in the tools/replica directory while instructions on how to use it is available in doc/Tools (in brief) and as a README file in tools/replica (in detail).

The last argument *index* in the temper command is optional and is used when restarting a tempering run from a set of restart files (one for each replica) which had previously swapped to new temperatures. The *index* value (from 0 to N-1, where N is the # of replicas) identifies which temperature the replica was simulating on the timestep the restart files were written. Obviously, this argument must be a variable so that each partition has the correct value. Set the variable to the *N* values listed in the log file for the previous run for the replica temperatures at that timestep. For example if the log file listed the following for a simulation with 5 replicas:

```
500000 2 4 0 1 3
```

then a setting of

```
variable w world 2 4 0 1 3
```

would be used to restart the run with a tempering command like the example above with $w as the last argument.

1.103.4 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the *Build package* doc page for more info.

1.103.5 Related commands

variable, *prd*, *neb*

1.103.6 Default

none

1.104 temper/grem command

1.104.1 Syntax

```
temper/grem N M lambda fix-ID thermostat-ID seed1 seed2 index
```

- N = total # of timesteps to run
- M = attempt a tempering swap every this many steps
- lambda = initial lambda for this ensemble
- fix-ID = ID of *fix grem*
- thermostat-ID = ID of the thermostat that controls kinetic temperature
- seed1 = random # seed used to decide on adjacent temperature to partner with
- seed2 = random # seed for Boltzmann factor in Metropolis swap
- index = which temperature (0 to N-1) I am simulating (optional)

1.104.2 Examples

```
temper/grem 100000 1000 ${lambda} fxgREM fxnvt 0 58728
temper/grem 40000 100 ${lambda} fxgREM fxnpt 0 32285 ${walkers}
```

1.104.3 Description

Run a parallel tempering or replica exchange simulation in LAMMPS partition mode using multiple generalized replicas (ensembles) of a system defined by *fix grem*, which stands for the generalized replica exchange method (gREM) originally developed by *(Kim)*. It uses non-Boltzmann ensembles to sample over first order phase transitions. The is done by defining replicas with an enthalpy dependent effective temperature

Two or more replicas must be used. See the *temper* command for an explanation of how to run replicas on multiple partitions of one or more MPI processes.

This command is a modification of the *temper* command and has the same dependencies, restraints, and input variables which are discussed there in greater detail.

Instead of temperature, this command performs replica exchanges in lambda as per the generalized ensemble enforced by *fix grem*. The desired lambda is specified by *lambda*, which is typically a variable previously set in the input script, so that each partition is assigned a different temperature. See the *variable* command for more details. For example:

```
variable lambda world 400 420 440 460
fix fxnvt all nvt temp 300.0 300.0 100.0
fix fxgREM all grem ${lambda} -0.05 -50000 fxnvt
temper/grem 100000 100 ${lambda} fxgREM fxnvt 3847 58382
```

would define 4 lambdas with constant kinetic temperature but unique generalized temperature, and assign one of them to *fix grem* used by each replica, and to the grem command.

As the gREM simulation runs for *N* timesteps, a swap between adjacent ensembles will be attempted every *M* timesteps. If *seed1* is 0, then the swap attempts will alternate between odd and even pairings. If *seed1* is non-zero then it is used as a seed in a random number generator to randomly choose an odd or even pairing each time. Each attempted swap of temperatures is either accepted or rejected based on a Metropolis criterion, derived for gREM by *(Kim)*, which uses *seed2* in the random number generator.

File management works identical to the *temper* command. Dump files created by this fix contain continuous trajectories and require post-processing to obtain per-replica information.

The last argument *index* in the grem command is optional and is used when restarting a run from a set of restart files (one for each replica) which had previously swapped to new lambda. This is done using a variable. For example if the log file listed the following for a simulation with 5 replicas:

```
500000 2 4 0 1 3
```

then a setting of

```
variable walkers world 2 4 0 1 3
```

would be used to restart the run with a grem command like the example above with ${walkers} as the last argument. This functionality is identical to *temper*.

1.104.4 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the *Build package* doc page for more info.

This command must be used with *fix grem*.

1.104.5 Related commands

1.105 temper/npt command

1.105.1 Syntax

```
temper/npt  N M temp fix-ID seed1 seed2 pressure index
```

- N = total # of timesteps to run

- M = attempt a tempering swap every this many steps
- temp = initial temperature for this ensemble
- fix-ID = ID of the fix that will control temperature and pressure during the run
- seed1 = random # seed used to decide on adjacent temperature to partner with
- seed2 = random # seed for Boltzmann factor in Metropolis swap
- pressure = setpoint pressure for the ensemble
- index = which temperature (0 to N-1) I am simulating (optional)

1.105.2 Examples

```
temper/npt 100000 100 $t nptfix 0 58728 1
temper/npt 2500000 1000 300 nptfix  0 32285 $p
temper/npt 5000000 2000 $t nptfix 0 12523 1 $w
```

1.105.3 Description

Run a parallel tempering or replica exchange simulation using multiple replicas (ensembles) of a system in the isothermal-isobaric (NPT) ensemble. The command temper/npt works like *temper* but requires running replicas in the NPT ensemble instead of the canonical (NVT) ensemble and allows for pressure to be set in the ensembles. These multiple ensembles can run in parallel at different temperatures or different pressures. The acceptance criteria for temper/npt is specific to the NPT ensemble and can be found in references *(Okabe)* and *(Mori)*.

Apart from the difference in acceptance criteria and the specification of pressure, this command works much like the *temper* command. See the documentation on *temper* for information on how the parallel tempering is handled in general.

1.105.4 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the *Build package* page for more info.

This command should be used with a fix that maintains the isothermal-isobaric (NPT) ensemble.

1.105.5 Related commands

1.106 thermo command

1.106.1 Syntax

```
thermo N
```

- N = output thermodynamics every N timesteps
- N can be a variable (see below)

1.106.2 Examples

```
thermo 100
```

1.106.3 Description

Compute and print thermodynamic info (e.g. temperature, energy, pressure) on timesteps that are a multiple of N and at the beginning and end of a simulation. A value of 0 will only print thermodynamics at the beginning and end.

The content and format of what is printed is controlled by the *thermo_style* and *thermo_modify* commands.

Instead of a numeric value, N can be specified as an *equal-style variable*, which should be specified as v_name, where name is the variable name. In this case, the variable is evaluated at the beginning of a run to determine the next timestep at which thermodynamic info will be written out. On that timestep, the variable will be evaluated again to determine the next timestep, etc. Thus the variable should return timestep values. See the stagger() and logfreq() and stride() math functions for *equal-style variables*, as examples of useful functions to use in this context. Other similar math functions could easily be added as options for *equal-style variables*.

For example, the following commands will output thermodynamic info at timesteps 0, 10, 20, 30, 100, 200, 300, 1000, 2000, *etc*:

```
variable        s equal logfreq(10,3,10)
thermo          v_s
```

1.106.4 Restrictions

flush value = yes or no
line value = one or multi or yaml
colname values =  ID string, or auto or default
  string = new column header name
  ID = integer from 1 to N, or integer from -1 to -N, where N = # of quantities␣
↪being output
      or a thermo keyword or reference to compute, fix, property or variable.
format values = line string, int string, float string, ID string, or none
  string = C-style format string
  ID = integer from 1 to N, or integer from -1 to -N, where N = # of quantities␣
↪being output
      or an integer range such as 2*6 (negative values are not allowed)
      or a thermo keyword or reference to compute, fix, property or variable.
temp value = compute ID that calculates a temperature
press value = compute ID that calculates a pressure
triclinic/general arg = yes or no
```

1.107.2 Examples

```
thermo_modify lost ignore flush yes
thermo_modify temp myTemp format 3 %15.8g
thermo_modify temp myTemp format line "%ld %g %g %15.8g"
thermo_modify line multi format float %g
thermo_modify line yaml format none
thermo_modify colname 1 Timestep colname -2 Pressure colname f_1[1] AvgDensity
```

1.107.3 Description

Set options for how thermodynamic information is computed and printed by LAMMPS.

Note

These options apply to the *currently defined* thermo style. When you specify a *thermo_style* command, all thermodynamic settings are restored to their default values, including those previously reset by a thermo_modify command. Thus if your input script specifies a thermo_style command, you should use the thermo_modify command **after** it.

The *lost* keyword determines whether LAMMPS checks for lost atoms each time it computes thermodynamics and what it does if atoms are lost. An atom can be "lost" if it moves across a non-periodic simulation box *boundary* or if it moves more than a box length outside the simulation domain (or more than a processor subdomain length) before reneighboring occurs. The latter case is typically due to bad dynamics (e.g., too large a time step and/or huge forces and velocities). If the value is *ignore*, LAMMPS does not check for lost atoms. If the value is *error* or *warn*, LAMMPS checks and either issues an error or warning. The simulation will exit with an error and continue with a warning. A warning will only be issued once, the first time an atom is lost. This can be a useful debugging option.

The *lost/bond* keyword determines whether LAMMPS throws an error or not if an atom in a bonded interaction (bond, angle, etc) cannot be found when it creates bonded neighbor lists. By default this is a fatal error. However in some scenarios it may be desirable to only issue a warning or ignore it and skip the computation of the missing bond, angle, etc. An example would be when gas molecules in a vapor are drifting out of the box through a fixed boundary condition (see the *boundary* command). In this case one atom may be deleted before the rest of the molecule is, on a later timestep.

The *warn* keyword allows you to control whether LAMMPS will print warning messages and how many of them. Most warning messages are only printed by MPI rank 0. They are usually pointing out important issues that should be investigated, but LAMMPS cannot determine for certain whether they are an indication of an error.

Some warning messages are printed during a run (or immediately before) each time a specific MPI rank encounters the issue (e.g., bonds that are stretched too far or dihedrals in extreme configurations). The number of these can quickly blow up the size of the log file and screen output. A limit of 100 warning messages is therefore applied by default. The warning count is applied to the entire input file, unless it is reset with a `thermo_modify warn reset` command. If there are more warnings than the limit, LAMMPS will print one final warning that it will not print any additional warning messages.

Note

The warning limit is enforced on either the per-processor count or the total count across all MPI processes. For efficiency reasons, however, the total count is only updated at steps with thermodynamic output. Thus when running on a large number of MPI processes in parallel, the total number of warnings printed can be significantly larger than the given limit.

Any number after the keyword *warn* will change the warning limit accordingly. With the value *ignore* all warnings will be suppressed, with the value *always* no limit will be applied and warnings will always be printed, with the value *reset* the internal warning counter will be reset to zero, and with the value *default*, the counter is reset and the limit set to 100. An example usage of either *reset* or *default* would be to re-enable warnings that were disabled or have reached the limit during equilibration, where the warnings would be acceptable while the system is still adjusting, but then change to all warnings for the production run, where they would indicate problems that would require a closer look at what is causing them.

The *norm* keyword determines whether various thermodynamic output values are normalized by the number of atoms or not, depending on whether it is set to *yes* or *no*. Different unit styles have different defaults for this setting (see below). Even if *norm* is set to *yes*, a value is only normalized if it is an "extensive" quantity, meaning that it scales with the number of atoms in the system. For the thermo keywords described by the page for the *thermo_style* command, all energy-related keywords are extensive, such as *pe* or *ebond* or *enthalpy*. Other keywords such as *temp* or *press* are "intensive" meaning their value is independent (in a statistical sense) of the number of atoms in the system and thus are never normalized. For thermodynamic output values extracted from fixes and computes in a *thermo_style custom* command, the page for the individual *fix* or *compute* lists whether the value is "extensive" or "intensive" and thus whether it is normalized. Thermodynamic output values calculated by a variable formula are assumed to be "intensive" and thus are never normalized. You can always include a divide by the number of atoms in the variable formula if this is not the case.

The *flush* keyword invokes a flush operation after thermodynamic info is written to the screen and log file. This ensures the output is updated and not buffered (by the application) even if LAMMPS halts before the simulation completes. Please note that this does not affect buffering by the OS or devices, so you may still lose data in case the simulation stops due to a hardware failure.

The *line* keyword determines whether thermodynamics will be output as a series of numeric values on one line ("one"), in a multi-line format with 3 quantities with text strings per line and a dashed-line header containing the timestep and CPU time ("multi"), or in a YAML format block ("yaml"). This modify option overrides the *one*, *multi*, or *yaml* thermo_style settings.

Added in version 4May2022.

The *colname* keyword can be used to change the default header keyword for a column or field of thermodynamic output. The column names can either be manually set by the user, or automatically generated for certain fixes and computes.

The setting for *ID string* replaces the default text with the provided string. *ID* can be a positive integer when it represents the column number counting from the left, a negative integer when it represents the column number from the right (i.e., -1 is the last column/keyword), or a thermo keyword (or compute, fix, property, or variable reference) and then it

replaces the string for that specific thermo keyword.

Added in version 10Dec2025.

With a setting of *auto*, certain fixes or computes will generate more descriptive strings as their thermo keywords, which are described in the 'output' section of their documentation. Current commands that automatically generate descriptive thermo output strings include 'fix nvt', 'fix npt', 'fix nph', 'compute reduce', and 'fix bond/react'.

With a *colname* setting of *default*, the default column names are used. The default column names follow the same convention as the arguments provided to the *thermo_style* command.

The *colname* keyword can be used multiple times. If multiple *colname* settings refer to the same keyword, the last setting has precedence. The *auto* keyword will only override user-provided strings for computes and fixes that support automatically generated column names. A setting of *default* clears all previous settings, reverting all values to their default values.

The *format* keyword can be used to change the default numeric format of any of quantities the *thermo_style* command outputs. All the specified format strings are C-style formats (i.e., as used by the C/C++ printf() command). The *line* keyword takes a single argument which is the format string for the entire line of thermo output, with *N* fields, which you must enclose in quotes if it is more than one field. The *int* and *float* keywords take a single format argument and are applied to all integer or floating-point quantities output. The setting for *ID string* also takes a single format argument that is used for the indexed value in each line. The interpretation is the same as for *colname* (i.e., a positive integer is the n-th value corresponding to the n-th thermo keyword, a negative integer is counting backwards, and a string matches the entry with the thermo keyword). For example, the fifth column is output in high precision for "format 5 %20.15g", and the pair energy for "format epair %20.15g". The *ID* field can be a range, such as "3*6", "*", "2*", or "*3"; in such cases, all fields in the range (inclusive) are set to the specified format string. Ranges containing negative numbers are not supported.

The *format* keyword can be used multiple times. The precedence is that for each value in a line of output, the *ID* format (if specified) is used, else the *int* or *float* setting (if specified) is used, else the *line* setting (if specified) for that value is used, else the default setting is used. A setting of *none* clears all previous settings, reverting all values to their default format.

Changed in version 2Sep2026.

Format strings are checked when the thermo output is set up and LAMMPS will stop with an error if a format string does not match the kind of value it is applied to, for example when a "%d" conversion is used for a floating-point value. Previously such a mismatch was not detected and silently produced incorrect output. A format string may still contain arbitrary literal text, and may leave trailing values unformatted.

Note

The thermo output values *step* and *atoms* are stored internally as 8-byte signed integers, rather than the usual 4-byte signed integers. You can use a "%d"-style format identifier for them in all variants of the *format* keyword and LAMMPS will convert it to the corresponding 8-byte form when it is applied to those keywords.

Changed in version 2Sep2026.

This conversion is now also applied to the *line* option and the *format ID string* option. Previously those required a format string appropriate for an 8-byte signed integer (i.e., one with "%ld" or "%lld", depending on the platform).

The *temp* keyword is used to determine how thermodynamic temperature is calculated, which is used by all thermo quantities that require a temperature ("temp", "press", "ke", "etotal", "enthalpy", "pxx", etc). The specified compute ID must have been previously defined by the user via the *compute* command and it must be a style of compute that calculates a temperature. As described in the *thermo_style* command, thermo output uses a default compute for temperature with ID = *thermo_temp*. This option allows the user to override the default.

The *press* keyword is used to determine how thermodynamic pressure is calculated, which is used by all thermo quan-

tities that require a pressure ("press", "enthalpy", "pxx", etc). The specified compute ID must have been previously defined by the user via the *compute* command and it must be a style of compute that calculates a pressure. As described in the *thermo_style* command, thermo output uses a default compute for pressure with ID = *thermo_press*. This option allows the user to override the default.

Note

If both the *temp* and *press* keywords are used in a single thermo_modify command (or in two separate commands), then the order in which the keywords are specified is important. Note that a *pressure compute* defines its own temperature compute as an argument when it is specified. The *temp* keyword will override this (for the pressure compute being used by thermodynamics), but only if the *temp* keyword comes after the *press* keyword. If the *temp* keyword comes before the *press* keyword, then the new pressure compute specified by the *press* keyword will be unaffected by the *temp* setting.

The *triclinic/general* keyword can only be used with a value of *yes* if the simulation box was created as a general triclinic box. See the *Howto_triclinic* doc page for a detailed explanation of orthogonal, restricted triclinic, and general triclinic simulation boxes.

If this keyword is *yes*, the output of the simulation box edge vectors and the pressure tensor components for the system are affected. These are specified by the *avec,bvec,cvec* and *pxx,pyy,pzz,pxy,pxz,pyz* keywords of the *thermo_style* command. See the *thermo_style* doc page for details.

1.107.4 Restrictions

none

1.107.5 Related commands

thermo, *thermo_style*

1.107.6 Default

The option defaults are lost = error, warn = 100, norm = yes for unit style of *lj*, norm = no for unit style of *real* and *metal*, flush = no, temp/press = compute IDs defined by thermo_style, and triclinic/general = no.

The defaults for the line and format options depend on the thermo style. For styles "one" and "custom", the line and format defaults are "one", "%10d", and "%14.8g". For style "multi", the line and format defaults are "multi", "%14d", and "%14.4f". For style "yaml", the line and format defaults are "%d" and "%.15g".

thermo_style custom step temp etotal c_myTemp[*] v_abc
```

1.108.3 Description

Set the style and content for printing thermodynamic data to the screen and log files. The units for each column of output corresponding to the list of keywords is determined by the *units* command for the simulation. E.g. energies will be in energy units, temperature in temperature units, pressure in pressure units.

Style *one* prints a single line of thermodynamic info that is the equivalent of "thermo_style custom step temp epair emol etotal press". The line contains only numeric values.

Style *multi* prints a multiple-line listing of thermodynamic info that is the equivalent of "thermo_style custom etotal ke temp pe ebond eangle edihed eimp evdwl ecoul elong press". The listing contains numeric values and a string ID for each quantity.

Added in version 24Mar2022.

Style *yaml* is similar to style *one* but prints the output in YAML format which can be easily read by a variety of script languages and data handling packages. Since LAMMPS may print other output before, after, or in between thermodynamic output, the YAML format content needs to be separated from the rest. All YAML format thermodynamic output can be matched with a regular expression and can thus be extracted with commands like `egrep` as follows:

```
egrep  '^(keywords:|data:$|---$|\.\.\.$|  - \[)' log.lammps > log.yaml
```

Information about processing such YAML files is in the *structured data output howto*.

Style *custom* is the most general setting and allows you to specify which of the keywords listed above you want printed on each thermodynamic timestep. Note that the keywords c_ID, f_ID, v_name are references to *computes*, *fixes*, and equal-style *variables* that have been defined elsewhere in the input script or can even be new styles which users have added to LAMMPS. See the *Modify* page for details on the latter. Thus the *custom* style provides a flexible means of outputting essentially any desired quantity as a simulation proceeds.

All styles except *custom* have *vol* appended to their list of outputs if the simulation box volume changes during the simulation.

The values printed by the various keywords are instantaneous values, calculated on the current timestep. Time-averaged quantities, which include values from previous timesteps, can be output by using the f_ID keyword and accessing a fix that does time-averaging such as the *fix ave/time* command.

Options invoked by the *thermo_modify* command can be used to set the one- or multi-line format of the print-out, the normalization of thermodynamic output (total values versus per-atom values for extensive quantities (ones which scale with the number of atoms in the system), and the numeric precision of each printed value.

Note

When you use a "thermo_style" command, all thermodynamic settings are restored to their default values, including those previously set by a *thermo_modify* command. Thus if your input script specifies a thermo_style command, you should use the thermo_modify command after it.

Several of the thermodynamic quantities require a temperature to be computed: "temp", "press", "ke", "etotal", "enthalpy", "pxx", etc. By default this is done by using a *temperature* compute which is created when LAMMPS starts up, as if this command had been issued:

```
compute thermo_temp all temp
```

See the *compute temp* command for details. Note that the ID of this compute is *thermo_temp* and the group is *all*. You can change the attributes of this temperature (e.g. its degrees-of-freedom) via the *compute_modify* command. Alternatively, you can directly assign a new compute (that calculates temperature) which you have defined, to be used for calculating any thermodynamic quantity that requires a temperature. This is done via the *thermo_modify* command.

Several of the thermodynamic quantities require a pressure to be computed: "press", "enthalpy", "pxx", etc. By default this is done by using a *pressure* compute which is created when LAMMPS starts up, as if this command had been issued:

```
compute thermo_press all pressure thermo_temp
```

See the *compute pressure* command for details. Note that the ID of this compute is *thermo_press* and the group is *all*. You can change the attributes of this pressure via the *compute_modify* command. Alternatively, you can directly assign a new compute (that calculates pressure) which you have defined, to be used for calculating any thermodynamic quantity that requires a pressure. This is done via the *thermo_modify* command.

Several of the thermodynamic quantities require a potential energy to be computed: "pe", "etotal", "ebond", etc. This is done by using a *pe* compute which is created when LAMMPS starts up, as if this command had been issued:

```
compute thermo_pe all pe
```

See the *compute pe* command for details. Note that the ID of this compute is *thermo_pe* and the group is *all*. You can change the attributes of this potential energy via the *compute_modify* command.

The kinetic energy of the system *ke* is inferred from the temperature of the system with $\frac{1}{2}k_BT$ of energy for each degree of freedom. Thus, using different *compute commands* for calculating temperature, via the *thermo_modify temp* command, may yield different kinetic energies, since different computes that calculate temperature can subtract out different non-thermal components of velocity and/or include different degrees of freedom (translational, rotational, etc).

The potential energy of the system *pe* will include contributions from fixes if the *fix_modify energy yes* option is set for a fix that calculates such a contribution. For example, the *fix wall/lj93* fix calculates the energy of atoms interacting with the wall. See the doc pages for "individual fixes" to see which ones contribute and whether their default *fix_modify energy* setting is *yes* or *no*.

A long-range tail correction *etail* for the van der Waals pairwise energy will be non-zero only if the *pair_modify tail* option is turned on. The *etail* contribution is included in *evdwl*, *epair*, *pe*, and *etotal*, and the corresponding tail correction to the pressure is included in *press* and *pxx*, *pyy*, etc.

Here is more information on other keywords whose meaning may not be clear.

The *step*, *elapsed*, and *elaplong* keywords refer to timestep count. *Step* is the current timestep, or iteration count when a *minimization* is being performed. *Elapsed* is the number of timesteps elapsed since the beginning of this run. *Elaplong* is the number of timesteps elapsed since the beginning of an initial run in a series of runs. See the *start* and *stop* keywords for the *run* for info on how to invoke a series of runs that keep track of an initial starting time. If these keywords are not used, then *elapsed* and *elaplong* are the same value.

The *dt* keyword is the current timestep size in time *units*. The *time* keyword is the current elapsed simulation time, also in time *units*, which is simply (step*dt) if the timestep size has not changed and the timestep has not been reset. If the timestep has changed (e.g. via *fix dt/reset*) or the timestep has been reset (e.g. via the "reset_timestep" command), then the simulation time is effectively a cumulative value up to the current point.

The *cpu* keyword is elapsed CPU seconds since the beginning of this run. The *tpcpu* and *spcpu* keywords are measures of how fast your simulation is currently running. The *tpcpu* keyword is simulation time per CPU second, where simulation time is in time *units*. E.g. for metal units, the *tpcpu* value would be picoseconds per CPU second. The *spcpu* keyword is the number of timesteps per CPU second. Both quantities are on-the-fly metrics, measured relative to the last time they were invoked. Thus if you are printing out thermodynamic output every 100 timesteps, the two keywords will continually output the time and timestep rate for the last 100 steps. The *tpcpu* keyword does not attempt to track any changes in timestep size, e.g. due to using the *fix dt/reset* command.

The *cpuuse* keyword represents the CPU utilization in percent on MPI rank 0 for the current run. This should typically be around 100% for single-threaded runs. Smaller values indicate that LAMMPS may be stalling on file I/O, or some other process is competing with LAMMPS for the same CPU. When using multi-threading through the KOKKOS, INTEL, or OPENMP packages the value can be larger than 100% and ideally should be close to *nthreads* x 100%. How close depends on how much of the execution time is spent in multi-threaded parts of the code versus the non-accelerated parts.

The *cpuremain* keyword estimates the CPU time remaining in the current run, based on the time elapsed thus far. It will only be a good estimate if the CPU time/timestep for the rest of the run is similar to the preceding timesteps. On the initial timestep the value will be 0.0 since there is no history to estimate from. For a minimization run performed by the "minimize" command, the estimate is based on the *maxiter* parameter, assuming the minimization will proceed for the maximum number of allowed iterations.

The *part* keyword is useful for multi-replica or multi-partition simulations to indicate which partition this output and this file corresponds to, or for use in a *variable* to append to a filename for output specific to this partition. See discussion of the *-partition command-line switch* for details on running in multi-partition mode.

The *timeremain* keyword is the seconds remaining when a timeout has been configured via the *timer timeout* command. If the timeout timer is inactive, the value of this keyword is 0.0 and if the timer is expired, it is negative. This allows for example to exit loops cleanly, if the timeout is expired with:

```
if "$(timeremain) < 0.0" then "quit 0"
```

The *ecouple* keyword is cumulative energy change in the system due to any thermostatting or barostatting fixes that are being used. A positive value means that energy has been subtracted from the system (added to the coupling reservoir). See the *econserve* keyword for an explanation of why this sign choice makes sense.

The *econserve* keyword is the sum of the potential and kinetic energy of the system as well as the energy that has been transferred by thermostatting or barostatting to their coupling reservoirs – that is, *econserve* = *pe* + *ke* + *ecouple*. Ideally, for a simulation in the NVT, NPH, or NPT ensembles, the *econserve* quantity should remain constant over time even though *etotal* may change.

In LAMMPS, the simulation box can be defined as orthogonal or triclinic (non-orthogonal). See the *Howto_triclinic* doc page for a detailed explanation of orthogonal, restricted triclinic, and general triclinic simulation boxes and how LAMMPS rotates a general triclinic box to be restricted triclinic internally.

The *lx*, *ly*, *lz* keywords are the extent of the simulation box in each dimension. The *xlo*, *xhi*, *ylo*, *yhi*, *zlo*, *zhi* keywords are the lower and upper bounds of the simulation box in each dimension. I.e. *lx* = *xhi* - *xlo*). These 9 values are the same for all 3 kinds of boxes. I.e. for a restricted triclinic box, they are the values as if the box were not tilted. For a general triclinic box, they are the values after it is internally rotated to be a restricted triclinic box.

The *xy*, *xz*, *yz* are the current tilt factors for a triclinic box. They are the same for restricted and general triclinic boxes.

The *avecx*, *avecy*, *avecz*, *bvecx*, *bvecy*, *bvecz*, *cvecx*, *cvecy*, *cvecz* are the components of the 3 edge vectors of the current general simulation box. If it is an orthogonal box the vectors are along the x, y, z coordinate axes. If it is a restricted triclinic box, the **A** vector is along the x axis, the **B** vector is in the xy plane with a +y coordinate, and the **C** vector has a +z coordinate, as explained on the *Howto_triclinic* doc page. If the *thermo_modify triclinic/general* option is set then they are the **A**, **B**, **C** vector which define the general triclinic box.

The *cella*, *cellb*, *cellc*, *cellalpha*, *cellbeta*, *cellgamma* keywords correspond to the usual crystallographic quantities that define the periodic simulation box of a crystalline system. See the *Howto triclinic* page for a precise definition of these quantities in terms of the LAMMPS representation of a restricted triclinic simulation box via *lx*, *ly*, *lz*, *yz*, *xz*, *xy*.

The *pxx,pyy,pzz,pxy,pxz,pyz* keywords are the 6 components of the symmetric pressure tensor for the system. See the *compute pressure* command doc page for details of how it is calculated.

If the *thermo_modify triclinic/general* option is set then the 6 components will be output as values consistent with the orientation of the general triclinic box relative to the standard xyz coordinate axes. If this keyword is not used, the values will be consistent with the orientation of the restricted triclinic box (which aligns with the xyz coordinate axes). As explained on the *Howto_triclinic* doc page, even if the simulation box is created as a general triclinic box, internally LAMMPS uses a restricted triclinic box.

Note that because the pressure tensor components are computed using force vectors and atom coordinates, both of which are rotated in the general versus restricted triclinic representation, the values will typically be different for the two cases.

The *fmax* and *fnorm* keywords are useful for monitoring the progress of an *energy minimization*. The *fmax* keyword calculates the maximum force in any dimension on any atom in the system, or the infinity-norm of the force vector for the system. The *fnorm* keyword calculates the 2-norm or length of the force vector.

The *nbuild* and *ndanger* keywords are useful for monitoring neighbor list builds during a run. Note that both these values are also printed with the end-of-run statistics. The *nbuild* keyword is the number of re-builds during the current run. The *ndanger* keyword is the number of re-builds that LAMMPS considered potentially "dangerous". If atom movement triggered neighbor list rebuilding (see the *neigh_modify* command), then dangerous reneighborings are those that were triggered on the first timestep atom movement was checked for. If this count is non-zero you may wish to reduce the delay factor to ensure no force interactions are missed by atoms moving beyond the neighbor skin distance before a rebuild takes place.

For output values from a compute or fix or variable, the bracketed index I used to index a vector, as in *c_ID[I]* or *f_ID[I]* or *v_name[I]*, can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form "*" or "*n" or "n*" or "m*n". If N = the size of the vector, then an asterisk with no numeric values means all indices from 1 to N. A leading asterisk means all indices from 1 to n (inclusive). A trailing asterisk means all indices from n to N (inclusive). A middle asterisk means all indices from m to n (inclusive).

Using a wildcard is the same as if the individual elements of the vector had been listed one by one. E.g. these 2 thermo_style commands are equivalent, since the *compute temp* command creates a global vector with 6 values.

```
compute myTemp all temp
thermo_style custom step temp etotal c_myTemp[*]
thermo_style custom step temp etotal &
             c_myTemp[1] c_myTemp[2] c_myTemp[3] &
             c_myTemp[4] c_myTemp[5] c_myTemp[6]
```

Note

For a vector-style variable, only the wildcard forms "*n" or "m*n" are allowed. You must specify the upper bound, because vector-style variable lengths are not determined until the variable is evaluated. If n is specified larger than the vector length turns out to be, zeroes are output for missing vector values.

The *c_ID* and *c_ID[I]* and *c_ID[I][J]* keywords allow global values calculated by a compute to be output. As discussed on the *compute* doc page, computes can calculate global, per-atom, local, and per-grid values. Only global values can be referenced by this command. However, per-atom compute values for an individual atom can be referenced in a *equal-style variable* and the variable referenced by thermo_style custom, as discussed below. See the discussion above for how the I in *c_ID[I]* can be specified with a wildcard asterisk to effectively specify multiple values from a global compute vector.

The ID in the keyword should be replaced by the actual ID of a compute that has been defined elsewhere in the input script. See the *compute* command for details. If the compute calculates a global scalar, vector, or array, then the keyword formats with 0, 1, or 2 brackets will reference a scalar value from the compute.

Note that some computes calculate "intensive" global quantities like temperature; others calculate "extensive" global quantities like kinetic energy that are summed over all atoms in the compute group. Intensive quantities are printed directly without normalization by thermo_style custom. Extensive quantities may be normalized by the total number of atoms in the simulation (NOT the number of atoms in the compute group) when output, depending on the *thermo_modify norm* option being used.

The *f_ID* and *f_ID[I]* and *f_ID[I][J]* keywords allow global values calculated by a fix to be output. As discussed on the *fix* doc page, fixes can calculate global, per-atom, local, and per-grid values. Only global values can be referenced by this command. However, per-atom fix values can be referenced for an individual atom in a *equal-style variable* and the variable referenced by thermo_style custom, as discussed below. See the discussion above for how the I in *f_ID[I]* can be specified with a wildcard asterisk to effectively specify multiple values from a global fix vector.

The ID in the keyword should be replaced by the actual ID of a fix that has been defined elsewhere in the input script. See the *fix* command for details. If the fix calculates a global scalar, vector, or array, then the keyword formats with 0, 1, or 2 brackets will reference a scalar value from the fix.

Note that some fixes calculate "intensive" global quantities like timestep size; others calculate "extensive" global quantities like energy that are summed over all atoms in the fix group. Intensive quantities are printed directly without normalization by thermo_style custom. Extensive quantities may be normalized by the total number of atoms in the simulation (NOT the number of atoms in the fix group) when output, depending on the *thermo_modify norm* option being used.

The *v_name* keyword allow the current value of a variable to be output. The name in the keyword should be replaced by the variable name that has been defined elsewhere in the input script. Only equal-style and vector-style variables can be referenced; the latter requires a bracketed term to specify the Ith element of the vector calculated by the variable. However, an equal-style variable can use an atom-style variable in its formula indexed by the ID of an individual atom. This is a way to output a specific atom's per-atom coordinates or other per-atom properties in thermo output. See the *variable* command for details. Note that variables of style *equal* and *vector* and *atom* define a formula which can reference per-atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when evaluated, so this is a very general means of creating thermodynamic output.

Note that equal-style and vector-style variables are assumed to produce "intensive" global quantities, which are thus printed as-is, without normalization by thermo_style custom. You can include a division by "natoms" in the variable formula if this is not the case.

1.108.4 Restrictions

This command must come after the simulation box is defined by a *read_data*, *read_restart*, or *create_box* command.

1.108.5 Related commands

thermo, *thermo_modify*, *fix_modify*, *compute temp*, *compute pressure*

1.108.6 Default

```
thermo_style one
```

1.109 third_order command

Accelerator Variant: third_order/kk

1.109.1 Syntax

```
third_order group-ID style delta args keyword value ...
```

- group-ID = ID of group of atoms to displace
- style = *regular* or *eskm*
- delta = finite different displacement length (distance units)
- one or more keyword/arg pairs may be appended

  keyword = *file* or *binary*
    file name = name of output file for the third order tensor
    binary arg = *yes* or *no* or *gzip*

1.109.2 Examples

```
third_order 1 regular 0.000001
third_order 1 eskm 0.000001
third_order 3 regular 0.00004 file third_order.dat
third_order 5 eskm 0.00000001 file third_order.dat binary yes
```

1.109.3 Description

Calculate the third order force constant tensor by finite difference of the selected group,

$$\Phi_{ijk}^{\alpha\beta\gamma} = \frac{\partial^3 U}{\partial x_{i,\alpha} \partial x_{j,\beta} \partial x_{k,\gamma}}$$

where Phi is the third order force constant tensor.

The output of the command is the tensor, three elements at a time. The three elements correspond to the three gamma elements for a specific i/alpha/j/beta/k. The initial five numbers are i, alpha, j, beta, and k respectively.

If the style eskm is selected, the tensor will be using energy units of 10 J/mol. These units conform to eskm style from the dynamical_matrix command, which will simplify operations using dynamical matrices with third order tensors.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

1.109.4 Restrictions

The command collects a 9 times the number of atoms in the group on every single MPI rank, so the memory requirements can be very significant for large systems.

This command is part of the PHONON package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

1.110 timer command

1.110.1 Syntax

```
timer args
```

- *args* = one or more of *off* or *loop* or *normal* or *full* or *sync* or *nosync* or *timeout* or *every*

off = do not collect or print any timing information
loop = collect only the total time for the simulation loop
normal = collect timer information broken down by sections (default)
full = like *normal* but also include CPU and thread utilization
sync = explicitly synchronize MPI tasks between sections
nosync = do not synchronize MPI tasks between sections (default)
timeout elapse = set wall time limit to *elapse*
every Ncheck = perform timeout check every *Ncheck* steps

1.110.2 Examples

```
timer full sync
timer timeout 2:00:00 every 100
timer loop
```

1.110.3 Description

Select the level of detail at which LAMMPS performs its CPU timings. Multiple keywords can be specified with the *timer* command. For keywords that are mutually exclusive, the last one specified takes precedence.

During a simulation run LAMMPS collects information about how much time is spent in different sections of the code and thus can provide information for determining performance and load imbalance problems. This can be done at different levels of detail and accuracy. For more information about the timing output, see the *Run output* doc page.

The *off* setting will turn all time measurements off. The *loop* setting will only measure the total time for a run and not collect any detailed per section information. With the *normal* setting, timing information for portions of the timestep (pairwise calculations, neighbor list construction, output, etc) are collected as well as information about load imbalances for those sections across MPI processes. The *full* setting adds information about CPU utilization and thread utilization, when multi-threading is enabled.

With the *sync* setting, all MPI tasks are synchronized at each timer call which measures load imbalance for each section more accurately, though it can also slow down the simulation by prohibiting overlapping independent computations on different MPI ranks. Using the *nosync* setting (which is the default) turns this synchronization off.

With the *timeout* keyword a wall time limit can be imposed, that affects the *run* and *minimize* commands. This can be convenient when calculations have to comply with execution time limits, e.g. when running under a batch system when you want to maximize the utilization of the batch time slot, especially for runs where the time per timestep varies much and thus it becomes difficult to predict how many steps a simulation can perform for a given wall time limit. This also applies for difficult to converge minimizations. The timeout *elapse* value should be somewhat smaller than the maximum wall time requested from the batch system, as there is usually some overhead to launch jobs, and it is advisable to write out a restart after terminating a run due to a timeout.

The timeout timer starts when the command is issued. When the time limit is reached, the run or energy minimization will exit on the next step or iteration that is a multiple of the *Ncheck* value which can be set with the *every* keyword. Default is checking every 10 steps. After the timer timeout has expired all subsequent run or minimize commands in the input script will be skipped. The remaining time or timer status can be accessed with the *thermo* variable *timeremain*, which will be zero, if the timeout is inactive (default setting), it will be negative, if the timeout time is expired and positive if there is time remaining and in this case the value of the variable are the number of seconds remaining.

When the *timeout* keyword is used a second time, the timer is restarted with a new time limit. The timeout *elapse* value can be specified as *off* or *unlimited* to impose a no timeout condition (which is the default). The *elapse* setting can be specified as a single number for seconds, two numbers separated by a colon (MM:SS) for minutes and seconds, or as three numbers separated by colons for hours, minutes, and seconds (H:MM:SS).

The *every* keyword sets how frequently during a run or energy minimization the wall clock will be checked. This check count applies to the outer iterations or time steps during minimizations or *r-RESPA runs*, respectively. Checking for

timeout too often, can slow a calculation down. Checking too infrequently can make the timeout measurement less accurate, with the run being stopped later than desired.

Note

Using the *full* and *sync* options provides the most detailed and accurate timing information, but can also have a negative performance impact due to the overhead of the many required system calls. It is thus recommended to use these settings only when testing tests to identify performance bottlenecks. For calculations with few atoms or a very large number of MPI processes, even the *normal* setting can have a measurable negative performance impact. In those cases you can just use the *loop* or *off* setting.

```

1.115.3 Description

This command sets the style of units used for a simulation. It determines the units of all quantities specified in the input script and data file, as well as quantities output to the screen, log file, and dump files. Typically, this command is used at the very beginning of an input script.

For all units except *lj*, LAMMPS uses physical constants from www.physics.nist.gov. For the definition of kcal in real units, LAMMPS uses the thermochemical calorie = 4.184 J.

The choice you make for units simply sets some internal conversion factors within LAMMPS. This means that any simulation you perform for one choice of units can be duplicated with any other unit setting LAMMPS supports. In this context "duplicate" means the particles will have identical trajectories and all output generated by the simulation will be identical. This will be the case for some number of timesteps until round-off effects accumulate, since the conversion factors for two different unit systems are not identical to infinite precision.

To perform the same simulation in a different set of units you must change all the unit-based input parameters in your input script and other input files (data file, potential files, etc) correctly to the new units. And you must correctly convert all output from the new units to the old units when comparing to the original results. That is often not simple to do.

Potential or table files may have a `UNITS:` tag included in the first line indicating the unit style those files were created for. If the tag exists, its value will be compared to the chosen unit style and LAMMPS will stop with an error message if there is a mismatch. In some select cases and for specific combinations of unit styles, LAMMPS is capable of automatically converting potential parameters from a file. In those cases, a warning message signaling that an automatic conversion has happened is printed to the screen.

For style *lj*, all quantities are unitless. Without loss of generality, LAMMPS sets the fundamental quantities mass, σ, ε, and the Boltzmann constant $k_B = 1$. The masses, distances, energies you specify are multiples of these fundamental values. The formulas relating the reduced or unitless quantity (with an asterisk) to the same quantity with units is also given. Thus you can use the mass, σ, and ε values for a specific material and convert the results from a unitless LJ simulation into physical quantities. Please note that using these three properties as base, your unit of time has to conform to the relation $\varepsilon = \frac{m\sigma^2}{\tau^2}$ since energy is a derived unit (in SI units you equivalently have the relation $1\,\mathrm{J} = 1\frac{\mathrm{kg}\cdot\mathrm{m}^2}{\mathrm{s}^2}$).

- mass = mass or m, where $M^* = \frac{M}{m}$

- distance = σ, where $x^* = \frac{x}{\sigma}$
- time = τ, where $\tau^* = \tau\sqrt{\frac{\varepsilon}{m\sigma^2}}$
- energy = ε, where $E^* = \frac{E}{\varepsilon}$
- velocity = $\frac{\sigma}{\tau}$, where $v^* = v\frac{\tau}{\sigma}$
- force = $\frac{\varepsilon}{\sigma}$, where $f^* = f\frac{\sigma}{\varepsilon}$
- torque = ε, where $t^* = \frac{t}{\varepsilon}$
- temperature = reduced LJ temperature, where $T^* = \frac{Tk_B}{\varepsilon}$
- pressure = reduced LJ pressure, where $p^* = p\frac{\sigma^3}{\varepsilon}$
- dynamic viscosity = reduced LJ viscosity, where $\eta^* = \eta\frac{\sigma^3}{\varepsilon\tau}$
- charge = reduced LJ charge, where $q^* = q\frac{1}{\sqrt{4\pi\varepsilon_0\sigma\varepsilon}}$
- dipole = reduced LJ dipole, moment where $\mu^* = \mu\frac{1}{\sqrt{4\pi\varepsilon_0\sigma^3\varepsilon}}$
- electric field = force/charge, where $E^* = E\frac{\sqrt{4\pi\varepsilon_0\sigma\varepsilon}\sigma}{\varepsilon}$
- density = mass/volume, where $\rho^* = \rho\frac{\sigma^{dim}}{m}$

Note that for LJ units, the default mode of thermodynamic output via the *thermo_style* command is to normalize all extensive quantities by the number of atoms. E.g. potential energy is extensive because it is summed over atoms, so it is output as energy/atom. Temperature is intensive since it is already normalized by the number of atoms, so it is output as-is. This behavior can be changed via the *thermo_modify norm* command.

For style *real*, these are the units:

- mass = grams/mole
- distance = Angstroms
- time = femtoseconds
- energy = kcal/mol
- velocity = Angstroms/femtosecond
- force = (kcal/mol)/Angstrom
- torque = kcal/mol
- temperature = Kelvin
- pressure = atmospheres
- dynamic viscosity = Poise
- charge = multiple of electron charge (1.0 is a proton)
- dipole = charge*Angstroms
- electric field = volts/Angstrom
- density = g/cm^dim

For style *metal*, these are the units:

- mass = grams/mole
- distance = Angstroms

- time = picoseconds
- energy = eV
- velocity = Angstroms/picosecond
- force = eV/Angstrom
- torque = eV
- temperature = Kelvin
- pressure = bars
- dynamic viscosity = Poise
- charge = multiple of electron charge (1.0 is a proton)
- dipole = charge*Angstroms
- electric field = volts/Angstrom
- density = gram/cm^dim

For style *si*, these are the units:

- mass = kilograms
- distance = meters
- time = seconds
- energy = Joules
- velocity = meters/second
- force = Newtons
- torque = Newton-meters
- temperature = Kelvin
- pressure = Pascals
- dynamic viscosity = Pascal*second
- charge = Coulombs (1.6021765e-19 is a proton)
- dipole = Coulombs*meters
- electric field = volts/meter
- density = kilograms/meter^dim

For style *cgs*, these are the units:

- mass = grams
- distance = centimeters
- time = seconds
- energy = ergs
- velocity = centimeters/second
- force = dynes
- torque = dyne-centimeters
- temperature = Kelvin

- pressure = dyne/cm^2 or barye = 1.0e-6 bars
- dynamic viscosity = Poise
- charge = statcoulombs or esu (4.8032044e-10 is a proton)
- dipole = statcoul-cm = 10^18 debye
- electric field = statvolt/cm or dyne/esu
- density = grams/cm^dim

For style *electron*, these are the units:

- mass = atomic mass units
- distance = Bohr
- time = femtoseconds
- energy = Hartrees
- velocity = Bohr/atomic time units [1.03275e-15 seconds]
- force = Hartrees/Bohr
- temperature = Kelvin
- pressure = Pascals
- charge = multiple of electron charge (1.0 is a proton)
- dipole moment = Debye
- electric field = volts/cm

For style *micro*, these are the units:

- mass = picograms
- distance = micrometers
- time = microseconds
- energy = picogram-micrometer^2/microsecond^2
- velocity = micrometers/microsecond
- force = picogram-micrometer/microsecond^2
- torque = picogram-micrometer^2/microsecond^2
- temperature = Kelvin
- pressure = picogram/(micrometer-microsecond^2)
- dynamic viscosity = picogram/(micrometer-microsecond)
- charge = picocoulombs (1.6021765e-7 is a proton)
- dipole = picocoulomb-micrometer
- electric field = volt/micrometer
- density = picograms/micrometer^dim

For style *nano*, these are the units:

- mass = attograms
- distance = nanometers

- time = nanoseconds
- energy = attogram-nanometer^2/nanosecond^2
- velocity = nanometers/nanosecond
- force = attogram-nanometer/nanosecond^2
- torque = attogram-nanometer^2/nanosecond^2
- temperature = Kelvin
- pressure = attogram/(nanometer-nanosecond^2)
- dynamic viscosity = attogram/(nanometer-nanosecond)
- charge = multiple of electron charge (1.0 is a proton)
- dipole = charge-nanometer
- electric field = volt/nanometer
- density = attograms/nanometer^dim

The units command also sets the timestep size and neighbor skin distance to default values for each style:

- For style *lj* these are dt = 0.005 τ and skin = 0.3 σ.
- For style *real* these are dt = 1.0 femtoseconds and skin = 2.0 Angstroms.
- For style *metal* these are dt = 0.001 picoseconds and skin = 2.0 Angstroms.
- For style *si* these are dt = 1.0e-8 seconds and skin = 0.001 meters.
- For style *cgs* these are dt = 1.0e-8 seconds and skin = 0.1 centimeters.
- For style *electron* these are dt = 0.001 femtoseconds and skin = 2.0 Bohr.
- For style *micro* these are dt = 2.0 microseconds and skin = 0.1 micrometers.
- For style *nano* these are dt = 0.00045 nanoseconds and skin = 0.1 nanometers.

1.116.2 Examples

```
variable x index run1 run2 run3 run4 run5 run6 run7 run8
variable LoopVar loop $n
variable beta equal temp/3.0
variable b1 equal x[234]+0.5*vol
variable b1 equal "x[234] + 0.5*vol"
variable b equal xcm(mol1,x)/2.0
variable b equal c_myTemp
variable b atom x*y/vol
variable foo string myfile
variable foo internal 3.5
variable myPy python increase
variable f file values.txt
variable temp world 300.0 310.0 320.0 ${Tfinal}
variable x universe 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15
variable x uloop 15 pad
variable str format x %.6g
variable myvec vector [1,3,7,10]
variable x delete
```

```
variable start timer
other commands
variable stop timer
print "Elapsed time: $(v_stop-v_start:%.6f)"
```

1.116.3 Description

This command assigns one or more strings to a variable name for evaluation later in the input script or during a simulation.

Variables can thus be useful in several contexts. A variable can be defined and then referenced elsewhere in an input script to become part of a new input command. For variable styles that store multiple strings, the *next* command can be used to increment which string is assigned to the variable. Variables of style *equal* store a formula which when evaluated produces a single numeric value which can be output either directly (see the *print*, *fix print*, and *run every* commands) or as part of thermodynamic output (see the *thermo_style* command), or used as input to an averaging fix (see the *fix ave/time* command). Variables of style *vector* store a formula which produces a vector of such values which can be used as input to various averaging fixes, or elements of which can be part of thermodynamic output.

Variables of style *atom* store a formula which when evaluated produces one numeric value per atom which can be output to a dump file (see the *dump custom* command) or used as input to an averaging fix (see the *fix ave/chunk* and *fix ave/atom* commands). Variables of style *atomfile* can be used anywhere in an input script that atom-style variables are used; they get their per-atom values from a file rather than from a formula.

Variables of style *python* can be hooked to Python functions using Python code you provide, so that the variable gets its value from the evaluation of the Python code. Variables of style *internal* are used by a few commands which set their value directly.

Note

As discussed on the *Commands parse* doc page, an input script can use "immediate" variables, specified as $(formula) with parenthesis, where the numeric formula has the same syntax as equal-style variables described on this page. This is a convenient way to evaluate a formula immediately without using the variable command to define a named variable and then evaluate that variable. The formula can include a trailing colon and format string which determines the precision with which the numeric value is generated. This is also explained on the *Commands parse* doc page.

In the discussion that follows, the "name" of the variable is the arbitrary string that is the first argument in the variable command. This name can only contain alphanumeric characters and underscores. The "string" is one or more of the subsequent arguments. The "string" can be simple text as in the first example above, it can contain other variables as in the second example, or it can be a formula as in the third example. The "value" is the numeric quantity resulting from evaluation of the string. Note that the same string can generate different values when it is evaluated at different times during a simulation.

Note

When an input script line is encountered that defines a variable of style *equal* or *vector* or *atom* or *python* that contains a formula or links to Python code, the formula or Python code is NOT immediately evaluated. Instead, it is evaluated each time the variable is **used**. If you simply want to evaluate a formula in place you can use a so-called immediate variable. as described in the preceding note. Or see the section below about "Immediate Evaluation of Variables" for more details on the topic. This is also true of a *format* style variable since it evaluates another variable when it is invoked.

Variables of style *equal* and *vector* and *atom* can be used as inputs to various other commands which evaluate their formulas as needed, e.g. at different timesteps during a *run*. In this context, variables of style *timer* or *internal* or *python* can be used in place of an equal-style variable, with the following two caveats.

First, internal-style variables require their values be set by code elsewhere in LAMMPS. When a LAMMPS input script or command evaluates an internal-style variable, it must have a current value set (internally) via that mechanism. Second, python-style variables can be used so long as the associated Python function, as defined by the *python* command,

returns a numeric value. When the LAMMPS command evaluates the python-style variable, the Python function will be executed.

Note

When a variable command is encountered in the input script and the variable name has already been specified, the command is ignored. This means variables can NOT be re-defined in an input script (with two exceptions, read further). This is to allow an input script to be processed multiple times without resetting the variables; see the *jump* or *include* commands. It also means that using the *command-line switch* -var will override a corresponding index variable setting in the input script.

There are two exceptions to this rule. First, variables of style *string*, *getenv*, *internal*, *equal*, *vector*, *atom*, and *python* ARE redefined each time the command is encountered. This allows these style of variables to be redefined multiple times in an input script. In a loop, this means the formula associated with an *equal* or *atom* style variable can change if it contains a substitution for another variable, e.g. $x or v_x.

Second, as described below, if a variable is iterated on to the end of its list of strings via the *next* command, it is removed from the list of active variables, and is thus available to be re-defined in a subsequent variable command. The *delete* style does the same thing.

Changed in version 4Jul2026.

Auto-deleted variables can lead to problems

Special care must be taken when iterated variables, e.g. file style variables are exhausted and thus get deleted **during** a run. For performance reasons, many features in LAMMPS cache how variables are looked up during a run or minimization for the duration of that run or minimization and this can lead to unexpected behavior when variables get auto-deleted. Evaluating a deleted variable returns 0.0 instead of creating an error for practical reasons. But LAMMPS prints a warning when a file or atomfile style variable is exhausted and auto-deleted. This can be avoided by making certain that those variables have additional elements. This condition is rare, but hard to debug, so make certain that when you see the warning about an auto-deleted variable, that this is the intended behavior.

Variables are **not** deleted by the *clear* command with the exception of atomfile-style variables.

The *Commands parse* page explains how occurrences of a variable name in an input script line are replaced by the variable's string. The variable name can be referenced as $x if the name "x" is a single character, or as ${LoopVar} if the name "LoopVar" is one or more characters.

As described below, for variable styles *index*, *loop*, *file*, *universe*, and *uloop*, which string is assigned to a variable can be incremented via the *next* command. When there are no more strings to assign, the variable is exhausted and a flag is set that causes the next *jump* command encountered in the input script to be skipped. This enables the construction of simple loops in the input script that are iterated over and then exited from.

As explained above, an exhausted variable can be reused in an input script. The *delete* style also removes the variable, the same as if it were exhausted, allowing it to be redefined later in the input script or when the input script is looped over. This can be useful when breaking out of a loop via the *if* and *jump* commands before the variable would become exhausted. For example,

```
label       loop
variable    a loop 5
print       "A = $a"
if          "$a > 2" then "jump in.script break"
```

(continues on next page)

(continued from previous page)

```
next        a
jump        in.script loop
label       break
variable    a delete
```

The next sections describe in how all the various variable styles are defined and what they store. The styles are listed alphabetically, except for the *equal* and *vector* and *atom* styles, which are explained together after all the others.

Many of the styles store one or more strings. Note that a single string can contain spaces (multiple words), if it is enclosed in quotes in the variable command. When the variable is substituted for in another input script command, its returned string will then be interpreted as multiple arguments in the expanded command.

For the *atomfile* style, a filename is provided which contains one or more sets of values, to assign on a per-atom basis to the variable. The format of the file is described below.

When an atomfile-style variable is defined, the file is opened and the first set of per-atom values are read and stored with the variable. This means the variable can then be evaluated as many times as desired and will return those values. There are two ways to cause the next set of per-atom values from the file to be read: use the *next* command or the next() function in an atom-style variable, as discussed below. Unlike most variable styles, which remain defined, atomfile-style variables are **deleted** during a *clear* command.

The rules for formatting the file are as follows. Each time a set of per-atom values is read, a non-blank line is searched for in the file. The file is read line by line but only up to 254 characters are used. The rest are ignored. A comment character "#" can be used anywhere on a line and all text following and the "#" character are ignored; text starting with the comment character is stripped. Blank lines are skipped. The first non-blank line is expected to contain a single integer number as the count N of per-atom lines to follow. N can be the total number of atoms in the system or less, indicating that data for a subset is read. The next N lines must consist of two numbers, the atom-ID of the atom for which a value is set followed by a floating point number with the value. The atom-IDs may be listed in any order.

Note

Every time a set of per-atom lines is read, the value of the atomfile variable for **all** atoms is first initialized to 0.0. Thus values for atoms whose ID do not appear in the set in the file will remain at 0.0.

Below is a small example for the atomfile variable file format:

```
# first set
4
# atom-ID value
3 1
4 -4
1 0.5
2 -0.5

# second set
2

2  1.0
4 -1.0
```

For the *file* style, a filename is provided which contains a list of strings to assign to the variable, one per line. The strings can be numeric values if desired. See the discussion of the next() function below for equal-style variables, which will convert the string of a file-style variable into a numeric value in a formula.

When a file-style variable is defined, the file is opened and the string on the first line is read and stored with the variable. This means the variable can then be evaluated as many times as desired and will return that string. There are two ways to cause the next string from the file to be read: use the *next* command or the next() function in an equal- or atom-style variable, as discussed below.

The rules for formatting the file are as follows. A comment character "#" can be used anywhere on a line; text starting with the comment character is stripped. Blank lines are skipped. The first "word" of a non-blank line, delimited by white-space, is the "string" assigned to the variable.

For the *format* style, an equal-style or compatible variable is specified along with a C-style format string, e.g. "%f" or "%.10g", which must be appropriate for formatting a double-precision floating-point value. The default format is "%.15g". This variable style allows an equal-style variable to be formatted precisely when it is evaluated.

Changed in version 2Sep2026.

A conversion in the format string must match a floating-point value. The string may now also contain additional text and use all flags and modifiers supported by the C library, e.g. "%+12.6e" or "<%.4f>", which were previously rejected.

Note that if you simply wish to print a variable value with desired precision to the screen or logfile via the *print* or *fix print* commands, you can also do this by specifying an "immediate" variable with a trailing colon and format string, as part of the string argument of those commands. This is explained on the *Commands parse* doc page.

For the *getenv* style, a single string is assigned to the variable which should be the name of an environment variable. When the variable is evaluated, it returns the value of the environment variable, or an empty string if it not defined. This style of variable can be used to adapt the behavior of LAMMPS input scripts via environment variable settings, or to retrieve information that has been previously stored with the *shell putenv* command. Note that because environment variable settings are stored by the operating systems, they persist even if the corresponding *getenv* style variable is deleted, and also are set for sub-shells executed by the *shell* command.

For the *index* style, one or more strings are specified. Initially, the first string is assigned to the variable. Each time a *next* command is used with the variable name, the next string is assigned. All MPI processes assign the same string to the variable.

Index-style variables with a single string value can also be set by using the *command-line switch -var*.

For the *internal* style a numeric value is provided. This value will be assigned to the variable until a LAMMPS command sets it to a new value.

Note however, that most commands which use internal-style variables do not require them to be defined in the input script. They create one or more internal-style variables if they do not already exist. Examples are these commands:

- *create_atoms*
- *fix deposit*
- *compute bond/local*
- *compute angle/local*

- *compute dihedral/local*
- *python* command in conjunction with Python function wrappers used in equal- and atom-style variable formulas

A command which does require an internal-style variable to be defined in the input script is the *fix controller* command, because another (arbitrary) command typically also references the variable.

The *loop* style is identical to the *index* style except that the strings are the integers from 1 to N inclusive, if only one argument N is specified. This allows generation of a long list of runs (e.g. 1000) without having to list N strings in the input script. Initially, the string "1" is assigned to the variable. Each time a *next* command is used with the variable name, the next string ("2", "3", etc) is assigned. All MPI processes assign the same string to the variable. The *loop* style can also be specified with two arguments N1 and N2. In this case the loop runs from N1 to N2 inclusive, and the string N1 is initially assigned to the variable. N1 <= N2 and N2 >= 0 is required.

For the *python* style a Python function name is provided. This needs to match a function name specified in a *python* command which returns a value to this variable as defined by its *return* keyword. For example these two commands would be self-consistent:

```
variable foo python myMultiply
python myMultiply return v_foo format f file funcs.py
```

The two commands can appear in either order so long as both are specified before the Python function is invoked for the first time.

Each time the variable is evaluated, the associated Python function is invoked, and the value it returns is also returned by the variable. Since the Python function can use other LAMMPS variables as input, or query internal LAMMPS quantities to perform its computation, this means the variable can return a different value each time it is evaluated.

The type of value stored in the variable is determined by the *format* keyword of the *python* command. It can be an integer (i), floating point (f), or string (s) value. As mentioned above, if it is a numeric value (integer or floating point), then the python-style variable can be used in place of an equal-style variable anywhere in an input script, e.g. as an argument to another command that allows for equal-style variables.

A python-style variable can also be used within the formula for an equal-style or atom-style formula in a Python function wrapper, as explained below for variable formulas. In this context, the usage syntax is py_varname(arg1,arg2,...), where varname is the name of the python-style variable. When a Python wrapper function is used in an atom-style formula, it can be invoked once per atom using arguments specific to each atom. The resulting values in the atom-style variable can thus be calculated by Python code.

For the *string* style, a single string is assigned to the variable. Two differences between this style and using the *index* style exist: a variable with *string* style can be redefined, e.g. by another command later in the input script, or if the script is read again in a loop. The other difference is that *string* performs variable substitution even if the string parameter is quoted.

The *uloop* style is identical to the *universe* style except that the strings are the integers from 1 to N. This allows generation of long list of runs (e.g. 1000) without having to list N strings in the input script.

For the *universe* style, one or more strings are specified. There must be at least as many strings as there are processor partitions or "worlds". LAMMPS can be run with multiple partitions via the *-partition command-line switch*. This variable command initially assigns one string to each world. When a *next* command is encountered using this variable, the first processor partition to encounter it, is assigned the next available string. This continues until all the variable

strings are consumed. Thus, this command can be used to run 50 simulations on 8 processor partitions. The simulations will be run one after the other on whatever partition becomes available, until they are all finished. Universe-style variables are incremented using the files "tmp.lammps.variable" and "tmp.lammps.variable.lock" which you will see in your directory during such a LAMMPS run.

For the *world* style, one or more strings are specified. There must be one string for each processor partition or "world". LAMMPS can be run with multiple partitions via the *-partition command-line switch*. This variable command assigns one string to each world. All MPI processes in the world are assigned the same string. The next command cannot be used with equal-style variables, since there is only one value per world. This style of variable is useful when you wish to run different simulations on different partitions, or when performing a parallel tempering simulation (see the *temper* command), to assign different temperatures to different partitions.

For the *equal* and *vector* and *atom* styles, a single string is specified which represents a formula that will be evaluated afresh each time the variable is used. If you want spaces in the string, enclose it in double quotes so the parser will treat it as a single argument. For *equal*-style variables the formula computes a scalar quantity, which becomes the value of the variable whenever it is evaluated. For *vector*-style variables the formula must compute a vector of quantities, which becomes the value of the variable whenever it is evaluated. The calculated vector can be of length one, but it cannot be a simple scalar value like that produced by an equal-style compute. I.e. the formula for a vector-style variable must have at least one quantity in it that refers to a global vector produced by a compute, fix, or other vector-style variable. For *atom*-style variables the formula computes one quantity for each atom whenever it is evaluated.

Note that *equal*, *vector*, and *atom* variables can produce different values at different stages of the input script or at different times during a run. For example, if an *equal* variable is used in a *fix print* command, different values could be printed each timestep it was invoked. If you want a variable to be evaluated immediately, so that the result is stored by the variable instead of the string, see the section below on "Immediate Evaluation of Variables".

The next command cannot be used with *equal* or *vector* or *atom* style variables, since there is only one string.

The formula for an *equal*, *vector*, or *atom* variable can contain a variety of quantities. The syntax for each kind of quantity is simple, but multiple quantities can be nested and combined in various ways to build up formulas of arbitrary complexity. For example, this is a valid (though strange) variable formula:

```
variable x equal "pe + c_MyTemp / vol^(1/3)"
```

Specifically, a formula can contain numbers, constants, thermo keywords, math operators, math functions, group functions, region functions, special functions, feature functions, Python function wrappers, atom values, atom vectors, custom atom properties, compute references, fix references, and references to other variables.

Number	0.2, 100, 1.0e20, -15.4, etc
Constant	PI, version, on, off, true, false, yes, no
Thermo keywords	vol, pe, ebond, etc
Math operators	(), -x, x+y, x-y, x*y, x/y, x^y, x%y, x == y, x != y, x < y, x <= y, x > y, x >= y, x && y, x || y, x |^ y, !x
Math functions	sqrt(x), exp(x), ln(x), log(x), abs(x), sign(x), sin(x), cos(x), tan(x), asin(x), acos(x), atan(x), atan2(y,x), random(x,y,z), normal(x,y,z), ceil(x), floor(x), round(x), ternary(x,y,z), ramp(x,y), stagger(x,y), logfreq(x,y,z), logfreq2(x,y,z), logfreq3(x,y,z), stride(x,y,z), stride2(x,y,z,a,b,c), vdisplace(x,y), swiggle(x,y,z), cwiggle(x,y,z)
Group functions	count(ID), mass(ID), charge(ID), xcm(ID,dim), vcm(ID,dim), fcm(ID,dim), bound(ID,dir), gyration(ID), ke(ID), angmom(ID,dim), torque(ID,dim), inertia(ID,dimdim), omega(ID,dim)
Region functions	count(ID,IDR), mass(ID,IDR), charge(ID,IDR), xcm(ID,dim,IDR), vcm(ID,dim,IDR), fcm(ID,dim,IDR), bound(ID,dir,IDR), gyration(ID,IDR), ke(ID,IDR), angmom(ID,dim,IDR), torque(ID,dim,IDR), inertia(ID,dimdim,IDR), omega(ID,dim,IDR)
Special functions	sum(x), min(x), max(x), ave(x), trap(x), slope(x), sort(x), rsort(x), gmask(x), rmask(x), grmask(x,y), next(x), is_file(name), is_os(name), extract_setting(name), label2type(kind,label), is_typelabel(kind,label), is_timeout()
Feature functions	is_available(category,feature), is_active(category,feature), is_defined(category,id)
Python func wrapper	py_varname(x,y,z,...)
Atom values	id[i], mass[i], type[i], mol[i], x[i], y[i], z[i], vx[i], vy[i], vz[i], fx[i], fy[i], fz[i], q[i]
Atom vectors	id, mass, type, mol, x, y, z, vx, vy, vz, fx, fy, fz, q
Custom atom properties	i_name, d_name, i_name[i], d_name[i], i2_name[i], d2_name[i], i2_name[i][j], d_name[i][j]
Compute references	c_ID, c_ID[i], c_ID[i][j], C_ID, C_ID[i]
Fix references	f_ID, f_ID[i], f_ID[i][j], F_ID, F_ID[i]
Other variables	v_name, v_name[i]

Most of the formula elements produce a scalar value. Some produce a global or per-atom vector of values. Global vectors can be produced by computes or fixes or by other vector-style variables. Per-atom vectors are produced by atom vectors, computes or fixes which output a per-atom vector or array, and variables that are atom-style variables. Math functions that operate on scalar values produce a scalar value; math function that operate on global or per-atom vectors

do so element-by-element and produce a global or per-atom vector.

A formula for equal-style variables cannot use any formula element that produces a global or per-atom vector. A formula for a vector-style variable can use formula elements that produce either a scalar value or a global vector value, but cannot use a formula element that produces a per-atom vector. A formula for an atom-style variable can use formula elements that produce either a scalar value or a per-atom vector, but not one that produces a global vector.

Atom-style variables are evaluated by other commands that define a *group* on which they operate, e.g. a *dump* or *compute* or *fix* command. When they invoke the atom-style variable, only atoms in the group are included in the formula evaluation. The variable evaluates to 0.0 for atoms not in the group.

Numbers, constants, and thermo keywords

Numbers can contain digits, scientific notation (3.0e20,3.0e-20,3.0E20,3.0E-20), and leading minus signs.

Constants are set at compile time and cannot be changed. *PI* will return the number 3.14159265358979323846; *on*, *true* or *yes* will return 1.0; *off*, *false* or *no* will return 0.0; *version* will return a numeric version code of the current LAMMPS version (e.g. version 2 Sep 2015 will return the number 20150902). The corresponding value for newer versions of LAMMPS will be larger, for older versions of LAMMPS will be smaller. This can be used to have input scripts adapt automatically to LAMMPS versions, when non-backwards compatible syntax changes are introduced. Here is an illustrative example (which will not work, since the *version* has been introduced more recently):

```
if $(version<20140513) then "communicate vel yes" else "comm_modify vel yes"
```

The thermo keywords allowed in a formula are those defined by the *thermo_style custom* command. Thermo keywords that require a *compute* to calculate their values such as "temp" or "press", use computes stored and invoked by the *thermo_style* command. This means that you can only use those keywords in a variable if the style you are using with the thermo_style command (and the thermo keywords associated with that style) also define and use the needed compute. Note that some thermo keywords use a compute indirectly to calculate their value (e.g. the enthalpy keyword uses temp, pe, and pressure). If a variable is evaluated directly in an input script (not during a run), then the values accessed by the thermo keyword must be current. See the discussion below about "Variable Accuracy".

Math Operators

Math operators are written in the usual way, where the "x" and "y" in the examples can themselves be arbitrarily complex formulas, as in the examples above. In this syntax, "x" and "y" can be scalar values or per-atom vectors. For example, "ke/natoms" is the division of two scalars, where "vy+vz" is the element-by-element sum of two per-atom vectors of y and z velocities.

Operators are evaluated left to right and have the usual C-style precedence: unary minus and unary logical NOT operator "!" have the highest precedence, exponentiation "^" is next; multiplication and division and the modulo operator "%" are next; addition and subtraction are next; the 4 relational operators "<", "<=", ">", and ">=" are next; the two remaining relational operators "==" and "!=" are next; then the logical AND operator "&&"; and finally the logical OR operator "||" and logical XOR (exclusive or) operator "|^" have the lowest precedence. Parenthesis can be used to group one or more portions of a formula and/or enforce a different order of evaluation than what would occur with the default precedence.

Note

Because a unary minus is higher precedence than exponentiation, the formula "-2^2" will evaluate to 4, not -4. This convention is compatible with some programming languages, but not others. As mentioned, this behavior can be easily overridden with parenthesis; the formula "-(2^2)" will evaluate to -4.

The 6 relational operators return either a 1.0 or 0.0 depending on whether the relationship between x and y is TRUE or FALSE. For example the expression x<10.0 in an atom-style variable formula will return 1.0 for all atoms whose x-coordinate is less than 10.0, and 0.0 for the others. The logical AND operator will return 1.0 if both its arguments are non-zero, else it returns 0.0. The logical OR operator will return 1.0 if either of its arguments is non-zero, else it returns 0.0. The logical XOR operator will return 1.0 if one of its arguments is zero and the other non-zero, else it returns 0.0. The logical NOT operator returns 1.0 if its argument is 0.0, else it returns 0.0.

These relational and logical operators can be used as a masking or selection operation in a formula. For example, the number of atoms whose properties satisfy one or more criteria could be calculated by taking the returned per-atom vector of ones and zeroes and passing it to the *compute reduce* command.

Math Functions

Math functions are specified as keywords followed by one or more parenthesized arguments "x", "y", "z", each of which can themselves be arbitrarily complex formulas. In this syntax, the arguments can represent scalar values or global vectors or per-atom vectors. In the latter case, the math operation is performed on each element of the vector. For example, "sqrt(natoms)" is the sqrt() of a scalar, where "sqrt(y*z)" yields a per-atom vector with each element being the sqrt() of the product of one atom's y and z coordinates.

Most of the math functions perform obvious operations. The ln() is the natural log; log() is the base 10 log.

Added in version 4Feb2025.

The sign(x) function returns 1.0 if the value is greater than or equal to 0.0, and -1.0 otherwise.

The random(x,y,z) function takes 3 arguments: x = lo, y = hi, and z = seed. It generates a uniform random number between lo and hi. The normal(x,y,z) function also takes 3 arguments: x = mu, y = sigma, and z = seed. It generates a Gaussian variate centered on mu with variance sigma^2. In both cases the seed is used the first time the internal random number generator is invoked, to initialize it. For equal-style and vector-style variables, every processor uses the same seed so that they each generate the same sequence of random numbers. For atom-style variables, a unique seed is created for each processor, based on the specified seed. This effectively generates a different random number for each atom being looped over in the atom-style variable.

Note

Internally, there is just one random number generator for all equal-style and vector-style variables and another one for all atom-style variables. If you define multiple variables (of each style) which use the random() or normal() math functions, then the internal random number generators will only be initialized once, which means only one of the specified seeds will determine the sequence of generated random numbers.

The ceil(), floor(), and round() functions are those in the C math library. Ceil() is the smallest integer not less than its argument. Floor() if the largest integer not greater than its argument. Round() is the nearest integer to its argument.

Added in version 7Feb2024.

Changed in version 22Jul2025: Evaluate only selected argument

The ternary(x,y,z) function is the equivalent of the ternary operator (? and :) in C or C++. It takes 3 arguments. The first argument is a conditional. The result of the function is y if x evaluates to true (non-zero). The result is z if x

evaluates to false (zero). Same as in C or C++ only the selected argument y or z is evaluated, so this function can be used to protect against crashes from evaluating invalid arguments, e.g. in the following example where "qval" is a variable with an expression that may become (slightly) negative due to floating-point math limitations.:

```
variable sqrtofqval equal "ternary(v_qval >= 0, sqrt(v_qval), 0.0)"
```

The ramp(x,y) function uses the current timestep to generate a value linearly interpolated between the specified x,y values over the course of a run, according to this formula:

```
value = x + (y-x) * (timestep-startstep) / (stopstep-startstep)
```

The run begins on startstep and ends on stopstep. Startstep and stopstep can span multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this. If called in between runs or during a *run 0* command, the ramp(x,y) function will return the value of x.

The stagger(x,y) function uses the current timestep to generate a new timestep. X,y > 0 and x > y are required. The generated timesteps increase in a staggered fashion, as the sequence x,x+y,2x,2x+y,3x,3x+y,etc. For any current timestep, the next timestep in the sequence is returned. Thus if stagger(1000,100) is used in a variable by the *dump_modify every* command, it will generate the sequence of output timesteps:

```
100,1000,1100,2000,2100,3000,etc
```

The logfreq(x,y,z) function uses the current timestep to generate a new timestep. X,y,z > 0 and y < z are required. The generated timesteps are on a base-z logarithmic scale, starting with x, and the y value is how many of the z-1 possible timesteps within one logarithmic interval are generated. I.e. the timesteps follow the sequence x,2x,3x,...y*x,x*z,2x*z,3x*z,...y*x*z,x*z^2,2x*z^2,etc. For any current timestep, the next timestep in the sequence is returned. Thus if logfreq(100,4,10) is used in a variable by the *dump_modify every* command, it will generate this sequence of output timesteps:

```
100,200,300,400,1000,2000,3000,4000,10000,20000,etc
```

The logfreq2(x,y,z) function is similar to logfreq, except a single logarithmic interval is divided into y equally-spaced timesteps and all of them are output. Y < z is not required. Thus, if logfreq2(100,18,10) is used in a variable by the *dump_modify every* command, then the interval between 100 and 1000 is divided as 900/18 = 50 steps, and it will generate the sequence of output timesteps:

```
100,150,200,...950,1000,1500,2000,...9500,10000,15000,etc
```

The logfreq3(x,y,z) function generates y points between x and z (inclusive), that are separated by a multiplicative ratio: (z/x)^(1/(y-1)). Constraints are: x,z > 0, y > 1, z-x >= y-1. For eg., if logfreq3(10,25,1000) is used in a variable by the *fix print* command, then the interval between 10 and 1000 is divided into 24 parts with a multiplicative separation of ~1.21, and it will generate the following sequence of output timesteps:

```
10, 13, 15, 18, 22, 27, 32,...384, 465, 563, 682, 826, 1000
```

The stride(x,y,z) function uses the current timestep to generate a new timestep. X,y >= 0 and z > 0 and x <= y are required. The generated timesteps increase in increments of z, from x to y, i.e. it generates the sequence x,x+z,x+2z,...,y. If y-x is not a multiple of z, then similar to the way a for loop operates, the last value will be one that does not exceed y. For any current timestep, the next timestep in the sequence is returned. Thus if stride(1000,2000,100) is used in a variable by the *dump_modify every* command, it will generate the sequence of output timesteps:

```
1000,1100,1200, ... ,1900,2000
```

The stride2(x,y,z,a,b,c) function is similar to the stride() function except it generates two sets of strided timesteps, one at a coarser level and one at a finer level. Thus it is useful for debugging, e.g. to produce output every timestep at the point in simulation when a problem occurs. X,y >= 0 and z > 0 and x <= y are required, as are a,b >= 0 and c > 0 and a < b. Also, a >= x and b <= y are required so that the second stride is inside the first. The generated timesteps increase

in increments of z, starting at x, until a is reached. At that point the timestep increases in increments of c, from a to b, then after b, increments by z are resumed until y is reached. For any current timestep, the next timestep in the sequence is returned. Thus if stride2(1000,2000,100,1350,1360,1) is used in a variable by the *dump_modify every* command, it will generate the sequence of output timesteps:

```
1000,1100,1200,1300,1350,1351,1352, ... 1359,1360,1400,1500, ... ,2000
```

The vdisplace(x,y) function takes 2 arguments: x = value0 and y = velocity, and uses the elapsed time to change the value by a linear displacement due to the applied velocity over the course of a run, according to this formula:

```
value = value0 + velocity*(timestep-startstep)*dt
```

where dt = the timestep size.

The run begins on startstep. Startstep can span multiple runs, using the *start* keyword of the *run* command. See the *run* command for details of how to do this. Note that the *thermo_style* keyword elaplong = timestep-startstep. If used between runs this function will return the value according to the end of the last run or the value of x if used before *any* runs. This function assumes the length of the time step does not change and thus may not be used in combination with *fix dt/reset*.

The swiggle(x,y,z) and cwiggle(x,y,z) functions each take 3 arguments: x = value0, y = amplitude, z = period. They use the elapsed time to oscillate the value by a sin() or cos() function over the course of a run, according to one of these formulas, where omega = 2 PI / period:

```
value = value0 + Amplitude * sin(omega*(timestep-startstep)*dt)
value = value0 + Amplitude * (1 - cos(omega*(timestep-startstep)*dt))
```

where dt = the timestep size.

The run begins on startstep. Startstep can span multiple runs, using the *start* keyword of the *run* command. See the *run* command for details of how to do this. Note that the *thermo_style* keyword elaplong = timestep-startstep. If used between runs these functions will return the value according to the end of the last run or the value of x if used before *any* runs. These functions assume the length of the time step does not change and thus may not be used in combination with *fix dt/reset*.

Group and Region Functions

Group functions are specified as keywords followed by one or two parenthesized arguments. The first argument *ID* is the group-ID. The *dim* argument, if it exists, is *x* or *y* or *z*. The *dir* argument, if it exists, is *xmin*, *xmax*, *ymin*, *ymax*, *zmin*, or *zmax*. The *dimdim* argument, if it exists, is *xx* or *yy* or *zz* or *xy* or *yz* or *xz*.

The group function count() is the number of atoms in the group. The group functions mass() and charge() are the total mass and charge of the group. Xcm() and vcm() return components of the position and velocity of the center of mass of the group. Fcm() returns a component of the total force on the group of atoms. Bound() returns the min/max of a particular coordinate for all atoms in the group. Gyration() computes the radius-of-gyration of the group of atoms. See the *compute gyration* command for a definition of the formula. Angmom() returns components of the angular momentum of the group of atoms around its center of mass. Torque() returns components of the torque on the group of atoms around its center of mass, based on current forces on the atoms. Inertia() returns one of 6 components of the symmetric inertia tensor of the group of atoms around its center of mass, ordered as Ixx,Iyy,Izz,Ixy,Iyz,Ixz. Omega() returns components of the angular velocity of the group of atoms around its center of mass.

Changed in version 2Sep2026.

The inertia() and angmom() functions now include the contributions of *finite-size particles*; previously all atoms were treated as point masses. This is independent of (and does not change) the angular-momentum removal performed by *fix momentum*, *velocity zero*, and *compute temp/rotate*, which continue to act on the point-mass (translational) angular momentum only.

Region functions are specified exactly the same way as group functions except they take an extra final argument *IDR* which is the region ID. The function is computed for all atoms that are in both the group and the region. If the group is "all", then the only criteria for atom inclusion is that it be in the region.

Special Functions

Special functions take specific kinds of arguments, meaning their arguments cannot be formulas themselves.

The sum(x), min(x), max(x), ave(x), trap(x), slope(x), sort(x), and rsort(x) functions each take 1 argument which is of the form "c_ID" or "c_ID[N]" or "f_ID" or "f_ID[N]" or "v_name". The first two are computes and the second two are fixes; the ID in the reference should be replaced by the ID of a compute or fix defined elsewhere in the input script. The compute or fix must produce either a global vector or array. If it produces a global vector, then the notation without "[N]" should be used. If it produces a global array, then the notation with "[N]" should be used, where N is an integer, to specify which column of the global array is being referenced. The last form of argument "v_name" is for a vector-style variable where "name" is replaced by the name of the variable.

The sum(x), min(x), max(x), ave(x), trap(x), and slope(x) functions operate on a global vector of inputs and reduce it to a single scalar value. This is analogous to the operation of the *compute reduce* command, which performs similar operations on per-atom and local vectors.

The sort(x) and rsort(x) functions operate on a global vector of inputs and return a global vector of the same length.

The sum() function calculates the sum of all the vector elements. The min() and max() functions find the minimum and maximum element respectively. The ave() function is the same as sum() except that it divides the result by the length of the vector.

The trap() function is the same as sum() except the first and last elements are multiplied by a weighting factor of 1/2 when performing the sum. This effectively implements an integration via the trapezoidal rule on the global vector of data. I.e. consider a set of points, equally spaced by 1 in their x coordinate: (1,V1), (2,V2), ..., (N,VN), where the Vi are the values in the global vector of length N. The integral from 1 to N of these points is trap(). When appropriately normalized by the timestep size, this function is useful for calculating integrals of time-series data, like that generated by the *fix ave/correlate* command.

The slope() function uses linear regression to fit a line to the set of points, equally spaced by 1 in their x coordinate: (1,V1), (2,V2), ..., (N,VN), where the Vi are the values in the global vector of length N. The returned value is the slope of the line. If the line has a single point or is vertical, it returns 1.0e20.

Added in version 27June2024.

The sort(x) and rsort(x) functions sort the data of the input vector by their numeric value: sort(x) sorts in ascending order, rsort(x) sorts in descending order.

The gmask(x) function takes 1 argument which is a group ID. It can only be used in atom-style variables. It returns a 1 for atoms that are in the group, and a 0 for atoms that are not.

The rmask(x) function takes 1 argument which is a region ID. It can only be used in atom-style variables. It returns a 1 for atoms that are in the geometric region, and a 0 for atoms that are not.

The grmask(x,y) function takes 2 arguments. The first is a group ID, and the second is a region ID. It can only be used in atom-style variables. It returns a 1 for atoms that are in both the group and region, and a 0 for atoms that are not in both.

The next(x) function takes 1 argument which is a variable ID (not "v_foo", just "foo"). It must be for a file-style or atomfile-style variable. Each time the next() function is invoked (i.e. each time the equal-style or atom-style variable is evaluated), the following steps occur.

For file-style variables, the current string value stored by the file-style variable is converted to a numeric value and returned by the function. And the next string value in the file is read and stored. Note that if the line previously read from the file was not a numeric string, then it will typically evaluate to 0.0, which is likely not what you want.

For atomfile-style variables, the current per-atom values stored by the atomfile-style variable are returned by the function. And the next set of per-atom values in the file is read and stored.

Since file-style and atomfile-style variables read and store the first line of the file or first set of per-atoms values when they are defined in the input script, these are the value(s) that will be returned the first time the next() function is invoked. If next() is invoked more times than there are lines or sets of lines in the file, the variable is deleted, similar to how the *next* command operates.

The is_file(name) function is a test whether *name* is a (readable) file and returns 1 in this case, otherwise it returns 0. For that *name* is taken as a literal string and must not have any blanks in it.

The is_os(name) function is a test whether *name* is part of the OS information that LAMMPS collects and provides in the `platform::os_info()` function. The argument *name* is interpreted as a regular expression as documented for the `utils::strmatch()` function. This allows to adapt LAMMPS inputs to the OS it runs on:

```
if $(is_os(^Windows)) then &
  "shell copy ${input_dir}\some_file.txt ." &
else &
  "shell cp ${input_dir}/some_file.txt ."
```

The extract_setting(name) function enables access to basic settings for the LAMMPS executable and the running simulation via calling the `lammps_extract_setting()` library function. For example, the number of processors (MPI ranks) being used by the simulation or the MPI process ID (for this processor) can be queried, or the number of atom types, bond types and so on. For the full list of available keywords *name* and their meaning, see the documentation for extract_setting() via the link in this paragraph.

The label2type(kind,label) function converts type labels into numeric types, using label maps created by the *labelmap* or *read_data* commands. The first argument is the label map kind (atom, bond, angle, dihedral, or improper) and the second argument is the label. The function returns the corresponding numeric type or triggers an error if the queried label does not exist.

Added in version 15Jun2023.

The is_typelabel(kind,label) function has the same arguments as label2type(), but returns 1 if the type label has been assigned, otherwise it returns 0. This function can be used to check if a particular type label already exists in the simulation.

Added in version 29Aug2024.

The is_timeout() function returns 1 when the *timer timeout* has expired otherwise it returns 0. This function can be used to check inputs in combination with the *if command* to execute commands after the timer has expired. Example:

```
variable timeout equal is_timeout()
timer timeout 0:10:00 every 10
run 10000
if ${timeout} then "print 'Timer has expired'"
```

Feature Functions

Feature functions allow probing of the running LAMMPS executable for whether specific features are available, active, or defined. All 3 of the functions take two arguments, a *category* and a category-specific second argument. Both are strings and thus cannot be formulas themselves; only $-style immediate variable expansion is possible. The return value of the functions is either 1.0 or 0.0 depending on whether the function evaluates to true or false, respectively.

The *is_available(category,name)* function queries whether a specific feature is available in the LAMMPS executable that is being run, i.e whether it was included or enabled at compile time.

This supports the following categories: *command*, *compute*, *fix*, *pair_style* and *feature*. For all the categories except *feature* the *name* is a style name, e.g. *nve* for the *fix* category. Note that many LAMMPS input script commands such as *create_atoms* are actually instances of a command style which LAMMPS defines, as opposed to built-in commands. For all of these styles except *command*, appending of active suffixes is also tried before reporting failure.

The *feature* category checks the availability of the following compile-time enabled features: GZIP support, PNG support, JPEG support, FFMPEG support, and C++ exceptions for error handling. Corresponding names are *gzip*, *png*, *jpeg*, *ffmpeg* and *exceptions*.

Example: Only dump in a given format if the compiled binary supports it.

```
if "$(is_available(feature,png))" then "print 'PNG supported'" else "print 'PNG not␣
↪supported'"
if "$(is_available(feature,ffmpeg)" then "dump 3 all movie 25 movie.mp4 type type zoom 1.
↪6 adiam 1.0"
```

The *is_active(category,feature)* function queries whether a specific feature is currently active within LAMMPS. The features are grouped by categories. Supported categories and features are:

- *package*: features = *gpu* or *intel* or *kokkos* or *omp*
- *newton*: features = *pair* or *bond* or *any*
- *pair*: features = *single* or *respa* or *manybody* or *tail* or *shift*
- *comm_style*: features = *brick* or *tiled*
- *min_style*: features = a minimizer style name
- *run_style*: features = a run style name
- *atom_style*: features = an atom style name
- *pair_style*: features = a pair style name
- *bond_style*: features = a bond style name
- *angle_style*: features = an angle style name
- *dihedral_style*: features = a dihedral style name
- *improper_style*: features = an improper style name
- *kspace_style*: features = a kspace style name

Most of the settings are self-explanatory. For the *package* category, a package may have been included in the LAMMPS build, but not have enabled by any input script command, and hence be inactive. The *single* feature in the *pair* category checks whether the currently defined pair style supports a Pair::single() function as needed by compute group/group and others features or LAMMPS. Similarly, the *respa* feature checks whether the inner/middle/outer mode of r-RESPA is supported by the current pair style.

For the categories with *style* in their name, only a single instance of the style is ever active at any time in a LAMMPS simulation. Thus the check is whether the currently active style matches the specified name. This check is also done using suffix flags, if available and enabled.

Example 1: Disable use of suffix for PPPM when using GPU package (i.e. run it on the CPU concurrently while running the pair style on the GPU), but do use the suffix otherwise (e.g. with OPENMP).

```
pair_style lj/cut/coul/long 14.0
if $(is_active(package,gpu)) then "suffix off"
kspace_style pppm
```

Example 2: Use r-RESPA with inner/outer cutoff, if supported by the current pair style, otherwise fall back to using r-RESPA with simply the pair keyword and reducing the outer time step.

```
timestep $(2.0*(1.0+2.0*is_active(pair,respa)))
if $(is_active(pair,respa)) then "run_style respa 4 3 2 2 improper 1 inner 2 5.5 7.0␣
↪outer 3 kspace 4" else "run_style respa 3 3 2 improper 1 pair 2 kspace 3"
```

The *is_defined(category,id)* function checks whether an instance of a style or variable with a specific ID or name is currently defined within LAMMPS. The supported categories are *compute*, *dump*, *fix*, *group*, *region*, and *variable*. Each of these styles (as well as the variable command) can be specified multiple times within LAMMPS, each with a unique *id*. This function checks whether the specified *id* exists. For category *variable", the *id* is the variable name.

Python Function wrapper

A Python function wrapper enables the formula for an equal-style or atom-style variable to invoke functions coded in Python. In the case of an equal-style variable, the Python-coded function will be invoked once. In the case of an atom-style variable, it can be invoked once per atom, if one or more of its arguments include a per-atom quantity, e.g. the position of an atom. As illustrated below, the reason to use a Python function wrapper is to make it easy to pass LAMMPS-related arguments to the Python-coded function associated with a python-style variable.

The syntax for defining a Python function wrapper is

```
py_varname(arg1,arg2,...argN)
```

where *varname* is the name of a python-style variable which couples to a Python-coded function. The function will be passed the zero or more arguments listed in parentheses: *arg1*, *arg2*, ... *argN*. As with Math Functions, each argument can itself be an arbitrarily complex formula.

A Python function wrapper can be used in the following manner by an input script:

```
variable        foo python truncate
python          truncate return v_foo input 1 v_arg format fi here """
def truncate(x):
 return int(x)
"""
variable        xtrunc atom py_foo(x)
variable        ytrunc atom py_foo(y)
variable        ztrunc atom py_foo(z)
dump            1 all custom 100 tmp.dump id x y z v_xtrunc v_ytrunc v_ztrunc
```

The first two commands define a python-style variable *foo* and couple it to the Python-coded function *truncate()* which takes a single floating point argument, and returns its truncated integer value. In this case, the Python code for truncate() is included in the *python* command; it could also be contained in a file. See the *python* command doc page for details.

The next three commands define atom-style variables *xtrunc*, *ytrunc*, and *ztrunc*. Each of them include the same Python function wrapper in their formula, with a different argument. The atom-style variable *xtrunc* will invoke the python-style variable *foo*, which will in turn invoke the Python-coded *truncate()* method. Because *xtrunc* is an atom-style variable, and the argument *x* in the Python function wrapper is a per-atom quantity (the x-coord of each atom), each processor will invoke the *truncate()* method once per atom, for the atoms it owns.

When invoked for the Ith atom, the value of the *arg* internal-style variable, defined by the *python* command, is set to the x-coord of the Ith atom. The call via python-style variable *foo* to the Python *truncate()* function passes the value of the *arg* variable as the function's first (and only) argument. Likewise, the return value of the Python function is stored by the python-style variable *foo* and used in the *xtrunc* atom-style variable formula for the Ith atom.

The resulting per-atom vector for *xtrunc* will thus contain the truncated x-coord of every atom in the system. The dump command includes the truncated xyz coords for each atom in its output.

See the *python* command for more details on options the *python* command can specify as well as examples of more complex Python functions which can be wrapped in this manner. In particular, the Python function can take a variety of arguments, some generated by the *python* command, and others by the arguments of the Python function wrapper.

Atom Values and Vectors

Atom values take an integer argument I from 1 to N, where I is the atom-ID, e.g. x[243], which means use the x coordinate of the atom with ID = 243. Or they can take a variable name, specified as v_name, where name is the name of the variable, like x[v_myIndex]. The variable can be of any style except *vector* or *atom* or *atomfile* variables. The variable is evaluated and the result is expected to be numeric and is cast to an integer (i.e. 3.4 becomes 3), to use an index, which must be a value from 1 to N. Note that a "formula" cannot be used as the argument between the brackets, e.g. x[243+10] or x[v_myIndex+1] are not allowed. To do this a single variable can be defined that contains the needed formula.

Note that the 0 < atom-ID <= N, where N is the largest atom ID in the system. If an ID is specified for an atom that does not currently exist, then the generated value is 0.0.

Atom vectors generate one value per atom, so that a reference like "vx" means the x-component of each atom's velocity will be used when evaluating the variable.

The meaning of the different atom values and vectors is mostly self-explanatory. *Mol* refers to the molecule ID of an atom, and is only defined if an *atom_style* is being used that defines molecule IDs.

Note that many other atom attributes can be used as inputs to a variable by using the *compute property/atom* command and then referencing that compute.

Custom atom properties

Added in version 7Feb2024.

Custom atom properties refer to per-atom integer and floating point vectors or arrays that have been added via the *fix property/atom* command. When that command is used specific names are given to each attribute which are the "name" portion of these references. References beginning with *i* and *d* refer to integer and floating point properties respectively. Per-atom vectors are referenced by *i_name* and *d_name*; per-atom arrays are referenced by *i2_name* and *d2_name*.

The various allowed references to integer custom atom properties in the variable formulas for equal-, vector-, and atom-style variables are listed in the following table. References to floating point custom atom properties are the same; just replace the leading "i" with "d".

equal	i_name[I]	element of per-atom vector (I = atom ID)
equal	i2_name[I][J]	element of per-atom array (I = atom ID)
vector	i_name[I]	element of per-atom vector (I = atom ID)
vector	i2_name[I][J]	element of per-atom array (I = atom ID)
atom	i_name	per-atom vector
atom	i2_name[I]	column of per-atom array

The I and J indices in these custom atom property references can be integers or can be a variable name, specified as v_name, where name is the name of the variable. The rules for this syntax are the same as for indices in the "Atom Values and Vectors" discussion above.

Compute References

Compute references access quantities calculated by a *compute*. The ID in the reference should be replaced by the ID of a compute defined elsewhere in the input script.

As discussed on the page for the *compute* command, computes can produce global, per-atom, local, and per-grid values. Only global and per-atom values can be used in a variable. Computes can also produce scalars (global only), vectors, and arrays. See the doc pages for individual computes to see what different kinds of data they produce.

An equal-style variable can only use scalar values, either from global or per-atom data. In the case of per-atom data, this would be a value for a specific atom.

A vector-style variable can use scalar values (same as for equal-style variables), or global vectors of values. The latter can also be a column of a global array.

Atom-style variables can use scalar values (same as for equal-style variables), or per-atom vectors of values. The latter can also be a column of a per-atom array.

The various allowed compute references in the variable formulas for equal-, vector-, and atom-style variables are listed in the following table:

equal	c_ID	global scalar
equal	c_ID[I]	element of global vector
equal	c_ID[I][J]	element of global array
equal	C_ID[I]	element of per-atom vector (I = atom ID)
equal	C_ID[I][J]	element of per-atom array (I = atom ID)
vector	c_ID	global vector
vector	c_ID[I]	column of global array
atom	c_ID	per-atom vector
atom	c_ID[I]	column of per-atom array

Note that if an equal-style variable formula wishes to access per-atom data from a compute, it must use capital "C" as the ID prefix and not lower-case "c".

Also note that if a vector- or atom-style variable formula needs to access a scalar value from a compute (i.e. the 5 kinds of values in the first 5 lines of the table), it can not do so directly. Instead, it can use a reference to an equal-style variable which stores the scalar value from the compute.

The I and J indices in these compute references can be integers or can be a variable name, specified as v_name, where name is the name of the variable. The rules for this syntax are the same as for indices in the "Atom Values and Vectors" discussion above.

If a variable containing a compute is evaluated directly in an input script (not during a run), then the values accessed by the compute should be current. See the discussion below about "Variable Accuracy".

Fix References

Fix references access quantities calculated by a *fix*. The ID in the reference should be replaced by the ID of a fix defined elsewhere in the input script.

As discussed on the page for the *fix* command, fixes can produce global, per-atom, local, and per-grid values. Only global and per-atom values can be used in a variable. Fixes can also produce scalars (global only), vectors, and arrays. See the doc pages for individual fixes to see what different kinds of data they produce.

An equal-style variable can only use scalar values, either from global or per-atom data. In the case of per-atom data, this would be a value for a specific atom.

A vector-style variable can use scalar values (same as for equal-style variables), or global vectors of values. The latter can also be a column of a global array.

Atom-style variables can use scalar values (same as for equal-style variables), or per-atom vectors of values. The latter can also be a column of a per-atom array.

The allowed fix references in variable formulas for equal-, vector-, and atom-style variables are listed in the following table:

equal	f_ID	global scalar
equal	f_ID[I]	element of global vector
equal	f_ID[I][J]	element of global array
equal	F_ID[I]	element of per-atom vector (I = atom ID)
equal	F_ID[I][J]	element of per-atom array (I = atom ID)
vector	f_ID	global vector
vector	f_ID[I]	column of global array
atom	f_ID	per-atom vector
atom	f_ID[I]	column of per-atom array

Note that if an equal-style variable formula wishes to access per-atom data from a fix, it must use capital "F" as the ID prefix and not lower-case "f".

Also note that if a vector- or atom-style variable formula needs to access a scalar value from a fix (i.e. the 5 kinds of values in the first 5 lines of the table), it can not do so directly. Instead, it can use a reference to an equal-style variable which stores the scalar value from the fix.

The I and J indices in these fix references can be integers or can be a variable name, specified as v_name, where name is the name of the variable. The rules for this syntax are the same as for indices in the "Atom Values and Vectors" discussion above.

Note that some fixes only generate quantities on certain timesteps. If a variable attempts to access the fix on non-allowed timesteps, an error is generated. For example, the *fix ave/time* command may only generate averaged quantities every 100 steps. See the doc pages for individual fix commands for details.

If a variable containing a fix is evaluated directly in an input script (not during a run), then the values accessed by the fix should be current. See the discussion below about "Variable Accuracy".

Variable References

Variable references access quantities stored or calculated by other variables, which will cause those variables to be evaluated. The name in the reference should be replaced by the name of a variable defined elsewhere in the input script.

As discussed on this doc page, equal-style variables generate a single global numeric value, vector-style variables generate a vector of global numeric values, and atom-style and atomfile-style variables generate a per-atom vector of numeric values. All other variables store one or more strings.

The formula for an equal-style variable can use any style of variable including a vector_style or atom-style or atomfile-style. For these 3 styles, a subscript must be used to access a single value from the vector-, atom-, or atomfile-style variable. If a string-storing variable is used, the string is converted to a numeric value. Note that this will typically produce a 0.0 if the string is not a numeric string, which is likely not what you want.

The formula for a vector-style variable can use any style of variable, including atom-style or atomfile-style variables. For these 2 styles, a subscript must be used to access a single value from the atom-, or atomfile-style variable.

The formula for an atom-style variable can use any style of variable, including other atom-style or atomfile-style variables. If it uses a vector-style variable, a subscript must be used to access a single value from the vector-style variable.

The allowed variable references in variable formulas for equal-, vector-, and atom-style variables are listed in the following table. Note that there is no ambiguity as to what a reference means, since referenced variables produce only a global scalar or global vector or per-atom vector.

equal	v_name	global scalar from an equal-style variable
equal	v_name[I]	element of global vector from a vector-style variable
equal	v_name[I]	element of per-atom vector (I = atom ID) from an atom- or atomfile-style variable
vector	v_name	global scalar from an equal-style variable
vector	v_name	global vector from a vector-style variable
vector	v_name[I]	element of global vector from a vector-style variable
vector	v_name[I]	element of per-atom vector (I = atom ID) from an atom- or atomfile-style variable
atom	v_name	global scalar from an equal-style variable
atom	v_name	per-atom vector from an atom-style or atomfile-style variable
atom	v_name[I]	element of global vector from a vector-style variable
atom	v_name[I]	element of per-atom vector (I = atom ID) from an atom- or atomfile-style variable

For the I index, an integer can be specified or a variable name, specified as v_name, where name is the name of the variable. The rules for this syntax are the same as for indices in the "Atom Values and Vectors" discussion above.

Vector Initialization

Added in version 15Jun2023.

Vector-style variables only can be initialized with a special syntax, instead of using a formula. The syntax is a bracketed, comma-separated syntax like the following:

```
variable myvec vector [1,3.5,7,10.2]
```

The 3rd argument formula is replaced by the vector values in brackets, separated by commas. This example creates a 4-length vector with specific numeric values, each of which can be specified as an integer or floating point value. Note that while whitespace can be added before or after individual values, no other mathematical operations can be specified. E.g. "3*10" or "3*v_abc" are not valid vector elements, nor is "10*[1,2,3,4]" valid for the entire vector.

Unlike vector variables specified with formulas, this vector variable is static; its length and values never changes. Its values can be used in other commands (including vector-style variables specified with formulas) via the usual syntax for accessing individual vector elements or the entire vector.

1.116.4 Immediate Evaluation of Variables

If you want an equal-style variable to be evaluated immediately, it may be the case that you do not need to define a variable at all. See the *Commands parse* page for info on how to use "immediate" variables in an input script, specified as $(formula) with parenthesis, where the formula has the same syntax as equal-style variables described on this page. This effectively evaluates a formula immediately without using the variable command to define a named variable.

More generally, there is a difference between referencing a variable with a leading $ sign (e.g. $x or ${abc}) versus with a leading "v_" (e.g. v_x or v_abc). The former can be used in any input script command, including a variable command. The input script parser evaluates the reference variable immediately and substitutes its value into the command. As explained on the *Commands parse* doc page, you can also use un-named "immediate" variables for this purpose. For example, a string like this $((xlo+xhi)/2+sqrt(v_area)) in an input script command evaluates the string between the parenthesis as an equal-style variable formula.

Referencing a variable with a leading "v_" is an optional or required kind of argument for some commands (e.g. the *fix ave/chunk* or *dump custom* or *thermo_style* commands) if you wish it to evaluate a variable periodically during a run. It can also be used in a variable formula if you wish to reference a second variable. The second variable will be evaluated whenever the first variable is evaluated.

As an example, suppose you use this command in your input script to define the variable "v" as

```
variable v equal vol
```

before a run where the simulation box size changes. You might think this will assign the initial volume to the variable "v". That is not the case. Rather it assigns a formula which evaluates the volume (using the thermo_style keyword "vol") to the variable "v". If you use the variable "v" in some other command like *fix ave/time* then the current volume of the box will be evaluated continuously during the run.

If you want to store the initial volume of the system, you can do it this way:

```
variable v equal vol
variable v0 equal $v
```

The second command will force "v" to be evaluated (yielding the initial volume) and assign that value to the variable "v0". Thus the command

```
thermo_style custom step v_v v_v0
```

would print out both the current and initial volume periodically during the run.

Note that it is a mistake to enclose a variable formula in double quotes if it contains variables preceded by $ signs. For example,

```
variable vratio equal "${vfinal}/${v0}"
```

This is because the quotes prevent variable substitution (explained on the *Commands parse* doc page), and thus an error will occur when the formula for "vratio" is evaluated later.

1.116.5 Variable Accuracy

Obviously, LAMMPS attempts to evaluate variables which contain formulas (*equal* and *vector* and *atom* style variables) accurately whenever the evaluation is performed. Depending on what is included in the formula, this may require invoking a *compute*, either directly or indirectly via a thermo keyword, or accessing a value previously calculated by a compute, or accessing a value calculated and stored by a *fix*. If the compute is one that calculates the energy or pressure of the system, then the corresponding energy or virial quantities need to be tallied during the evaluation of the interatomic potentials (pair, bond, etc) on any timestep that the variable needs the tallies. An input script can also request variables be evaluated before or after or in between runs, e.g. by including them in a *print* command.

LAMMPS keeps track of all of this as it performs a *run* or *minimize* simulation, as well as in between simulations. An error will be generated if you attempt to evaluate a variable when LAMMPS knows it cannot produce accurate values. For example, if a *thermo_style custom* command prints a variable which accesses values stored by a *fix ave/time* command and the timesteps on which thermo output is generated are not multiples of the averaging frequency used in the fix command, then an error will occur.

However, there are two special cases to be aware when a variable requires invocation of a compute (directly or indirectly). The first is if the variable is evaluated before the first *run* or *minimize* command in the input script. In this case, LAMMPS will generate an error. This is because many computes require initializations which have not yet taken place. One example is the calculation of degrees of freedom for temperature computes. Another example are the computes mentioned above which require tallying of energy or virial quantities; these values are not tallied until the first simulation begins.

The second special case is when a variable that depends on a compute is evaluated in between *run* or *minimize* commands. It is possible for other input script commands issued following the previous run, but before the variable is evaluated, to change the system. For example, the *delete_atoms* command could be used to remove atoms. Since the compute will not re-initialize itself until the next simulation or it may depend on energy/virial computations performed before the system was changed, it will potentially generate an incorrect answer when evaluated. Note that LAMMPS will not generate an error in this case; the evaluated variable may simply be incorrect.

The way to get around both of these special cases is to perform a 0-timestep run before evaluating the variable. For example, these commands

```
# delete_atoms random fraction 0.5 yes all NULL 49839
# run 0 post no
variable t equal temp    # this thermo keyword invokes a temperature compute
print "Temperature of system = $t"
run 1000
```

will generate an error if the "run 1000" command is the first simulation in the input script. If there were a previous run, these commands will print the correct temperature of the system. But if the *delete_atoms* command is uncommented, the printed temperature will be incorrect, because information stored by temperature compute is no longer valid.

Both these issues are resolved, if the "run 0" command is uncommented. This is because the "run 0" simulation will initialize (or re-initialize) the temperature compute correctly.

1.116.6 Restrictions

Indexing any formula element by global atom ID, such as an atom value, requires the *atom style* to use a global mapping in order to look up the vector indices. By default, only atom styles with molecular information create global maps. The *atom_modify map* command can override the default, e.g. for atomic-style atom styles.

All *universe*- and *uloop*-style variables defined in an input script must have the same number of values.

1.117 velocity command

1.117.1 Syntax

```
velocity group-ID style args keyword value ...
```

- group-ID = ID of group of atoms whose velocity will be changed
- style = *create* or *set* or *scale* or *ramp* or *zero*

```
create args = temp seed
  temp = temperature value (temperature units)
  seed = random # seed (positive integer)
set args = vx vy vz
  vx,vy,vz = velocity value or NULL (velocity units)
  any of vx,vy,vz can be a variable (see below)
scale arg = temp
  temp = temperature value (temperature units)
ramp args = vdim vlo vhi dim clo chi
  vdim = vx or vy or vz
  vlo,vhi = lower and upper velocity value (velocity units)
  dim = x or y or z
  clo,chi = lower and upper coordinate bound (distance units)
zero arg = linear or angular
  linear = zero the linear momentum
  angular = zero the angular momentum
```

- zero or more keyword/value pairs may be appended
- keyword = *dist* or *sum* or *mom* or *rot* or *temp* or *bias* or *loop* or *rigid* or *units*

```
dist value = uniform or gaussian
sum value = no or yes
mom value = no or yes
rot value = no or yes
temp value = temperature compute ID
bias value = no or yes
loop value = all or local or geom
rigid value = fix-ID
  fix-ID = ID of rigid body fix
units value = box or lattice
```

1.117.2 Examples

```
velocity all create 300.0 4928459 rot yes dist gaussian
velocity border set NULL 4.0 v_vz sum yes units box
velocity flow scale 300.0
velocity flow ramp vx 0.0 5.0 y 5 25 temp mytemp
velocity all zero linear
```

1.117.3 Description

Set or change the velocities of a group of atoms in one of several styles. For each style, there are required arguments and optional keyword/value parameters. Not all options are used by each style. Each option has a default as listed below.

The *create* style generates an ensemble of velocities using a random number generator with the specified seed at the specified temperature.

The *set* style sets the velocities of all atoms in the group to the specified values. If any component is specified as NULL, then it is not set. Any of the vx,vy,vz velocity components can be specified as an equal-style or atom-style *variable*. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated, and its value used to determine the velocity component. Note that if a variable is used, the velocity it calculates must be in box units, not lattice units; see the discussion of the *units* keyword below.

Equal-style variables can specify formulas with various mathematical functions, and include *thermo_style* command keywords for the simulation box parameters or other parameters.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus it is easy to specify a spatially-dependent velocity field.

The *scale* style computes the current temperature of the group of atoms and then rescales the velocities to the specified temperature.

The *ramp* style is similar to that used by the *compute temp/ramp* command. Velocities ramped uniformly from vlo to vhi are applied to dimension vx, or vy, or vz. The value assigned to a particular atom depends on its relative coordinate value (in dim) from clo to chi. For the example above, an atom with y-coordinate of 10 (1/4 of the way from 5 to 25), would be assigned a x-velocity of 1.25 (1/4 of the way from 0.0 to 5.0). Atoms outside the coordinate bounds (less than 5 or greater than 25 in this case), are assigned velocities equal to vlo or vhi (0.0 or 5.0 in this case).

The *zero* style adjusts the velocities of the group of atoms so that the aggregate linear or angular momentum is zero. No other changes are made to the velocities of the atoms. If the *rigid* option is specified (see below), then the zeroing is performed on individual rigid bodies, as defined by the *fix rigid or fix rigid/small* commands. In other words, zero linear will set the linear momentum of each rigid body to zero, and zero angular will set the angular momentum of each rigid body to zero. This is done by adjusting the velocities of the atoms in each rigid body.

All temperatures specified in the velocity command are in temperature units; see the *units* command. The units of velocities and coordinates depend on whether the *units* keyword is set to *box* or *lattice*, as discussed below.

For all styles, no atoms are assigned z-component velocities if the simulation is 2d; see the *dimension* command.

The keyword/value options are used in the following ways by the various styles.

The *dist* keyword is used by *create*. The ensemble of generated velocities can be a *uniform* distribution from some minimum to maximum value, scaled to produce the requested temperature. Or it can be a *gaussian* distribution with a mean of 0.0 and a sigma scaled to produce the requested temperature.

The *sum* keyword is used by all styles, except *zero*. The new velocities will be added to the existing ones if sum = yes, or will replace them if sum = no.

The *mom* and *rot* keywords are used by *create*. If mom = yes, the linear momentum of the newly created ensemble of velocities is zeroed; if rot = yes, the angular momentum is zeroed.

If specified, the *temp* keyword is used by *create* and *scale* to specify a *compute* that calculates temperature in a desired way, e.g. by first subtracting out a velocity bias, as discussed on the *Howto thermostat* doc page. If this keyword is not specified, *create* and *scale* calculate temperature using a compute that is defined internally as follows:

```
compute velocity_temp group-ID temp
```

where group-ID is the same ID used in the velocity command. i.e. the group of atoms whose velocity is being altered. This compute is deleted when the velocity command is finished. See the *compute temp* command for details. If the calculated temperature should have degrees-of-freedom removed due to fix constraints (e.g. SHAKE or rigid-body constraints), then the appropriate fix command must be specified before the velocity command is issued.

The *bias* keyword with a *yes* setting is used by *create* and *scale*, but only if the *temp* keyword is also used to specify a *compute* that calculates temperature in a desired way. If the temperature compute also calculates a velocity bias, the bias is subtracted from atom velocities before the *create* and *scale* operations are performed. After the operations, the bias is added back to the atom velocities. See the *Howto thermostat* page for more discussion of temperature computes with biases. Note that the velocity bias is only applied to atoms in the temperature compute specified with the *temp* keyword.

As an example, assume atoms are currently streaming in a flow direction (which could be separately initialized with the *ramp* style), and you wish to initialize their thermal velocity to a desired temperature. In this context thermal velocity means the per-particle velocity that remains when the streaming velocity is subtracted. This can be done using the *create* style with the *temp* keyword specifying the ID of a *compute temp/ramp* or *compute temp/profile* command, and the *bias* keyword set to a *yes* value.

The *loop* keyword is used by *create* in the following ways.

If *loop* = *all*, then each processor loops over all atoms in the simulation to create velocities, but only stores velocities for atoms it owns. This can be a slow loop for a large simulation. If atoms were read from a data file, the velocity assigned to a particular atom will be the same, independent of how many MPI processes are being used. This will not be the case if atoms were created using the *create_atoms* command, since atom IDs will likely be assigned to atoms differently.

If *loop* = *local*, then each processor loops over only its atoms to produce velocities. The random number seed is adjusted to give a different set of velocities on each processor. This is a fast loop, but the velocity assigned to a particular atom will depend on which processor owns it. Thus the results will always be different when a simulation is run on a different number of MPI processes.

If *loop* = *geom*, then each processor loops over only its atoms. For each atom a unique random number seed is created, based on the atom's xyz coordinates. A velocity is generated using that seed. This is a fast loop and the velocity assigned to a particular atom will be the same, independent of how many MPI processes are used. However, the set of generated velocities may be more correlated than if the *all* or *local* keywords are used.

Note

The *loop geom* keyword will not necessarily assign identical velocities for two simulations run on different machines. This is because the computations based on xyz coordinates are sensitive to tiny differences in the double-precision value for a coordinate as stored on a particular machine.

The *rigid* keyword only has meaning when used with the *zero* style. It allows specification of a fix-ID for one of the *rigid-body fix* variants which defines a set of rigid bodies. The zeroing of linear or angular momentum is then performed for each rigid body defined by the fix, as described above.

The *units* keyword is used by *set* and *ramp*. If units = box, the velocities and coordinates specified in the velocity command are in the standard units described by the *units* command (e.g. Angstroms/fs for real units). If units = lattice, velocities are in units of lattice spacings per time (e.g. spacings/fs) and coordinates are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacing.

1.117.4 Restrictions

Assigning a temperature via the *create* style to a system with *rigid bodies* or *SHAKE constraints* may not have the desired outcome for two reasons. First, the velocity command can be invoked before all of the relevant fixes are created and initialized and the number of adjusted degrees of freedom (DOFs) is known. Thus it is not possible to compute

the target temperature correctly. Second, the assigned velocities may be partially canceled when constraints are first enforced, leading to a different temperature than desired. A workaround for this is to perform a *run 0* command, which ensures all DOFs are accounted for properly, and then rescale the temperature to the desired value before performing a simulation. For example:

```
velocity all create 300.0 12345
run 0                          # temperature may not be 300K
velocity all scale 300.0       # now it should be
```

1.117.5 Related commands

fix rigid, *fix shake*, *lattice*

1.117.6 Default

The keyword defaults are dist = uniform, sum = no, mom = yes, rot = no, bias = no, loop = all, and units = lattice. The temp and rigid keywords are not defined by default.

1.118 write_coeff command

1.118.1 Syntax

```
write_coeff file
```

- file = name of data file to write out

1.118.2 Examples

```
write_coeff polymer.coeff
```

1.118.3 Description

Write a text format file with the currently defined force field coefficients in a way, that it can be read by LAMMPS with the *include* command. In combination with the nocoeff option of *write_data* this can be used to move the Coeffs sections from a data file into a separate file.

Note

The write_coeff command is not yet fully implemented as some pair styles do not output their coefficient information. This means you will need to add/copy this information manually.

1.118.4 Restrictions

none

1.119 write_data command

1.119.1 Syntax

```
write_data file keyword value ...
```

- file = name of data file to write out
- zero or more keyword/value pairs may be appended
- keyword = *nocoeff* or *nofix* or *nolabelmap* or *triclinic/general* or *types* or *pair*

```
nocoeff = do not write out force field info
nofix = do not write out extra sections read by fixes
nolabelmap = do not write out type labels
triclinic/general = write data file in general triclinic format
types value = numeric or labels
pair value = ii or ij
  ii = write one line of pair coefficient info per atom type
  ij = write one line of pair coefficient info per IJ atom type pair
```

1.119.2 Examples

```
write_data data.polymer
write_data data.polymer.gz
write_data data.*
write_data data.solid triclinic/general
```

1.119.3 Description

Write a data file in text format of the current state of the simulation. Data files can be read by the *read data* command to begin a simulation.

Added in version 11Feb2026.

The file may also be a compressed text file (detected by its suffix) if LAMMPS has been compiled with support for *compression commands* and the corresponding compression program is available.

Similar to *dump* files, the data filename can contain a "*" wild-card character. The "*" is replaced with the current timestep value.

Data in Coeff sections

The write_data command may not always write all coefficient settings to the corresponding Coeff sections of the data file. This can have one of multiple reasons. 1) The style may be a hybrid style. In that case *no* coeff information is written. 2) A few styles may be missing the code that would write those sections (This is rare these days, but if you come across one, please notify the LAMMPS developers). 3) Some pair styles require a single pair_coeff statement and those are not compatible with data files. 4) The default for write_data is to write a PairCoeff section, which has only entries for atom types i == j. The remaining coefficients would be inferred through the currently selected mixing rule. If there has been a pair_coeff command with i != j, this setting would be lost. LAMMPS will detect this and print a warning message unless *pair ij* is appended to the write_data command. This will request writing a PairIJCoeff section which has information for all pairs of atom types. In cases where the coefficient data in the data file is incomplete, you will need to re-specify that information in your input script that reads the data file.

Because a data file is in text format, if you use a data file written out by this command to restart a simulation, the initial state of the new run will be slightly different than the final state of the old run (when the file was written) which was represented internally by LAMMPS in binary format. A new simulation which reads the data file will thus typically diverge from a simulation that continued in the original input script.

If you want to do more exact restarts, using binary files, see the *restart*, *write_restart*, and *read_restart* commands. You can also convert binary restart files to text data files, after a simulation has run, using the *-r command-line switch*.

Note

Only limited information about a simulation is stored in a data file. For example, no information about atom *groups* and *fixes* are stored. *Binary restart files* store more information.

Bond interactions (angle, etc) that have been turned off by the *fix shake* or *delete_bonds* command will be written to a data file as if they are turned on. This means they will need to be turned off again in a new run after the data file is read.

Bonds that are broken (e.g. by a bond-breaking potential) are not written to the data file. Thus these bonds will not exist when the data file is read.

Use of the *nocoeff* keyword means no force field parameters are written to the data file. This can be helpful, for example, if you want to make significant changes to the force field or if the force field parameters are read in separately, e.g. from an include file.

Use of the *nofix* keyword means no extra sections read by fixes are written to the data file (see the *fix* option of the *read_data* command for details). For example, this option excludes sections for user-created per-atom properties from *fix property/atom*.

The *nolabelmap* and *types* keywords refer to type labels that may be defined for numeric atom types, bond types, angle types, etc. The label map can be defined in two ways, either by the *labelmap* command or in data files read by the *read_data* command which have sections for Atom Type Labels, Bond Type Labels, Angle Type Labels, etc. See the *Howto type labels* doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

Use of the *nolabelmap* keyword means that even if type labels exist for a given type-kind (Atoms, Bonds, Angles, etc.), type labels are not written to the data file. By default, they are written if they exist. A type label must be defined for every numeric type (within a given type-kind) to be written to the data file.

Use of the *triclinic/general* keyword will output a data file which specifies a general triclinic simulation box as well as per-atom quantities consistent with the general triclinic box. The latter means that per-atom vectors, such as velocities and dipole moments will be oriented consistent with the 3d rotation implied by the general triclinic box (relative to the associated restricted triclinic box).

This option can only be requested if the simulation box was initially defined to be general triclinic. If if was and the *triclinic/general* keyword is not used, then the data file will specify a restricted triclinic box, since that is the internal format LAMMPS uses for both general and restricted triclinic simulations. See the *Howto triclinic* doc page for more explanation of how general triclinic simulation boxes are supported by LAMMPS. And see the *read_data* doc page for details of how the format is altered for general triclinic data files.

The *types* keyword determines how atom types, bond types, angle types, etc are written into these data file sections: Atoms, Bonds, Angles, etc. The default is the *numeric* setting, even if type label maps exist. If the *labels* setting is used, type labels will be written to the data file, if the corresponding label map exists. Note that when using *types labels*, the *nolabelmap* keyword cannot be used.

The *pair* keyword lets you specify in what format the pair coefficient information is written into the data file. If the value is specified as *ii*, then one line per atom type is written, to specify the coefficients for each of the I=J interactions. This means that no cross-interactions for I != J will be specified in the data file and the pair style will apply its mixing

rule, as documented on individual *pair_style* doc pages. Of course this behavior can be overridden in the input script after reading the data file, by specifying additional *pair_coeff* commands for any desired I,J pairs.

If the value is specified as *ij*, then one line of coefficients is written for all I,J pairs where I <= J. These coefficients will include any specific settings made in the input script up to that point. The presence of these I != J coefficients in the data file will effectively turn off the default mixing rule for the pair style. Again, the coefficient values in the data file can be overridden in the input script after reading the data file, by specifying additional *pair_coeff* commands for any desired I,J pairs.

Note

Before the data file is written, LAMMPS migrates atoms to their owning subdomains, which deletes any atoms that lie outside of non-periodic boundaries. If this changes the total number of atoms, the *thermo_modify lost* setting determines what happens: with the default *error* setting LAMMPS aborts and does not write the file; with *warn* or *ignore* the stored atom count is reset to the actual number of atoms so that a self-consistent data file is written (with a warning printed for *warn*).

Changed in version 4Jul2026.

Previously, with the *warn* or *ignore* lost-atoms setting, the atom count in the data file header could disagree with the number of atoms actually written (a corrupted data file). The count is now reset so the written file is always self-consistent.

1.119.4 Restrictions

This command requires inter-processor communication to migrate atoms before the data file is written. This means that your system must be ready to perform a simulation before using this command (force fields setup, atom masses initialized, etc).

To write compressed data files, you must compile LAMMPS with the `-DLAMMPS_GZIP` option. See the *Build settings* doc page for details.

1.120 write_dump command

1.120.1 Syntax

```
write_dump group-ID style file dump-args modify dump_modify-args
```

- group-ID = ID of the group of atoms to be dumped
- style = any of the supported *dump styles*
- file = name of file to write dump info to
- dump-args = any additional args needed for a particular *dump style*
- modify = all args after this keyword are passed to *dump_modify* (optional)

- dump-modify-args = args for *dump_modify* (optional)

1.120.2 Examples

```
write_dump all atom dump.atom
write_dump subgroup atom dump.run.bin
write_dump all custom dump.myforce.* id type x y vx fx
write_dump flow custom dump.%.myforce id type c_myF[3] v_ke modify sort id
write_dump all xyz system.xyz modify sort id element O H
write_dump all image snap*.jpg type type size 960 960 modify backcolor white
write_dump all image snap*.jpg element element &
   bond atom 0.3 shiny 0.1 ssao yes 6345 0.2 size 1600 1600  &
   modify backcolor white element C C O H N C C C O H H S O H
write_dump all atom/gz dump.atom.gz modify compression_level 9
write_dump flow custom/zstd dump.%.myforce.zst &
               id type c_myF[3] v_ke &
               modify sort id &
               compression_level 15
```

1.120.3 Description

Dump a single snapshot of atom quantities to one or more files for the current state of the system. This is a one-time immediate operation, in contrast to the *dump* command which will will set up a dump style to write out snapshots periodically during a running simulation.

The syntax for this command is mostly identical to that of the *dump* and *dump_modify* commands as if they were concatenated together, with the following exceptions: There is no need for a dump ID or dump frequency and the keyword *modify* is added. The latter is so that the full range of *dump_modify* options can be specified for the single snapshot, just as they can be for multiple snapshots. The *modify* keyword separates the arguments that would normally be passed to the *dump* command from those that would be given the *dump_modify*. Both support optional arguments and thus LAMMPS needs to be able to cleanly separate the two sets of args.

Note that if the specified filename uses wildcard characters "*" or "%", as supported by the *dump* command, they will operate in the same fashion to create the new filename(s). Normally, *dump image* files require a filename with a "*" character for the timestep. That is not the case for the write_dump command; no wildcard "*" character is necessary.

1.120.4 Restrictions

All restrictions for the *dump* and *dump_modify* commands apply to this command as well, with the exception of the *dump image* filename not requiring a wildcard "*" character, as noted above.

Since dumps are normally written during a *run* or *energy minimization*, the simulation has to be ready to run before this command can be used. Similarly, if the dump requires information from a compute, fix, or variable, the information needs to have been calculated for the current timestep (e.g. by a prior run), else LAMMPS will generate an error message.

For example, it is not possible to dump per-atom energy with this command before a run has been performed, since no energies and forces have yet been calculated. See the *variable* doc page section on Variable Accuracy for more information on this topic.

1.120.5 Related commands

dump, *dump image*, *dump_modify*

1.120.6 Default

The defaults are listed on the doc pages for the *dump* and *dump image* and *dump_modify* commands.

1.121 write_molecule command

1.121.1 Syntax

```
write_molecule mol-ID file
```

- mol-ID = ID of the molecule template to be written
- file = name of file to write the molecule template to

1.121.2 Examples

```
write_molecule mol1 molecule1.mol
write_molecule mol1 molecule1.json
write_molecule twomols template_set%.mol
```

1.121.3 Description

Added in version 10Dec2025.

Write the data from a *molecule template* to a molecule file.

The molecule file format is determined by the file name: if the file name ends in `.json` the file will be written in JSON format, otherwise the file is written in the native LAMMPS molecule file format.

When the molecule template contains multiple molecules, as defined by a *molecule command* with multiple molecule files, the filename *must* contain a '%' character. That '%' character will be replaced by the molecule number (starting from 1) and each molecule is written to a separate file.

1.121.4 Output Format

The output format follows the description of the molecule file format in the *molecule command documentation*. When parsing molecule files there are a few requirement about the order of sections for the native format, but generally the order of list entries can be chosen freely. On writing, however, a specific ordering is enforced following the lists given below. All sections with per-atom data are sorted by the atom-ID value starting from 1. The list of bonds is ordered by the atom-ID of the first atom in the bond. The lists of angles, dihedrals, and impropers are ordered by the atom-ID of the second atom in the definition. For entries with the same atom-ID, the order in which they were defined in the original input data is maintained.

Native Format

The native format starts with a title line similar to the following where the angular brackets are replaced with the actual data:

```
# MOLECULE <molecule-ID>, unit = <units setting>, set <set-ID> of <nsets>, <original␣
↪title>
```

This followed by a header section with the following keywords in the listed order:

- *atoms* (required keyword)
- *bonds* (if non-zero)
- *angles* (if non-zero)
- *dihedrals* (if non-zero)
- *impropers* (if non-zero)
- *fragments* (if non-zero)
- *mass* (if present in original input)
- *body* (if present in original input)
- *com* (if present in original input)
- *inertia* (if present in original input)

The header section is followed by individual data sections in the order given below if the corresponding data was provided in the original input or explicitly added later:

- *Coords*
- *Types*
- *Molecules*
- *Fragments*
- *Charges*
- *Diameters*
- *Dipoles*
- *Masses*
- *Bonds*
- *Angles*
- *Dihedrals*
- *Impropers*
- *Special Bond Counts*
- *Special Bonds*
- *Shake Flags*
- *Shake Atoms*
- *Shake Bond Types*
- *Body Integers*
- *Body Doubles*

JSON Format

The JSON output is written as a text file in strict JSON format with an indentation level of 2 and following the layout given in the JSON schema file available for download at https://download.lammps.org/json/molecule-schema.json

Unlike for the native format output, there is no need to provide any counts for the number of entries for keys containing lists of settings with a specified format, since those can be directly inferred from the data structures after parsing a JSON file. The top level keys are ordered as follows:

- *application*
- *format*
- *revision*
- *schema*
- *title*
- *units*
- *masstotal* (if present in original input)
- *com* (if present in original input)
- *inertia* (if present in original input)
- *coords* (if present in molecule data)
- *types*
- *molecules* (if present in molecule data)
- *fragments* (if present in molecule data)
- *charges* (if present in molecule data)
- *diameters* (if present in molecule data)
- *dipoles* (if present in molecule data)
- *masses* (if present in molecule data)
- *bonds* (if present in molecule data)
- *angles* (if present in molecule data)
- *dihedrals* (if present in molecule data)
- *impropers* (if present in molecule data)
- *special* (if present in original input)
- *shake* (if present in molecule data)
- *body* (if present in molecule data)

1.122 write_restart command

1.122.1 Syntax

```
write_restart file keyword value ...
```

- file = name of file to write restart information to
- zero or more keyword/value pairs may be appended
- keyword = *fileper* or *nfile*

```
fileper arg = Np
  Np = write one file for every this many MPI processes
nfile arg = Nf
  Nf = write this many files, one from each of Nf MPI processes
```

1.122.2 Examples

```
write_restart restart.equil
write_restart poly.%.* nfile 10
```

1.122.3 Description

Write a binary restart file of the current state of the simulation.

During a long simulation, the *restart* command is typically used to output restart files periodically. The write_restart command is useful after a minimization or whenever you wish to write out a single current restart file.

Similar to *dump* files, the restart filename can contain two wild-card characters. If a "*" appears in the filename, it is replaced with the current timestep value. If a "%" character appears in the filename, then one file is written by each processor and the "%" character is replaced with the MPI rank ID from 0 to *P*-1. An additional file with the "%" replaced by "base" is also written, which contains global information. For example, the files written for `filename restart.%` would be `restart.base`, `restart.0`, `restart.1`, ... `restart.P-1`. This creates smaller files and can be a fast mode of output and subsequent input on parallel machines that support parallel I/O. The optional *fileper* and *nfile* keywords discussed below can alter the number of files written.

Restart files can be read by a *read_restart* command to restart a simulation from a particular state. Because the file is binary (to enable exact restarts), it may not be readable on another machine. In this case, you can use the *-r command-line switch* to convert a restart file to a data file.

Note

Although the purpose of restart files is to enable restarting a simulation from where it left off, not all information about a simulation is stored in the file. For example, the list of fixes that were specified during the initial run is not stored, which means the new input script must specify any fixes you want to use. Even when restart information is stored in the file, as it is for some fixes, commands may need to be re-specified in the new input script, in order to

reuse that information. Details are usually given in the documentation of the respective command. Also, see the *read_restart* command for general information about what is stored in a restart file.

The optional *nfile* or *fileper* keywords can be used in conjunction with the "%" wildcard character in the specified restart file name. As explained above, the "%" character causes the restart file to be written in pieces, one piece for each of *P* MPI processes. By default *P* = the number of MPI processes the simulation is running on. The *nfile* or *fileper* keyword can be used to set *P* to a smaller value, which can be more efficient when running on a large number of MPI processes.

The *nfile* keyword sets *P* to the specified *Nf* value. For example, if *Nf* = 4, and the simulation is running on 100 MPI processes, 4 files will be written, by MPI ranks 0, 25, 50, and 75. Each will collect information from itself and the next 24 MPI processes and write it to a restart file.

For the *fileper* keyword, the specified value of *Np* means write one file for every *Np* MPI processes. For example, if *Np* = 4, every fourth MPI rank (0, 4, 8, 12, *etc.*) will collect information from itself and the next 3 MPI processes and write it to a restart file.

1.122.4 Restrictions

This command requires inter-processor communication to migrate atoms before the restart file is written. This means that your system must be ready to perform a simulation before using this command (force fields setup, atom masses initialized, *etc.*).

CHAPTER

TWO

FIX STYLES

2.1 fix accelerate/cos command

2.1.1 Syntax

```
fix ID group-ID accelerate value
```

- ID, group-ID are documented in *fix* command
- accelerate/cos = style name of this fix command
- value = amplitude of acceleration (in unit of velocity/time)

2.1.2 Examples

```
fix 1 all accelerate/cos 2.0e-7
```

2.1.3 Description

Give each atom a acceleration in x-direction based on its z coordinate. The acceleration is a periodic function along the z-direction:

$$a_x(z) = A \cos\left(\frac{2\pi z}{l_z}\right)$$

where A is the acceleration amplitude, l_z is the z-length of the simulation box. At steady state, the acceleration generates a velocity profile:

$$v_x(z) = V \cos\left(\frac{2\pi z}{l_z}\right)$$

The generated velocity amplitude V is related to the shear viscosity η by:

$$V = \frac{A\rho}{\eta}\left(\frac{l_z}{2\pi}\right)^2$$

and it can be obtained from ensemble average of the velocity profile:

$$V = \frac{\sum_i 2m_i v_{i,x} \cos\left(\frac{2\pi z_i}{l_z}\right)}{\sum_i m_i},$$

where m_i, $v_{i,x}$, and z_i are the mass, x-component velocity, and z-coordinate of a particle, respectively.

The velocity amplitude V can be calculated with *compute viscosity/cos*, which enables viscosity calculation with periodic perturbation method, as described by *Hess*. Because the applied acceleration drives the system away from equilibration, the calculated shear viscosity is lower than the intrinsic viscosity due to the shear-thinning effect. Extrapolation to zero acceleration should generally be performed to predict the zero-shear viscosity. As the shear stress decreases, the signal-to-noise ratio decreases rapidly, and the simulation time must be extended accordingly to get converged results.

In order to get meaningful results, the group ID of this fix should be all.

2.1.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command.

This fix is not invoked during energy minimization.

2.1.5 Restrictions

This fix is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

Since this fix depends on the z-coordinate of atoms, it cannot be used in 2d simulations.

2.1.6 Related commands

2.2 fix acks2/reaxff command

Accelerator Variants: *acks2/reaxff/kk*

2.2.1 Syntax

```
fix ID group-ID acks2/reaxff Nevery cutlo cuthi tolerance params args
```

- ID, group-ID are documented in *fix* command
- acks2/reaxff = style name of this fix command
- Nevery = perform ACKS2 every this many steps
- cutlo,cuthi = lo and hi cutoff for Taper radius
- tolerance = precision to which charges will be equilibrated
- params = reaxff or a filename
- one or more keywords or keyword/value pairs may be appended

```
keyword = maxiter
  maxiter N = limit the number of iterations to N
```

2.2.2 Examples

```
fix 1 all acks2/reaxff 1 0.0 10.0 1.0e-6 reaxff
fix 1 all acks2/reaxff 1 0.0 10.0 1.0e-6 param.acks2 maxiter 500
```

2.2.3 Description

Perform the atom-condensed Kohn–Sham DFT to second order (ACKS2) charge equilibration method as described in *(Verstraelen)*. ACKS2 impedes unphysical long-range charge transfer sometimes seen with QEq (e.g., for dissociation of molecules), at increased computational cost. It is typically used in conjunction with the ReaxFF force field model as implemented in the *pair_style reaxff* command, but it can be used with any potential in LAMMPS, so long as it defines and uses charges on each atom. For more technical details about the charge equilibration performed by fix acks2/reaxff, see the *(O'Hearn)* paper.

The ACKS2 method minimizes the electrostatic energy of the system by adjusting the partial charge on individual atoms based on interactions with their neighbors. It requires some parameters for each atom type. If the *params* setting above is the word "reaxff", then these are extracted from the *pair_style reaxff* command and the ReaxFF force field file it reads in. If a file name is specified for *params*, then the parameters are taken from the specified file and the file must contain one line for each atom type. The latter form must be used when performing QeQ with a non-ReaxFF potential. The lines should be formatted as follows:

```
bond_softness
itype chi eta gamma bcut
```

where the first line is the global parameter *bond_softness*. The remaining 1 to Ntypes lines include *itype*, the atom type from 1 to Ntypes, *chi*, the electronegativity in eV, *eta*, the self-Coulomb potential in eV, *gamma*, the valence orbital exponent, and *bcut*, the bond cutoff distance. Note that these 4 quantities are also in the ReaxFF potential file, except that eta is defined here as twice the eta value in the ReaxFF file. Note that unlike the rest of LAMMPS, the units of this fix are hard-coded to be Å, eV, and electronic charge.

The optional *maxiter* keyword allows changing the max number of iterations in the linear solver. The default value is 200.

Note

In order to solve the self-consistent equations for electronegativity equalization, LAMMPS imposes the additional constraint that all the charges in the fix group must add up to zero. The initial charge assignments should also satisfy this constraint. LAMMPS will print a warning if that is not the case.

2.2.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. This fix computes a global scalar (the number of iterations) for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

This fix is invoked during *energy minimization*.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

2.2.5 Restrictions

This fix is part of the REAXFF package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This fix does not correctly handle interactions involving multiple periodic images of the same atom. Hence, it should not be used for periodic cell dimensions smaller than the non-bonded cutoff radius, which is typically 10 Å for ReaxFF simulations.

This fix may be used in combination with *fix efield* and will apply the external electric field during charge equilibration, but there may be only one fix efield instance used, it may only use a constant electric field, and the electric field vector may only have components in non-periodic directions.

2.3 fix adapt command

2.3.1 Syntax

```
fix ID group-ID adapt N attribute args ... keyword value ...
```

- ID, group-ID are documented in *fix* command
- adapt = style name of this fix command
- N = adapt simulation settings every this many timesteps
- one or more attribute/arg pairs may be appended
- attribute = *pair* or *bond* or *angle* or *dihedral* or *improper* or *kspace* or *atom*

```
pair args = pstyle pparam I J v_name
  pstyle = pair style name (e.g., lj/cut)
  pparam = parameter to adapt over time
  I,J = type pair(s) to set parameter for (integer or type label)
  v_name = variable with name that calculates value of pparam
bond args = bstyle bparam I v_name
  bstyle = bond style name (e.g., harmonic)
  bparam = parameter to adapt over time
  I = type bond to set parameter for (integer or type label)
```

```
    v_name = variable with name that calculates value of bparam
  angle args = astyle aparam I v_name
    astyle = angle style name (e.g., harmonic)
    aparam = parameter to adapt over time
    I = type angle to set parameter for (integer or type label)
    v_name = variable with name that calculates value of aparam
  dihedral args = dstyle dparam I v_name
    dstyle = dihedral style name (e.g., quadratic)
    dparam = parameter to adapt over time
    I = type dihedral to set parameter for (integer or type label)
    v_name = variable with name that calculates value of iparam
  improper args = istyle iparam I v_name
    istyle = improper style name (e.g., cvff)
    iparam = parameter to adapt over time
    I = type improper to set parameter for (integer or type label)
    v_name = variable with name that calculates value of iparam
  kspace arg = v_name
    v_name = variable with name that calculates scale factor on k-space terms
  atom args = atomparam v_name
    atomparam = charge or diameter or diameter/disc = parameter to adapt over time
    v_name = variable with name that calculates value of atomparam
```

- zero or more keyword/value pairs may be appended
- keyword = *scale* or *reset* or *mass*

```
  scale value = no or yes
    no = the variable value is the new setting
    yes = the variable value multiplies the original setting
  reset value = no or yes
    no = values will remain altered at the end of a run
    yes = reset altered values to their original values at the end of a run
  mass value = no or yes
    no = mass is not altered by changes in diameter
    yes = mass is altered by changes in diameter
```

2.3.2 Examples

```
fix 1 all adapt 1 pair soft a 1 1 v_prefactor
fix 1 all adapt 1 pair soft a 2* 3 v_prefactor
fix 1 all adapt 1 pair lj/cut epsilon * * v_scale1 pair coul/cut scale 3 3 v_scale2␣
↪scale yes reset yes
fix 1 all adapt 10 atom diameter v_size

variable ramp_up equal "ramp(0.01,0.5)"
fix stretch all adapt 1 bond harmonic r0 1 v_ramp_up

labelmap atom 1 c1
fix 1 all adapt 1 pair soft a c1 c1 v_prefactor
```

2.3.3 Description

Change or adapt one or more specific simulation attributes or settings over time as a simulation runs. Pair potential and *k*-space and atom attributes which can be varied by this fix are discussed below. Many other fixes can also be used to time-vary simulation parameters (e.g., the *fix deform* command will change the simulation box size/shape and the *fix move* command will change atom positions and velocities in a prescribed manner). Also note that many commands allow variables as arguments for specific parameters, if described in that manner on their doc pages. An equal-style variable can calculate a time-dependent quantity, so this is another way to vary a simulation parameter over time.

If N is specified as 0, the specified attributes are only changed once, before the simulation begins. This is all that is needed if the associated variables are not time-dependent. If $N > 0$, then changes are made every N steps during the simulation, presumably with a variable that is time-dependent.

Depending on the value of the *reset* keyword, attributes changed by this fix will or will not be reset back to their original values at the end of a simulation. Even if *reset* is specified as *yes*, a restart file written during a simulation will contain the modified settings.

If the *scale* keyword is set to *no*, which is the default, then the value of the altered parameter will be whatever the variable generates. If the *scale* keyword is set to *yes*, then the value of the altered parameter will be the initial value of that parameter multiplied by whatever the variable generates (i.e., the variable is now a "scale factor" applied in (presumably) a time-varying fashion to the parameter).

Note that whether scale is *no* or *yes*, internally, the parameters themselves are actually altered by this fix. Make sure you use the *reset yes* option if you want the parameters to be restored to their initial values after the run.

The *pair* keyword enables various parameters of potentials defined by the *pair_style* command to be changed, if the pair style supports it. Note that the *pair_style* and *pair_coeff* commands must be used in the usual manner to specify these parameters initially; the fix adapt command simply overrides the parameters.

Note

Pair_coeff settings must be made **explicitly** in order for fix adapt to be able to change them. Settings inferred from mixing are not suitable. If necessary all mixed settings can be output to a file using the *write_coeff command* and then the desired mixed pair_coeff settings copied from that file.

The *pstyle* argument is the name of the pair style. If *pair_style hybrid or hybrid/overlay* is used, *pstyle* should be a sub-style name. If there are multiple sub-styles using the same pair style, then *pstyle* should be specified as "style:N", where N is which instance of the pair style you wish to adapt (e.g., the first or second). For example, *pstyle* could be specified as "soft" or "lubricate" or "lj/cut:1" or "lj/cut:2". The *pparam* argument is the name of the parameter to change. This is the current list of pair styles and parameters that can be varied by this fix. See the doc pages for individual pair styles and their energy formulas for the meaning of these parameters:

born	a, c, d	type pairs
born/coul/long, born/coul/msm	cut_coul	type global

Note

It is easy to add new pairwise potentials and their parameters to this list. All it typically takes is adding an extract() method to the pair_*.cpp file associated with the potential.

Some parameters are global settings for the pair style (e.g., the viscosity setting "mu" for *pair_style lubricate*). Other parameters apply to atom type pairs within the pair style (e.g., the prefactor *a* for *pair_style soft*).

Note that for many of the potentials, the parameter that can be varied is effectively a prefactor on the entire energy expression for the potential (e.g., the lj/cut epsilon). The parameters listed as "scale" are exactly that, since the energy expression for the *coul/cut* potential (for example) has no labeled prefactor in its formula. To apply an effective prefactor to some potentials, multiple parameters need to be altered. For example, the *Buckingham potential* needs both the A and C terms altered together. To scale the Buckingham potential, you should thus list the pair style twice, once for A and once for C.

If a type pair parameter is specified, the I and J settings should be specified to indicate which type pairs to apply it to. If a global parameter is specified, the I and J settings still need to be specified, but are ignored.

Similar to the *pair_coeff command*, I and J can be specified in one of several ways. Explicit numeric values can be used for each, as in the first example above. Or, one or both of the types in the I,J pair can be a *type label*. LAMMPS sets the coefficients for the symmetric J, I interaction to the same values.

A wild-card asterisk can be used in place of or in conjunction with the I, J arguments to set the coefficients for multiple pairs of atom types. This takes the form "*" or "*n" or "m*" or "m*n". If N is the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from m to N (inclusive). A middle asterisk means all types from m to n (inclusive). For the asterisk syntax, note that only type pairs with $I \leq J$ are considered; if asterisks imply type pairs where $J < I$, they are ignored.

IMPORTANT NOTE: If *pair_style hybrid or hybrid/overlay* is being used, then the *pstyle* will be a sub-style name. You must specify I, J arguments that correspond to type pair values defined (via the *pair_coeff* command) for that sub-style.

The *v_name* argument for keyword *pair* is the name of an *equal-style variable* which will be evaluated each time this fix is invoked to set the parameter to a new value. It should be specified as v_name, where name is the variable name. Equal-style variables can specify formulas with various mathematical functions, and include *thermo_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify parameters that change as a function of time or span consecutive runs in a continuous fashion. For the latter, see the *start* and *stop* keywords of the *run* command and the *elaplong* keyword of *thermo_style custom* for details.

For example, these commands would change the prefactor coefficient of the *pair_style soft* potential from 10.0 to 30.0 in a linear fashion over the course of a simulation:

```
variable prefactor equal ramp(10,30)
fix 1 all adapt 1 pair soft a * * v_prefactor
```

The *bond* keyword uses the specified variable to change the value of a bond coefficient over time, very similar to how the *pair* keyword operates. The only difference is that now a bond coefficient for a given bond type is adapted.

A wild-card asterisk can be used in place of or in conjunction with the bond type argument to set the coefficients for multiple bond types. This takes the form "*" or "*n" or "m*" or "m*n". If *N* is the number of bond types, then an asterisk with no numeric values means all types from 1 to *N*. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from m to *N* (inclusive). A middle asterisk means all types from m to n (inclusive).

If *bond_style hybrid* is used, *bstyle* should be a sub-style name. The bond styles that currently work with fix adapt are:

class2	k2, k3, k4, r0	type bonds
fene	k, r0	type bonds
fene/expand	k, r0, epsilon, sigma, shift	type bonds
fene/nm	k, r0	type bonds
gromos	k, r0	type bonds
harmonic	k, r0	type bonds
harmonic/restrain	k	type bonds
harmonic/shift	k, r0, r1	type bonds
harmonic/shift/cut	k, r0, r1	type bonds
mm3	k2, r0	type bonds
morse	d0, alpha, r0	type bonds
nonlinear	lamda, epsilon, r0	type bonds

Added in version 4May2022.

The *angle* keyword uses the specified variable to change the value of an angle coefficient over time, very similar to how the *pair* keyword operates. The only difference is that now an angle coefficient for a given angle type is adapted.

A wild-card asterisk can be used in place of or in conjunction with the angle type argument to set the coefficients for multiple angle types. This takes the form "*" or "*n" or "m*" or "m*n". If *N* is the number of angle types, then an asterisk with no numeric values means all types from 1 to *N*. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from m to *N* (inclusive). A middle asterisk means all types from m to n (inclusive).

If *angle_style hybrid* is used, *astyle* should be a sub-style name. The angle styles that currently work with fix adapt are:

amoeba	k2, k3, k4, k5, k6, theta0	type angles
charmm	k, theta0	type angles
class2, class2xe	k2, k3, k4, theta0	type angles
class2/p6	k2, k3, k4, k5, k6, theta0	type angles
cosine	k	type angles
cosine/buck6d	k, th0	type angles
cosine/delta	k, theta0	type angles
cosine/periodic	k	type angles
cosine/squared	k, theta0	type angles
cosine/squared/restricted	k, theta0	type angles
dipole	k, gamma0	type angles
fourier	k, C0, C1, C2	type angles
fourier/simple	k, C, N	type angles
harmonic	k, theta0	type angles
mm3	k2, theta0	type angles
mwlc	k1, k2, mu, temp	type angles
quartic	k2, k3, k4, theta0	type angles
spica	k, theta0	type angles

Note that internally, theta0 is stored in radians, so the variable this fix uses to reset theta0 needs to generate values in radians.

Added in version 12Jun2025.

The *dihedral* keyword uses the specified variable to change the value of a dihedral coefficient over time, very similar to how the *angle* keyword operates. The only difference is that now a dihedral coefficient for a given dihedral type is adapted.

A wild-card asterisk can be used in place of or in conjunction with the dihedral type argument to set the coefficients for multiple dihedral types. This takes the form "*" or "*n" or "m*" or "m*n". If *N* is the number of dihedral types, then an asterisk with no numeric values means all types from 1 to *N*. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from m to *N* (inclusive). A middle asterisk means all types from m to n (inclusive).

If *dihedral_style hybrid* is used, *dstyle* should be a sub-style name. The dihedral styles that currently work with fix adapt are:

charmm	k	type dihedrals
charmmfsw	k	type dihedrals
class2, class2xe	k1, k2, k3, phi1, phi2, phi3	type dihedrals
cosine/squared/restricted	k, phi0	type dihedrals
helix	a, b, c	type dihedrals
multi/harmonic	a1, a2, a3, a4, a5	type dihedrals
opls	k1, k2, k3, k4	type dihedrals
quadratic	k, phi0	type dihedrals

Note that internally, phi0 is stored in radians, so the variable this fix use to reset phi0 needs to generate values in radians.

Added in version 2Apr2025.

The *improper* keyword uses the specified variable to change the value of an improper coefficient over time, very similar to how the *angle* keyword operates. The only difference is that now an improper coefficient for a given improper type is adapted.

A wild-card asterisk can be used in place of or in conjunction with the improper type argument to set the coefficients for multiple improper types. This takes the form "*" or "*n" or "m*" or "m*n". If *N* is the number of improper types, then an asterisk with no numeric values means all types from 1 to *N*. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from m to *N* (inclusive). A middle asterisk means all types from m to n (inclusive).

If *improper_style hybrid* is used, *istyle* should be a sub-style name. The improper styles that currently work with fix adapt are:

amoeba	k	type impropers
class2	k, chi0	type impropers
cossq	k, chi0	type impropers
cvff	k,	type impropers
distance	k2, k4	type impropers
distharm	k, d0	type impropers
fourier	k, C0, C1, C2	type impropers
harmonic	k, chi0	type impropers
inversion/harmonic	k, w0	type impropers
ring	k, theta0	type impropers
umbrella	k, w0	type impropers
sqdistharm	k	type impropers

Note that internally, chi0 and theta0 are stored in radians, so the variable this fix use to reset chi0 or theta0 needs to generate values in radians.

The *kspace* keyword used the specified variable as a scale factor on the energy, forces, virial calculated by whatever *k*-space solver is defined by the *kspace_style* command. If the variable has a value of 1.0, then the solver is unaltered.

The *kspace* keyword works this way whether the *scale* keyword is set to *no* or *yes*.

The *atom* keyword enables various atom properties to be changed. The *aparam* argument is the name of the parameter to change. This is the current list of atom parameters that can be varied by this fix:

- charge = charge on particle
- diameter or diameter/disc = diameter of particle

The *v_name* argument of the *atom* keyword is the name of an *equal-style variable* which will be evaluated each time this fix is invoked to set, or scale the parameter to a new value. It should be specified as v_name, where name is the variable name. See the discussion above describing the formulas associated with equal-style variables. The new value is assigned to the corresponding attribute for all atoms in the fix group.

If the atom parameter is *diameter* and per-atom density and per-atom mass are defined for particles (e.g., *atom_style granular*), then the mass of each particle is, by default, also changed when the diameter changes. The mass is set from the particle volume for 3d systems (density is assumed to stay constant). For 2d, the default is for LAMMPS to model particles with a radius attribute as spheres. However, if the atom parameter is *diameter/disc*, then the mass is set from the particle area (the density is assumed to be in mass/distance^2 units). The mass of the particle may also be kept constant if the *mass* keyword is set to *no*. This can be useful to account for diameter changes that do not involve mass changes (e.g., thermal expansion).

For example, these commands would shrink the diameter of all granular particles in the "center" group from 1.0 to 0.1 in a linear fashion over the course of a 1000-step simulation:

```
variable size equal ramp(1.0,0.1)
fix 1 center adapt 10 atom diameter v_size
```

This fix can be used in long simulations which are restarted one or more times to continuously adapt simulation parameters, but it must be done carefully. There are two issues to consider. The first is how to adapt the parameters in a continuous manner from one simulation to the next. The second is how, if desired, to reset the parameters to their original values at the end of the last restarted run.

Note that all the parameters changed by this fix are written into a restart file in their current changed state. A new restarted simulation does not know the original time=0 values, unless the input script explicitly resets the parameters (after the restart file is read) to the original values.

Also note that the time-dependent variable(s) used in the restart script should typically be written as a function of time elapsed since the original simulation began.

With this in mind, if the *scale* keyword is set to *no* (the default) in a restarted simulation, original parameters are not needed. The adapted parameters should seamlessly continue their variation relative to the preceding simulation.

If the *scale* keyword is set to *yes*, then the input script should typically reset the parameters being adapted to their original values, so that the scaling formula specified by the variable will operate correctly. An exception is if the *atom* keyword is being used with *scale yes*. In this case, information is added to the restart file so that per-atom properties in the new run will automatically be scaled relative to their original values. This will only work if the fix adapt command specified in the restart script has the same ID as the one used in the original script.

In a restarted run, if the *reset* keyword is set to *yes*, and the run ends in this script (as opposed to just writing more restart files), parameters will be restored to the values they were at the beginning of the run command in the restart script, which as explained above, may or may not be the original values of the parameters. Again, an exception is if the *atom* keyword is being used with *reset yes* (in all the runs). In that case, the original per-atom parameters are stored in the restart file, and will be restored when the restarted run finally completes.

2.3.4 Restart, fix_modify, output, run start/stop, minimize info

If the *atom* keyword is used and the *scale* or *reset* keyword is set to *yes*, then this fix writes information to a restart file so that in a restarted run scaling can continue in a seamless manner and/or the per-atom values can be restored, as explained above.

None of the *fix_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

For *rRESPA time integration*, this fix changes parameters on the outermost rRESPA level.

2.3.5 Restrictions

none

2.3.6 Related commands

compute ti, *fix adapt/fep*

2.3.7 Default

The option defaults are scale = no, reset = no, mass = yes.

2.4 fix adapt/fep command

2.4.1 Syntax

```
fix ID group-ID adapt/fep N attribute args ... keyword value ...
```

- ID, group-ID are documented in *fix* command
- adapt/fep = style name of this fix command

- N = adapt simulation settings every this many timesteps
- one or more attribute/arg pairs may be appended
- attribute = *pair* or *kspace* or *atom*

```
pair args = pstyle pparam I J v_name
  pstyle = pair style name (e.g., lj/cut)
  pparam = parameter to adapt over time
  I,J = type pair(s) to set parameter for (integer or type label)
  v_name = variable with name that calculates value of pparam
kspace arg = v_name
  v_name = variable with name that calculates scale factor on K-space terms
atom args = aparam v_name
  aparam = parameter to adapt over time
  I = type(s) to set parameter for (integer or type label)
  v_name = variable with name that calculates value of aparam
```

- zero or more keyword/value pairs may be appended
- keyword = *scale* or *reset* or *after*

```
scale value = no or yes
  no = the variable value is the new setting
  yes = the variable value multiplies the original setting
reset value = no or yes
  no = values will remain altered at the end of a run
  yes = reset altered values to their original values at the end
  of a run
after value = no or yes
  no = parameters are adapted at timestep N
  yes = parameters are adapted one timestep after N
```

2.4.2 Examples

```
fix 1 all adapt/fep 1 pair soft a 1 1 v_prefactor
fix 1 all adapt/fep 1 pair soft a 2* 3 v_prefactor
fix 1 all adapt/fep 1 pair lj/cut epsilon * * v_scale1 coul/cut scale 3 3 v_scale2 scale␣
↪yes reset yes
fix 1 all adapt/fep 10 atom diameter 1 v_size

labelmap atom 1 c1
fix 1 all adapt/fep 1 pair soft a c1 c1 v_prefactor
```

Example input scripts available: examples/PACKAGES/fep

2.4.3 Description

Change or adapt one or more specific simulation attributes or settings over time as a simulation runs.

This is an enhanced version of the *fix adapt* command with two differences:

- It is possible to modify the charges of chosen atom types only, instead of scaling all the charges in the system.
- There is a new option *after* for better compatibility with *fix ave/time*.

This version is suited for free energy calculations using *compute ti* or *compute fep*.

If *N* is specified as 0, the specified attributes are only changed once, before the simulation begins. This is all that is needed if the associated variables are not time-dependent. If *N* > 0, then changes are made every *N* steps during the simulation, presumably with a variable that is time-dependent.

Depending on the value of the *reset* keyword, attributes changed by this fix will or will not be reset back to their original values at the end of a simulation. Even if *reset* is specified as *yes*, a restart file written during a simulation will contain the modified settings.

If the *scale* keyword is set to *no*, then the value the parameter is set to will be whatever the variable generates. If the *scale* keyword is set to *yes*, then the value of the altered parameter will be the initial value of that parameter multiplied by whatever the variable generates (i.e., the variable is now a "scale factor" applied in (presumably) a time-varying fashion to the parameter). Internally, the parameters themselves are actually altered; make sure you use the *reset yes* option if you want the parameters to be restored to their initial values after the run.

If the *after* keyword is set to *yes*, then the parameters are changed one timestep after the multiple of N. In this manner, if a fix such as "fix ave/time" is used to calculate averages at every N timesteps, all the contributions to the average will be obtained with the same values of the parameters.

The *pair* keyword enables various parameters of potentials defined by the *pair_style* command to be changed, if the pair style supports it. Note that the *pair_style* and *pair_coeff* commands must be used in the usual manner to specify these parameters initially; the fix adapt command simply overrides the parameters.

Note

Pair_coeff settings must be made **explicitly** in order for fix adapt/fep to be able to change them. Settings inferred from mixing are not suitable. If necessary all mixed settings can be output to a file using the *write_coeff command* and then the desired mixed pair_coeff settings copied from that file.

The *pstyle* argument is the name of the pair style. If *pair_style hybrid or hybrid/overlay* is used, *pstyle* should be a sub-style name. For example, *pstyle* could be specified as "soft" or "lubricate". The *pparam* argument is the name of the parameter to change. This is the current list of pair styles and parameters that can be varied by this fix. See the doc pages for individual pair styles and their energy formulas for the meaning of these parameters:

born	a, c, d	type pairs

yukawa, yukawa/colloid	alpha	type pairs

Note

It is easy to add new potentials and their parameters to this list. All it typically takes is adding an extract() method to the pair_*.cpp file associated with the potential.

Note that for many of the potentials, the parameter that can be varied is effectively a prefactor on the entire energy expression for the potential (e.g., the lj/cut epsilon). The parameters listed as "scale" are exactly that, since the energy expression for the *coul/cut* potential (for example) has no labeled prefactor in its formula. To apply an effective prefactor to some potentials, multiple parameters need to be altered. For example, the *Buckingham potential* needs both the A and C terms altered together. To scale the Buckingham potential, you should thus list the pair style twice, once for A and once for C.

If a type pair parameter is specified, the I and J settings should be specified to indicate which type pairs to apply it to. If a global parameter is specified, the I and J settings still need to be specified, but are ignored.

Similar to the *pair_coeff command*, I and J can be specified in one of several ways. Explicit numeric values can be used for each, as in the first example above. Or, one or both of the types in the I,J pair can be a *type label*. LAMMPS sets the coefficients for the symmetric J, I interaction to the same values.

A wild-card asterisk can be used in place of or in conjunction with the I, J arguments to set the coefficients for multiple pairs of atom types. This takes the form "*" or "*n" or "m*" or "m*n". If N is the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from m to N (inclusive). A middle asterisk means all types from m to n (inclusive).

For the asterisk syntax, note that only type pairs with $I \leq J$ are considered; if asterisks imply type pairs where $J < I$, they are ignored.

IMPORTANT NOTE

If *pair_style hybrid or hybrid/overlay* is being used, then the *pstyle* will be a sub-style name. You must specify I, J arguments that correspond to type pair values defined (via the *pair_coeff* command) for that sub-style.

The *v_name* argument for keyword *pair* is the name of an *equal-style variable* which will be evaluated each time this fix is invoked to set the parameter to a new value. It should be specified as v_name, where name is the variable name. Equal-style variables can specify formulas with various mathematical functions, and include *thermo_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify parameters that change as a function of time or span consecutive runs in a continuous fashion. For the latter, see the *start* and *stop* keywords of the *run* command and the *elaplong* keyword of *thermo_style custom* for details.

For example, these commands would change the prefactor coefficient of the *pair_style soft* potential from 10.0 to 30.0 in a linear fashion over the course of a simulation:

```
variable prefactor equal ramp(10,30)
fix 1 all adapt 1 pair soft a * * v_prefactor
```

The *kspace* keyword used the specified variable as a scale factor on the energy, forces, virial calculated by whatever *k*-space solver is defined by the *kspace_style* command. If the variable has a value of 1.0, then the solver is unaltered.

The *kspace* keyword works this way whether the *scale* keyword is set to *no* or *yes*.

The *atom* keyword enables various atom properties to be changed. The *aparam* argument is the name of the parameter to change. This is the current list of atom parameters that can be varied by this fix:

- charge = charge on particle
- diameter = diameter of particle

The *I* argument indicates which atom types are affected. A wild-card asterisk can be used in place of or in conjunction with the *I* argument to set the coefficients for multiple atom types.

The *v_name* argument of the *atom* keyword is the name of an *equal-style variable* which will be evaluated each time this fix is invoked to set the parameter to a new value. It should be specified as v_name, where name is the variable name. See the discussion above describing the formulas associated with equal-style variables. The new value is assigned to the corresponding attribute for all atoms in the fix group.

If the atom parameter is *diameter* and per-atom density and per-atom mass are defined for particles (e.g., *atom_style granular*), then the mass of each particle is also changed when the diameter changes (density is assumed to stay constant).

For example, these commands would shrink the diameter of all granular particles in the "center" group from 1.0 to 0.1 in a linear fashion over the course of a 1000-step simulation:

```
variable size equal ramp(1.0,0.1)
fix 1 center adapt 10 atom diameter * v_size
```

For *rRESPA time integration*, this fix changes parameters on the outermost rRESPA level.

2.4.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

2.4.5 Restrictions

The keyword "scale yes" is not supported for scaling per-atom parameters diameter and change. You can use *fix adapt* for those.

2.4.6 Related commands

compute fep, *fix adapt*, *compute ti*, *pair_style */soft*

2.4.7 Default

The option defaults are scale = no, reset = no, after = no.

2.5 fix add/heat command

2.5.1 Syntax

```
fix ID group-ID add/heat style args keyword values ...
```

- ID, group-ID are documented in *fix* command
- add/heat = style name of this fix command
- style = *constant* or *linear* or *quartic*

```
constant args = rate
  rate = rate of heat flow (energy/time units)
linear args = Ttarget k
  Ttarget = target temperature (temperature units)
  k = prefactor (energy/(time*temperature) units)
quartic args = Ttarget k
  Ttarget = target temperature (temperature units)
  k = prefactor (energy/(time*temperature^4) units)
```

- zero or more keyword/value pairs may be appended to args
- keyword = *overwrite*

```
overwrite value = yes or no
  yes = sets current heat flow of particle
  no = adds to current heat flow of particle
```

2.5.2 Examples

```
fix 1 all add/heat constant v_heat
fix 1 all add/heat linear 10.0 1.0 overwrite yes
```

2.5.3 Description

This fix adds heat to particles with the temperature attribute every timestep at a given rate. Note that this is an internal temperature of a particle intended for use with non-atomistic models like the discrete element method.

For the *constant* style, heat is added at the specified rate. For the *linear* style, heat is added at a rate of $k(T_{target} - T)$ where k is the specified prefactor, T_{target} is the specified target temperature, and T is the temperature of the atom. This may be more representative of a conductive process. For the *quartic* style, heat is added at a rate of $k(T_{target}^4 - T^4)$, akin to radiative heat transfer.

The rate or temperature can be can be specified as an equal-style or atom-style *variable*. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each time step, and its value will be used to determine the rate of heat added.

Equal-style variables can specify formulas with various mathematical functions and include *thermo_style* command keywords for the simulation box parameters, time step, and elapsed time to specify time-dependent heating.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates to specify spatially-dependent heating.

If the *overwrite* keyword is set to *yes*, this fix will set the total heat flow on a particle every timestep, overwriting contributions from pair styles or other fixes. If *overwrite* is *no*, this fix will add heat on top of other contributions.

2.5.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

2.5.5 Restrictions

This pair style is part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This fix requires that atoms store temperature and heat flow as defined by the *fix property/atom* command or included in certain atom styles, such as atom_style rheo/thermal.

2.5.6 Related commands

fix heat/flow, *fix property/atom*, *fix rheo/thermal*

2.5.7 Default

The default for the *overwrite* keyword is *no*

2.6 fix addforce command

Accelerator Variants: *addforce/kk*

2.6.1 Syntax

```
fix ID group-ID addforce fx fy fz keyword value ...
```

- ID, group-ID are documented in *fix* command
- addforce = style name of this fix command

- fx,fy,fz = force component values (force units)

```
any of fx,fy,fz can be a variable (see below)
```

- zero or more keyword/value pairs may be appended to args
- keyword = *every* or *region* or *energy*

```
every value = Nevery
  Nevery = add force every this many time steps
region value = region-ID
  region-ID = ID of region atoms must be in to have added force
energy value = v_name
  v_name = variable with name that calculates the potential energy of each atom in␣
↪the added force field
```

2.6.2 Examples

```
fix kick flow addforce 1.0 0.0 0.0
fix kick flow addforce 1.0 0.0 v_oscillate
fix ff boundary addforce 0.0 0.0 v_push energy v_espace
```

2.6.3 Description

Add (f_x, f_y, f_z) to the corresponding component of the force for each atom in the group. This command can be used to give an additional push to atoms in a simulation, such as for a simulation of Poiseuille flow in a channel.

Any of the three quantities defining the force components, namely f_x, f_y, and f_z, can be specified as an equal-style or atom-style *variable*. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each time step, and its value(s) will be used to determine the force component(s).

Equal-style variables can specify formulas with various mathematical functions and include *thermo_style* command keywords for the simulation box parameters, time step, and elapsed time. Thus, it is easy to specify a time-dependent force field.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus, it is easy to specify a spatially-dependent force field with optional time-dependence as well.

If the *every* keyword is used, the *Nevery* setting determines how often the forces are applied. The default value is 1, for every time step.

If the *region* keyword is used, the atom must also be in the specified geometric *region* in order to have force added to it.

Adding a force to atoms implies a change in their potential energy as they move due to the applied force field. For dynamics via the "run" command, this energy can be optionally added to the system's potential energy for thermodynamic output (see below). For energy minimization via the "minimize" command, this energy must be added to the system's potential energy to formulate a self-consistent minimization problem (see below).

The *energy* keyword is not allowed if the added force is a constant vector $\vec{F} = (f_x, f_y, f_z)$, with all components defined as numeric constants and not as variables. This is because LAMMPS can compute the energy for each atom directly as

$$E = -\vec{x} \cdot \vec{F} = -(xf_x + yf_y + zf_z),$$

so that $-\vec{\nabla}E = \vec{F}$.

The *energy* keyword is optional if the added force is defined with one or more variables, and if you are performing dynamics via the *run* command. If the keyword is not used, LAMMPS will set the energy to 0.0, which is typically fine for dynamics.

The *energy* keyword is required if the added force is defined with one or more variables, and you are performing energy minimization via the "minimize" command. The keyword specifies the name of an atom-style *variable* which is used to compute the energy of each atom as function of its position. Like variables used for f_x, f_y, f_z, the energy variable is specified as v_name, where name is the variable name.

Note that when the *energy* keyword is used during an energy minimization, you must ensure that the formula defined for the atom-style *variable* is consistent with the force variable formulas (i.e., that $-\vec{\nabla}E = \vec{F}$). For example, if the force were a spring-like, $\vec{F} = -k\vec{x}$, then the energy formula should be $E = \frac{1}{2}kx^2$. If you do not do this correctly, the minimization will not converge properly.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

Note

The region keyword is supported by Kokkos, but a Kokkos-enabled region must be used. See the region *region* command for more information.

2.6.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix_modify energy* option is supported by this fix to add the potential energy inferred by the added force to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix_modify energy no*. Note that this energy is a fictitious quantity but is needed so that the *minimize* command can include the forces added by this fix in a consistent manner (i.e., there is a decrease in potential energy when atoms move in the direction of the added force).

The *fix_modify virial* option is supported by this fix to add the contribution due to the added forces on atoms to both the global pressure and per-atom stress of the system via the *compute pressure* and *compute stress/atom* commands. The former can be accessed by *thermodynamic output*. The default setting for this fix is *fix_modify virial no*.

The *fix_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar and a global three-vector of forces, which can be accessed by various *output commands*. The scalar is the potential energy discussed above. The vector is the total force on the group of atoms before the forces on individual atoms are changed by the fix. The scalar and vector values calculated by this fix are "extensive".

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command. You should not specify force components with a variable that has time-dependence for use with a minimizer, since the minimizer increments the time step as the iteration count during the minimization.

Note

If you want the fictitious potential energy associated with the added forces to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the *fix_modify energy* option for this fix.

2.6.5 Restrictions

none

2.6.6 Related commands

fix setforce, *fix aveforce*

2.6.7 Default

The option default for the every keyword is every = 1.

2.7 fix addtorque/atom command

Accelerator Variants: *addtorque/atom/kk*

2.7.1 Syntax

```
fix ID group-ID addtorque/atom tx ty tz keyword value ...
```

- ID, group-ID are documented in *fix* command
- addtorque/atom = style name of this fix command
- tx,ty,tz = torque component values (torque units) .. parsed-literal:

  ```
  any of tx,ty,tz can be a variable (see below)
  ```

- zero or more keyword/value pairs may be appended to args
- keyword = *every* or *region*

  ```
  every value = Nevery
    Nevery = add torque every this many time steps
  region value = region-ID
    region-ID = ID of region atoms must be in to have added torque
  ```

2.7.2 Examples

```
fix kick flow addtorque/atom 1.0 0.0 0.0
fix kick flow addtorque/atom 1.0 0.0 v_oscillate
fix ff boundary addtorque/atom 0.0 0.0 v_push
```

2.7.3 Description

Added in version 10Dec2025.

This fix is intended to add a peratom torque of each individual finite-sized atom in the group to the specified values. Unlike *fix addtorque/group*, it does not apply a collective torque to a set of point particles.

Add (t_x, t_y, t_z) to the corresponding component of the torque for each atom in the group. Any of the three quantities defining the torque components, namely t_x, t_y, and t_z, can be specified as an equal-style or atom-style *variable*. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each time step, and its value(s) will be used to determine the torque component(s).

Equal-style variables can specify formulas with various mathematical functions and include *thermo_style* command keywords for the simulation box parameters, time step, and elapsed time. Thus, it is easy to specify a time-dependent torque field.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus, it is easy to specify a spatially-dependent torque field with optional time-dependence as well.

If the *every* keyword is used, the *Nevery* setting determines how often the torques are applied. The default value is 1, for every time step.

If the *region* keyword is used, the atom must also be in the specified geometric *region* in order to have torque added to it.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

2.7.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix_modify* *respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its torques. Default is the outermost level.

This fix computes a global three-vector of torques which can be accessed by various *output commands*. The vector is the total torque on the group of atoms before the torques on individual atoms are changed by the fix. The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The torques due to this fix are imposed during an energy minimization, invoked by the *minimize* command. You should not specify torque components with a variable that has time-dependence for use with a minimizer, since the minimizer increments the time step as the iteration count during the minimization.

> **Note**
>
> This fix is not (currently) designed to be used with rigid fixes. While it will apply additional torques to all of the atoms in a rigid body as described above, there is not always an easy mapping between these peratom torques and the torque experienced by the body.

2.7.5 Restrictions

Fix *addtorque/atom* is part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

2.7.6 Related commands

fix settorque/atom, *fix addforce*

2.7.7 Default

The option default for the every keyword is every = 1.

2.8 fix addtorque/group command

Accelerator Variant: *addtorque/group/kk*

2.8.1 Syntax

```
fix ID group-ID addtorque/group Tx Ty Tz
```

- ID, group-ID are documented in *fix* command
- addtorque/group = style name of this fix command
- Tx,Ty,Tz = torque component values (torque units)
- any of Tx,Ty,Tz can be a variable (see below)

2.8.2 Examples

```
fix kick bead addtorque/group 2.0 3.0 5.0
fix kick bead addtorque/group 0.0 0.0 v_oscillate
```

2.8.3 Description

Changed in version 10Dec2025: Fix *addtorque* was renamed to fix *addtorque/group*

Add a set of forces to each atom in the group such that:

- the components of the total torque applied on the group (around its center of mass) are T_x, T_y, and T_z
- the group would move as a rigid body in the absence of other forces.

This command can be used to drive a group of atoms into rotation by adding forces to the atoms. To apply a torque to individual finite-size atoms, use *fix addtorque/atom* instead.

Any of the three quantities defining the torque components can be specified as an equal-style *variable*, namely *Tx*, *Ty*, *Tz*. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the torque component.

Equal-style variables can specify formulas with various mathematical functions, and include *thermo_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent torque.

Note

Fix *addtorque/group* previously was known as fix *addtorque* and was renamed to clarify that the fix operates on a group of atoms as opposed to individual finite-size atoms.

2.8.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix_modify* *energy* option is supported by this fix to add the potential "energy" inferred by the added torques to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix_modify energy no*. Note that this is a fictitious quantity but is needed so that the *minimize* command can include the forces added by this fix in a consistent manner (i.e., there is a decrease in potential energy when atoms move in the direction of the added forces).

The *fix_modify* *respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its torque. Default is the outermost level.

This fix computes a global scalar and a global 3-vector, which can be accessed by various *output commands*. The scalar is the potential energy discussed above. The vector is the total torque on the group of atoms before the forces on individual atoms are changed by the fix. The scalar and vector values calculated by this fix are "extensive".

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command.

Note

If you want the fictitious potential energy associated with the added forces to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the *fix_modify* *energy* option for this fix.

Note

You should not specify force components with a variable that has time-dependence for use with a minimizer, since the minimizer increments the timestep as the iteration count during the minimization.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

2.8.5 Restrictions

The *addtorque/group/kk* accelerator variant cannot (yet) be used with *run_style respa* and stops with an error in that case.

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

2.8.6 Related commands

fix addforce *fix addtorque/atom*

2.8.7 Default

2.9 fix alchemy command

2.9.1 Syntax

```
fix ID group-ID alchemy v_name
```

- ID, group-ID are documented in *fix* command
- alchemy = style name of this fix command
- v_name = variable with name that determines the λ_R value

2.9.2 Examples

```
fix trans all alchemy v_ramp
```

2.9.3 Description

Added in version 28Mar2023.

This fix command enables an "alchemical transformation" to be performed between two systems, whereby one system slowly transforms into the other over the course of a molecular dynamics run. This is useful for measuring thermodynamic differences between two different systems. It also allows transformations that are not easily possible with the *pair style hybrid/scaled*, *fix adapt* or *fix adapt/fep* commands.

Example inputs are included in the `examples/PACKAGES/alchemy` directory for (a) transforming a pure copper system into a copper/aluminum bronze alloy and (b) transforming two water molecules in a box of water into a hydronium and a hydroxyl ion.

The two systems must be defined as *separate replica* and run in separate partitions of processors using the *-partition* command-line switch. Exactly two partitions must be specified, and each partition must use the same number of processors and the same domain decomposition.

Because the forces applied to the atoms are the same mix of the forces from each partition and the simulation starts with the same atom positions across both partitions, they will generate the same trajectory of coordinates for each atom, and the same simulation box size and shape. The latter two conditions are *enforced* by this fix; it exchanges coordinates

and box information between the replicas. This is not strictly required, but since MD simulations are an example of a chaotic system, even the tiniest random difference will eventually grow exponentially into an unwanted divergence.

Otherwise, the properties of each atom (type, charge, bond and angle partners, etc.), as well as energy and forces between interacting atoms (pair, bond, angle styles, etc.) can be different in the two systems.

This can be initialized in the same input script by using commands which only apply to one or the other replica. The example scripts use a world-style *variable* command along with *if/then/else* commands for this purpose. The *partition* command can also be used.

```
create_box 2 box
create_atoms 1 box
pair_style eam/alloy
pair_coeff * * AlCu.eam.alloy Cu Al

# replace 5% of copper with aluminum on the second partition only

variable name world pure alloy
if "${name} == alloy" then &
  "set type 1 type/fraction 2 0.05 6745234"
```

Both replicas must define an instance of this fix, but with a different *v_name* variable. The named variable must be an equal-style or equivalent *variable*. The two variables should be defined so that one ramps *down* from 1.0 to 0.0 for the *first* replica (*R=0*) and the other ramps *up* from 0.0 to 1.0 for the *second* replica (*R=1*). A simple way is to do this is linearly, which can be done using the ramp() function of the *variable* command. You could also define a variable which returns a value between 0.0 and 1.0 as a non-linear function of the timestep. Here is a linear example:

```
partition yes 1 variable ramp equal ramp(1.0,0.0)
partition yes 2 variable ramp equal ramp(0.0,1.0)
fix 2 all alchemy v_ramp
```

Note

For an alchemical transformation, the two variables should sum to exactly 1.0 at any timestep. LAMMPS does *NOT* check that this is the case.

If you use the `ramp()` function to define the two variables, this fix can easily be used across successive runs in the same input script by ensuring each instance of the *run* command specifies the appropriate *start* or *stop* options.

At each timestep of an MD run, the two instances of this fix evaluate their respective variables as a λ_R factor, where R = 0 or 1 for each replica. The forces used by each system for the propagation of their atoms is set to the sum of the forces for the two systems, each scaled by their respective λ_R factor. Thus, during the MD run, the system will transform incrementally from the first system to the second system.

Note

As mentioned above, the coordinates of the atoms and box size/shape must be exactly the same in the two replicas. Therefore, it is generally not a good idea to initialize the two replicas by reading different data files or creating them individually from scratch. Rather, a single system should be initialized and then desired modifications applied to the system to either replica. If your input script somehow induces the two systems to become different (e.g. by performing *atom_modify sort* differently, or by adding or depositing a different number of atoms), then LAMMPS will detect the mismatch and generate an error. This is done by ensuring that each step the number and ordering of atoms is identical within each pair of processors in the two replicas.

2.9.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix_modify* options are relevant to this fix.

This fix stores a global scalar (the current value of λ_R) and a global vector of length 3 which contains the potential energy of the first partition, the second partition and the combined value, respectively. The global scalar is unitless and "intensive", the vector is in *energy units* and "extensive". These values can be used by any command that uses a global value from a fix as input. See the *output howto* page for an overview of LAMMPS output options.

This fix is not invoked during *energy minimization*.

2.9.5 Restrictions

This fix is part of the REPLICA package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

There may be only one instance of this fix in use at a time within each replica.

2.9.6 Related commands

compute pressure/alchemy command, *fix adapt* command, *fix adapt/fep* command, *pair_style hybrid/scaled* command.

2.9.7 Default

2.10 fix align/self command

2.10.1 Syntax

```
fix ID group-ID align/self mode magnitude keyword values
```

- ID, group-ID are documented in *fix* command
- align/self = style name of this fix command
- mode = *dipole* or *quat*
- magnitude = magnitude of self-alignment torque
- zero or one keyword/value pairs may be appended
- keyword = *qvector*

  qvector value = direction of self-propulsion force in ellipsoid frame
    sx, *sy*, *sz* = components of *qvector*

2.10.2 Examples

```
fix active all align/self dipole 40.0
fix active all align/self quat 15.7 qvector 1.0 0.0 0.0
```

2.10.3 Description

Added in version 10Dec2025.

Add a torque to each atom in the group which accounts for the reorientation of each particle toward its own velocity, a generic phenomenon called self-alignment (see *(Baconnier2025)*). The torque is given by :

$$\tau_i = \zeta(\mathbf{e}_i \times \mathbf{v}_i)$$

where i is the particle the torque is being applied to, ζ is the magnitude of the torque, $\mathbf{e}_i$ is the orientation of the particle, and $\mathbf{v}_i$ is its velocity. The self-alignment term, introduced in *(Shimoyama1996)* with the study of collective motion in systems of self-propelled particles, is an effective torque arising from differential drag in asymmetric rigid bodies.

For mode *dipole*, e_i is just equal to the dipole vectors of the atoms in the group. Therefore, if the dipoles are not unit vectors, the e_i will not be unit vectors.

Note

If another command changes the magnitude of the dipole, the applied torque will change accordingly and no warning will be provided by LAMMPS. This is almost never what you want, so ensure you are not changing dipole magnitudes with another LAMMPS fix or pair style. Furthermore, self-propulsion forces (almost) always set e_i to be a unit vector for all times, so it's best to set all the dipole magnitudes to 1.0 unless you have a good reason not to (see the *set* command on how to do this).

For mode *quat*, e_i points in the direction of a unit vector, oriented in the coordinate frame of the ellipsoidal particles, which defaults to point along the x-direction. This default behavior can be changed by via the *qvector* keyword.

The optional *qvector* keyword specifies the direction of self-propulsion via a unit vector (sx,sy,sz). The arguments *sx*, *sy*, and *sz*, are defined within the coordinate frame of the atom's ellipsoid. For instance, for an ellipsoid with long axis along its x-direction, if one wanted the self-propulsion force to also be along this axis, set *sx* equal to 1 and *sy*, *sz* both equal to zero. This keyword may only be specified for mode *quat*.

Note

In using keyword *qvector*, the three arguments *sx*, *sy*, and *sz* will be automatically normalized to components of a unit vector internally to avoid users having to explicitly do so themselves. Therefore, in mode *quat*, the vectors e_i will always be of unit length.

2.10.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. No global or per-atom quantities are stored by this fix for access by various *output commands*.

Changed in version 30Sep2026.

The *fix_modify* *respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its torques. Default is the outermost level. Previous versions did not apply the torque with *run_style respa*.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

2.10.5 Restrictions

This fix is part of the BROWNIAN package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

The keyword *dipole* requires that atoms store torque as defined by the *atom_style sphere* command, as well as a dipole moment as defined by the *atom_style dipole* command which is part of the DIPOLE package. The keyword *quat* requires that atoms store torque and quaternions as defined by the *atom_style ellipsoid* command.

2.11 fix amoeba/bitorsion command

2.11.1 Syntax

```
fix ID group-ID ameoba/bitorsion filename
```

- ID, group-ID are documented in *fix* command
- amoeba/bitorsion = style name of this fix command
- filename = force-field file with AMOEBA bitorsion coefficients

2.11.2 Examples

```
fix           bit all amoeba/bitorsion bitorsion.ubiquitin.data
read_data     proteinX.data fix bit bitorsions BiTorsions
fix_modify    bit energy yes
```

2.11.3 Description

This command enables 5-body torsion/torsion interactions to be added to simulations which use the AMOEBA and HIPPO force fields. It matches how the Tinker MD code computes its torsion/torsion interactions for the AMOEBA and HIPPO force fields. See the *Howto amoeba* doc page for more information about the implementation of AMOEBA and HIPPO in LAMMPS.

Bitorsion interactions add additional potential energy contributions to pairs of overlapping phi-psi dihedrals of amino-acids, which are important to properly represent their conformational behavior. Each bitorsion interaction is thus defined for a 5-tuple of atoms $IJKLM$ with bonds between successive atoms in the list, i.e. two overlapping dihedral interactions for atoms $IJKL$ and $JKLM$.

The examples/amoeba directory has a sample input script and data file for ubiquitin, which illustrates use of the fix amoeba/bitorsion command.

As in the example above, this fix should be used before reading a data file that contains a listing of bitorsion interactions. The *filename* specified should contain the bitorsion parameters for the AMOEBA or HIPPO force field.

The data file read by the *read_data* command must contain the topology of all the bitorsion interactions, similar to the topology data for bonds, angles, dihedrals, etc. Specifically it should have a line like this in its header section:

```
N bitorsions
```

where *N* is the number of bitorsion 5-body interactions. It should also have a section in the body of the data file like this with *N* lines:

```
BiTorsions

       1       1       8      10      12      18      20
       2       5      18      20      22      25      27
       [...]
       N       3     314     315     317     318     330
```

The first column is an index from 1 to *N* to enumerate the bitorsion 5-atom tuples; it is ignored by LAMMPS. The second column is the *type* of the interaction; it is an index into the bitorsion force field file. The remaining 5 columns are the atom IDs of the atoms (in order) for the 5-tuple *IJKLM*, as described above.

Note that the *bitorsions* and *BiTorsions* keywords for the header and body sections match those specified in the *read_data* command following the data file name.

The data file should be generated by using the tools/tinker/tinker2lmp.py conversion script which creates a LAMMPS data file from Tinker input files, including its PRM file which contains the parameters necessary for computing bitorsion interactions. The script must be invoked with the optional "-bitorsion" flag to do this; see the example for the ubiquitin system in the tools/tinker/README file. The same conversion script also creates the file of bitorsion coefficient data which is read by this command.

The potential energy associated with bitorsion interactions can be output as described below. It can also be included in the total potential energy of the system, as output by the *thermo_style* command, if the *fix_modify energy* command is used, as in the example above. See the note below about how to include the bitorsion energy when performing an *energy minimization*.

2.11.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the list of bitorsion interactions to *binary restart files*. See the *read_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The *fix_modify energy* option is supported by this fix to add the potential energy of the bitorsion interactions to both the global potential energy and peratom potential energies of the system as part of *thermodynamic output* or output by the *compute pe/atom* command. The default setting for this fix is *fix_modify energy yes*.

The *fix_modify virial* option is supported by this fix to add the contribution due to the bitorsion interactions to both the global pressure and per-atom stress of the system via the *compute pressure* and *compute stress/atom* commands. The former can be accessed by *thermodynamic output*. The default setting for this fix is *fix_modify virial yes*.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the potential energy discussed above. The scalar value calculated by this fix is "extensive".

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command.

The *fix_modify* *respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its forces. Default is the outermost level.

Note

For energy minimization, if you want the potential energy associated with the bitorsion terms forces to be included in the total potential energy of the system (the quantity being minimized), you MUST not disable the *fix_modify* *energy* option for this fix.

2.11.5 Restrictions

To function as expected this fix command must be issued *before* a *read_data* command but *after* a *read_restart* command.

This fix can only be used if LAMMPS was built with the AMOEBA package. See the *Build package* page for more info.

2.11.6 Related commands

fix_modify, *read_data*

2.12 fix amoeba/pitorsion command

2.12.1 Syntax

```
fix ID group-ID ameoba/pitorsion
```

- ID, group-ID are documented in *fix* command
- amoeba/pitorsion = style name of this fix command

2.12.2 Examples

```
fix            pit all amoeba/pitorsion
read_data      proteinX.data fix pit "pitorsion types" "PiTorsion Coeffs" &
               fix pit pitorsions PiTorsions
fix_modify     pit energy yes
```

2.12.3 Description

This command enables 6-body pitorsion interactions to be added to simulations which use the AMOEBA and HIPPO force fields. It matches how the Tinker MD code computes its pitorsion interactions for the AMOEBA and HIPPO force fields. See the *Howto amoeba* doc page for more information about the implementation of AMOEBA and HIPPO in LAMMPS.

Pitorsion interactions add additional potential energy contributions to 6-tuples of atoms $IJKLMN$ that have a bond between atoms K and L, where both K and L are additionally bonded to exactly two other atoms. Namely, K is also bonded to I and J, and L is also bonded to M and N.

The examples/amoeba directory has a sample input script and data file for ubiquitin, which illustrates use of the fix amoeba/pitorsion command.

As in the example above, this fix should be used before reading a data file that contains a listing of pitorsion interactions.

The data file read by the *read_data* command must contain the topology of all the pitorsion interactions, similar to the topology data for bonds, angles, dihedrals, etc. Specifically, it should have two lines like these in its header section:

```
M pitorsion types
N pitorsions
```

where *N* is the number of pitorsion 6-body interactions and *M* is the number of pitorsion types. It should also have two sections in the body of the data file like these with *M* and *N* lines each:

```
PiTorsion Coeffs

      1 6.85
      2 10.2
      [...]
      M 6.85
```

```
PiTorsions

      1       1       2       4       3       20      21      24
      2       5       21      23      22      37      38      41
      [...]
      N       7       27      29      28      30      35      36
```

For PiTorsion Coeffs, the first column is an index from 1 to *M* to enumerate the pitorsion types. The second column is the single prefactor coefficient needed for each type.

For PiTorsions, the first column is an index from 1 to *N* to enumerate the pitorsion 6-atom tuples; it is ignored by LAMMPS. The second column is the "type" of the interaction; it is an index into the PiTorsion Coeffs. The remaining 6 columns are the atom IDs of the atoms (in order) for the 6-tuple *IJKLMN*, as described above.

Note that the *pitorsion types* and *pitorsions* and *PiTorsion Coeffs* and *PiTorsions* keywords for the header and body sections of the data file match those specified in the *read_data* command following the data file name.

The data file should be generated by using the tools/tinker/tinker2lmp.py conversion script which creates a LAMMPS data file from Tinker input files, including its PRM file which contains the parameters necessary for computing pitorsion interactions.

The potential energy associated with pitorsion interactions can be output as described below. It can also be included in the total potential energy of the system, as output by the *thermo_style* command, if the *fix_modify energy* command is used, as in the example above. See the note below about how to include the pitorsion energy when performing an *energy minimization*.

2.12.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the list of pitorsion interactions to *binary restart files*. See the *read_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The *fix_modify energy* option is supported by this fix to add the potential energy of the pitorsion interactions to both the global potential energy and peratom potential energies of the system as part of *thermodynamic output* or output by the *compute pe/atom* command. The default setting for this fix is *fix_modify energy yes*.

The *fix_modify virial* option is supported by this fix to add the contribution due to the pitorsion interactions to both the global pressure and per-atom stress of the system via the *compute pressure* and *compute stress/atom* commands. The former can be accessed by *thermodynamic output*. The default setting for this fix is *fix_modify virial yes*.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the potential energy discussed above. The scalar value calculated by this fix is "extensive".

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command.

The *fix_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its forces. Default is the outermost level.

Note

For energy minimization, if you want the potential energy associated with the pitorsion terms forces to be included in the total potential energy of the system (the quantity being minimized), you MUST not disable the *fix_modify energy* option for this fix.

2.12.5 Restrictions

To function as expected this fix command must be issued *before* a *read_data* command but *after* a *read_restart* command.

This fix can only be used if LAMMPS was built with the AMOEBA package. See the *Build package* page for more info.

2.13 fix append/atoms command

2.13.1 Syntax

```
fix ID group-ID append/atoms face ... keyword value ...
```

- ID, group-ID are documented in *fix* command
- append/atoms = style name of this fix command
- face = *zhi*
- zero or more keyword/value pairs may be appended
- keyword = *basis* or *size* or *freq* or *temp* or *random* or *units*

```
basis values = M itype
  M = which basis atom
  itype = atom type (1-N) to assign to this basis atom
size args = Lz
  Lz = z size of lattice region appended in a single event(distance units)
```

```
  freq args = freq
    freq = the number of timesteps between append events
  temp args = target damp seed extent
    target = target temperature for the region between zhi-extent and zhi␣
 ↪(temperature units)
    damp = damping parameter (time units)
    seed = random number seed for langevin kicks
    extent = extent of thermostatted region (distance units)
  random args = xmax ymax zmax seed
    xmax, ymax, zmax = maximum displacement in particular direction (distance units)
    seed = random number seed for random displacement
  units value = lattice or box
    lattice = the wall position is defined in lattice units
    box = the wall position is defined in simulation box units
```

2.13.2 Examples

```
fix 1 all append/atoms zhi size 5.0 freq 295 units lattice
fix 4 all append/atoms zhi size 15.0 freq 5 units box
fix A all append/atoms zhi size 1.0 freq 1000 units lattice
```

2.13.3 Description

This fix creates atoms on a lattice, appended on the zhi edge of the system box. This can be useful when a shock or wave is propagating from zlo. This allows the system to grow with time to accommodate an expanding wave. A simulation box must already exist, which is typically created via the *create_box* command. Before using this command, a lattice must also be defined using the *lattice* command.

This fix will automatically freeze atoms on the zhi edge of the system, so that overlaps are avoided when new atoms are appended.

The *basis* keyword specifies an atom type that will be assigned to specific basis atoms as they are created. See the *lattice* command for specifics on how basis atoms are defined for the unit cell of the lattice. By default, all created atoms are assigned type = 1 unless this keyword specifies differently.

The *size* keyword defines the size in z of the chunk of material to be added.

The *random* keyword will give the atoms random displacements around their lattice points to simulate some initial temperature.

The *temp* keyword will cause a region to be thermostatted with a Langevin thermostat on the zhi boundary. The size of the region is measured from zhi and is set with the *extent* argument.

The *units* keyword determines the meaning of the distance units used to define a wall position, but only when a numeric constant is used. A *box* value selects standard distance units as defined by the *units* command (e.g., Å for units = real or metal. A *lattice* value means the distance units are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacings.

2.13.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

2.13.5 Restrictions

This fix style is part of the SHOCK package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

The boundary on which atoms are added with append/atoms must be shrink/minimum. The opposite boundary may be any boundary type other than periodic.

2.13.6 Related commands

fix wall/piston command

2.13.7 Default

The keyword defaults are size = 0.0, freq = 0, units = lattice. All added atoms are of type 1 unless the basis keyword is used.

2.14 fix atc command

Removed in version 10Sep2025.

The ATC package and the *fix atc* command have been removed from LAMMPS.

2.15 fix atom/swap command

2.15.1 Syntax

```
fix ID group-ID atom/swap N X seed T keyword values ...
```

- ID, group-ID are documented in *fix* command
- atom/swap = style name of this fix command
- N = invoke this fix every N steps
- X = number of swaps to attempt every N steps
- seed = random # seed (positive integer)
- T = scaling temperature of the MC swaps (temperature units)
- one or more keyword/value pairs may be appended to args
- keyword = *types* or *mu* or *ke* or *semi-grand* or *region*

```
types values = two or more atom types (1-Ntypes or type label)
mu values = chemical potential of swap types (energy units)
ke value = no or yes
  no = no conservation of kinetic energy after atom swaps
  yes = kinetic energy is conserved after atom swaps
semi-grand value = no or yes
  no = particle type counts and fractions conserved
  yes = semi-grand canonical ensemble, particle fractions not conserved
region value = region-ID
  region-ID = ID of region to use as an exchange/move volume
```

2.15.2 Examples

```
fix 2 all atom/swap 1 1 29494 300.0 ke no types 1 2
fix myFix all atom/swap 100 1 12345 298.0 region my_swap_region types 5 6
fix SGMC all atom/swap 1 100 345 1.0 semi-grand yes types 1 2 3 mu 0.0 4.3 -5.0
```

2.15.3 Description

This fix performs Monte Carlo swaps of atoms of one given atom type with atoms of the other given atom types. The specified scaling temperature T is used in the Metropolis criterion dictating swap probabilities.

Perform X swaps of atoms of one type with atoms of another type according to a Monte Carlo probability. Swap candidates must be in the fix group, must be in the region (if specified), and must be of one of the listed types. Swaps are attempted between candidates that are chosen randomly with equal probability among the candidate atoms. Swaps are not attempted between atoms of the same type since nothing would happen.

All atoms in the simulation domain can also be moved using regular time integration displacements (e.g., via *fix nvt*), resulting in a hybrid MC+MD simulation, where X MC swap attempts are made once every N MD steps. A smaller-than-usual timestep size may be needed when running such a hybrid simulation, especially if the swapped atoms are not well equilibrated.

Note

To run an MC-only simulation (no MD), you should define no time-integration fix, set the *thermo* command to 1, set N to 1, and set X small enough to see the MC evolution of the system. But if X is too small, the overhead at the start and stop of MC moves each timestep will slow down the simulation.

The *types* keyword is required. At least two atom types must be specified. If not using *semi-grand*, exactly two atom types are required.

The *ke* keyword can be set to *no* to turn off kinetic energy conservation for swaps. The default is *yes*, which means that swapped atoms have their velocities scaled by the ratio of the masses of the swapped atom types. This ensures that the kinetic energy of each atom is the same after the swap as it was before the swap, even though the atom masses have changed.

The *semi-grand* keyword can be set to *yes* to switch to the semi-grand canonical ensemble as discussed in *(Sadigh)*. This means that the total number of each particle type does not need to be conserved. The default is *no*, which means that the only kind of swap allowed exchanges an atom of one type with an atom of a different given type. In other words, the relative mole fractions of the swapped atoms remains constant. Whereas in the semi-grand canonical ensemble, the composition of the system can change. Note that when using *semi-grand*, atoms in the fix group whose type is not listed in the *types* keyword are ineligible for attempted conversion. An attempt is made to switch the selected atom (if eligible) to one of the other listed types with equal probability. Acceptance of each attempt depends upon the Metropolis criterion.

The *mu* keyword allows users to specify chemical potentials. This is required and allowed only when using *semi-grand*. All chemical potentials are absolute, so there is one for each swap type listed following the *types* keyword. In semi-grand canonical ensemble simulations the chemical composition of the system is controlled by the difference in these values. So shifting all values by a constant amount will have no effect on the simulation.

This command may optionally use the *region* keyword to define swap volume. The specified region must have been previously defined with a *region* command. It must be defined with side = *in*. Swap attempts occur only between atoms that are both within the specified region. Swaps are not otherwise attempted.

You should ensure you do not swap atoms belonging to a molecule, or LAMMPS will eventually generate an error when it tries to find those atoms. LAMMPS will warn you if any of the atoms eligible for swapping have a non-zero molecule ID, but does not check for this at the time of swapping.
